As with ESA-listed salmon discussed in the previous section, the principal impact to marine mammals under the alternatives would be due to take mortality from interaction with trawl gear. Take is a function of the abundance and distribution of the animal and characteristics of the fishing gear and fishery operations, which contribute to overall vulnerability to take in the fishery. Changes in the level and distribution of fishing effort under the action alternatives can be only be assessed qualitatively, and information on the distribution of affected marine mammal species pertains to broad regions and habitat types. Therefore, it is difficult to forecast whether the action alternatives would affect protected species differently than they are affected under status quo. Information on incidental takes under status quo can be presented, and certain features of the action alternatives, which may affect bycatch rates, can be discussed.

Table 4-83 reproduces indicators of marine mammal stock status from 2009 SARs (Allen and Angliss 2009; Carretta, *et al.* 2009). Except for the Eastern U.S. Stellar sea lion stock, which is reported in the Alaska SAR, the stocks are reported in the Pacific SAR. One stock is classified as strategic, the Eastern U.S. Stellar sea lion stock. Table 4-84 and Table 4-85 report marine mammal bycatch (incidental take) estimates from the At-sea Hake Observer Program and WCGOP for the 2002-to-2006 and 2002-to-2005 periods, respectively (NMFS SHOP & WCGOP 2008). Taking the point estimates from the tables below and averaging them over the time period suggests that the whiting fishery takes 0.98 California sea lions, 1.86 Steller sea lions, 0.86 northern elephant seals, and 0.5 harbor seals on average per year. A similar calculation can be made for the nonwhiting fishery. This indicates an average of 58.47 California sea lions, 3.36 Stellar sea lions, 0.62 harbor porpoise, and 1.5 white-sided dolphins taken annually by this fishery sector.[118] Compared to the overall estimate of fisheries injury/mortality for the stocks, the values suggest the groundfish trawl fisheries are a modest contributor to impacts to these stocks.

[118] Since the report includes unidentified sea lion take, that take is distributed proportionately between the two species to arrive at the estimate.

Table 4-83. Stock indicators reported in 2009 Stock Assessment Reports.

Stock	N Estimate	N min	PBR	Fisheries Injury/Mortality	Strategic ?	SAR Last Revised
California Sea Lion (U.S.)	238,000	141,842	8,511	≥159	N	2007
Stellar Sea Lion (E. U.S.)	45,095-55,832	44,404	1,998	1.4	Y	2009
Northern Elephant Seal (CA breeding)	124,000	74,913	4,382	≥8.8	N	2007
Harbor Seal (CA)	34,233	31,600	1,896	389	N	2005
Harbor Seal (OR/WA)	24,732	22,380	1,343	≥13	N	2007
Harbor Porpoise (N. OR/S. CA)	39,581	28,833	114	≥0.8	N	2009
Harbor Porpoise (N. OR/WA coast)	15,674	11,383	114	≥0.8	N	2009
Pacific White-sided Dolphin (CA/OR/WA)	20,719	17,201	155	1.4	N	2008

Table 4-84. Bycatch estimates of marine mammals in the whiting fishery.

	2002	2003	2004	2005	2006
California Sea Lion	0	0	2.1 (1.5-3.0)	0	2.5 (1.4-4.6)

Harbor Seal	0	0	0	1.2 (0.6-2.7)	1.3 (0.6-2.9)

Table 4-85. Bycatch estimates of marine mammals in the nonwhiting fishery.

	2002	2003	2004	2005
California Sea Lion	34.8 (17.9-67.5)	163.1 (103.0-258.4)	10.0 (4.6-21.4)	19.7 (9.7-39.9)
Stellar Sea Lion	11.5 (4.4-30.3)	0	0	0
Unidentified Sea Lion	7.8 (2.1-28.8)	0	0	0
Harbor Porpoise	0	0	3.1 (0.9-10.0)	0
Pacific White-sided Dolphin	0	7.5 (2.0-27.4)	0	0

The SHOP/WCGOP report also presents information on seabird take. In the whiting fishery, the following species were observed, and bycatch estimates were made: black-footed albatross (2-3/year, 2003 to 2006), common murre (<2/year), northern fulmar (~6/year), and sooty shearwater (<1/year). In addition, unidentified auklets or murrelets and other unidentified seabirds were taken in low numbers (<2/year). In the nonwhiting fishery Brandts cormorants, common murres, Leachs storm petrels, and northern fulmars were observed taken, 2002 to 2006. In addition unidentified cormorants, gulls and storm petrels were observed taken. The total number of seabirds estimated taken during the period was 575, 50 percent of which were common murres. However, the bycatch estimate was driven by one observation of 33 murres taken in a single tow in 2003.

As noted previously, there is no information to indicate definitively how changes in management would affect marine mammal and seabird take. In the absence of information, it may be assumed that the level of take reported above for status quo management of fisheries would continue under any of the action alternatives. However, several factors could alter the level of take. Although it is difficult to predict what the effect would be, the following changes could occur under the action alternatives.

Fleet consolidation could lead to an increase in target species CPUE. As a result, the amount of overall fishing effort could decline, remain stable, or increase, and the number of vessels is expected to decline. Effort would decline if overall catch remains constant relative to status quo; however, harvesters may be able to access greater amounts of target species yield, resulting in stable or increasing levels of effort. A combination of fewer vessels expending the same or diminished level of fishing effort could result in fewer interactions with protected species.

Individual accountability (control of QSs or co-op shares) is expected to reduce Olympic or race-for-fish conditions in the fishery. This would give harvesters the opportunity to make more efforts to avoid protected species bycatch, if technically or operationally feasible. However, the program does not include individual incentives for protected species bycatch reduction, so it would be matter of individual harvesters' recognizance.

As discussed above (Sections 4.18 and 4.14), consolidation could also lead to changes in the distribution of fishing effort. This could affect the bycatch of protected species. Looking at the observer data referenced above, the Monterey INPFC area (Cape Mendocino to Point Sur) showed the highest number of marine mammal takes (11 out of 17). This is also the area with the highest number of observed seabird takes. Central California shoreward of the RCA is an area where trawl fishing may decline according to the comparative advantage analysis (Appendix C, Section C.1). To the degree that trawl fishing declines in this area, this may reduce incidental takes of marine mammals, given that the species observed taken are more likely to occur closer to the coast (i.e., shoreward of the RCA).

The program feature with the greatest implications for protected species bycatch is the gear switching provision. This principally applies to vessels managed with IFQ that have sufficient QSs for species that can be efficiently targeted with fixed gear (e.g., sablefish, Pacific cod). They can harvest species against their QSs/QPs using any legal groundfish gear, and fixed gear (pot, bottom longline) would be the most likely choice. The SHOP/WCGOP report (NMFS SHOP & WCGOP 2008) also includes estimates of marine mammal and seabird bycatch in the LE fixed gear fishery. The only marine mammal observed taken, 2002 to 2005, was the California sea lion. Black footed albatross, western gulls, brown pelican, unidentified cormorants and unidentified birds were observed, and bycatch estimates were derived. As noted in Section 3.19, the brown pelican is listed as endangered under the ESA.

For 2009, the sablefish pot fishery was uplisted from a Category III fishery to a Category II fishery under the MMPA, because of interactions with the endangered humpback whale (2009 List of Fisheries, 73 FR 73032; December 1, 2008). Humpback whale interactions with pot and trap gear fisheries off the west coast (including the commercial sablefish pot gear fisheries) were documented in data available from the NMFS Large Whale Disentanglement Network. Based on analysis of these data, NMFS estimated that three humpback whales were seriously injured or killed between 2002 and 2006 due to entanglements with pot or trap gear, one of which was with sablefish pot gear in September 2006. A single serious injury or mortality of a humpback whale results in a level of take of 0.2 animals per year, or 8 percent of the PBR. In addition to data from the Large Whale Disentanglement Network, NMFS also considered other factors prior to its listing of the pot or trap gear fisheries as Category II, including the type of gear being used, stranding records, and the distribution of marine mammals in the area of the fishery. Gear switching by trawl vessels under the action alternatives could increase the risk of such takes (and other marine mammals as discussed above), especially since analysis elsewhere in this chapter suggests that gear switching is more likely to occur among trawl vessels operating in the Central California region.

4.19.3 Cumulative Effects on Other Protected Species (Marine Mammals and Seabirds)

Both marine mammals and seabirds are subject to various sources of human-induced and natural mortality, and other factors affecting population viability. These are catalogued in the SARs (Allen and Angliss 2009; Carretta, *et al.* 2009)and incorporated by reference. Exogenous factors include the following:

- Take of marine mammals and seabirds in other fisheries (fishery mortality/injury estimates in the SARs capture all these sources)
- Nonfishing sources of direct mortality (e.g., ship strikes, oil spills), also discussed in the SARs
- Degradation of nesting habitat for seabirds and disturbance of haul out areas for marine mammals
- Climate forcing affecting food chain dynamics, producing more or less prey (further discussed in Section 4.20)

These exogenous factors have an equal effect under all of the alternatives; therefore, while they would increase the overall magnitude of impacts under each alternative they do not change the relative impact when comparing the alternatives.

4.19.4 Summary of the Impact of the Alternatives on Other Protected Species (Marine Mammals and Seabirds)

Three factors were identified that could affect incidental take of marine mammals: fleet consolidation affecting the distribution of fishing effort, reduction in Olympic (race-for-fish) fishery conditions leading to greater ability to avoid takes, and trawl vessels managed under IFQs switching to fixed gear, which may have different impacts on these protected species compared to trawl gear. Alternative 2 would likely lead to the greatest level of consolidation, while Alternatives 1 (no action) and 3 would result in the least consolidation, and Alternative 4 would result in an intermediate level (see discussion in previous sections for rationale for this conclusion). Consolidation could lead to fishing areas where observed take of marine mammals and seabirds is relatively higher (i.e., Central California shoreward of the RCA). In Alternative 1 (no action), Olympic fishery conditions are more pervasive in the whiting fishery, since it is under season/quota management compared to trip limit management for the nonwhiting sector. All the action alternatives implement catch control tools for the whiting sectors (either IFQs or co-ops) that would reduce Olympic conditions in the whiting sectors. However, the action alternatives do not contain any individual incentives for harvesters to avoid protected species take, so any such change in fishery conditions may not have any effects compared to no action. Finally, the gear switching provision, which is part of all the action alternatives for IFQ managed fisheries, could increase the risk of takes of some protected species over the no action alternative (Alternative 1). In particular, it was noted that the current sablefish pot fishery has been recategorized as a Category II fishery under the MMPA because of interactions with humpback whales. A Category II fishery is one where annual mortality and serious injury of a stock in a given fishery is greater than 1 percent and less than 50 percent of the PBR level.

4.20 Habitat and Ecosystem

A description of the California Current large marine ecosystem can be found in Section 3.20. Below is a brief description of the California Current ecosystem model used to further the understanding of complex interactions off the west coast.

The California Current ecosystem model, dubbed "Atlantis," was constructed by the Northwest Fishery Science Center scientists and included dynamics of species and functional groups of ecologically similar species, predator/prey interactions, oceanographic/climatic features (daily hydrodynamic flows, salinity, temperature), and fishery removals (Brand, *et al.* 2007). Examples of functional groups include habitat-forming species (kelp, corals, and sponges), benthic invertebrates, zooplankton, phytoplankton, and vertebrates. The California Current model extends from the U.S./Canada border to Point Conception, California, and out to the 1,200-m isobaths. In the model, this area is divided into 62 spatial zones, including depth layers. This three-dimensional aspect of the model allows for input and modeling of fish migrations and movement behavior, fleet dynamics, and spatial management. The full parameterization for the California Current is described in Brand et al. (2007), although some modifications and additions have been made since, including the addition of canary rockfish and English sole groups, minor updates to stock abundance, and updated diet data.

The Atlantis model was used to assess the ecosystem impacts of trawl rationalization. These effects are measured through the indirect effects fishing will have on other species based on known relationships in the food web. The results shown here serve only as an indication of the type of effect that may occur.

4.20.1 Broad-Level Effects of Rationalization on the California Current Ecosystem

The California Current large marine ecosystem is not predicted to be substantially impacted by rationalization, although it is difficult to make predictions about a complicated system that has many inputs to productivity. Changes in catch induced by moving from status quo management to share-based management, may result in changes to the ecosystem's food web that are perceptible. Changes in location of catch and changes in the type of gear utilized may result in changes to the amount and kind of EFH impacted. Such changes in habitat impacts may have an effect on the ecosystem; however, that link, while logical, is difficult to demonstrate, as noted in the EFH EIS (PFMC 2004c). Direct effects of fishing are most accurately captured in projections from single species stock assessments, which are evaluated in Section 4.16.

Indirect effects that could occur include keystone predation (a predator indirectly increases the abundance of competitors of its prey via consumption of the prey); tri-trophic interactions (increase in plant/algal abundance caused by the control of herbivores by prey); exploitation completion (a reduction in a consumer or producer resulting from the reduction of its prey or resources by another consumer species); apparent competition (reduction of a species resulting from increase in a second species that enhances predation by a shared enemy); indirect mutualism (positively correlated changes in two species resulting from predation by each on the competition of the other's main prey); indirect commensalism (similar to indirect mutualism, but one potential indirect mutualist is more generalized in diet and also feeds on the main prey of the other indirect mutualist); habitat facilitation (one organism indirectly improves the habitat of a second by altering the abundance of a third interactor); apparent predation (an indirect decrease in a nonprey produced by a predator or herbivore, e.g., a predator removes a prey species, and the decline of the prey results in the decline of a third species); and indirect defense (the indirect reduction of a predator or herbivore by a nonprey; e.g., competition by a nonprey can reduce the abundance of a prey and this its predator) (Menge 1997). The Atlantis model predicted minor indirect effects on prey species.

While not captured in the Atlantis model, rationalization is expected to result in fleet consolidation. A broad-level effect of consolidation is that some fishing vessels are expected to become inactive and may fall into disrepair. This was seen after the buyback program consolidated the trawl fleet, and several of those vessels have become public health, safety, and environmental health problems that harbor masters and port authorities are forced to address. There are no mitigating measures in the trawl rationalization

program to help vessel owners, harbors, and communities deal with potential derelict vessels that may result from trawl rationalization consolidation.

4.20.2 Potential Impacts, Mechanisms, and Metrics

Change in condition of the ecosystem (as indicated by minor indirect effects on prey species) was not substantially different under any of the program's proposed analytical scenarios. Therefore, the change in condition of the ecosystem will be evaluated by comparing conditions under status quo management to conditions under a rationalized management program.

Several catch scenarios were developed that could occur in a rationalized fishery. The following metrics were utilized to examine the potential impacts of the catch scenarios under rationalization on the California Current ecosystem in comparison to the status quo management catch scenario.

Table 4-86 provides an overview of the analytical approach used to compare baseline and future conditions of the California Current large marine ecosystem under the alternatives, including EFH. The analytical approach includes 1) potential impacts, 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact, and 4) models and data sets used in the analysis.

Table 4-86. Overview of analytical approach used to compare baseline and future conditions of the ecosystem under the alternatives.

Potential Impacts	Impact Mechanisms	Measurement Criteria or Indicators	Data and Models
Changes species abundance	Changes in catch that can be traced through the food web	Changes in predator and prey abundance and trophic relationships	Atlantis ecosystem model
Changes in fishing effects (and area management) on EFH	Shifts in location of catch and gear switching	Description of changes in area and duration of bottom contact of groundfishing gears	Geographic shift model and qualitative assessment

Change in the Catch Amount of Target Species and Key Predator/Prey Species: Trawl rationalization is anticipated to result in an increased amount of target species catch. Other species are expected to have variable levels of utilization, including maximum utilization (taking the full allocation or OY) of some species. This high utilization of target and other species could have an impact on the California Current ecosystem, especially if those species are important predators or prey in the food web. This potential impact was evaluated by applying several catch scenarios to the Atlantis model. Direct effects of fishing (catch and fishing mortality) were modeled with the intent of detecting indirect effects, primarily through predator/prey tradeoffs under each catch scenario. Outputs of this model are primarily a qualitative assessment of changes in dominant trophic relationships resulting from the four catch scenarios.

Four scenarios for future catch (landings and discards) under a rationalized trawl fishery were developed for input to the Atlantis model. The scenarios were based on the idea that the behavior of harvesters would change under a rationalized fishery and that change would allow them to access more target species than had been accessed under status quo management.

Constraining overfished species include canary rockfish (*Sebastes pinniger*), yelloweye rockfish (*S. ruberrimus*), darkblotched rockfish (*S. crameri*), Pacific ocean perch (*S. alutus*), bocaccio rockfish

(*S. paucispinis*), and cowcod (*S. levis*)**.** Underutilized species include arrowtooth flounder (*Atheresthes stomias*), Dover sole (*Microstomus pacificus*), shortspine (*Sebastolobus alascanus*) and longspine thornyheads (*S. altivelis*), slope rockfish, chilipepper rockfish (*Sebastes goodie*), yellowtail rockfish (*S. flavidus*), lingcod (*Ophiodon elongatus*), and various flatfish species that make up the "other flatfish" complex.

The catch scenarios were as follows:

- Status Quo = catch roughly the same as those that occurred from 2003 to 2006.
- Scenario 1 (low-catch amount scenario) = minimal increases in catch of underutilized species compared to the status quo scenario. Bycatch rates are assumed to be 55 percent of status quo.
- Scenario 2 (moderate or medium-catch amount scenario) = moderate increases in catch of some underutilized species. Bycatch rates are assumed to be 30 percent of status quo.
- Scenario 3 (high-catch amount scenario) = substantial increase in catch of underutilized species. Bycatch rates are assumed to be 15 percent of status quo.

In all the Atlantis model catch scenarios, total catch of constraining species (e.g., canary rockfish) remained constant or increased only slightly. An assumption in the model was that harvesters have the highest preference for flatfish stocks and thornyheads due to the ability to catch these stocks with low bycatch rates, and other target species have a lower harvester preference.

The Effect of Shifts in Fishing Locations on EFH: Trawl rationalization is anticipated to result in geographic changes in harvest patterns, and consequently, the potential for changes in impacts to EFH. Trawling occurs over hard or soft substrates, and general shifts in fishing location would translate to either an increase or decrease of trawling in certain areas. No change in trawled substrate type would occur in areas that are currently closed to trawling, because no changes are anticipated to RCAs or other EFH conservation measures. To examine this impact, the model described in Section 4.2.1.3 is used to illustrate the predicted geographic shifts in fishing patterns. This is paired with either a hard or soft bottom substrate type, which was obtained from the 2004 EFH EIS (PFMC 2004c). A qualitative discussion follows, indicating whether that area may see an increase, decrease or no change to fishing effort.

The Effect of Shifts in Gear Types on EFH: Trawl rationalization is also anticipated to result in opportunity to switch from trawl gear to fixed-gear, which is thought to be less destructive to bottom habitat. One specific provision of Amendment 20, Adaptive Management, could provide an incentive to switch from bottom trawl to fixed-gear, which could have implications on EFH conservation.

4.20.3 Direct and Indirect Impacts of the Alternatives

4.20.3.1 Change in the Catch Amount of Target Species and Key Predator/ Prey Species

The potential change in catch volumes as a result of trawl rationalization was run through the Atlantis model. The results illustrated several findings:

- Miscellaneous nearshore species and small, shallow-water rockfish showed the most noticeable change in abundance in the model through indirect effects. This is driven by higher fishing-induced lingcod mortality than under status quo, which subsequently reduced lingcod predation on such species.
- Differences in groundfish mortality as a result of rationalization were not predicted by the model to have strong impacts on the food web, beyond the direct effects on harvested species.

- Strong indirect effects appear to be limited only to forage species such as nearshore fish, and were not seen on target species.

Tradeoffs were observed between large demersal predators (lingcod) and two principal prey items: miscellaneous nearshore fish and shallow small rockfish. The high catch amount scenarios led to the highest levels of depletion of target species, including large flatfish (e.g., arrowtooth flounder), large demersal predators (lingcod), deep small rockfish (e.g., longspine thornyhead), midwater rockfish (e.g., yellowtail and chilipepper rockfish), deep large rockfish (e.g., shortspine thornyhead), and small flatfish (e.g., Dover sole). Those high catch amount scenarios resulted in reduced predation on those species' prey. Prey species that showed increases in the model include sculpin (Cottidae) and white croaker (*Genyonemus lineatus*), particularly in response to the reduced abundance of lingcod. Twenty percent of lingcod diet is composed of nearshore fish species. Minor increases (2 percent) in abundance of shallow small rockfish (such as shortbelly rockfish *Sebastes jordani*) also showed in the model. Twenty-one percent of lingcod diet consists of shallow small rockfish.

4.20.3.2 The Effect of Shifts in Fishing Locations on EFH

In order to determine what impacts would occur to habitat from changing to rationalized fishery management from status quo, the areas fished were examined (before and after rationalization), as well as which habitat types occurred in those areas. The following table shows the delineated bycatch areas (GeoHab Areas) and the amount and percentage of each polygon associated with either a hard or soft substrate.

Table 4-87. Induration composition of bycatch polygons (areas in hectares).

GeoHab Area	blank	hard	soft	Grand Total	blank	hard	soft

EEZ-N to 47d 40', out			19,169.2	19,169.2	0.00%	0.00%	100.00%
Grand Total	6,618.7	83,052.6	1,194,905.8	1,284,577.1	0.52%	6.47%	93.02%

The polygons highlighted in grey are those areas that are predicted to experience a decrease in fishing effort (see Section 4.2.1.3 and Appendix C for the geographical shift model description), and, therefore, a decrease in trawl gear contact with the bottom. In four areas (grey rows in Table 4-87), the majority (88 percent to 98.7 percent) of the substrate is soft bottom.

All other polygons (white rows in Table 4-39) may or may not have a complementary increase in trawl fishing effort after the implementation of trawl rationalization. It is difficult to determine which areas may have an increase in trawl effort. Impacts to EFH from trawl gear have been mitigated by past and ongoing Council actions.

4.20.3.3 The Effect of Shifts in Gear Types on EFH

Gear switching may reduce the impacts to habitat that is currently trawled; however, since many types of habitat are not accessed by trawl gear because of footrope restrictions (such as rocky reef habitat), gear switching may result in more fishing effort being exerted on untrawlable habitat. Use of fixed gear could have modest adverse impacts on untrawlable habitat. The EFH EIS (evaluating Amendment 18) (NMFS 2005) describes impacts to bottom habitat from pot and longline gear (Sections 3.5.8.5 and 3.5.9.4), and that information is incorporated by reference. Shifting of pots and lines during retrieval, entanglement of lines with biogenic habitat, and lost gear can adversely affect untrawlable habitat, particularly areas with complex biogenic features (corals, sponges, etc.). The specific effects on any gear switching cannot be predicted, because it is unknown whether this would result in an increase in fishing in sensitive habitats compared to status quo, and the intensity of effects depends on the way the gear is deployed.

4.20.4 Cumulative Effects of on Habitat and Ecosystem

A discussion of cumulative effects on the California Current ecosystem includes trends and actions that are occurring, have occurred, or would be expected to occur exogenous to rationalization, as well as effects that could likely occur under a rationalized management program. The Atlantis model was able to produce a simple simulation of the California Current ecosystem with some, but not all, RFFAs and trends. Therefore, Atlantis is useful in evaluating some cumulative effects related to these actions and trends. Furthermore, as discussed above, there are no discernable differences in terms of the effects of the action alternatives compared to one another; the analysis focuses on the contrast between status quo (Alternative 1) and the general effects of trawl rationalization (action alternatives) on habitat and ecosystem.

Sections 3.3 and 3.4 describe historic fishery management decisions, the RFFAs, and the identifiable trends and Section 3.20 describes baseline conditions of the ecosystem. Past, present, and RFFAs that apply to the ecosystem include the overfished status of seven groundfish species and related rebuilding efforts; bycatch reduction; designation of EFH; and MPAs and RCA closured areas applicable to groundfish trawl gear. Trends that apply to the ecosystem include changes in the use of ocean areas (such as additional wave energy sites and MPAs), changes in land use, continued rebuilding of overfished species, and cyclical and continuing climate change.

Regardless of the fishery management program, the effort to rebuild species and reduce bycatch will continue to influence the amount and type of fish removed by the trawl fishery and will, therefore, affect ecosystem function to some degree. There would be much more individual accountability for fishery removals under the action alternatives (rationalized fishery management program), supported by higher levels of observer coverage (at or near 100 percent). Status quo (Alternative 1) management has shown that closed areas have contributed to the reduction of bycatch of overfished rockfish species, and the benefits of those closed areas would be expected to continue under rationalization.

Changing ocean uses, such as adding alternative energy arrays, create de facto MPAs where fish harvesting is restricted or banned. Changing uses, combined with the present protected/conservation areas, will create more localized protection for groundfish in that particular area, but may do little to

further decrease bycatch of key constraining species or bolster overall integrity of the large marine ecosystem. Climate change may alter the areas where groundfish species occur and can be harvested, but the effect of this on the ecosystem under status quo or rationalization is unknown.

The Atlantis model was used to simulate possible outcomes as a result of climate change. These outcomes were combined with possible catch scenarios under rationalization to estimate the cumulative effect of both rationalization and fishing under an environment altered as a result of climate change. The model was "forced" to account for climate change by depleting shelled benthos, such as bivalves, snails, corals, and sea urchins. A reduction in the populations of these types of species is expected as a result of ocean acidification that is linked to climate change. The noteworthy changes in results that stemmed from food web connections were declines in English sole and dogfish. Compared to a case without ocean acidification where the populations of English sole doubles, under the ocean acidification condition, the population of English sole fell to 6 to 40 percent of initial levels (depending on fishing mortality). Dogfish were not affected to the same degree: without acidification, they increase in abundance to levels that are approximately double initial levels; with ocean acidification, they increase to 1.9 times initial levels (or a 10 percent difference).

Other possibilities stemming from ocean acidification were run through the model. These possibilities resulted in a decline in skates and rays and an increase in miscellaneous nearshore fish species such as croakers and sculpins. The decline in skates was linked to a simulated extinction of sea urchins, while miscellaneous nearshore species increased as a result of a decline in their predator, dogfish.

Overall, the groundfish resource under rationalized fishery management is anticipated to be harvested closer to the OY for many of the species than it would be under status quo. The effect of rationalization on the marine ecosystem is predicted to be minor, but, when combined with possibilities under a more acidic ocean, some species may see reductions in biomass levels. To the extent that these potential effects are known ahead of time, managers have the possibility of adjusting harvest specifications to be more in line with what the resource can sustain under those more acidic conditions.

Current and future MPAs, as well as trawl gear improvements/modifications, could reduce the effect trawling has on the ecosystem. Increased catch accounting and bycatch accountability associated with the rationalization program would reduce uncertainty in stock assessments, as well as providing more accurate catch information, additional information on seabird and marine mammal takes in groundfish trawl fisheries, and better tools for dealing with fish stock range changes due to climate change compared to status quo.

4.20.5 Summary of the Impact of the Alternatives on Habitat and Ecosystem

As discussed above, the features of the alternatives that would have potential effects on habitat and ecosystem are common to all of the action alternatives. For that reason, it is only possible to contrast the effects of the action alternatives collectively with ongoing effects under the no action alternative (Alternative 1). Nearshore species and small, shallow-water rockfish may see increased abundance due to higher lingcod fishing mortality, a predator on these stocks. Expected increases in fishing mortality on target stocks are not expected to have strong impacts on the food web. High-relief bottom habitat, especially areas with substantial biogenic presence, is more sensitive to the adverse effects of fishing, with groundfish trawl gear having greater effects than other types of groundfish gear. Past actions limiting the use of certain types of gear (e.g., large footropes) and EFH closed areas have mitigated the impacts of trawling. Fleet consolidation and related factors under the action alternatives could change the spatial distribution of fishing effort, having differential impacts on EFH compared to no action (Alternative 1). An examination of the areas where fishing effort may decrease, according to the

geographic shift model described in Appendix C, shows that 6.9 percent of the area is classified as hard substrate compared to 6.47 percent of the mapped area of the west coast EEZ (Table 4-87). Although this indicates that these areas have a slightly higher proportion of hard substrate than the total area, there is considerable variation within particular areas, and any redistribution of effort into these areas cannot be predicted. Gear switching, a feature of all the action alternatives, could result in an increase in deployment of fixed gear in some untrawlable areas compared to the no action alternative (Alternative 1). Although fixed gear results in fewer impacts compared to trawl gear, an overall increase in the use of this gear in high relief, untrawlable areas could have an adverse effect compared to no action.

CHAPTER 5 SUMMARY OF OTHER ENVIRONMENTAL MANAGEMENT ISSUES

Federal regulations at 40 CFR 1502.16 require an EIS to compare the environmental impact of the alternatives considered in the analysis. Chapter 4 comprehensively assesses these impacts. However, the regulations identify classes of impacts that, while inherent in the analysis, are not explicitly discussed in Chapter 4. For that reason, these types of impacts are briefly discussed here, based on the information provided in Chapter 4.

Short-term uses versus long-term productivity. The proposed action does not directly affect the tradeoff between short-term use and long-term productivity of fish stocks since this is a function of setting harvest limits (OYs/ACLs), done under a separate periodic process. By requiring individual accountability and requiring comprehensive catch monitoring, the proposed action should make short-term use (catches) consistent with sustaining long-term productivity. However, this relationship ultimately depends on the correct specification of harvest levels.

Irreversible resource commitments. An irreversible commitment represents some permanent loss of an environmental attribute or service. The proposed action is likely to result in an irreversible commitment of some economic resources. Under rationalization, the groundfish trawl fleet is likely to consolidate, resulting in a smaller fleet size. Similarly, there is likely to be some consolidation of at-sea and shore-based processing facilities. The resulting impact of consolidation on communities is treated in detail in Section 4.14. Some of the surplus physical capital (e.g., vessels) may be put to other uses, for example in nongroundfish fisheries (Section 4.8). Other, less-mobile assets, such as shore-based processing plants, may not be redeployed.

Irretrievable resource commitments. A resource is irretrievably committed if its use is lost for time, but is not actually or practically lost permanently. The proposed action does not involve any direct irretrievable resource commitment, except for the fish that are harvested in the groundfish fishery.

Energy requirements and conservation potential of the alternatives. The proposed action may indirectly affect energy use through fleet consolidation. A smaller fleet, assuming that CPUE increases, would result in an overall reduction in vessel fuel use. However, there are various other factors that likely have a greater effect on overall energy use and efficient utilization. Changes in fuel prices, for example, could affect the level of fishing vessel operations independent of fleet consolidation.

Urban quality, historic resources, and the design of the built environment. The proposed action has no direct effect on these resources. However, impacts to communities related to consolidation could cumulatively affect private and public investment in coastal communities, including marine-related businesses and port-related infrastructure. These changes could also affect cultural and historic resources as fishing and fishing-dependent activities are supplanted, or simply disappear, changing the character of a coastal community. This concern is particularly true for those communities identified as vulnerable. See Section 4.14.

Possible conflicts between the proposed action and other plans and policies for the affected area. The proposed action is unlikely to substantially conflict with other plans and policies. The Council's other FMPs (salmon, CPS, and HMS) are most relevant to the proposed action in terms of the geographic area and resources covered. Section 4.8, nontrawl commercial harvesters, and Section 4.17.2.3, other fish resources, discuss the effects of the proposed action on other fisheries, which may be managed under Council FMPs.

Unavoidable adverse impacts. Impacts of the alternatives on the human environment are identified and evaluated in Chapter 4 of this EIS. The Executive Summary summarizes these impacts.

Mitigation. An EIS must discuss "means to mitigate the adverse environmental impacts" stemming from the proposed action (40 CFR 1502.16(h)), even if the adverse impacts are not by themselves significant. The mitigation measure incorporated into the proposed action and included in the preferred alternative (Alternative 4b) is the adaptive management provision, which annually sets aside up to 10 percent of the QPs in the shore-based IFQ fishery and up to 10 percent of the available aggregate harvest pounds for the Pacific whiting cooperative program. This harvest opportunity would then be allocated by the Council to meet specified objectives, including unforeseen impacts, such as geographic shifts in catch or landings, previously unidentified impacts to participants (e.g., processors), or unexpected barriers to new entry into the fishery.

CHAPTER 6 CONSISTENCY WITH THE WEST COAST GROUNDFISH FMP AND MSA NATIONAL STANDARDS AND REQUIREMENTS

6.1 FMP Goals and Objectives

The Groundfish FMP contains three broad goals and 17 objectives intended to achieve those goals. Many of these are similar to the MSA's National Standards described in Section 6.2.

Management Goals

Goal 1 – Conservation. Prevent overfishing and rebuild overfished stocks by managing for appropriate harvest levels and prevent, to the extent practicable, any net loss of the habitat of living marine resources.

Goal 2 – Economics. Maximize the value of the groundfish resource as a whole.

Goal 3 – Utilization. Within the constraints of overfished species rebuilding requirements, achieve the maximum biological yield of the overall groundfish fishery, promote year-round availability of quality seafood to the consumer, and promote recreational fishing opportunities.

Objectives.

To accomplish these management goals, a number of objectives will be considered and followed as closely as practicable:

Conservation

Objective 1. Maintain an information flow on the status of the fishery and the fishery resource which allows for informed management decisions as the fishery occurs.

Objective 2. Adopt harvest specifications and management measures consistent with resource stewardship responsibilities for each groundfish species or species group. Achieve a level of harvest capacity in the fishery that is appropriate for a sustainable harvest and low discard rates,

and which results in a fishery that is diverse, stable, and profitable. This reduced capacity should lead to more effective management for many other fishery problems.

Objective 3. For species or species groups that are overfished, develop a plan to rebuild the stock as soon as possible, taking into account the status and biology of the stock, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem.

Objective 4. Where conservation problems have been identified for nongroundfish species and the best scientific information shows that the groundfish fishery has a direct impact on the ability of that species to maintain its long-term reproductive health, the Council may consider establishing management measures to control the impacts of groundfish fishing on those species. Management measures may be imposed on the groundfish fishery to reduce fishing mortality of a nongroundfish species for documented conservation reasons. The action will be designed to minimize disruption of the groundfish fishery, in so far as consistent with the goal to minimize the bycatch of nongroundfish species, and will not preclude achievement of a quota, harvest guideline, or allocation of groundfish, if any, unless such action is required by other applicable law.

Objective 5. Describe and identify EFH, adverse impacts on EFH, and other actions to conserve and enhance EFH, and adopt management measures that minimize, to the extent practicable, adverse impacts from fishing on EFH.

Economics

Objective 6. Within the constraints of the conservation goals and objectives of the FMP, attempt to achieve the greatest possible net economic benefit to the nation from the managed fisheries.

Objective 7. Identify those sectors of the groundfish fishery for which it is beneficial to promote year-round marketing opportunities and establish management policies that extend those sectors fishing and marketing opportunities as long as practicable during the fishing year.

Objective 8. Gear restrictions to minimize the necessity for other management measures will be used whenever practicable. Encourage development of practicable gear restrictions intended to reduce regulatory and/or economic discards through gear research regulated by EFP.

Utilization

Objective 9. Develop management measures and policies that foster and encourage full utilization (harvesting and processing), in accordance with conservation goals, of the Pacific Coast groundfish resources by domestic fisheries.

Objective 10. Recognizing the multispecies nature of the fishery, establish a concept of managing by species and gear or by groups of interrelated species.

Objective 11. Develop management programs that reduce regulations-induced discard and/or which reduce economic incentives to discard fish. Develop management measures that minimize bycatch to the extent practicable and, to the extent that bycatch cannot be avoided, minimize the mortality of such bycatch. Promote and support monitoring programs to improve estimates of total fishing-related mortality and bycatch, as well as those to improve other information necessary to determine the extent to which it is practicable to reduce bycatch and bycatch mortality.

Social Factors

Objective 12. When conservation actions are necessary to protect a stock or stock assemblage, attempt to develop management measures that will affect users equitably.

Objective 13. Minimize gear conflicts among resource users.

Objective 14. When considering alternative management measures to resolve an issue, choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and the environment.

Objective 15. Avoid unnecessary adverse impacts on small entities.

Objective 16. Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.

Objective 17. Promote the safety of human life at sea.

The trawl rationalization program is consistent with the management goals (Goals 1, 2, and 3) outlined in the groundfish FMP. The program is designed to improve conservation, in part, through total catch accounting (i.e., retained catch and discards) with 100 percent monitoring. The program is designed to improve the economics of the groundfish resource by increasing the profitability of participants in the fishery and increasing opportunities to harvest target species. The program is also designed to fully utilize the healthy groundfish stocks while remaining within harvest constraints of overfished species.

The trawl rationalization program is consistent with the objectives within the Groundfish FMP. The program is consistent with conservation objectives 1, 2, 4, and 5. The program is consistent with objective 1 because it continues to maintain an information flow on the status of the fishery and the fishery resource, which allows for informed management decisions as the fishery occurs. One hundred percent monitoring should provide for more informed management decisions as the fishery occurs. In addition, for the shoreside IFQ fishery, it strives to make catch (retained and discarded) information available to participants much sooner via electronic reporting. The program addresses conservation objective 2 by creating a market system where harvest capacity can be better matched with the available resource. In addition, the program may lower discard rates through increased accountability and total catch accounting. The trawl rationalization program is intended to increase stability and profitability of the fishery. The program is consistent with objective 4 because it is intended to reduce the incidental take of Pacific halibut, a nongroundfish species, which will be managed under the trawl rationalization program with halibut IBQ. The program is consistent with objective 5. Fishing in different areas and using different gear (e.g., switching to fixed-gear or modifying trawl gear) would change how much and what kind of EFH would be affected by fishing. However, the RCAs, areas closed to fishing with trawl and nontrawl gear, and EFH conservation areas will remain in place under the trawl rationalization program. Section 6.3 below describes the EFH assessment of the proposed action.

The program is consistent with economic objectives 6, 7, and 8. The program attempts to achieve the greatest possible net economic benefit to the nation from the managed fisheries (objective 6) by transitioning the trawl fishery to catch shares. The program is consistent with objective 7 by continuing to support year-round fishing and marketing opportunities and decreasing the risk of early season closures. The program is consistent with objective 8 by providing an opportunity for gear switching as an option for reducing regulatory or economic discards.

The program is consistent with utilization objectives 9, 10, and 11. The trawl rationalization program is intended to increase utilization of the groundfish resource by increasing opportunities to harvest healthy groundfish species while remaining within the constraints of overfished species (objective 9). The program continues to recognize the multispecies nature of the fishery and manage the fishery according to the species and groupings listed in the ABC/OY tables from 50 CFR 660, subpart G (objective 10). The program is consistent with objective 11, minimizing bycatch, as described in section 6.2 under MSA National Standard 9. It is also consistent with objective 11 by creating a program with 100 percent monitoring (i.e., total catch accounting) to improve estimates of total fishing-related mortality.

The program is consistent with the social factors described in objectives 14 through 17. The program is consistent with objective 14, accomplishes the change with the least disruption, because most current participants in the fishery would be eligible to receive harvest privileges. In addition, it continues year-round fishing opportunities. The program is consistent with objective 15 by creating a program where most recent participants in the fishery (many of which are small entities) would be eligible to continue participating in the fishery. Those small entities that choose to exit the fishery should receive financial compensation from selling their permit or share of the resource. In addition, for the shoreside IFQ fishery, an AMP would be allocated an amount of harvest privileges that could be used to mitigate any adverse impacts, including impacts on small entities, that might result from the trawl rationalization program. The program is consistent with objective 16, minimizing adverse economic impacts on fishing communities, as described in section 6.2 under MSA National Standard 8. The program is consistent with objective 17, safety at sea, as described in section 6.2 under MSA National Standard 10.

For Groundfish FMP objectives not discussed above, the trawl rationalization program is still consistent with those objectives. However, those objectives are not specifically addressed through the trawl rationalization program.

6.2 National Standards

An FMP or plan amendment and any pursuant regulations must be consistent with ten national standards contained in the MSA (§301).

National Standard 1 states that conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield from each fishery for the United States fishing industry.

> The alternatives for rationalization of the trawl fishery would support efforts to achieve OY and prevent overfishing. Both the co-op and the IFQ alternative would increase individual accountability for total catch, including bycatch, and would give fishermen greater discretion as to when and how to fish. This would be expected to provide greater opportunity to extract the full OY of higher biomass species while avoiding lower biomass species. The 100 percent monitoring and increased accountability should reduce the risk of overfishing. The no action alternative would retain the current management regime which can result in forgone harvest of higher biomass species due to closures caused by harvest of lower biomass species.

National Standard 2 states that conservation and management measures shall be based on the best scientific information available.

> The analyses contained in this document constitute the best available scientific information.

National Standard 3 states that, to the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

The EIS for the 2009 Groundfish Specifications, describes the management units for Pacific Coast groundfish. None of the alternatives analyzed in this document would modify those management units.

National Standard 4 states that conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various United States fishermen, such allocation shall be (A) fair and equitable to all such fishermen; (B) reasonably calculated to promote conservation; and (C) carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.

The trawl rationalization program was developed through the Council process, which facilitates substantial participation by state representatives. Generally, state proposals are brought forward when alternatives are crafted and integrated to the degree practicable. Decisions about catch allocation between different sectors or gear groups are also part of this participatory process, and emphasis is placed on equitable division while ensuring conservation goals. None of the alternatives analyzed would discriminate against residents of different states. However, both the co-op and the IFQ alternative would establish a foundation for making allocations of harvest privileges. These alternatives were structured to provide fair and equitable allocations of both target species and overfished species to participants. The proposed action is intended, in part, to reduce bycatch and improve total catch accounting. Some important components of the trawl rationalization program that will promote conservation are (1) 100 percent observer coverage and dockside monitoring for total catch accounting (landings and discards), (2) increased individual accountability for catch should reduce the risk of OY overages, (3) increased target catches and minimized bycatch, (4) reduced number of active fishing vessels and increased operating efficiency may reduce gear and habitat or protected species interactions, and (5) allowing trawlers to switch to longline or pot gear may reduce some habitat impacts. The alternatives include provisions to guard against accumulation of excessive shares including provisions for accumulation limits and divestiture.

National Standard 5 states that conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.

None of the alternatives analyzed in this document was designed solely for the purpose of economic allocation. However, NMFS and the Council have been working in this fishery to address the need for reduction in fleet capacity. In addition to meeting the conservation and management needs of the fishery, the alternatives analyzed in this document are expected to economically rationalize the groundfish trawl fishery.

National Standard 6 states that conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

The approach in the co-op and IFQ alternatives would be to provide greater flexibility to individual fishermen to determine when and how to fish. This flexibility would enhance the ability of fishermen and managers to respond to unexpected circumstances. In addition, the preferred alternative includes an adaptive management reserve of harvest privileges that could be used to address unexpected contingencies.

National Standard 7 states that conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

Generally, by coordinating management, monitoring, and enforcement activities between NMFS and the three west coast states, duplication, and thus cost, is minimized. Monitoring and enforcement programs, such as the use of fishery observers, are very important to the success of the rationalization alternatives. While these features would increase management costs, they are necessary to effective management. The analysis does consider cost-control mechanisms such as limiting landing hours and landing sites. In addition, fisherman may form co-ops or pool their resources, including sharing quota on a single vessel and sharing observers among vessels, to reduce costs.

National Standard 8 states that conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

This document evaluates the effects of the alternatives on fishing communities (Chapter 4), and these effects have been taken into account in developing the preferred alternative. The preferred alternative represents the Council's judgment of the best way to conserve and rebuild fish stocks as soon as possible while taking into account the trawl industry and coastal fishing communities. The analysis indicates that some side effects of rationalization may include geographic shifts in fishing effort and location of processors. To the extent that these shifts do occur, some communities could experience negative impacts. The preferred alternative would minimize the negative impacts to the extent possible by limiting the amount of quota that can be consolidated. In addition, the preferred alternative includes an AMP that would be allocated an amount of harvest privileges that could be used to mitigate any adverse impacts, including community impacts, that might result from the trawl rationalization program.

National Standard 9 states that conservation and management measures shall, to the extent practicable, (A) minimize bycatch and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.

The rationalization alternatives are designed to improve total catch accounting and to reduce bycatch. The alternatives should reduce regulatory discards, increase target catches, and promote greater individual responsibility for avoiding bycatch. They would also provide for greater flexibility for fishermen to decide how, when, and where to fish, including allowing trawlers to switch to longline or pot gear that may reduce some habitat impacts or minimize bycatch of certain species. In addition, closed areas that keep fishing away from areas where overfished species are most abundant would remain in place and would, therefore, reduce bycatch.

National Standard 10 states that conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.

The preferred alternative would provide fishermen with increased flexibility in determining when, where, and how to fish. This is expected to reduce incentives to fish in unsafe conditions.

6.3 Other Applicable MSA Provisions

The preferred alternatives are intended to facilitate harvest of OY while allowing for rebuilding of overfished stocks in compliance with section 304(e) of the MSA.

Chapter 4.20 in this EIS constitutes an EFH assessment of the proposed action's impacts, as required by 50 CFR 600.920 (e)(3).

6.4 Goals and Objectives of This Proposed Action

Over the past 20 years, fishery management programs—from limited license entry to IFQs to fishing cooperatives—have evolved. In 1999, the NRC produced a study of share-based fishery management programs around the country called *Sharing the Fish* (NRC 1999), which helped refine the national discussion of the pros and cons of this type of natural resource management. Since then, Congress has allowed IFQ programs to be developed, and several such programs have been implemented around the country. The MSA was reauthorized in 2007, with specific sections added to set the national standards and requirements of LAPP—a catch-all phrase that includes ITQ, IFQ, and cooperative fishery management programs. In addition to the requirements laid out in the MSA, the Council has region-specific goals and objectives for the west coast groundfish fishery in the groundfish FMP and in Amendment 20 of the FMP.

Table 6-1 summarizes guidelines, objectives, and goals identified for this action (Section 1.2.3), in the groundfish FMP (Chapter 2.0 in the FMP), and in the MSA (including Section 301(a), National Standards for fishery conservation and management, and Section 303A, LAPPs). The guidance is organized into 11 topic areas: conservation; net benefits and efficiency; disruption; excessive shares; fairness and equity, sector health; labor (captains, crew, and processing plant workers); communities; small vessels, small entities, and new entrants; auctions and cost recovery; and program performance monitoring and modification. This guidance was used to develop the alternatives and to evaluate the effects of the alternatives.

Table 6-1. Policy guidance from MSA, Groundfish FMP, and Amendment 20 (A-20) goals and objectives.

Guidance	Reference
Conservation	
Allocations Reasonably Calculated to **Promote Conservation**	MSA - National Standard 4(b)
LAPPs shall **assist in rebuilding** overfished species	MSA - 303A(c)(1)(A)
LAPPs shall **promote fishery conservation** and management	MSA - 303A(c)(1)(C)(ii)
Maintain an **information flow** on the status of the fishery… as the fishery occurs	GF FMP Objective 1
Reduce **nongroundfish mortality**	GF FMP Objective 4
Minimize adverse impacts on **EFH**	GF FMP - Objective 5
Total catch accounting; Reduce bycatch, discard mortality, and ecological impacts	A-20 Objective 1 and 3
Consider biological stock structure, not exceeding the OY/ABC, minimizing localized concentrations of fishing effort, and accounting for total mortality	A-20 Constraints 1, 2, 3, and 4
Net Benefits and Efficiency	
Consider Efficiency	MSA - National Standard 5
Contribute to **reducing capacity**	MSA - 303A(c)(1)(B)
Attempt to achieve the greatest net economic **benefit to the nation**	GF FMP Objective 6
Maximize the value of the groundfish resource as a whole	GF FMP Goal 2
Provide for a[n] … efficient groundfish fishery	A-20 Objective 2
Promote measurable economic benefits	A-20 Objective 6
Disruption	
Accomplish change with the least disruption of current domestic fishing practices, marketing procedures, and the environment	GF FMP Objective 14

Guidance	Reference
Excessive Shares	
No particular individual, corporation, or other entity [shall] acquire an **excessive share** of privileges	MSA - National Standard 4(c)
Address concerns over **excessive geographic or other consolidation** in the harvesting or processing sectors of the fishery	MSA - 303A(c)(5)(B)(ii)
Ensure that LAPP holders do not acquire an excessive share by (i) establishing a **maximum share** to hold, acquire or use, and (ii) establishing other measures to prevent inequitable concentration	MSA - 303A(c)(5)(D)
Avoid excessive quota concentration	A-20 Constraint 6
Establish a review process to determine whether any illegal antitrust acts have occurred.	MSA - 303A(c)(1)(J)
Fairness and Equity The excessive share objectives also relate to fairness and equity considerations.	
Allocation shall be fair and equitable to all such fishermen	MSA - National Standard 4(a)
Establish procedures to ensure **fair and equitable** initial allocations, including consideration of (i) **current and historical** harvests; (ii) **employment** in the harvesting and processing sectors; (iii) **investments** in, and dependence upon, the fishery; and (iv) the **current and historical participation** of fishing communities;	MSA - 303A(c)(5)(A)
Issue privileges to persons who **substantially participate** in the fishery (as specified by the Council)	MSA - 303A(c)(5)(E)
Provide an administrative **appeals process** regarding initial allocation decisions	MSA - 303A(c)(1)(I)
Environmental Justice: **Identify and address**, as appropriate, **disproportionately high and adverse** human health and environmental effects of its programs...**on minority populations and low income populations.**	EO 12898
Avoid provisions where the primary intent is a **change in marketing power balance** between harvesting and processing sectors	A-20 Constraint 5
Sector Health	
Provide for a **viable, profitable** . . . groundfish fishery	A-20 Objective 2
Promote **measurable economic . . . benefits** through the seafood catching, processing, distribution elements, and support sectors of the industry	A-20 Objective 6
Maximize the value of the groundfish resource as a whole	GF FMP Goal 2
Promote **year-round marketing opportunities** and extend those opportunities as long as practicable during the fishing year	GF FMP Objective 7
Avoid unnecessary **adverse impacts on small entities**	GF FMP Objective 15
Labor: Captains, Crew, and Processing Plant Workers	
Include measures to **assist… entry-level and small vessel owner-operators, captains, crew… through set-asides** of allocations… or economic assistance in the purchase of quota	MSA - 303A(c)(5)(C)
Promote measurable… **employment benefits** through the seafood catching, processing, distribution elements, and support sectors of the industry	A-20 Objective 6
Promote the **safety of human life at sea**	MSA - National Standard 10 GF FMP - Objective 17
Communities	
Consider importance of fishing to communities in order to provide sustained participation and to **minimize adverse impacts**	MSA - National Standard 8 GF FMP Objective 16 A-20 Objective 5
Consider basic cultural and social framework of the fishery through (i) the development of **policies to promote sustained participation** of… fishing communities that depend on the fisheries, including regional or port-specific landing and delivery requirement; (ii) procedures to **address concerns over excessive geographic** or other **consolidation** in the harvesting or processing sectors of the fishery	MSA - 303A(c)(5)(B)
Include measures to **assist**, when necessary and appropriate… fishing communities through **set-asides of harvesting allocations**… or economic assistance in the purchase of quota	MSA - 303A(c)(5)(C)

Guidance	Reference
If a program is created in which fishing communities are given a special standing (e.g., a direct allocation to qualified fishing communities), the Council is required to consider the following criteria: (i) Traditional fishing or processing practices in, and dependency on, the fishery; (ii) The cultural and social framework relevant to the fishery; (iii) Economic barriers to access the fishery; (iv) Existence and severity of projected economic and social impacts associated with implementation…; (v) Expected effectiveness, transparency and equitability; and (vi) Potential for improving economic conditions in remote coastal communities…	MSA - 303A(c)(3)(B)
Minimize negative impacts resulting from **localized concentrations** of fishing effort (this constraint is also listed under "Conservation")	A-20 Constraint 3
Small Vessels, Small Entities, and New Entrants	
Promote sustained participation of small owner-operated fishing vessels	MSA - 303A(c)(5)(B)(i)
Include measures to **assist**, when necessary and appropriate, entry level and small vessel owner-operators . . . through **set-asides of harvesting allocations**… or economic assistance in the purchase of quota [119]	MSA - 303A(c)(5)(C)
Avoid unnecessary **adverse impacts** on small entities	GF FMP Objective 15
Auctions and Cost Recovery	
Auctions, or other **systems to collect royalties**, shall be considered for initial or any subsequent allocation	MSA - 303A(d)
Assess and provide a program of **fees paid by the quota holders** that will cover the costs of management, data collection and analysis, and enforcement activities	MSA - 303A(e)
Program Performance Monitoring and Modification	
Take into account the **management and administrative costs** of implementing and overseeing the IFQ or co-op program and complementary catch monitoring programs, and the limited state and federal resources available.	A-20 Constraint 9
Regular **review and monitoring of the program** for progress in meeting the goals, 5 year formal review	MSA - 303A(c)(1)(G)
Privileges may be revoked, limited or modified at anytime. Provide for revocation	MSA - 303A(b)(2) MSA - 303A(c)(1)(K)

[119] An Assisted Purchase Program may be developed to aid in financing quota purchase by small vessel fishermen and first time purchase by entry-level fishermen (MSA - 303A(g)(1)).

CHAPTER 7 CROSS-CUTTING MANDATES

7.1 Other Federal Laws

7.1.1 Coastal Zone Management Act

Section 307(c)(1) of the Federal Coastal Zone Management Act (CZMA) of 1972 requires that all Federal activities that directly affect the coastal zone be consistent with approved state coastal zone management programs to the maximum extent practicable. The Council's preliminary preferred alternative would be implemented in a manner that is consistent, to the maximum extent practicable, with the enforceable policies of the approved coastal zone management programs of Washington, Oregon, and California. This determination will be submitted to the responsible state agencies for review under Section 307(c)(1) of the CZMA. The relationship of the groundfish FMP with the CZMA is discussed in Section 11.7.3 of the Groundfish FMP. The Groundfish FMP has been found to be consistent with the Washington, Oregon, and California coastal zone management programs. The recommended action is consistent and within the scope of the actions contemplated under the framework FMP.

7.1.2 Endangered Species Act

As described in Section 3.10, a variety of ESA-listed threatened and endangered species occur within the action area. These include salmon, marine mammals, turtles, and seabirds. While some of the alternatives may alter the timing, intensity, and location of fishing activities, these changes are not expected to significantly affect interactions of the fishery with protected species. With respect to ESA-listed salmon, only Chinook are expected to interact with the fishery. NMFS manages the trawl fishery to comply with incidental take levels of Chinook set forth in ESA section 7 consultations.

7.1.3 Marine Mammal Protection Act

The MMPA of 1972 is the principle Federal legislation that guides marine mammal species protection and conservation policy in the United States. Under the MMPA, NMFS is responsible for the management and conservation of 153 stocks of whales, dolphins, porpoise, as well as seals, sea lions, and fur seals; while the USFWS is responsible for walrus, sea otters, and the West Indian manatee.

Off the west coast, the Steller sea lion (*Eumetopias jubatus*) eastern stock, Guadalupe fur seal (*Arctocephalus townsendi*), and Southern sea otter (*Enhydra lutris*) California stock are listed as

threatened under the ESA. The sperm whale (*Physeter macrocephalus*) Washington, Oregon, and California stock, humpback whale (*Megaptera novaeangliae*) Washington, Oregon, and California - Mexico Stock, blue whale (*Balaenoptera musculus*) eastern north Pacific stock, and Fin whale (*Balaenoptera physalus*) Washington, Oregon, and California stock are listed as depleted under the MMPA. Any species listed as endangered or threatened under the ESA is automatically considered depleted under the MMPA.

West coast groundfish fisheries are considered Category III fisheries, indicating a remote likelihood of or no known serious injuries or mortalities to marine mammals, in the annual list of fisheries published in the FR. Based on its Category III status, the incidental take of marine mammals in the west coast groundfish fisheries does not significantly impact marine mammal stocks. However, recent west coast fixed-gear fisheries, including sablefish pot fisheries, have demonstrated a take of humpback whales, which may result in a recategorization of these fisheries to Category II. Consultation under the MMPA would then be needed to implement Category II fisheries in the next biennium. The proposed action could affect the intensity, duration, and location of groundfish fisheries through processes such as fleet consolidation and gear conversion. Impacts to marine mammals are discussed in Chapter 4.

7.1.4 Paperwork Reduction Act

The purposes of the Paperwork Reduction Act (PRA) are to minimize the burden of information collection by the Federal Government on the public; maximize the utility of any information thus collected; improve the quality of information used in Federal decisionmaking, minimize the cost of collection, use, and dissemination of such information; and improve accountability. The PRA requires Federal agencies to obtain clearance from the Office of Management and Budget before collecting information. This clearance requirement is triggered if certain conditions are met. "Collection of information" is defined broadly. In summary, it means obtaining information from third parties or the public by or for an agency through a standardized method imposed on 10 or more persons. Collection of information need not be mandatory to meet the trigger definition. Even information collected by a third party, if at the behest of a Federal agency, may trigger the clearance requirement. Within NMFS, the Office of the Chief Information Officer is responsible for PRA compliance. Obtaining clearance can take up to 9 months and is one aspect of NMFS's review and approval of Council decisions.

The proposed action, as implemented by any of the alternatives considered in this EIS, may require collection of information subject to the PRA.

7.1.5 Regulatory Flexibility Act

The purpose of the RFA is to relieve small businesses, small organizations, and small governmental entities of burdensome regulations and recordkeeping requirements. Major goals of the RFA are (1) to increase agency awareness and understanding of the impact of their regulations on small business, (2) to require agencies communicate and explain their findings to the public, and (3) to encourage agencies to use flexibility and to provide regulatory relief to small entities. The RFA emphasizes predicting impacts on small entities as a group distinct from other entities and the consideration of alternatives that may minimize the impacts while still achieving the stated objective of the action. An IRFA is conducted unless it is determined that an action will not have a "significant economic impact on a substantial number of small entities." The RFA requires that an IRFA include elements that are similar to those required by EO 12866 and NEPA. Therefore, the IRFA has been combined with the RIR, and both are substantially based on the analyses contained in this EIS document. Appendix H contains analytical conclusions specific to the RFA and EO 12866.

7.2 Executive Orders

7.2.1 EO 12866 (Regulatory Impact Review)

EO 12866, Regulatory Planning and Review, was signed on September 30, 1993, and established guidelines for promulgating new regulations and reviewing existing regulations. The EO covers a variety of regulatory policy considerations and establishes procedural requirements for analysis of the benefits and costs of regulatory actions. Section 1 of the EO deals with the regulatory philosophy and principles that are to guide agency development of regulations. It stresses that, in deciding whether and how to regulate, agencies should assess all of the costs and benefits across all regulatory alternatives. Based on this analysis, NMFS should choose those approaches that maximize net benefits to society, unless a statute requires another regulatory approach.

The RIR and IRFA determinations are part of the combined summary analysis presented in preliminary draft form in Appendix H of this document.

7.2.2 EO 12898 (Environmental Justice)

EO 12898 obligates Federal agencies to identify and address disproportionately high adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations in the United States as part of any overall environmental impact analysis associated with an action. NOAA guidance (NOAA Administrative Order [NAO] 216-6, at §7.02, states that "consideration of EO 12898 should be specifically included in the NEPA documentation for decision-making purposes."

Section 8.5 in Appendix A to the 2005-06 groundfish harvest specifications EIS (PFMC 2004a) describes a methodology, using 2000 U.S. Census data, to identify potential "communities of concern" because their populations have a lower income or a higher proportion of minorities than comparable communities in their region. Based on this information, but focusing on more isolated, rural coastal communities, Section 4.14 of this document discusses the potential effects of the proposed action on communities. Fishery participants make up a small proportion of the total population in these communities, and their demographic characteristics may be different from the community as a whole. However, information specific to fishery participants is not available. Furthermore, various segments of the fishery-involved population may differ demographically. For example, workers in fish processing plants may more often be from a minority population, while deckhands may be more frequently low income in comparison to vessel owners.

Participation in decisions about the proposed action by communities that could experience disproportionately high and adverse impacts is another important principle of the EO. The Council offers a range of opportunities for participation by those affected by its actions and disseminates information to affected communities about its proposals and their effects through several channels. In addition to Council membership, which includes representatives from the fishing industries affected by Council action, the GAP, a Council advisory body, draws membership from fishing communities affected by the proposed action. While no special provisions are made for membership to include representatives from low-income and minority populations, concerns about disproportionate effects on minority and low-income populations could be voiced through this body or to the Council directly. Although Council meetings are not held in isolated coastal communities for logistical reasons, they are held in different places up and down the west coast to increase accessibility.

The Council disseminates information about issues and actions through several media. Although not specifically targeted at low-income and minority populations, these materials are intended for

consumption by affected populations. Materials include a newsletter, describing business conducted at Council meetings, notices for meetings of all Council bodies, and fact sheets intended for the general reader. The Council maintains a postal and electronic mailing list to disseminate this information. The Council also maintains a website (www.pcouncil.org) providing information about the Council, its meetings, and decisions taken. Most of the documents produced by the Council, including NEPA documents, can be downloaded from the website.

7.2.3 EO 13132 (Federalism)

EO 13132, which revoked EO 12612, an earlier federalism EO, enumerates eight fundamental federalism principles. The first of these principles states Federalism is rooted in the belief that issues that are not national in scope or significance are most appropriately addressed by the level of government closest to the people. In this spirit, the EO directs agencies to consider the implications of policies that may limit the scope of or preempt states' legal authority. Preemptive action having such federalism implications is subject to a consultation process with the states; such actions should not create unfunded mandates for the states; and any final rule published must be accompanied by a federalism summary impact statement.

The Council process offers many opportunities for states (through their agencies, Council appointees, consultations, and meetings) to participate in the formulation of management measures. This process encourages states to institute complementary measures to manage fisheries under their jurisdiction that may affect federally managed stocks.

7.2.4 EO 13175 (Consultation and Coordination with Indian Tribal Government)

EO 13175 is intended to ensure regular and meaningful consultation and collaboration with tribal officials in the development of Federal policies that have tribal implications, to strengthen the United States government-to-government relationships with Indian tribes, and to reduce the imposition of unfunded mandates upon Indian tribes.

The Secretary recognizes the sovereign status and co-manager role of Indian tribes over shared Federal and tribal fishery resources. At Section 302(b)(5), the MSA reserves a seat on the Council for a representative of an Indian tribe with Federally recognized fishing rights from California, Oregon, Washington, or Idaho.

The U.S. government formally recognizes that the four Washington coastal tribes (Makah, Quileute, Hoh, and Quinault) have treaty rights to fish for groundfish. In general terms, the quantification of those rights is 50 percent of the harvestable surplus of groundfish available in the tribes U&A fishing areas (described at 50 CFR 660.324). Each of the treaty tribes has the discretion to administer its fisheries and to establish its own policies to achieve program objectives.

Section 4.15 describes the effects of the proposed action on tribal fisheries. The proposed action does not affect the tribes' treaty rights. Through the Council process the proposed action has been developed in consultation with the affected tribes through their representative on the Council.

CHAPTER 8 LIST OF PREPARERS

Council Staff

Name	Primary Contribution
Merrick Burden	Analytical design; model development; impact analysis (harvesters, captain and crew, nontrawl commercial harvesters, processors, communities), Appendix A contributor, Appendix B, Appendix C
Heather Brandon	Impact analysis (management agencies, groundfish, protected species, ecosystem), Appendix A contributor
John Coon	Project management
Christopher "Kit" Dahl	Analytical design; document management; Executive Summary, Chapter 1, Chapter 2, impact analysis (labor, input suppliers, tribal harvesters)
Jennifer Gilden	Impact analysis (communities)
Jim Seger	Project management, model development, Chapter 2, Appendix A, Appendix E

Other Contributors

Name	Affiliation	Participation
Stephen Freese	NMFS Northwest Region	Appendix A contributor (tracking, monitoring and enforcement; NMFS impacts)
Jamie Goen	NMFS Northwest Region	NMFS Project manager, Chapter 2
Michael Taylor	Consultant	Impact analysis, processors; model development
Ed Waters	Consultant	Data analysis, model development, income impact estimates
Kevin C. Duffy	NMFS Northwest Region	Document management for completion of EIS

CHAPTER 9 ACRONYMS AND GLOSSARY

Acronym	Definition
ABC	allowable biological catch. The ABC is a scientific calculation of the sustainable harvest level of a fishery and is used to set the upper limit of the annual TAC. It is calculated by applying the estimated (or proxy) harvest rate that produces maximum sustainable yield to the estimated exploitable stock biomass (the portion of the fish population that can be harvested).
ACL	annual catch limit
AFA	1998 American Fisheries Act
AMP	Adaptive Management Program
BCC	Bird of Conservation Concern
B_{MSY}	the biomass that allows maximum sustainable yield to be taken
BRD	bycatch reduction device
BSAI	Bering Sea/Aleutian Islands
Bycatch EIS	The Pacific Coast Groundfish Fishery Management Plan Bycatch Mitigation Program Final Environmental Impact Statement
CCA	Cowcod Conservation Area(s)
CDFG	California Department of Fish and Game
CDQ	community development quotas
CEQ	Council on Environmental Quality
CFA	Community Fishing Association
CFGC	California Fish and Game Commission
CFR	Code of Federal Regulations
Council	Pacific Fishery Management Council
CPS	coastal pelagic species
CPUE	catch per unit of effort
CV	coefficient of variation

Acronym	Definition
CZMA	Federal Coastal Zone Management Act
DAP	dedicated access privilege
DEIS	draft environmental impact statement
DSL	Division of State Lands
DTS	Dover sole, thornyhead, and trawl-caught sablefish complex
EA	environmental assessment
EBFM	ecosystem-based fishery management
EC	Enforcement Consultants
EEZ	Exclusive Economic Zone
EFH	essential fish habitat
EFHRC	Essential Fish Habitat Review Committee
EFP	exempted fishing permit
EIS	environmental impact statement
EMS	electronic monitoring system
ENSO	*El Niño* Southern Oscillation
EO	Executive Order
EPA	U.S. Environmental Protection Agency
ESA	Endangered Species Act
F	The instantaneous rate of fishing mortality. The term "fishing mortality rate" is a technical fishery science term that is often misunderstood. It refers to the rate at which animals are removed from the stock by fishing. The fishing mortality rate can be confusing because it is an "instantaneous" rate that is useful in mathematical calculations, but is not easily translated into the more easily understood concept of "percent annual removal."
FCZ	Fisheries Conservation Zone
FEAM	Fishery Economic Assessment Model
FEIS	final environmental impact statement
FEP	Fishery Ecosystem Plan
FERC	Federal Energy Regulatory Commission
FMA	Fishermen's Marketin g Association
FMP	fishery management plan
F_{MSY}	the fishing mortality rate that maximizes catch biomass in the long term
FMU	fishery management unit
FR	Federal Register

Acronym	Definition
GAC	Groundfish Allocation Committee
GAO	Government Accountability Office
GAP	Groundfish Advisory Subpanel
GCA	groundfish conservation area
GMT	Groundfish Management Team
GOA	Gulf of Alaska
GPS	global positioning system
HAPC	habitat areas of particular concern
HG	harvest guideline(s)
HMS	highly migratory species
IBQ	Individual bycatch quota
IEP	Independent Experts Panel
IFQ	individual fishing quota
IMPLAN	Impact Analysis for Planning - a regional economic impact model
INPFC	International North Pacific Fishery Commission
IPHC	International Pacific Halibut Commission
IRFA	initial regulatory flexibility analysis
LAP	limited access privilege
LAPP	limited access privilege program
LE	LE fishery
LEP	Limited Entry Permits
LO	lack of objection
M	instantaneous rate of natural mortality (as opposed to F, fishing mortality)
MAFMC	Mid-Atlantic Fishery Management Council
MBNMS	Monterey Bay National Marine Sanctuary
MBTA	Migratory Bird Treaty Act
MFMT	maximum fishing mortality threshold
MLPA	Marine Life Protection Act
MMPA	Marine Mammal Protection Act
MPA	marine protected areas
MSA	Magnuson-Stevens Fishery Conservation and Management Act
MSC	Marine Stewardship Council

Acronym	Definition
MSST	minimum stock size threshold
MSY	maximum sustainable yield
mt	metric ton
NAO	NOAA Administrative Order
NEPA	National Environmental Policy Act
NIST	National Institute of Standards and Technology
NMFS	National Marine Fisheries Service
NOAA	National Oceanic and Atmospheric Administration – the parent agency of National Marine Fisheries Service
NOI	notice of intent
NPFMC	North Pacific Fishery Management Council
NPOA	National Plan of Action
NRC	National Research Council
NTEP	National Type Evaluation Program
NWFSC	Northwest Fisheries Science Center
NWR	National Marine Fisheries Service, Northwest Region
OAR	Oregon Administrative Rules
ODFW	Oregon Department of Fish and Wildlife
OFWC	Oregon Fish and Wildlife Commission
OLE	Office of Law Enforcement
OPAC	Ocean Policy Advisory Council
OSCZ	Ocean Salmon Conservation Zone
OSHUA	Optimum Species Harvesting Unified Allocation
OTC	Oregon Trawl Commission
OY	optimum yield
PacFIN	Pacific Coast Fisheries Information Network. Provides commercial fishery information for Washington, Oregon, and California. Maintained by the Pacific States Marine Fisheries Commission.
PBR	potential biological removal
PDO	Pacific decadal oscillation
POP	Pacific ocean perch – a rockfish species that was declared overfished in 1999
PRA	Paperwork Reduction Act
PSMFC	Pacific States Marine Fisheries Commission

Acronym	Definition
QP	quota pound
QS	quota share
QSM	quota species monitoring
RCA	Rockfish Conservation Area
RCW	Revised Code of Washington
RFA	Regulatory Flexibility Analysis, or Regulatory Flexibility Act
RFFA	reasonably foreseeable future action
RIR	Regulatory Impact Review
ROD	Record of Decision
RPC	raw product costs
SAC	Sanctuary Advisory Council
SAFE	stock assessment and fishery evaluation
SAFMC	South Atlantic Fishery Management Council
SAR	stock assessment reports
SFA	Sustainable Fisheries Act of 1996 – amended the MSFCMA
SFT	selective flatfish trawl
SHOP	Shoreside Hake Observation Program
SPR	spawning potential ratio
SRP	Scientific Research Permits
SSC	Scientific and Statistical Committee
TAC	total allowable catch
TIQC	Trawl Individual Quota Committee
TISEC	tital in-stream energy conversion
T_{MAX}	the maximum time to rebuild an overfished stock, according to National Standard Guidelines. Depends on biological, environmental, and legal/policy factors
T_{MEDIAN}	median year
T_{MIN}	The minimum time to rebuild an overfished stock, according to National Standard Guidelines. Technically, this is the minimum amount of time in which a fish stock will have a 50 percent chance of rebuilding if no fishing occurs (depends on biological and environmental factors).
T_{TARGET}	the target year, set by policy, for a fish stock to be completely rebuilt
U&A	usual and accustomed (usually used when referring to tribal fishing, hunting or gathering areas)

Acronym	Definition
USFWS	U.S. Fish and Wildlife Service – a representative of USFWS is a nonvoting member of the Council
VMS	vessel monitoring system
WCGOP	West Coast Groundfish Observer Program
WCN	World Conservation Union
WDFW	Washington Department of Fish and Wildlife – a representative of WDFW sits on the Council
WFWC	Washington Fish and Wildlife Commission
WPFMC	Western Pacific Fishery Management Council
YRCA	Yelloweye Rockfish Conservation Area

CHAPTER 10 COMMENTS ON THE DEIS AND RESPONSES

10.1 The Proposed Action

10.1.1 Program Costs

Commenters: Fishermen's Marketing Association; Fort Bragg fishery participants; Environmental Defense Fund et al.; Oregon Trawl Commission; Pacific Coast Federation of Fishermen's Association; The Nature Conservancy; Tommy's Marine Service

Seven commenters directly addressed program costs. Those comments are summarized as follows along with our response. Other commenters addressed program costs as a justification for modifying elements of the tracking and monitoring program. These comments are summarized and responded to under the section on tracking and monitoring.

Comment 1: Costs are not fully divulged or analyzed. The range of cost estimates varies greatly. Industry-born costs and fee structures are not specified. Incremental costs have to be specified, as well as areas of cost savings. Only costs directly necessary for the management of the trawl rationalization program should be included (costs related to the collection and processing of data not needed for the catch shares program should not be included). The lack of well-developed cost information violates NEPA.

Response: The DEIS covered a range of potential costs. The economic information provided was sufficient for NEPA purposes and adequate for a reasoned choice among the alternatives.

Additional economic information is provided in RIR/IRFA in this FEIS (see Appendix H). This additional information describes costs along with estimates of the distribution of these costs between the Federal government and the private sector.

Comment 2: Costs are more than industry can bear and the amount industry pays should be limited to the 3 percent specified in the MSA. Catch monitoring should not impose a disproportionate cost on small vessels.

Response: Analyses indicate that the program benefits will outweigh the program costs. One commenter mentioned that program compliance costs in combination with the costs of acquiring QS would be too much of a burden. In response, it should be noted that the amounts that industry must pay to support program costs should reduce the value of the QS. For those participants who feel the costs are too much of a burden, they have the option of selling or leasing their QS.

The MSA states that fees charged for LAPPs are in addition to other fees charged under the MSA. Congress explicitly allows the Secretary to require use of specified gear, require that observers be carried on vessels, and collect royalties. Requiring that industry make arrangements for the presence of a trained observer as a condition for participating in the program does not violate the 3 percent limit on cost recovery, which is specified in the statute to collect agency costs of implementing the LAPP programs. Industry payments for observers go directly to private companies and will vary based on labor markets and private contractual arrangements rather than any fee established by the government.

Since arrangements to pay for observers will be among private parties, the government has little control over the payment structures and the relative costs imposed on small vessels. As noted at the April 2010 Council meeting (http://www.pcouncil.org/wp-content/uploads/I1b_SUP_PSMFC_RPT_APRIL_2010_BB.pdf), the agency intends to cover part of the observer costs, subject to the availability of Federal funding, during the first three years of the program.. In addition, as stated at Council meetings, vessels can and are encouraged to coordinate with each other and with the observer providers to reduce costs and provide more efficiency.

Comment 3: Intent to have industry directly pay for some costs (in excess of 3 percent) should have been disclosed in the EIS.

Response: The analysis in Section A-2.2.3 of the EIS indicates that it is likely that industry would have to pay for the observer and shoreside monitoring costs as a payment in addition to the 3 percent. Direct payment for observers is also mentioned at the bottom of page 293 and page 297 of the DEIS. Adjustments will be made to the sections on impacts on harvesters so that it will be easier for the public to find this information. It is also highlighted in the RIR/IRFA attached to this FEIS. The public will have additional opportunity to comment on the Council recommendations during the comment period on the Amendments and on the proposed rules to implement the Amendments.

Comment 4: Benefits will lag costs. Industry will not be able to cover increased costs, particularly for observers, in the interim or the long-term.

Response: As noted at the April Council meeting, the agency intends to cover part of the observer costs, subject to the availability of Federal funding, during the first three years of the program (see document on website provided above). This is intended, in part, to address the transition period.

In specific response to this comment, the EIS recognizes that not all benefits from the program will occur at inception (page 295). The EIS anticipates that the value of the fishery will increase through a variety of mechanisms, including increased efficiency of operations of existing vessels, the transfer of effort to the most efficient vessels, and increased retention of target species. For the nonwhiting trawl fleet alone, it is anticipated that the first two of these mechanisms may yield benefits of around $14 million. With respect to transfer of quota to more efficient vessels, while QS transfers will be prohibited in the first two years, there would be an opportunity for QP to be transferred annually to the most efficient producers. The more difficult it is for vessels to cover their costs, the more likely and rapidly transfer of QP to most efficient operators will occur. The EIS discusses the possibility that it may take more time for markets to develop to absorb increases in the retention of target species.

However, it is expected that the initial benefits from increased efficiency should compensate for the increased compliance costs.

In general, within the limits of the available data and the models that can be constructed using that data, the analysis projects impacts. The Council and the agency recognize there is uncertainty about the eventual impacts; the program contains many opportunities for adaptive response if actual impacts vary from those projected in a substantially negative fashion.

The Council and the MSA are both very clear that the LAPP systems provide revocable non-compensable privileges, subject to modification. The MSA and the Council's FMP allow the Council to modify the program at any time, after going through the appropriate public process. Additionally, the Council specifically set aside 10 percent of quota for adaptive management, included a program review after five years, and a review of accumulation limits after two years. Also, there will be additional opportunity for review and modification during the specification process through which the Council establishes its biennial regulations.

10.1.2 Monitoring, Compliance, and Control Systems

Commenters: Arctic Storm Management Group, Environmental Defense Fund, Oregon Trawl Commission, The Nature Conservancy, Tommy's Marine Service, United Catcher Boats

Comment 5: In order to reduce costs, the catch monitoring program should be a simple, "bare minimum" program sufficient to verify catch and make the IFQ/co-op programs work.

Response: NMFS will implement a monitoring program sufficient to make the trawl rationalization program work while minimizing cost where possible. As the commenter states, full catch accounting is crucial to the program's success. This will be accomplished through at-sea observers to monitor discards, shoreside monitors to document landings, and the requisite reporting, data processing, and data storage systems. Harvesters will face costs from several sources, including costs specifically for at-sea observers and cost recovery fees intended to recover the agency's actual costs directly related to the management, data collection, and enforcement of the LAPP program.

While NMFS will establish observer duties and priorities, as well as specify harvesters' obligations through regulation, the amount charged for observers will be determined by third party providers and is also governed by applicable maritime wage laws. Observer work duties would prioritize catch monitoring over other duties as long as any other statutory requirements can be fulfilled (e.g., documenting protected species interactions consistent with the ESA). Since vessels are typically assessed at a flat daily rate based on time on board the vessel, there is likely little or no incremental cost of additional duties (e.g., biological sampling) as long as these tasks can be accomplished in a normal work day in addition to all duties related to catch monitoring.

Shoreside monitors also will be contracted through third party providers, with any costs for their services negotiated between the provider and first receiver (the responsible party for landings) with NMFS establishing basic requirements including job qualifications. In that respect the discussion above is relevant, MSA §303A(e) states that cost recovery under LAPPs shall be for programs "directly related to and in support of" the LAPP. NMFS must implement an adequate monitoring program to make the trawl rationalization program work effectively. These types of costs would be covered through a cost recovery fee (up to 3 percent of ex-vessel revenues), rather than third party contractual arrangements. The cost recovery rulemaking will be done as a trailing action after the Council has developed the mechanism, per the statutory requirements.

Comment 6: Fishery observers should not be placed on catcher vessels in the whiting mothership sector, because monitoring of the small amount of discards likely to occur could be accomplished just as effectively and at less cost with EMS, including cameras. A similar comment was made with respect to shoreside whiting catcher vessels.

Response: The preferred alternative specifies observers on whiting catcher vessels. NMFS has stated that it intends to work with the Council in the future to determine whether EMS might be an appropriate type of monitoring for both mothership and shoreside whiting catcher vessels.

Although neither whiting mothership catcher vessels nor shoreside whiting catcher vessels engage in sorting of catch at sea, they vary somewhat in operational characteristics. Mothership catcher vessels detach the codend from the trawl net and deliver it to the processor. Shoreside catcher vessels dump unsorted catch into the fish hold for delivery to the processing plant. In both cases, the intention is that all of the catch is retained for delivery with monitoring occurring at the processing location. Compliance with this requirement may be relatively straightforward, but accurate estimation of discards, whether unintentional or due to exigent circumstances (e.g., equipment failure, emergency) may not be possible with current EMS technology. Although discards may be low in most cases, there may be situations where large volumes of fish are discarded (because of problems with the trawl net, for example).

Similarly, even small amounts of bycatch species discard need to be identified by species if constraining sector allocations apply. Current technology may not allow accurate species identification in these situations. Commenters note that EMS with cameras has been tried in the shoreside whiting fishery under EFPs. The Council Enforcement Committee has stated that human observation will be necessary because currently this fishery is subject to a "maximized retention" requirement that allows some level of self-reported discards, while under IFQ management this will change to a full retention requirement (see Agenda Item E.10b, Supplemental EC Report, June 2009). Furthermore, incentives will change under IFQs, which make harvesters fully accountable to cover all catch with QP and increase the motivation to misreport or under-report discards (especially of highly constraining bycatch species). Harvesters are likely to be more motivated to evade detection so the greater scope for vigilance offered by a human observer is necessary.

Comment 7: Shoreside monitoring provisions could be streamlined, which would lower costs. Recommendations are to allow substantial flexibility in the deployment of observers to various tasks (e.g., shoreside compliance monitors, redeployment among vessels as part of a single contract); eliminate processor production reports because compliance monitors will be gathering the same information; ensure that compliance requirements (landing declarations, site licensing) do not reduce vessels' flexibility in determining landing locations; use observer and shoreside compliance monitor supplied information to track catch against IFQ, rather than the official record of landed catch; and do not require electronic logbooks unless cost savings can be demonstrated.

Response: As supported in the attached RIR/IRFA (Appendix H), the DEIS found that harvesters are likely to experience revenues greater than costs (see also Appendix A, pp 409-418). The monitoring and compliance program will be specified through rulemaking (the program components rule). With respect to measures to allow greater flexibility in deploying observers and shoreside compliance monitors, NMFS intends to streamline regulatory requirements through the public Council process to achieve flexibility.

Comment 8: Develop EMS for fixed gear used under the IFQ program, because use of fixed gear provides economic and environmental benefits. However, because of lower catch volume and associated revenue, observer costs would be a disincentive to switch from trawl gear to fixed gear.

Response: As stated in other responses, the monitoring program must accurately account for total catch. If the efficacy of an EMS can be demonstrated (either through the EFP as discussed by the commenter, through the adaptive management program implemented in year 3 of the program, or other means) future Council decision-making could lead to program modifications to allow EMS to substitute for observers. The Council, in developing their preferred alternative, intended to provide fishermen with the flexibility to use fixed gear under the IFQ program. Overall, IFQs are intended to give fishermen greater flexibility to discover profitable fishing strategies based on costs and opportunities. This might prompt innovation by harvesters to find ways to profitably use fixed gear even with the additional cost of paying for observers. At the same time, the Council and NMFS support continued trials to test EMS for this use.

Comment 9: Baseline socioeconomic data should be collected prior to implementation as well as post-implementation to better understand program effects, but the DEIS does not explain why such baseline data are not being collected.

Response: The Council's preferred alternative (element A-2.3.2) includes a mandatory data collection program for socioeconomic data (costs, revenues, ownership, and employment), which would be implemented as part of the proposed action, and notes that collection before program implementation would be beneficial (see Appendix D, p. D-17, D22-23). The DEIS does specify that baseline socioeconomic data should be collected both before and after program implementation. These regulations will be proposed in the program components rule.

In addition to the mandatory data collection program, NMFS Northwest Fisheries Science Center is developing a voluntary data collection program regarding social impacts. The collection is designed to provide a baseline description of the industry, as well as allow for analysis of changes the program may create for individuals and communities in the fishery. The study includes both pre-implementation information and post-implementation information (see 75 Federal Register 26197, May 11, 2010).

Comment 10: The EIS should explain what protections would be applied to confidential business information that might be collected. In particular, information on sale and lease prices for IFQs and co-op shares may be collected in a "central registry" and this information should not be made public, especially in unaggregated form.

Response: Release of information is controlled by the Freedom of Information Act and the data confidentiality provisions in MSA §402(b) (and pursuant regulations at 50 CFR 660 Subpart E). Generally speaking, unaggregated data cannot be released.

Comment 11: Because violations can be detected through catch monitoring data systems, additional enforcement presence seems unnecessary under the program.

Response: The Council has an ongoing role in the design of the enforcement program through its Enforcement Consultants (EC) committee. The EC represents both state and Federal enforcement agencies. Preliminary estimates of changes in enforcement staff necessary for the trawl rationalization program are found on page 577 of the DEIS. The RIR/IRFA in this document includes enforcement cost estimates based on a plan adopted by the Council at the April 2010 meeting. As the commenter notes, "enforcement is a critical piece of management," but the assertion that the catch monitoring system alone will be a sufficient enforcement tool is incorrect. Many types of violations by their very

nature will not be detected through catch monitoring, because their intent is to frustrate the monitoring system.

Catch shares (IFQs, co-op shares) fundamentally change the incentive system. While individual accountability is expected to result in positive behavioral changes, such as the discovery of bycatch reduction methods, the incentive to evade catch accounting can increase. Enforcement is thus a critical piece of the program's integrity; if participants are not confident that others are playing by the rules, or will be prosecuted if cheating, each person's willingness to abide by the rules is degraded. In addition, given the likelihood that the violations most likely to threaten the integrity of the program are those where catch monitoring is evaded, enforcement is more than just detection. It also involves developing cases by bringing forward admissible evidence and pursuing prosecutions. To the degree that changed incentives increase the likelihood of catch accounting evasion, more enforcement presence will be necessary.

10.1.3 Initial Allocation of Catch Shares, IFQ

Commenters: Arctic Storm Management Group; Coos Bay Trawlers Association; Crab Boat Owners Association; Deronden-Pos, Henry; Hawley, Keith; Fishermen's Marketing Association; Fort Bragg fishery participants; Natural Resource Consultants (Pacific Dawn Fisheries); The Nature Conservancy; Ocean Gold Seafoods, Inc.; Oregon Trawl Commission; Starbound LLC; United Catcher Boats; and Yeck, Fred Seadawn Fisheries

10.1.3.1 General Comments on Allocation of Catch Shares

Comment 12: Creating a fishing business is capital intensive. The next generation won't be able to afford to fish. Fishing has always been a "work your way up from the bottom" business. We need a forward-looking management plan that provides a transition to a rationalized fishery, without the burdens of significant additional investment the average fisherman cannot afford and will likely not make. It will require the redirection of limited capital, badly needed for infrastructure and vessel improvement to acquisition of needed quota.

Response: This is a forward-looking management program. It is expected to improve the economics of the overall trawl fishery. Economic analysis of the fishery indicates that the average nonwhiting shoreside fisherman is either breaking even or losing money (not fully covering its capital costs). Fishing businesses that don't receive an initial allocation may participate either by acquiring QP each year from quota shareholders or acquiring long-term security through the purchase of QS. Those fishing businesses that do not choose to acquire QS will have to compete each year in the market for QP. Their ability to purchase QP will depend on their ability to be more efficient than other fishing businesses, and thereby more able to offer a higher price for the QP. Fishing businesses that choose to do so will be able to increase the security of their investments by acquiring QS.

The Council recognizes that for new entrants, the cost of acquiring individual quota will add to the expense of entering the fishery. An increase in profits (before taking into account the cost of the quota and normal profits after taking into account the cost of the quota) and stability is expected to compensate for the increase in costs. Under status quo management, the value of a new entrant's capital investment would be at greater risk because of the potential erosion of fishing opportunity through the increased effort of others. With respect to the capital badly needed for infrastructure and vessel improvements, this is a condition that has occurred under status quo management. There is no reason to believe that continuation of status quo would improve the situation; however, under IFQs, greater

economic stability may facilitate a safer fleet with a stronger infrastructure. Section A-2.2.2.d of Appendix A to the EIS identifies ways in which the Council considered the needs of new entrants.

With respect to new entrants working their way up from the bottom, the QS system provides an opportunity for individuals such as crew members to accumulate capital. For example, crew members might invest in some QS and sell their QP to the vessel each year, creating a stream of income which may be accumulated to allow them to purchase more QS and eventually a vessel.

Comment 13: The initial allocation of harvest privileges to shoreside fish processors is not legal. Specifically, the Council lacks statutory authority for such allocations. Shoreside processors do not "substantially participate" in the fishery. Even if shoreside processors could receive direct allocations to harvest fish, the allocations are based on processing history and are in effect shoreside processing privileges, which are not authorized under the MSA. In addition, the allocations will reduce competition and have anticompetitive effects. Finally, the allocation to processors are not "fair and equitable" as required by National Standard 4: 20 percent of the available harvest is taken off the top and allocated to processors, and harvesters' bargaining power is decreased while processors' power is increased.

Response: The Council's preferred alternative designated that 20 percent of the shoreside harvest allocation of whiting would be initially allocated to shoreside processors, based on those processors' history. The Council concluded that this initial allocation was fair and equitable, thus consistent with section 303A(c)(5) of the MSA, which requires the Council to "ensure fair and equitable allocations, including consideration of (i) current and historical harvests; (ii) employment in the harvesting and processing sectors; (iii)investments in, and dependence upon, the fishery; and (iv) the current and historical participation of fishing communities ." As explained in Section A-2.1.1.a (Appendix A) of the EIS, the Council took the statutory factors into account and determined that, among the various alternatives under consideration, the initial allocation of whiting harvesting privileges as a 20/80 percent split to processors and current permit holders was fair and equitable.

NOAA does not interpret MSA 303A(c)(5)(E) to prevent shoreside processors from receiving harvesting privileges. Section 303A(c)(5)(E) states that in developing a LAPP to harvest fish, a Council shall "authorize LAP to harvest fish to be held, acquired, used by, or issued under the system to persons who substantially participate in the fishery, including in a specific sector of such fishery, as specified by the Council." The agency's interpretation of that provision is that those who substantially participate in the fishery must be among those eligible to acquire QS, but are not the only entities or persons who can receive QS. In other words, as long as those who substantially participate in the fishery are included as those eligible, the provision of the statute is satisfied. The Council's eligibility criteria provide QS to all owners of existing limited entry permits; hence to those entities that currently substantially participate in the trawl fishery.

As noted above, Section 303A(c)(5)(A) covers initial allocation and requires that the Council consider four factors in determining what would be a fair and equitable initial allocation. Of these four factors, three either implicitly or explicitly require the Council to take into account processing activities: (ii) employment in the harvesting and processing sectors; (iii) investments in, and dependence upon, the fishery; and (iv) the current and historical participation of fishing communities. As explained above, the Council considered a variety of different initial allocation criteria, and concluded that the preferred alternative was fair and equitable, and took into account the required factors.

The commenter also asserts that the allocation of harvesting privileges to processors constitutes the allocation of an opportunity to process a certain share of the catch and is therefore a processing privilege, and as noted by the commenter, such allocation would be inconsistent with past agency legal

opinions. In response, the nature of the primary business activities of those owning the QS does not change the nature of the privilege. The privilege represented by the IFQ is the privilege of catching the fish, nothing else

Finally, the commenter objects to the allocation of QS to processors because such an allocation will reduce competition and have anticompetitive impacts. This issue and the potential for anticompetitive results has been analyzed extensively in the EIS and was discussed and considered carefully by the Council. During development of the trawl rationalization program, the NOAA Office of General Counsel (GC) had informal consultations with the Antitrust Division of the U.S. Department of Justice. Based on those informal consultations and analysis of relevant facts and applicable legal rules, NOAA GC submitted a letter to the Council dated October 11, 2008, in which the antitrust savings clause in Section 303A of the MSA was noted and advised "that any fishery participants that are uncertain about the legality under the antitrust laws of the Unites States of any of their anticipated activities should consult legal counsel prior to commencing those activities." The NOAA GC letter provided citations to guidance or resource documents available on the Federal Trade Commission website. The NOAA GC letter is available on the Pacific Council's website at http://www.pcouncil.org/bb/2008/1108/F3d_SUP_GC_1108.pdf.

Comment 14: As a substantial participant in the fishery, the Nature Conservancy should be allocated quota.

Response: The Nature Conservancy cites as evidence of its status as a fishery participant its ownership of limited entry permits and that it has partnered with fishermen and local communities to continue fishing those permits using more sustainable practices. The EIS assumptions and the policy recommended by the Council both anticipate that the Nature Conservancy would receive an initial allocation of QS based on the permits it owns, i.e., they will qualify for QS just as any other permit holder qualifies for QS.

10.1.3.2 Allocation Formula, General

Comment 15: With respect to the initial allocation of catch history to catcher vessels in the mothership sector, the commenter supports the allocation periods and criteria but states that it is important to recognize that in the original Council motion, the word "worst" was purposefully not included and the motion just stated: "drop 2 years." It was the intent of the PFMC to allow the permit owner the ability to decide which years to drop. Furthermore, there is no requirement for a vessel dually qualified in the MS and SS whiting fisheries to have the same drop years in both sectors.

Response: The word "worst" was used in the write up of the Council motions based on the assumption that no permit holder would choose to drop years that would result in a lesser allocation. Worst was interpreted to mean "worst" after taking into account relative catch history. Nevertheless, the commenter is correct and the language has been adjusted to state only that "two years" will be dropped, so that the permit owners might be allowed to choose to drop years other than their worst years. The commenter is correct that there is no requirement for a vessel dually qualified in the MS and SS whiting fisheries to have the same drop years in both sectors.

Comment 16: With respect to the analysis, one commenter noted that analysis of the impacts relative to the recent fleet activities might be improved.

Response: Some of the information sought by the commenter was available in Appendix A, covering the IFQ program. However, in response to this comment, Appendix B, covering the co-op program, has been augmented with (1) counts of the numbers of vessels participating in recent years and those eligible to participate under Amendment 15; and (2) a graph comparing the allocation of QS to each permit against the permit's recent harvest shares.

Comment 17: One commenter opposes the inclusion of additional qualifying years for determining the initial allocation and/or imposing a recent harvesting requirement, another supports the allocation qualification and catch history requirements for mothership catcher vessels that were adopted, and another voiced general support of the initial allocation formulas.

Response: No additional qualifying years or recent harvesting requirements have been imposed. For the at-sea mothership delivered, estimates of quota allocations have been updated based on new vessel identifier information acquired by PacFIN.

Comment 18: Several commenters addressed the allocation qualification and catch history requirements. Two commenters expressed a belief that MSA recency requirements are not being met because the allocation period of 1994-2003 is too out of date. One commenter suggested extending the history years to include years 2004 up to 2009 or as recent as possible. Another suggested increasing emphasis on recent years by moving the start of the allocation period from 1994 to 1997 and the end from 2003 to 2006 (and using 2003 through 2006 for the allocation period for overfished species), recognizing a new control date of January 1, 2007. The commenter further stated:

- **This plan considers historical participation that will be 17 years old at the time of implementation (including harvest taken leading up to the groundfish disaster) but not 7-year-old history.**
- **It rewards the inefficiencies, inadequate infrastructure and lack of investment that characterized the qualifying year window. Since 2000 we have seen significant changes in the markets and technology in groundfish processing. Active fishermen will be required to buy or lease quota upon implementation of this program just to achieve their status quo fishing levels prior to its implementation.**
- **Approximately 40 percent of the nonwhiting groundfish allocated under this plan go to permits that are not active participants in the fishery. The initial allocation and species mix do not provide enough fish to live on.**
- **The allocation period includes years with inaccurate species composition and discard data that will skew the picture of the true state of nature.**

Several other commenters voiced support for the Council's qualifying years. Those commenters expressed concern that any amendment to the allocation qualification and catch history requirements would result in delay in implementation.

Response: In determining initial allocations, the Council is required to consider several factors including current harvests and historic harvests. See 16 U.S.C. § 1853a(c)(5)(A); see also 16 U.S.C. § 1853(b)(6). Appendix A to the EIS includes a review of the Council's consideration of all of these factors, including a discussion of the rationale for considering a variety of dates for the allocation period, including start dates of 1994 and each year from 1997 through 2001. The allocation dates selected represent a balance between emphasis on more recent history and considering the historic fishing opportunities which may have had a determining effect on the levels of capital investment by individual firms. The start date of 1994 was selected because 1994 was the first year of the license

limitation program. The decision to utilize a long allocation period was deliberate; it is likely that capital investment is based on longer term opportunity and that capital persists after contractions in the fishery such as that reflected by the disaster declaration in 2000. On this basis it is appropriate to give some weight to landings from the 1990s. Because more fish was taken during that time period, the relative pounds approach (measuring catch history as a vessel's share of total catch) reduces the emphasis on a pound of fish caught in the 1990s as compared to a pound of fish caught after 2000. While some argue that fishermen who caught fish in the mid-1990s caused the disaster and should not receive QS for that fish, the catch taken in the mid-1990s was in line with what was allowed under the regulations and believed to be sustainable at the time.

The Council selected the ending year of 2003 because that year corresponds to the previously announced control date for the fishery. The Council adopted and published the control date of November 6, 2003. See 69 Fed. Reg. 1563 (Jan. 9, 2004); 70 Fed. Reg. 29713 (May 24, 2005). The Council believes it very important that the 2003 control date be used in order to prevent future fishery disruptions. The purpose of announcing a control date in advance of developing a LAPP is to discourage speculative entry into a fishery and increased harvest while the Council goes through the process of developing the program details. If the Council develops a pattern of announcing and abandoning control dates, then the announcement of control dates will become a signal to harvesters to intensify their efforts to catch fish in order to increase their odds of qualifying for greater initial allocations. Such a response would be disruptive to fisheries and exacerbate the challenges of meeting conservation objectives. Additionally, abandoning the original control date would reduce the perceived fairness of the program by rewarding those who fished speculatively after the control date (fishing primarily on the chance that the control date would be abandoned and they would acquire more quota as a result of their post control date fishing) at the expense of those who heeded the control date.

Further, the public was given significant notice of the use November 6, 2003, as a potential control date. The notice was originally published in the Federal Register on January 9, 2004, and an additional notice was published on May 24, 2005. Both notices were posted on the Council's website, with an explanation of the possible consequences of the control date. In addition, starting in October 2003, the Council and its Trawl Individual Quota Committee, held numerous public meetings and discussions at Council meetings on the trawl rationalization program, including the use of the control date and the alternative qualifying periods.

The Council disagrees with the commenter's assertion that Amendment 15 to the Groundfish management plan created a new control date of January 1, 2007, that should be controlling here. Nowhere does Amendment 15 address the 2003 control date or purport to change the qualifying period for the Groundfish trawl program. Amendment 15 was a limited interim action for the non-Tribal whiting fishery issued in anticipation of the trawl rationalization that in no way attempted to address matters beyond its limited scope. Moreover, the Council has explicitly stated that vessels that qualified for whiting fishery participation under Amendment 15 were not guaranteed future participation or inclusion in the Pacific whiting fishery under the provisions of Amendment 20 (see http://www.pcouncil.org/groundfish/fishery-management-plan/fmp-amendment-15/)

With regards to "recency" concerns, the Council does take into account recent participation patterns in the fishery by allocating QS to current permit holders rather than to individuals or vessels that originally caught the fish. In this way, during the extensive period required to develop a program of this kind, entry and exit can occur and QS can be allocated in a less disruptive manner than would occur if the allocations went to the individuals who caught the fish historically.

While the overfished species allocation formula includes logbooks for 2003-2006, these records are used to determine the fishing pattern, not the overall level of harvest activity. The Council's

methodology for allocating overfished species is significantly different than the methodology for allocating target catch. The 1994-2003 period is still used to determine the target species allocation, and the harvest patterns from the 2003-2006 logbooks are used to determine the amount of overfished species an entity would need to take its target species. In this fashion, more recent information for the fishery is used without rewarding post control date increases in effort. The 1994-2003 harvest patterns were not used to determine a target species QS recipients need for overfished species QS. This is because of the substantial changes in fishing patterns which were induced by the determination that some species were overfished and the implementation of the RCAs and because the RCAs will remain in place after the trawl rationalization system is put into place. Therefore the Council considered that an estimate of likely patterns of activity should be based on a period of time when the RCAs were in place. The RCAs were not in place for most of the 1994-2003 period but were in place for 2003-2006.

One commenter made the point that the initial allocation, because it is different from the current distribution of harvest, may reward inefficiencies and reverse recent conservation gains, including reductions in bycatch. While it is possible that the initial allocation may not go to the most efficient and innovative harvesters, because of the need to draw a balance between control date and disruption, fairness and equity, recent participation and historic participation issues, it is expected that society will benefit over the long haul as the quota is transferred to use by the most efficient harvesters as the program progresses. Independent of the initial allocation, the QS system is expected to provide substantial incentive for vessels to avoid bycatch. One hundred percent observer coverage will ensure full individual vessel accountability. These individual vessel incentives are expected to preserve gains made in bycatch avoidance in recent years.

The same commenter also made the point that the discard and catch composition data quality from those years is poor and will skew the picture of the true state of nature. The allocation formula does not use discard data from the mid-1990s. With respect to catch composition data, it has been accepted that these data may skew the mix of species any particular permit would receive away from its actual catch, simply because the catch composition data was designed to estimate catch at the fleet level rather than the individual vessel level. Catch composition data has the same problem whether it is from the mid-1990s or early 2000s. While the catch composition data might be of better quality in more recent years, the Council felt that it was more important that the control date and longer allocation period be maintained and worth the tradeoff entailed in relying on older catch composition data.

In summary, the Council did not revisit the qualifying period for initial allocation—no additional qualifying years will be considered. The Council does not anticipate delays in implementation related to the initial allocations.

Comment 19: There are many permit holders who haven't delivered a fish in 20 years that have gotten larger allotments than more active vessels. It is unfair that permits that have not made payments for the buyback program will receive an initial allocation.

Response: The permit system has only been in place since 1994 and only one permit has no shoreside landings during that period of time. All permits will receive an initial allocation of non-overfished species, Petrale sole, and canary rockfish based on the equal division of QS associated with the history of the permits bought back plus an amount of QS related to the actual 1994-2003 deliveries by the permit. The Council was aware that this will include some permits that have not made landings since the inception of the buyback loan payback program (December 2003). The Council has chosen what it believes to be the best balance among a variety of possible allocation approaches.

Comment 20: The Nature Conservancy strongly supports the Council's action to allow entities who qualify for an amount of QS in excess of the accumulation caps a reasonable period of time (four years from the initial allocation of QS under the program) to divest of their excess quota.

Response: This is part of the Council's final recommendations.

10.1.3.3 Allocation of bycatch/overfished species IFQ

Comment 21: Bycatch mortality rates should be applied to all management units to determine catch amounts debited to quota pounds, just as it is for Pacific halibut.

The Council considered whether the IFQ fishery should have mandatory retention of IFQ species or if participants could discard IFQ species. Application of discard mortality rates was not included for IFQ species because most bycatch species expected to constrain target fisheries assume discard mortality rates of 100 percent. For the few IFQ species that may have greater viability, tracking of discard mortality would be impracticable because it would increase the complexity and costs of the program. Complexity would increase because protocols for determination of viability have not been developed for application to voluntary discards of IFQ species. Costs would increase because of the research necessary to develop such protocols, and because of the substantial additional time an observer would need to spend documenting the amount and condition of the fish being discarded.

The situation for Pacific halibut is quite different from that of IFQ species bycatch. Pacific halibut is regulated under an international treaty with specific prohibitions, including the prohibition of retention of halibut by vessels with trawl gear. Trawl vessels are required to discard all halibut immediately. Observers track viability of halibut as part of their sampling duties; unlike other species, observers have established methods for evaluating the survival likelihood of individual halibut in order to report mortality estimates to the International Pacific Halibut Commission. Moreover, the amount of halibut bycatch in any particular tow is quite low; such that observers are able to accommodate viability sampling for Pacific halibut in addition to the observer's other duties.

Comment 22: Fort Bragg fishery participants will be adversely affected by the allocation formula for canary rockfish. Fort Bragg nonwhiting trawl vessels will only receive the minimum allocation of canaries, since they did not get any under the Council's final preferred alternative ("FPA"). In general, the FPA formula for the IC/IFQs gives more fish to permit holders who did not fish for certain species than to those who did. The program has been compromised by a Council decision to not allocate "overfished" species in the same manner as all the other species, but to use a method based on a constrained fleet outside of the time frame which the rest of the program is based. The allocation of overfished species should have been treated the same as all other species instead of using a different date range and methodology.

Response: The Council considered and rejected the option of allocating overfished species for nonwhiting trips using the same method as for other nonwhiting IFQ species as not appropriate under the circumstances. In particular, the relative weighting approach, by which landings for a year are measured as a percent of all landings for the year and species, would have given a particularly high amount of credit for pounds caught during the rebuilding period. Additionally, QS would have been allocated to those who targeted some of the overfished species in the mid-1990s (before they were declared overfished) rather than to those who need such QS to access current target species. Accordingly, the Council rejected the approach of using the same allocation formula for overfished species as for nonwhiting target species based on the desire to not reward bycatch during the rebuilding

period and in order to provide QS to those who would need it to cover incidental catch taken with their target species QS allocation.

In response to the situation of the Fort Bragg vessels, the Council revised its initial FPA so that all permits would receive an allocation of canary rockfish from the equal division of the pool of QS associated with the catch history of the buyback permits. This amounts to the equal division of about 45 percent of all the canary QS.

Comment 23: On page 546 of the DEIS, the Council and NMFS speculate that "Fort Bragg's vessels do not appear to rely on fishing grounds with a relatively high bycatch of constraining overfished stocks. Therefore, covering constraining overfished species with IFQ is not expected to substantially affect Fort Bragg." This is incorrect. Because we will not receive IFQs anywhere near our needs under the FPA for overfished incidental catch species other than canaries, we will be unable to fish for our long-time target species if Amendment 20 is passed as written.

Response: The statement that Fort Bragg vessels do not appear to rely on fishing grounds with relatively high bycatch rates of constraining overfished stocks is based on vessel logbooks from 2003 through 2006 (to determine fishing patterns) and 2003 through 2006 West Coast Groundfish Observer Program observations (to determine fleet bycatch rates). Both of these sources of data were used to analyze the alternative to allocate overfished species based on QS allocations of nonwhiting target species.

After the adoption of its FPA, the Council heard public comment with regard to concerns of the owners of Fort Bragg trawl vessels over the initial allocation of QS for constraining overfished species. The Council considered such testimony and subsequently revised its initial FPA so that all permits would receive an allocation of canary rockfish from the equal division of the pool of QS associated with the catch history of the buyback permits. The Council declined to revise the FPA for constraining overfished species other than canary.

Comment 24: Vessels should not be rewarded with larger initial allocations of QS for exceeding trip limits or being allowed to fish in restricted areas under an exempted fishing permit.

Response: The Council considered whether illegal landings or landings from trips under EFPs should be used as a basis for the calculation of initial allocations of QS. The Council motion disallows use of illegal landings, such as landings in excess of cumulative trip limits, in QS calculations. With regard to landings history from EFPs, the Council considered not only that vessels fishing under EFPs had opportunities that were not available to other vessels, but also that had the vessels not been taking part in these special activities they would have put more effort into other fisheries or groundfish targeting strategies. If vessels fishing under EFPs had put their effort into other available groundfish strategies, they would have more landings history, regulations would have been more constraining on the fleet, and the landings opportunity for other vessels not fishing under EFPs would have been diminished. After considering these issues, the Council determined that landings from trips under EFPs would count as a basis for initial allocations of QS, but landings from nonwhiting EFP trips that are in excess of the cumulative trip limits in place for non-EFP fishery would not count.

10.1.4 Ownership of catch shares, IFQ

Commenters: Environmental Defense Fund; Food and Water Watch; The Nature Conservancy; Pacific Coast Federation of Fishermen's Association

Comment 25: The proposed action should have included an owner-operator provision that limits who can hold quota to those who actually participate in the fishery.

Response: An owner-operator or owner-on-board provision was considered but rejected. In Section A-11 of Appendix A, three reasons are identified for rejection of the provisions: first, the impracticality of such a provision in a multispecies fishery which would rely heavily on quota trading to match quota mix to catch mix; second, the substantial increase in tracking and monitoring costs that such a provision would entail; and third, the owner-operator mode of organization is less dominant in the trawl fleet than in other, smaller boat, fisheries.

Comment 26: Eligibility to own language may be overly broad. This could lead to QS being held by some outside the fishery which could dissipate the economic benefits to fishery participants and fishing dependent communities. Therefore, we propose that the Council (1) identify tracking ownership patterns as a critical data collection need and (2) commit to evaluating the effectiveness of eligibility rules in meeting the objectives of the IFQ program during the 5-year review.

Response: As identified by this commenter, the Council considered this issue several times but decided to retain broad "eligibility to own" rules because of other concerns such as enforceability and tracking issues. NMFS has already published a final rule to collect information needed to track ownership patterns, and the effectiveness of eligibility rules will automatically be reviewed with all other program provisions during the 5-year review. The commenter suggested that participants be put on notice of a potential change in ownership rules. The regulations will specify and participants will be on notice from the start of the program that the quota system constitutes the granting of a fishing privilege, not a right, and any aspect of the program may be changed without compensation. The commenter also proposed that information be collected on the disposition of QP issued to QS holders. Tracking the use of QP was considered at length as part of a use-or-lose provision and it was determined that such a tracking system would be cost prohibitive.

Comment 27: The DEIS should give greater specificity to the need for a clearly defined and enforceable limit on control. Despite Council action to the contrary, given the great complexity of relationships in the fishing industry between and among fishermen and processors, the commenter believes the affiliate test would be a more clear way to determine control. The Council should then establish a "safe harbor" exemption from control limits for certain types of desirable and transparent arrangements that promote community stability, reduce bycatch, and improve monitoring and accountability. The commenter strongly supports Council action to create such a safe harbor through a "Community Fishing Association" program.

Response: The commenter acknowledges the individual and collective rule adopted by the Council, and that types of control other than ownership are still subject to the control limits. The commenter suggests the superiority of an affiliation test under which all of the QS owned by an entity would count against any other entity that owns more than a 10 percent share of the QS owning entity. This is supported as providing a "bright-line rule" for the evaluation of ownership.

In the program adopted by the Council, control is evaluated through relationships that go beyond direct ownership. The commenter suggests nine other control standards based on rules from the Alaskan fishery. These same standards are identified in the DEIS as ones that NMFS might incorporate into its rules in order to implement the general policy guidance provided by the Council (pages A-318 and A-319). The commenter also provides different situations and arrangements that should be considered. Each of these situations is covered in the EIS.

In addition, during the Council "deeming" process on the initial allocation and appeals regulations, the Council requested that NMFS revise the original draft implementing language to make it clear that in certain situations someone could control QS by controlling QP, which would constitute a violation of the control limit. At the April 2010 Council meeting, the Council deemed the revised draft implementing language as necessary or appropriate to implement Amendment 20.

The Council has committed to evaluation of a special control limit ("safe harbor") for community fishing associations as part of a trailing amendment.

Comment 28: Lower accumulation limits should be included in the preferred alternative. Alternative 4b supports QS accumulation limits that are so high as to be meaningless. There are no control limits on quota pounds at all.

Response: The Council adopted accumulation limits that reflect the current level of concentration in the fleet, as reflected by the harvest activity of individual permits. After consideration of a variety of approaches, the Council adopted control at levels more constraining than necessary to address concerns related to the effective functioning of QS markets. This was done in order to achieve certain objectives related to the distribution of QS ownership. The method used to develop the QS control limits is explained in the EIS. The commenter does not provide the standard by which the evaluation is made that the control limits are "meaningless." With respect to limits on the control of QP, the limits on QP control are in place but indirect. As explained in the previous response, the Council adopted revised regulatory language to make it clear that in certain situations someone could control QS by controlling QP, which would constitute a violation of the control limit.

Comment 29: The Council should have considered the needs of smaller ports and fishing communities when setting accumulation limits. One percent is normally considered a prudent accumulation limit in IFQ fisheries. Some of the smaller ports along the West Coast could vanish completely under the scenarios adopted by the Council.

Response: Accumulation limits for IFQ fisheries range widely depending on the needs and circumstances of any particular fishery. The U.S. surf clam and Wreckfish IFQ programs have no limits and rely on antitrust laws to ensure excessive control does not occur. Limits in the New Zealand system range from 10 to 40 percent, and limits in Iceland's IFQ system run from 12 to 35 percent. Nova Scotia has a limit of 2 percent. Limits in the halibut and sablefish IFQ fisheries in Alaska are set at 0.5 and 1.0 percent. The Council has set aggregate limits that will facilitate fleet consolidation and an increase in efficiency. It is recognized that fleet consolidation will have an impact on communities; however, other measures are provided to mitigate impacts on communities (see Section 10.1.5). Under an IFQ program, communities will have opportunities to plan and control their destiny through the acquisition of QS, if they so desire. Furthermore, the Council may use part or all of the 10 percent quota set aside in the AMP to mitigate impacts on communities and will be considering a trailing amendment to allow community fishing associations to acquire quota, potentially in excess of control limits.

10.1.5 Community involvement and Community Fishing Associations

Commenters: Crab Boat Owners Association, Food and Water Watch, Pacific Coast Federation of Fishermen's Associations, The Nature Conservancy

Comment 30: The preferred alternative should include provisions allowing CFAs to be established rather than deferring this program component to a later, trailing action. Fishing community representatives were not adequately consulted, CFAs were not adequately considered

by the Council, and CFAs were not sufficiently analyzed in the EIS as required by the MSA. Without CFAs, the trawl rationalization IFQ will only go to limited entry trawl permit holders and not to offset effects of consolidation on other fishermen and smaller ports. One commenter provided detailed comment on how CFAs should be structured under a trailing action.

Response: The assertion that community representatives were not adequately consulted or involved in the development of the program is incorrect. The community representative on the TIQC engaged in significant outreach efforts that included meetings with community and local environmental group representatives and distribution of information to an extensive contact list. The results of this outreach effort and community concerns thereby raised was summarized in Appendix H to the Council's 2005 scoping report (see pp. 108-112). The TIQC also discussed community-related issues at length; as with all Council committees, their meetings were open to the public and opportunities for public comments from non-committee members were provided.

Another example of community outreach may be found in the 2004 Environmental Defense report submitted to the Council summarizing the results of a survey of community stakeholders and their concerns over the development of the trawl rationalization program.

The Council also distributed information to communities through various channels. First, the Council regularly publishes a newsletter detailing Council activities, including the development of the proposed trawl rationalization program ultimately becoming the preferred alternative detailed in the DEIS. In 2004, the Council also distributed a scoping information pamphlet on the proposal as part of the scoping process, which was widely distributed. An information pamphlet directed at captain and crew members in the groundfish fleet was also distributed in both English and Spanish and was posted in affected ports by Sea Grant extension agents during this scoping period. These information materials described the Council's proposed action, and explained how comments could be submitted to the Council and how to engage in the Council process.

In June 2005, the Council directed the analytical team in consultation with the Council's SSC to draft a range of alternatives for community involvement in the trawl rationalization program. Then in November 2005, the Council devoted substantial time to the consideration of options to address community impacts, including the distribution of QS to communities. DEIS Appendix A, pp. A-41 to A-42, summarizes results of the process, noting the difficulty in identifying an appropriate representative body within the community that would hold QS. As described there, at that time community leaders did not express interest in receiving an initial allocation of QS because of the administrative and political costs of managing such an allocation. Furthermore, communities (through whatever organizational mechanism) have not been precluded from acquiring groundfish limited entry trawl permits, which would make them eligible for the initial allocation of QS associated with a permit. Additionally, the Council's preferred alternative includes a very broad definition of who may own QS so communities are not precluded from acquiring QS once the program is implemented. Appendix A of the 2005 Council's scoping report also contains an analysis of community measures and effects in the context of the use of regional area restrictions.

Although the Council considered incorporating provisions for CFAs into the alternatives early in the development process, no strong recommendation or advocacy was voiced by members of the public or representatives on the TIQC, which was intended to represent a cross section of interests for the development of recommendations on structuring the trawl rationalization program. Proposals for including provisions for CFAs in the program emerged later on, when the Council was at the point of adopting a preferred alternative in November 2008, in part tied to the issue of how to deal with QS holding in excess of accumulation limits. Further refinement of the preferred alternative, which occurred at Council meetings in 2009, included additional consideration of CFA provisions.

Specifically, at the April 2009 Council meeting, Agenda Item F.4 addressed CFAs, and it was at this time that the Council concluded that it would be more appropriate for CFA provisions to be implemented through a trailing action. However, the moratorium on the transfer of QS during the first twp years of the program, combined with provisions to allow divestiture of QS over accumulation limits during years 3 and 4 of the program, were designed to facilitate the transfer of QS to CFAs. The moratorium is in part intended to slow the movement of QS holdings out of communities during a time when the trailing action for CFAs can be developed and implemented in a considered fashion. Recommendations for how to structure the CFA provisions in a trailing action, provided by one commenter, are welcome and should be brought forward as that proposal is developed. The Council is likely to begin developing CFA provisions in 2010 so that they could be in place before the QWS divestiture period begins.

10.1.6 Adaptive Management Program

Commenters: Environmental Defense Fund; Pacific Coast Federation of Fishermen's Associations; Radtke, Hans

Comment 31: The DEIS should better describe the process for designing and implementing the AMP and include a quantitative analysis of the adverse effects on communities stemming from delayed implementation. The AMP should be implemented before the third year of the IFQ program, as proposed in the preferred alternative, in order to better address the adverse effects stemming from the transition from the current management system to IFQ management.

Response: Quantitative analysis of the potential impacts of delayed implementation is hampered by lack of specifics about how the program would function.[120] The AMP would not change the total amount of QP available to cover catch; instead it affects the distribution of the QP reserved for the AMP. The difference in the way QP or resulting landings would be distributed due to the AMP and the distribution based on initial quota allocations would depend on program objectives and the particular distribution formula used. Although the Council considered various approaches to how quota would be distributed under the AMP, no final recommendations for distribution formulas were identified as part of the preferred alternative. Without this information, it is not possible to quantify the differential effects of not implementing the program in the first two years.

One of the uses of the AMP is to react to unanticipated and unintended consequences of the program. By definition, it is not possible to predict associated impacts of unanticipated consequences. Given these impediments to a quantitative prediction, the DEIS presents a qualitative description of the potential range of impacts and their intensity.

With respect to the recommendation that the AMP should be implemented on day 1 of the program, it should be noted that it would still take time for the impacts of IFQ management to emerge and then to craft an appropriate response through the AMP. Thus, implementing the AMP on day 1 of year 3 may not in practice delay very much the application of AMP to emerging impacts compared to having a program framework set up on day 1 but still needing to identify the impacts that need to be addressed with AMP quota. Development of the AMP during the first two years of the program can take into account adverse impacts of the program as they emerge.

[120] These details are to be worked out during the two years before the AMP goes into effect.

10.1.7 Designating the Whiting Sector Co-ops Limited Access Privilege Programs

Commenters: Arctic Storm Management Group, Food and Water Watch, Pacific Whiting Conservation Cooperative, United Catcher Boats

Comment 32: In relation to these provisions, the co-ops for whiting mothership catcher vessels and for catcher-processors do not meet the definition of a LAPP. Furthermore, if they are considered LAPPs, any fees assessed should only be for the applicable costs directly attributable to the two fishery sectors within which the co-ops would be established and not to cross-subsidize the IFQ program for the nonwhiting fishery. One commenter supported defining the catcher-processor sector as a LAPP.

Response: At the time the DEIS was published (November 2009), the Council had taken the position that a permit should not be required for the catcher-processor co-op and that therefore the catcher-processor sectors would be a LAPP. In June 2008, the Council was advised by legal counsel that "if the allocation is issued to the co-op and the co-op is required to have a permit then the program would be a LAP but if the co-op is not required to hold a co-op permit then it would not be a LAP" (minutes of the 194th Pacific Fishery Management Council Meeting, June 6-13, 2008, p. 51). On this basis, the Council voted down a motion to include a requirement for permits for the catcher-processor co-op made by the NMFS representative to the Council (Amendment 3 to Motion 41).

However, during the regulatory deeming process, the Council decided to reconsider the issue of requiring permits for co-ops. After providing advance notice of its intent to reconsider this issue, the Council changed its position by agreeing that a permit should be required for co-ops formed as part of the trawl rationalization program in both the mothership and catcher-processor sectors. NMFS advised the Council of the necessity of permitting co-ops so that they could be effectively tracked and held accountable. By issuing a permit to the co-ops as described in the Council program, the co-ops meet the definition of a LAPP.

As indicated in the comments, the question of whether the co-ops in either sector are determined to be part of a LAPP is of concern because of the provisions in the MSA on cost recovery. Section 304(d)(2)(A) authorizes NMFS to collect fees "to recover the actual costs directly related to the management, data collection, and enforcement" of a LAPP, which "shall not exceed 3 percent of the ex-vessel value of the fish harvested." Issues related to these cost recovery provisions will be taken up as part of a trailing action when the Council develops the cost recovery methodology required by section 303(A)(e) and NMFS during the implementation of the cost recovery program.

10.1.8 Expressions of Support for Program or Program Elements

Commenters: Midwater Trawlers Cooperative; Moore, Steve; Pacific Whiting Conservation Cooperative; United Catcher Boats

Comments 33:

- **The members of United Catcher Boats support the declaration system for participation in mothership co-ops as outlined in the preferred alternative. United Catcher Boats also supports the provision of a 20 percent minimum of catcher vessel permit holders necessary to form a co-op and that co-op membership is voluntary.**

- **The members of United Catcher Boats support the Council's preferred alternative that requires hard cap management at the co-op level of widow, canary, darkblotched rockfish,**

and Pacific Ocean Perch and the allocation methods presented in the final Council analysis and in the DEIS.

- **Pacific Whiting Conservation Cooperative fully supports the final preferred alternative with respect to the catcher-processor sector.**

- **Midwater Trawlers Cooperative fully supports the Pacific Fisheries Management Council,and NMFS' development of Trawl Individual Quota (TIQ) for the Pacific trawl fisheries. Midwater Trawlers Cooperative has been a participant in the TIQ process at both Council and Committee meetings since inception in 2003.**

- **I am in favor of the individual quotas.**

Response: We note these expressions of support for the program.

10.1.9 Mothership Co-op Declaration Date

Comment 34: The FEIS should explicitly identify September 1 as the date for notification of NMFS under the mothership co-op declaration system.

Response: At its April 2010 meeting, after providing public notice of its intent to reconsider its final action on this matter, the Council modified its final motion to specify that by September 1 mothership catcher-vessel permits must notify the mothership of their intent to change their mothership affiliation, and that by December 1 they must notify NMFS of the new mothership to which they are obligated for the coming year.

10.2 Need for Action, Problem Statement

Commenters: Food and Water Watch; Forve, Matt; West Coast Seafood Processors Association

Comment 35: The need for action lacks a clearly articulated vision of desired outcomes or problem statement. Furthermore, "rationalization" is not a clearly defined concept; the commenter concludes that it means "the fishery is being privatized and commoditized at the behest of special interests, and they, to persuade the public and possibly themselves, rationalize their anti-social actions." Instead, the action should focus on an outcome in the best interests of society as a whole, which would require estimates of nonmarket (unpriced) benefits.

Response: The commenter presents a lengthy discussion of possible definitions of the term rationalization, based on a footnote to the description of the proposed action on page 3 of the DEIS that lists a variety of commonly accepted definitions, which are not in any case mutually exclusive. In fact, the term "trawl rationalization" is a shorthand intended to capture social and economic objectives and associated conservation benefits of a proposed management program that includes both IFQs and co-ops. While this term may connote various aspects of all the commonly accepted definitions in the footnote, the commenter's exercise in semantics to derive an alternative rationale does not substitute for the actual, and clearly articulated, rationale laid out in the next two sections of the DEIS. DEIS Section 1.2.3 includes a succinctly stated goal: "Create and implement a capacity *rationalization plan* that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch" (emphasis added), capturing the intended meaning of the term rationalization. The

commenter's exposition of the term mainly serves to support an alternative vision, or rationale, that the commenter believes the Council should have substituted for the rationale that they actually adopted.

Comment 36: The need for action based on the claim that the trawl fishery is currently viewed as economically unsustainable is unsupported by the evidence presented in the DEIS. Second, the claim that the proposed action will reduce bycatch is not supported by the DEIS analysis.

Response: The EIS provides a detailed problem statement developed by the Council early in the process highlighting the interconnected problems of capacity, economic inefficiency, and bycatch management, which together have made it difficult for groundfish trawl sectors, and groundfish fisheries in general, to achieve optimum yield. The actual problem statement does not claim that the purported economic unsustainability of the fishery is the sole basis for the proposed action. It is relevant to note that economic analysis of the fishery indicates that the average nonwhiting shoreside fisherman is either breaking even or losing money

The second claim, that the proposed action will not reduce bycatch, uses a partial citation; the sentence in full reads "By itself an IFQ program may have few direct conservation benefits, *but substantial indirect benefits*" (emphasis added). The commenter then implies that if IFQs (or more generally, management measures making harvesters fully accountable for their catch) have no conservation benefits, then it must be instead that the proposed management program relies on a "stimulation of a conservation ethic" suggesting voluntary compliance based on a perfect alignment of self interest and social objectives in the absence of other institutional constraints. Nowhere in the DEIS is there a claim that a so-called conservation ethic by itself would be sufficient to meet the objectives of the proposed action. However, a study ((Redstone Strategy Group and Environmental Defense 2007) analyzing pre- and post-implementation performance of 10 LAPPs, including all seven U.S. programs, cites interviews with fishery participants and other sources showing that QS value "transformed the mindset of fishermen, who developed a real stake in the outcome of their fishing practices" (p. 7).

The commenter further claims that the bycatch reduction objective is not supported by analysis, and argues that the main piece of empirical evidence used to model possible bycatch reduction scenarios, results from an exempted fishing permit (the "arrowtooth EFP"), is of limited applicability, which is not acknowledged in the DEIS. In fact the uncertainties associated with using the EFP data are disclosed and discussed in Appendix C (on page C-19), containing detailed documentation of the models used in support of the impact analyses. The analysis in the DEIS supporting predictions that trawl rationalization will lead to reductions in the bycatch has a theoretical basis, informed by empirical evidence; in this context the results from the arrowtooth EFP are indicative, not predictive. The arrowtooth EFP was conducted "with requirements nearly identical to what would be expected under a rationalized fishery" (p. 244) and thus a parallel set of incentives. The model is used to show "order of magnitude" estimates of the amount of regulatory discard occurring under status quo regulations and associated loss of revenue and to present a range of increases in fleetwide revenue that could result if bycatch rates were reduced.

Conditions in the west coast groundfish trawl fishery, and characteristics of the proposed action, are in important ways unique. No other IFQ program includes complete monitoring and full accountability for such a wide range of species and is so constrained by the kind of low harvest limits imposed to rebuild overfished stocks. However, the lack of specific empirical evidence does not invalidate the expectation that under the proposed action harvesters have more incentive to avoid overfished species compared to status quo regulations, because of individual accountability and greater access to target species if bycatch rates are reduced. Other studies and reviews support the proposition that individual accountability fostered by IFQs (or the small group collective responsibility of the whiting co-ops) helps to reduce bycatch. *Sharing the Fish* ((NRC 1999), a report on IFQs requested by Congress from the

NRC, includes bycatch reduction as part of the rationale for implementing IFQs, noting that harvesters can more carefully choose their time and area of fishing, which may "reduce bycatch of non-target species since operations can be moved to target more favorable harvesting conditions, or it might allow the opportunity to develop practices that could reduce bycatch" (p. 35). The aforementioned report ((Redstone Strategy Group and Environmental Defense 2007) found that "nearly all the fisheries experienced decreases in their respective discard rates" when the LAPP was implemented.

The commenter references the "rebuilding paradox" where increasing abundance of overfished species is lagged by comparable increases in harvest limits; as bycatch becomes harder to avoid so it becomes harder to keep catches below established limits. Although it is true that bycatch will become harder to avoid as these stocks recover, the underlying incentive structure in the proposed action would still operate. Harvesters would have incentive to engage in both behavioral changes and invest in or discover bycatch reducing technology as long as these investments are less than the imputed cost of the IFQ needed to cover bycatch species.

Comment 37: The proposed action does not meet the stated purposes of increasing net economic benefits, creating individual economic stability, providing full utilization of the trawl sector allocation, mitigating environmental impacts, and achieving individual accountability of catch and bycatch.

Response: We disagree. Chapter 4 of the DEIS extensively evaluates the effects of the preferred alternative and offers evidence on how the action may address the purpose and need. Appendices A and B contain additional detailed analysis of specific program elements.

10.3 Range of Alternatives

Commenters: Daspit, William; Ecotrust; Food and Water Watch

Comment 38: Commenters claim that the Council did not consider a sufficiently broad range of alternatives. One commenter argues that alternatives should have been presented across a range "from the broad public interest at one end, to the interests of a very few at the other." As such, the public and policymakers were not presented with a real set of choices. Commenters proposed alternatives that should have been evaluated in the DEIS but were not:

- **Food and Water Watch proposes a "cap-rent-recycle model of catch share management" using fixed terms for QS ownership coupled with periodic auctions to recover resource rent. Resulting revenues would be used by government to "support eco-friendly community-based cooperative catching and marketing business models." The commenter argues that under this alternative the social (external) cost of resource extraction would be recovered by the public. The commenter cites a statement by the Council's SSC suggesting that fixed-term QS and auctions was not sufficiently analyzed in the DEIS (see Appendix F). A second commenter also advocated including fixed-term QS and auctions in the range of alternatives.**
- **Ecotrust argues for genuine "mitigation" measures to address environmental objectives. The DEIS should have included alternatives with strong incentives to reduce bycatch of overfished species and encourage switching to nontrawl gear. The commenter recommends several mechanisms that could be used to penalize fishermen who catch overfished species, but protect against market distortion and hording of overfished species quota. The commenter argues that the only mechanism included in the alternatives that**

could potentially address these objectives—the AMP—is subject to multiple, competing claims and won't be implemented until year 3 of the program.

- **Ecotrust also advocates for initial allocation of quota shares and pounds to community entities and crew and captains or facilitating such allocation in the future (e.g., by holding back a portion of the quota share to allocate once communities have organized appropriate receiving entities). The commenter argues that the Council did a poor job in outreach to communities, which contributed to lack of inclusion of such alternatives.**
- **Mr. Daspit presents the "Optimum Species-Harvesting Unified Allocation (OSHUA) plan" that proposes a different mechanism to allocate harvest opportunity to individual fishery participants. Under this plan, catch shares would be allocated to groundfish limited entry permits (fixed gear permits, open access, and trawl). The commenter includes a detailed description of the plan in his comment, which he notes was described at Council meetings during public comment periods.**

Response: CEQ regulations at 40 CFR 1502.14 call on agencies to "rigorously explore and objectively evaluate all reasonable alternatives." Case law on this topic links the range of reasonable alternatives to the definition of the proposed action. The DEIS on page 3 describes the proposed action as creating "a management regime under which the owners of Pacific Coast groundfish limited entry permits with trawl endorsements are more individually accountable for catch of target and nontarget species harvest by the vessels that their permits are registered to." This action is intended to address "problems with capacity, economic inefficiency, and bycatch management interconnected with problems related to the ability to achieve optimum yield (OY), the need for a precautionary management approach, the need for a flexible system that allows for variations and contingencies, long-term and short-term concerns for communities, and safety" (DEIS, p. 3, footnote omitted).

Furthermore, the Council engaged in a lengthy scoping process during which they solicited public input on a wide range of issues and proposals not only, in the words of CEQ, "to identify significant environmental issues deserving of study, but also to deemphasize insignificant issues, narrowing the scope of the environmental impact statement process accordingly" (40 CFR 1500.4(g)). Bearing in mind the proposed action, purpose and need, and scoping process, below is a consideration of commenters' proposed alternatives, which either were not considered, or considered but eliminated from further detailed analysis.

The "cap-rent-recycle model" alternative

This alternative would have government capture resource rents to be used for public purposes. The use of fixed-term QS that would be auctioned off periodically is one method to achieve such "rent capture." The Council considered fixed terms and auctions but rejected this mechanism from further detailed study. In doing so, the Council considered the analysis contained in Appendix F of the EIS and the critique of the analysis presented by their SSC. The Council rejected inclusion of fixed-term QS and auctions in the range of alternatives, because (1) auctioning quota at the outset of the program could make it more difficult for the groundfish trawl fleet to successfully transition to IFQ/co-op management, and (2) exclusion of auctions from the range of alternative does not imply that access privileges have been irrevocably distributed.

The Council intends to give further consideration of auctioning harvest privileges during the 5-year program review required in the program adopted by the Council.

Ecotrust's environmental "mitigation alternative"

These proposals focus on using environmental performance standards and other means to encourage trawlers to switch to fixed gear, which they assert has fewer adverse impacts on benthic habitat, to reduce and/or avoid bycatch, and to achieve other environmental benefits. In response, we note that such measures may be proposed if not already a part of the proposed action (40 CFR 1502.14(f)) but such separate measures do not have to be implemented. (Broadly, the alternatives include measures to mitigate various adverse effects to harvesters and other stakeholders and resources described in the DEIS.) Consistent with 40 CFR 1502.14(f), no additional mitigation measures have been identified. The commenter's mitigation proposals are viewed in this context. While considering and possibly mitigating new adverse habitat impacts is an MSA provision—indeed, in 2006, the Council and NMFS implemented Groundfish FMP Amendment 19 to comprehensively address fishing-related impacts to essential fish habitat—this action is not expected to result in new habitat impacts for which mitigation could be proposed. The preferred alternative would allow IFQ holders to use fixed gear, if they choose to pursue such a strategy. While there are no incentives to encourage gear switching, the existing provision alone may have a mitigating effect compared to status quo, since trawl-endorsed permits are currently prohibited from using other gear types to fish against their bimonthly limits. Any vessel switching gear types with less habitat impacts would represent a reduction in impacts compared to existing, ongoing habitat impacts due to trawl fishing under status quo.

The commenter also recommends environmental performance standards tied to preferential allocation of quota. Such proposals may go beyond the scope of the proposed action, which focuses on creating new incentives based on individual accountability for catch, and certainly goes beyond mitigating any effects associated with the proposed action. The commenter's bycatch reduction proposals tend to focus more on the claimed market distorting effects that quota scarcity may engender (note that the DEIS impact analysis includes an evaluation of "thin market conditions" resulting from quota scarcity).[121] As stated in their comment letter, the commenter's proposals would "punish less responsible fishermen and safeguard against malicious market manipulation." Such proposals would add additional complexity to the program by introducing "market distortions" linked to particular policy objectives. The purported adverse effects to be so mitigated, although identified in the DEIS, cannot be precisely specified or fully predicted, making it impractical to specify such measures in advance. In this regard, the Council included the AMP in its proposal as another mitigation measure. The commenter suggests this is the only means to mitigate bycatch and so its delayed implementation means there are "no mitigation measures in place on day 1 of the Program." However, as explained above, the proposed action as a whole is intended to be mitigative so the AMP is not the only means of mitigating adverse impacts. Also, as discussed elsewhere in these responses (see Section 10.1.6), the initial two-year hiatus in the AMP (when reserved QP are "passed through" pro rata to quota shareholders) may not make a substantial material difference in actual implementation, given that the Council would have needed time to develop methods and procedures to allocate AMP quota in any case. Additionally, since AMP quota is designed to address impacts from the program and unintended consequences, it follows that those impacts must occur before they can be addressed.

[121] Furthermore, reducing bycatch, as it defined in the MSA as discards, does not by itself necessarily reduce fishing mortality—the ultimate environmental objective—if discards are converted into retained catch (in other words, the same fishing mortality rate applies). The program will result in more accurate monitoring and accounting of total catch, which will yield environmental benefits when coupled with the fact that the sum of quota pound holdings (and co-op catch history assignments) cannot exceed the trawl sector's allocated portion of the OY/ACL. However, as discussed in Chapter 1 of the DEIS, these catch limits are specified external to this proposed action.

Initial allocation of QS to communities and to captain and crew was considered in the development of the alternatives but rejected from further consideration. The 2005 Scoping Results Document reflects preliminary consideration of these allocations. Appendix A (Section A-2.1.1) discusses the reasons why allocation proposals of this type were rejected from further consideration. In addition, response to comments on community involvement (see Section 10.1.5) discusses Council efforts to solicit input from communities during the development of the trawl rationalization proposal.

The OSHUA Plan

The OSHUA plan is beyond the scope of the proposed action, given that it considers the application of a catch privilege system to all groundfish fishery sectors. The Council discussed the OSHUA plan. Some components of the plan were part of the alternatives while other aspects were rejected. However, the Council concluded that OSHUA measures addressing the groundfish trawl fishery alone were so complicated and contentious that any expansion of scope to other sectors would have likely paralyzed the decision-making process. In the FEIS, Chapter 2 has been augmented to provide a more complete explanation of the challenges presented by the OSHUA plan.

10.4 Resources and Stakeholder Profiles (Chapter 3) and Effects of the Alternatives (Chapter 4)

10.4.1 Harvesters, Harvesting, and Bycatch

Commenters: Food and Water Watch, Tommy's Marine Service, West Coast Seafood Processors Association

Comment 39: The claim that the proposed action will increase ex-vessel revenue and profits is not supported. There is no comparison of revenue under the alternatives compared to no action (Section 4.6.2). The DEIS asserts that it is likely that buyers will be able to find new markets, yet offers no analysis or evidence. Given the impacts of increased aquaculture and imports, combined with lower per capita consumption rates, we find it impossible to understand how the DEIS can reach this conclusion.

Response: We disagree. The analysis looks at the profitability of the nonwhiting shoreside fishery before and after ITQs; it indicates that profits will increase even if revenues do not. However, the expectation is that revenues will increase as a result of more efficient use of the bycatch being allocated to them. Figure 4-7 compares ex-vessel revenue under status quo to the action alternatives. Table 4-13 provides the estimated change in efficiency as a result of consolidation. Additional program costs are taken into account in the Lian et al. (2008) analysis cited in the footnote on page 297 of the DEIS.

The commenter cites a declining per capita consumption rate and increased aquaculture production among the reasons not to expect new markets to develop. The commenter is correct that aquaculture production has increased substantially over the last 10 years (U.S. Fisheries Statistics 2008), and is correct that there has been a slight dip in the US per capita consumption (comparing 2007 and 2008 to 2006). Overall per capita seafood consumption is up by roughly just over one pound relative to the mid-1990s (from about 15 pounds to just above 16 pounds). At the same time, the price index for groundfish was at 100 in 1997 and at 165 in 2008 (a 65 percent increase). Over that same period, the gross domestic product implicit price deflator has increased by only 28 percent (U.S. Fisheries Statistics 2003; 2008). Given these changes since the 1990s and given that West Coast nonwhiting landings are approximately one half of what they were in the mid-1990s (Table 3-17), it seems reasonable to expect that there is some opportunity to redevelop markets for West Coast groundfish that were lost only due to

constraints to protect overfished species. With respect to future allocations under status quo or the alternatives, the analysis demonstrates performance of the different alternatives using a baseline.

This commenter also noted that in order to properly assess impacts on profits, the analysis needs to use monitoring and implementation costs that were produced by NMFS at the same time the DEIS was finalized (November 2009). The cost estimates used in the DEIS were those available at the time the document was drafted. Updated monitoring costs based on the Council's adopted plan are provided in the RIR/IRFA .

Comment 40: Economic benefits will accrue to the fishery only with access to larger volumes of target species which, in turn, occurs only if bycatch is reduced. The claim that bycatch reduction will occur is not well supported. Bycatch reduction and resulting revenue increases that drive the "success" of the rationalization alternatives are not well analyzed or supported and demonstrate a major weakness in the DEIS (Subsection 4.2.1.3, Section 4.4.4, Section 4.6.2.1).

Response: Economic benefits are expected even without an increase in the volume of target species landed. The bycatch reduction expectations are supported by substantial empirical experiences and models based on behavior theory and substantial empirical evidence. See Section 10.2 of response to comments for additional response.

Comment 41: On a technical matter, Figures 4-4 and 4-5 are both blank on the compact disc provided to the public and on the DEIS posted on the Council web site.

Response: This has been corrected.

Comment 42: The buyback program and the QS associated with buyback history should be discussed. The public should be informed as to why this buyback catch history is being reallocated, including why the QS effectively purchased by taxpayers (noting that it is a public resource to begin with) is being given to private entities. Also, it is not clear if any of this allocation is going to the crab and shrimp sectors that were part of the original buyback agreement.

Response: The buyback program is described in Section 3.3.3.3 of the DEIS. The buyback program bought back Federal groundfish permits and state shrimp and crab permits. The buyback program is part of the baseline from which impacts are assessed. While for simplicity of reference and establishing a standard there are references to the QS associated with the buyback permits, there is in fact no such association until one is created (i.e., there is no prior claim that these permits had some QS which is now being reallocated to others). For example, the Council considered an option that would have allocated all the QS based on landing history of current permits and none based on the landing history of the buyback permits (i.e., no equal allocation element). The designation of an equal allocation amount based on the history of the buyback permits was viewed as an equitable way to help resolve the initial allocation issue, ensuring that the smaller producing harvesters were more likely to receive an initial allocation adequate to cover their needs while the larger producing harvesters, more likely to be better financed, might have to purchase more QS to maintain their recent harvest levels.

Nevertheless, in response to the commenter we note that the industry is actively paying landings taxes to pay back the public loan that was made to support the buyback program. The schedule calls for that loan to be paid back over about 20 years. The amount that was directly paid for by the Federal government ($10 million) was based on an estimate of the tax revenue that the Federal government would receive from those who reported a capital gain as a result of selling their permits and vessels. With respect to allocations to those in the crab and shrimp sectors, such vessels will receive allocations

in proportion to their participation in the groundfish trawl fishery. The crab and shrimp vessels receive other benefits from the buyback program (the reduction in the number of vessels and permits participating in their respective fisheries).

10.4.2 Quota Allocation, Ownership, and Transfer, Including Auctions

Commenters: Ecotrust, Food & Water Watch, Pacific Whiting Conservation Cooperative, West Coast Seafood Processors Association

Comment 43: The analysis underlying the dismissal of fixed terms and auctions is unsatisfactory and too qualitative to warrant the strong conclusions, as recognized by the Council's own SSC.

Response: The SSC's report was part of the public record. The Council was aware of the concerns expressed by its SSC when it made its decision to defer consideration of an auction until the 5-year program review. The EIS has been revised to explicitly acknowledge the SSC's concerns about the analysis contained in Appendix F of the EIS. One concern about using an auction for initial allocation was its potentially disruptive effects, particularly with respect to smaller, less well-financed harvesting operations. This issue is discussed further in Section 10.5.1.

Comment 44: All information about the proposed IFQ market should be disclosed in the EIS. This includes the identity of all limited entry trawl permit holders and/or all participants; all QS and QP holders; all transfers and amounts, dates, and prices; all landing locations and landing and discard information; all infringements; and all other relevant business information required to ascertain control, eligibility, accumulation, and other matters of public interest including the operations of cooperatives.

All information that is not subject to state and Federal confidentiality laws has been released. Similarly, all information that is collected in the future will be released except to the extent that state and Federal laws prohibit its release.

Comment 45: The Council fails to comprehensively analyze the environmental effects of its allocation formula for overfished species. There are several problems with the Council's approach. First, the equal division and fleet-wide bycatch rate approaches are positively related to past bycatch landings during times when overfishing was occurring in the fishery. This perpetuates the root cause for the overfished status of several species—that is, the fact that historically too many of them were caught. Second, the allocation rules as designed also have the rather counter intuitive effect of penalizing fishermen who have historically been more successful at avoiding bycatch.

Response: The QS initial allocation formulas attempt to balance a number of issues including fairness and equity and trying to put the QS into the hands of those most likely to need it. The fishery is complex and constantly changing, and "perfect" information is not always available. Any initial allocation formula is controversial and because any formula represents balancing a number of different objectives, it will not be optimal with respect to any particular objective or all participants. However, the performance of the IFQ program with respect to bycatch control and reduction is not dependent on the initial allocation. The program includes individual vessel accountability for all bycatch and 100 percent observer coverage. On this basis, it is expected that catch limits will not be exceeded and over time quota will be transferred to those vessels able to make most effective use of it.

The commenter is incorrect in stating that any part of the formula is based on a particular permit's past catch of an overfished bycatch species. The allocation of overfished species is based on the depths and latitudinal strata in which the permit was fished during the rebuilding period (2003-2006), fleet-wide average bycatch rates for those strata that were observed by the WCGOP, and the amount of target species QS allocated to the permit. The equal allocation component of the program was included for equity reasons and benefits small vessels, as described in Section 10.4.1 in the response on the rationale for the treatment of the buyback permits.

Comment 46: The lack of provisions facilitating the buying, selling and leasing of QS or QP has environmental and economic implications omitted from the analysis. Search costs and asymmetric information will interfere with the negotiation process, and brokers will absorb most of the economic rents that are supposed to make the fleet more viable.

Response: It is incorrect that provisions are not included pertaining to the QS and QP markets. The Council's proposal calls for the publication of transfer prices and lists will be available indicating who owns the QS (as is currently the case with respect to information about who owns limited entry permits). Public release of all information will be consistent with the confidentiality provisions of the MSA and other relevant statutes; in general, NMFS intends to provide aggregate price information and the names of QS owners. Availability of appropriate information will reduce information asymmetry, reduce fishermen's search costs, and allow fishermen (or other QS buyers) to know whether the prices they are offering or being asked to pay are within a reasonable range.

The economic rents that are absorbed in the QS and asscociated transaction costs are not what make the fleet more viable over the long-term. Over the long-term new entrants will have had to purchase their QS, and the price paid for the QS, including transaction costs sometimes paid as brokerage fees, should represent the above normal profits that otherwise would have been available in the fishery. The long-term benefit of the program for industry is more stability at a normal profit level. To stay in business, brokers must provide a service that reduces the costs of transactions enough to pay for their fees.

Comment 47: There is a complete failure to account for the effects of permanently consigning 90 percent or more of all groundfish to the bottom trawl sector. The claim that "trawl gear is the only gear that can viably harvest much of the groundfish" (DEIS p. 52) has not been validated, and in any case, it does not apply to several species in question, including lingcod, thornyhead rockfish, and sablefish that are viably harvested by fixed gear, including longlines and pots.

Response: It is incorrect that there is a permanent consignment of 90 percent of the groundfish to the bottom trawl sector. First, no allocations are permanent; they may be changed by appropriate Council or agency action. In addition, Amendment 20 only pertains to the method used to manage the trawl allocation, regardless of the amount of fish allocated to the trawl fishery. Recent harvest levels were used for purpose of the analysis but such harvest levels are not necessary to maintain the program or justify program costs. The commenter is correct that not all species can only be harvested primarily by trawl gear and we note that for the species cited the allocation to trawl gear in Amendment 21 will be less than 90 percent. For other species where trawl gear is dominant (in many cases harvesting 99+ percent) to-date there have been no allocations in place that would have prevented other gear from harvesting those species if it were economically viable for them to do so. Nevertheless, in Amendment 21, if approved, the Council will be constraining trawl shares to somewhat lower levels to provide an opportunity for alternative fisheries to develop. If such fisheries do begin to develop, there would be an opportunity in the future to consider reallocations away from the trawl fishery.

Comment 48: Section 4.1.3 does not include in the reasonably foreseeable future action bullet points any reference to increased tribal allocations for Pacific whiting. Since tribal allocations are

taken "off the top" of available harvest, increases will have a direct impact on the amount of whiting available to both harvesters and processors. A reasonable range of increases needs to be analyzed under all alternatives.

Response: This is not a reasonably foreseeable future action. It is acknowledged that this negotiation process is underway, but resolution is at least two to three years out and the outcome is uncertain at this time. The action has not reached a proposal stage, the criterion listed in Section 4.1.3 for including a future event as in the list of reasonably foreseeable future actions. See previous comment regarding change in the trawl allocation.

Comment 49: The notes following Table 4-2 need clarification. Note #2 states the Council's preferred alternative does not apply accumulation limits to QP. While this is correct, it should make clear that vessel limits still apply to QP.

Response: This clarification will be made. However, it should be noted that certain usage of QP may be used as evidence of the control of the underlying QS, as reflected in the Council's discussion at the April meeting.

Comment 50: A commenter recommends that the EIS be expanded to evaluate the redistribution of quota from present to past participants in the Pacific whiting mothership sector under Amendment 20. Specifically, it was suggested that the EIS compare and contrast the number of vessels qualifying for the cooperative with the number of vessels qualifying under Amendment 15 and with the number of vessels actively participating in the fishery since 2000 until the present. Data should also be provided that shows the actual harvest of the vessels actively participating in the fishery since 2000 (status quo).

Response: The FEIS has been augmented to take this comment into account.

Comment 51: Chapter 4 refers to four CP companies, which was true when Chapter 4 was originally drafted, but, subsequently, there are now three companies with vessels licensed to participate in the CP sector. We recommend the DEIS be reviewed to ensure the CP sector is characterized accurately.

Response: We acknowledge that ownership in the CP sector has changed. Ownership in the fishery is frequently changing and it is not feasible or practical to keep the EIS completely up to date with these constantly changing conditions. In general, the standard that is followed is to use information on conditions in the fishery as it was available when the NOI to develop an EIS is published.

10.4.3 Participation by and Effect on Nontrawl Fisheries

Commenters: Ecotrust, Food and Water Watch, Pacific Coast Federation of Fishermen's Associations

Comment 52: The analysis is predicated on the assumption that the only economical way to extract groundfish biomass from the ocean is through a small fleet of large trawlers. The economic analysis in the DEIS should have examined whether the fishery could be prosecuted using smaller vessels with different gear types.

Response: The analysis does not assume that the only way to economically extract groundfish is through a small fleet of large trawlers but rather includes that as a predicted outcome. With respect to the assumption that it is the trawl fleet that will access most of the fish, this assumption is based on

observations that, for most species and species groups (particularly flatfish species and whiting), no other fleet or gear type has developed to harvest the quantities of groundfish accessed by the trawl fleet, despite the absence of regulations which would prevent that from occurring under status quo. With respect to the analytical treatment of the policy options considered, the analysis does take into account that vessels may switch gears and that nontrawl vessels may acquire a trawl permit and quota.

The issue of whether other options should have been considered, such as providing nontrawl vessels greater opportunity to access the trawl allocation, is discussed in Section 10.1.8.

Comment 53: The DEIS fails to identify and evaluate impacts associated with the portfolio role of groundfish in many ports and fishing communities and the reduced flexibility for participating that would occur as a result of the trawl rationalization program.

Response: The commenter is incorrect regarding the impacts on flexibility. The DEIS identifies that trawl rationalization increases regulatory flexibility rather than decreases such flexibility. This conclusion applies to vessels using a variety of fishing strategies, including portfolio strategies (generally one vessel fishing in a number of different fisheries) used by both trawl and nontrawl gear, used within and across years, and used by communities. The issue of whether an option should have been considered to increase such flexibility even further by not requiring that a vessel hold a trawl permit in order to fish in the trawl fishery is addressed in Section 10.1.8.

Whether a vessel is using trawl or nontrawl gear in its portfolio approach, the portfolio approach would be more viable under trawl rationalization because permit operators will have the option to use different gears. Under the IFQ program, nontrawl vessels can acquire a trawl permit and QS and fish trawl QS using nontrawl gears. If an alternative gear type makes more sense financially, the permit operator has the option of fishing that gear.

The trawl rationalization program also provides vessels with more flexibility with respect to the timing of the groundfish harvest, making it easier to work the groundfish in around other fishing opportunities. Flexibility is provided by the trawl rationalization program whether a vessel rotates through its portfolio of fisheries on an annual basis or across many years, taking advantage of the opportunities present for a particular year. Vessels for which the portfolio pattern crosses many years can either acquire QP through leasing in years they participate or buy QS and lease their QP out in years they don't participate themselves.

For portfolio vessels using nontrawl gear, the IFQ program itself presents a new participation opportunity not present under status quo. Status quo provides no opportunity for these vessels to access the trawl allocation except through the acquisition of a trawl permit and use of trawl gears.

Under the trawl rationalization program, some communities will benefit while others won't. If the program results in fleet consolidation and the departure of trawl vessels from a particular port, there is concern that infrastructure may collapse and other fisheries will be forced out of the community. This possibility is one that is identified in the EIS, albeit not specifically labeled as a portfolio issue. The EIS identifies numerous ways in which impacts on communities are considered and all communities are provided some opportunity to have more control of the future of their own fishing industry through the trawl rationalization program. Options for communities include the direct purchase and control of QS to use as incentives to maintain fleet deliveries in the communities.

While the DEIS does not specifically name portfolio strategies and break out the impacts of the IFQ program on portfolio strategies, there is substantial discussion of the flexibility the IFQ program provides to vessels for determining their optimum mode of participation. The nature of the expected

effect is that rather than a vessel having to be "all in" or "all out," as under status quo, the trawl rationalization program facilitates vessel participation at a variety of levels of production. While the model used to predict potential benefits predicts the benefits will be achieved through specialization, a portfolio approach will persist and may increase to the degree that it is competitive with or superior to the specialized approach.

Comment 54: There is insufficient analysis of the cumulative and secondary impacts with respect to spillover into other fisheries. The buyback program carefully took into account spillover effects and the trawl rationalization program the Council has not, instead relying on state-managed limited access systems to control spillover. In this context it is surprising, and inconsistent with its own previous mitigation measures, that the Council has made no efforts to avoid such negative spillover effects of Amendment 20.

Response: The analysis identifies spillover as a potential effect of the trawl IFQ program, the conditions for spillover and the fisheries into which spillover is likely to occur (Section 4.8.2).

The buyback program and mitigation measures were a Congressional program that was not implemented under Council authority. The Council does not have authority to implement complementary adjustments that might be appropriate for the state limited entry programs that control the fisheries into which spillover is likely to occur. The scope of action available to Congress in designing the buyback program was much greater than that available to the Councils.

There is also a key difference between the buyback and trawl rationalization programs. The buyback program provided a direct and immediate infusion of cash into the fishery, through the purchases of vessels and permits. This left active fishermen who sold out with an opportunity to use that cash to reenter and expand their effort into other fisheries, to the degree that permits in those other fisheries were available. The buyback program reduced the number of permits in other fisheries in order to limit this spillover effect. The trawl rationalization program does not provide a direct infusion of cash. An asset is created, the IFQ or mothership catcher vessel permit and history. Fishermen will receive cash only through the sales of these assets; however, such sales are more likely to represent transfer payments among members of industry

The Council took spillover factors into account when it rejected the option of providing "sideboards" to limit groundfish trawl vessels from expanding into other fisheries. Such provisions would have added to program complexity and inhibited flexibility. For example, see Section 4.8.2.

Comment 55: There is insufficient analysis of the cumulative and secondary impacts because of the omission of the impacts of a prior trawl rationalization program, the 2003 vessel buyback. The buyback was supposed to permanently retire the 40 percent of catch history associated with these vessels, and resulted in higher trip limits in the second half of the decade. These higher limits were not considered in the initial allocation calculation of the preferred alternative; instead, the Council chose to allocate based on the sum of the buyback history and the individual qualifying amounts. This may be a nuance, since arguably the total TAC remains the same, but the effect nonetheless is one of diluting the environmental benefits of the buyback program.

Response: We disagree. The purpose of the buyback program was to reduce the number of vessels that participate in the fishery. It was not intended to "bank" or remove the catch history of buyback vessels and preclude the use of that history by other vessels. It is not clear why the commenter believes that a different distribution of the allocation of trawl QS among trawl permits (one that takes the history of the buyback permits into account in a different way) changes the environmental effects of the program. The IFQ program is the means used to manage the trawl allocation. If the point of the comment is that there

should be a reduction in the trawl allocation, this issue is more directly addressed through intersector allocation (Amendment 21). Such a reallocation would reduce the higher trip limits cited by the commenter as a benefit recently received by the trawl fishery. See Section 10.1.8 for additional response on the issue of the amount allocated to the trawl sector.

Comment 56: There is insufficient analysis of the cumulative and secondary impacts because there is no analysis of Amendment 22, which contemplates the conversion of the open access fishery to limited entry.

Response: Under Amendment 22, the Council did not adopt a limited entry system for the open access fishery.

Comment 57: The DEIS is devoid of a meaningful discussion of the interlinked harvest strategies that fishermen employ to reach their livelihood goals. A more meaningful characterization of the interlinked harvest strategies would have shown earnings from groundfish as a percentage of overall revenues, whether by port, permit holder, or—with only a little more analytical effort—harvest portfolios. The picture that would then emerge is that the trawl rationalization program with the limitations it places on some of the LE fixed gear and OA groups significantly reduces those fishermen's flexibility to respond to a variety of contingencies.

Response: We disagree. The DEIS addressed flexibility and a variety approaches (see above discussion on portfolios). The trawl IFQ program provides more access opportunities for non-trawl vessels rather than less.

Comment 58: The description of the natural environment in Chapter 3 is inadequate because it does not adequately address the considerable impacts the RCAs have had on consolidation of the open access and fixed gear ground fish fleets.

Response: The health of the open access and limited entry fixed gear fleets has been affected by many factors including the RCAs, increasing fuel prices, increasing insurance costs, etc. The RCAs do not cause the relative impacts of the alternatives to vary. The effects of the trawl rationalization program on the nontrawl fleets are analyzed.

Comment 59: Under the Council's proposal, trawlers can switch to fixed gear and thereby compete with this other harvesting sector. In fact, this measure "could depress the price of fixed-gear-caught sablefish slightly if IFQ holders are more efficient producers" (p. 574). By contrast, fixed gear vessels cannot buy or lease trawl quota without purchasing a limited entry trawl permit.

Response: The commenter objects to fixed gear vessels having to buy a trawl permit to access trawl quota. Those trawlers who have entered the fishery since 1994 have had to buy trawl permits to access the trawl quota, thus in this respect other vessels would be on an even footing with trawl vessels. The reasons for requiring a trawl permit to participate in the IFQ program (as opposed to allowing anyone to acquire trawl IFQ) are discussed in the response to comment 62. Additionally, there seems to be a concern that if trawlers use fixed gear to catch trawl quota that fixed gear prices will be depressed, yet the commenter wants to increase fixed gear vessels' ability to access trawl quota, not to use trawl gear but in order to use fixed gear. This would have a similar effect on prices, adversely impacting those fixed gear vessels that chose not to supplement their harvest by acquiring trawl IFQ.

Comment 60: The IFQ program protects the trawl fleet, a fleet with a number of undesirable characteristics. The DEIS is cognizant of the market trends that put a "premium for products

and services that can be produced with demonstrably lower environmental impacts" (p. 100), yet the permanent allocation of the lion's share of groundfish to the trawl sector undercuts those other gear sectors that have a demonstrably lower impact on the environment. Gear types should be allowed to compete for access to the groundfish resource based on their ability to minimize bycatch and habitat damage.

Response: We disagree with the commenter's characterization of the trawl fleet. That said, the DEIS identifies and discloses the potential adverse impacts of trawl gear cited by this commenter. To the degree that these impacts may exist, they are not increased under trawl rationalization and may be reduced because it allows more opportunities for use of fixed gear to harvest the trawl allocation. The Council actions under Amendment 20 provide an opportunity for the transition of harvest away from the trawl sector and its action under Amendment 21 limits the trawl fleet allocation to the lower end of its recent harvest share. Furthermore, the allocations provided to trawlers in Amendment 21 are not permanent and may be changed in the future as it is determined to be appropriate. Additionally, trawl rationalization is expected to decrease total trawling hours required to take a given amount of harvest. Amendment 20 allows some movement of harvest toward the nontrawl gear through gear switching and the transfer of IFQ to the nontrawl fleet. For the time being, that movement is constrained by the number of trawl permits available and the dictates of the market place, combined with any incentives or subsidies that may be created, which are discussed further below.

Comment 61: Trawl vessels would have a tough time competing in the free market with other gears in avoiding overfished species. Gear types should be allowed to compete for access to the groundfish resource based on their ability to minimize bycatch and habitat damage.

Response: The program as developed allows gear switching and the transfer of QS to nontrawl vessels that acquire trawl permits. If there is a competitive advantage in the use of nontrawl gear, there will be opportunity for that advantage to show itself in how the trawl IFQ is used. If it becomes apparent on that basis that the transfer of IFQ to nontrawl gear is being constrained by the IFQ programs, and that it is a problem, adjustments to the program can be made in the future.

Comment 62: The number of limited entry permits issued is arbitrary and has no impact or good rationale in a fishery regime making allocations to individual entities Possession of a groundfish limited entry trawl permit should not be required to fish with IFQ using other gear types. This will allow the trawl allocation to support the most appropriate number of participants using the best mix of harvest strategies and gear. An IFQ system is supposed to be a "free market" solution to avoiding overfished species and rewarding the most efficient vessels, yet the market for which vessels can fish the QS is strictly limited to those who own a trawl permit. Thus, while the Council created a supposedly free market system, they also artificially restricted the market for QS down to the 150 or so permit holders.

Response: Under the Council's FPA, the program would start off requiring possession of a limited entry trawl permit for a number of reasons. First, the scope of the action pertains to how the trawl allocation will be managed, the allocation for which a vessel is required to have a trawl permit. Those permits were issued as part of the Amendment 6 license limitation program. There is nothing in the program that would prevent a follow-on action with a broader scope. Second, the trawl permit requirement limits the maximum number of vessels which may participate in the fishery and therefore assists in the initial planning for the tracking and monitoring program and keeps program costs down. Third, there is an equity perception that it would be unfair to allow one gear group to acquire the allocation given to another but not the other way around, for example, the trawlers would not be given the opportunity to buy limited entry fixed gear sablefish quota for use with trawl gear.

Even though a trawl permit will be required, it is not required that the vessel with which the permit is registered use trawl gear or even be capable of using trawl gear. Moreover, on average there are about 120 trawl vessels that participate in the fishery each year. There are about 168 permits. This indicates some opportunity for nontrawl vessels to acquire trawl permits and use trawl IFQ. Further, it is expected that there will be consolidation in the trawl fleet, increasing the number of trawl permits potentially available for use by nontrawl vessels. Thus, despite the limited scope the IFQ system will allow for some use of trawl IFQ by nontrawl vessels.

Comment 63: Fixed gear vessels are unfairly disadvantaged while allowing trawl-permitted vessels to use fixed gear. The gear switching provision in Amendment 20, which allows trawl vessels to switch to limited entry gear (longlines or pots), effectively gives trawl vessels a fixed gear endorsement. Fixed gear vessels are not given trawl permits. So while trawl vessels get to have it both ways, open access boats and fixed gear limited entry boats are prevented from acquiring quota.

Response: Under the license limitation program, trawl vessels are already allowed to use fixed gear to take the trawl allocation, albeit they must do so under the open access regulations, which have much lower limits. Fixed gear endorsements give a vessel access to the fixed gear allocation. Allowing trawl vessels to gear switch (or other vessels to acquire a trawl permit and IFQ) does not give trawl permitted vessels access to the fixed gear quota; it merely allows the vessel to use nontrawl gear to take the trawl IFQ. Therefore, the IFQ program does not effectively give trawl vessels a fixed gear endorsement. On the other hand, a fixed gear vessel could acquire a trawl permit and trawl quota and would not have to use trawl gear to take that quota, it could use fixed gear. This allows nontrawl vessels to access the trawl IFQ allocation.

10.4.4 Processors

Commenters: Pacific Seafood Group, West Coast Seafood Processors Association

Comment 64: In Chapter 3, Table 3-1 on page 64 is inaccurate in that it assumes there is no effect on shoreside processors of trawl groundfish from bycatch reduction, sector allocations, habitat/ecosystem protection, or wind energy.

Response: With regard to Table 3-1, the accompanying narrative states that the table "shows which environmental components these categories of actions are most likely to affect." There is no assertion that environmental components may not be affected in some way by the various categories of ongoing actions listed in the table, but analysts concluded that any such effects do not contribute in a substantial way to the types of cumulative effects disclosed and evaluated in Chapter 4. Acknowledging that there is the possibility of some kind of effect from these actions, the table key will be modified to state the blank cells indicate "minimal effect expected" rather than "no effect expected."

Comment 65: Chapter 3 of the DEIS provides no basis for the claim that increased protein demand is likely to lead to an increase in real prices for wild-caught fish.

Response: The discussion of protein demand affecting prices is part of an enumeration of trends that may contribute to the cumulative effects of the proposed action. The commenter notes that the DEIS uses 2006 data to show that seafood consumption has been modestly increasing in the U.S. while more recent data show a decline in consumption between 2006 and 2008. The report cited by the commenter ((NMFS 2009a) shows that over a longer time horizon per capita seafood consumption is variable but increasing. For example, per capita seafood consumption was 12.5 pounds in 1980 and had increased to

16 pounds in 2008 with some oscillation in between, including the decline between 2006 and 2008 noted by the commenter. The DEIS more generally explains that increases in global population and living standards are likely to increase demand. Given that the supply of wild-caught fish is fixed by generalized maximum sustainable yield it is reasonable to assert that price increases could be an outcome. However, this discussion is qualified by acknowledging that increasing prices may be offset by other factors such as lower cost production and availability of substitute products.

Comment 66: In Chapter 3, the statement in Section 3.9 that many of the businesses that process west coast harvests are also involved in Alaska and foreign fisheries is not supported with any evidence.

Response: The statement about west coast processors being involved in Alaskan and foreign fisheries is part of a general introductory description of the west coast processing sector. A cursory search of the Web indicates that some west coast processing companies are also involved in Alaskan fisheries. However, we acknowledge that the number of processors involved in such activities is not enumerated. For that reason the statement will be revised to indicate that while there is anecdotal evidence of such involvement, it is not quantified in the description.

Comment 67: The commenter also had several recommended technical corrections to Chapter 3, including correcting references to whiting processors that should be to nonwhiting processors in Section 3.9.2 and reporting a firm no longer in business in Table 3-59.

Response: The text of the DEIS will be revised to ensure references to whiting and nonwhiting fisheries are correct. The caption for Table 3-59 will be revised to indicate the year for which the inventory of seafood processing companies is applicable rather than deleting the company the commenter notes has gone out of business. Because baseline conditions are continually changing (as reflected in the discussion of ongoing trends in Chapter 3), a time period needs to be chosen for data that is used to represent the baseline in the analysis. As discussed in Section 4.1.2, the baseline uses data from the 2004-2008 period (see Table 4-1). For that reason, indicating the time period in the table caption is deemed a better solution since there may be other changes in the status of listed companies since the information was compiled.

Comment 68: Section 4.5.4 in Chapter 4 makes a number of claims for benefits to consumers, which the commenters argue are unsupported or incorrect. They argue that "consumers will receive no benefits and perhaps will even suffer losses as a result of rationalization."

Response: Section 4.5.4 concludes that "trawl rationalization is expected to have a modest beneficial impact to consumers" after enumerating several possible benefits. The commenter argues that claimed benefits are incorrect: greater product availability depends on bycatch reduction, which is unlikely to occur; groundfish is already available throughout the year and fleet consolidation is more likely to reduce year-round availability; and there is no evidence that new product forms will be developed. To respond, we believe our statements about potential benefits are valid, and we reiterate the qualified nature in which they are presented in the DEIS. First, based on review of other quota programs, it is reasonable to expect that trawl rationalization will lead to bycatch avoidance and greater product availability as discussed in comment response Section 10.2. Second, we do not expect that fleet consolidation will lead to reduced seasonal availability of product; consolidation better matches physical capacity to resource availability and will not restrict the ability to harvest throughout the year, subject to other constraints such as market demand and weather. Third, as discussed in the DEIS, the whiting fishery currently operates under derby conditions; trawl rationalization is expected to eliminate these conditions and allow a more measured pace of harvest. Although nonwhiting groundfish are generally available year-round under trip limit management, rationalization will give harvesters more flexibility

over the timing of harvests. Fourth, we recognize that the development of new products is not a given; however, trawl rationalization is expected to allow harvesters and processors to pursue different market opportunities, which may include new product forms, because the management system is structured to give harvesters much greater flexibility in making decisions about when and how to harvest.

Comment 69: Decreased production costs, increased utilization, more even timing of deliveries to processing plants, and market development are claimed as benefits (in Section 4.9), contrary to the commenter's perspective.

Response: With respect to Section 4.9 (impacts to shoreside processors), first, the commenter asserts that the DEIS uses old and limited data and presents conflicting claims with respect to the potential for per-unit production costs to fall for harvesters. The FEIS in Section 4.9 has been revised to state clearly that the data used in the 2000 EA are the best available; they are the only data the agency has on this issue. As explained in that section, the information presented in Table 4-57 is useful to show that excess capacity existed for shoreside processors in 1997 and in 2000 after regulations that restricted fishing were implemented. This information supports the generally accepted view that there is excess capacity in the shoreside processing industry.

The commenter asserts that a statement made in the discussion of cumulative effects to communities (Section 4.14.6.1) that "changes in production costs have made it more expensive to harvest and process fish, and are likely to continue doing so" conflicts with the claim in Section 4.9 of reduced costs. The statement in Section 4.14.6.1 describes general trends applicable to both harvesting and processing. The discussion in Section 4.9 presents information suggesting that there may continue to be excess processing capacity. If the volume of fish landed increases, which the DEIS analysis finds likely, this spare capacity could be more efficiently used, a countervailing effect. In other words, overall costs may increase, but the availability of spare processing capacity could curb the rate of increase in costs, at least over the short-term.

In addition, the commenter asserts that the effects of cost increases on invested capital value and employment are not addressed in the DEIS. In response, the potential for stranded capital is discussed on pp. 425-426, and Section 4.12 discusses impacts to processing and other labor.

Next, the commenter disputes a claim that current regulatory discards of rockfish would be landed under trawl rationalization, increasing utilization and benefitting processors, noting that "many of these discards are due small size or the fact that the species is overfished." In response, the DEIS specifically references regulatory discards, which are required to be discarded, while "economic discards," which include small fish, are discarded for economic reasons (i.e., they are unmarketable). Overfished species are currently regulatory discards: very low trip limits or retention prohibitions are set for these species. Under trawl rationalization, these species could be retained with the only constraint being the requirement to match catch with QP. Increased landings of marketable species, especially of higher value rockfish, should benefit processors by increasing revenues and normal profits.

In addition, the commenter asserts that due to consolidation the "year-round fishery is likely to disappear" preventing the benefit of better matching deliveries to plant capacity. As discussed above, we disagree that consolidation will necessarily eliminate a year-round fishery; consolidation is expected to result in a better match between harvesting capacity and resource availability; although there may be substantially fewer vessels, they would have the capacity to deliver fish in response to any seasonal demand for product by processors (as reflected by processor willingness to pay for year round deliveries).

Finally, the commenter argues that "if the projected impacts of allocating all quota shares to harvesters (i.e., close to zero profits for processors) are correct, there is no money available to develop … new markets." Under the Council's preferred alternative, 20 percent of whiting QS will be allocated to eligible processors (based on processing history). It is unclear what the commenter means by saying there will be "no money available" to processors for this purpose. Generally, market development is a financial decision made by the firm based on the expectation that resulting revenues will exceed the costs entailed and we expect that the program will enhance these expectations. If markets are not available, ex-vessel prices are likely to drop enough to allow the development of needed markets.

Comment 70: Aquaculture as an exogenous factor adversely affecting processors (by increasing price competition for groundfish products) is not mentioned in Section 4.9.4.2.

Response: On page 99, the DEIS identifies aquaculture as part of the "increased demand for protein affecting real prices" reasonably foreseeable future trend, stating "price increases may be mitigated by lower cost production methods in aquaculture and agriculture." Section 4.9.4.2 does identify increased protein demand as an exogenous trend affecting processors. However, the discussion will be supplemented to note the qualification made in Chapter 3 that aquaculture could have a mitigating effect on this trend.

Comment 71: Monitoring costs are not identified as a cost to processors.

Response: The commenter points out that processors will be required to have plant monitors present for every groundfish offload. At the time the DEIS was drafted, it was unclear who would be responsible for covering the costs for shoreside compliance monitors to be on hand for deliveries will devolve to harvesters under the trawl rationalization program. However, in the development of proposed regulations, NMFS has determined that processors will be obligated to pay for shoreside catch monitors; the agency has announced its intent to cover in the first year 90 percent of the cost of hiring the monitor, subject to the availability of Federal funding (and phasing out the government portion by 2014). In practice, who actually pays the cost for shoreside catch monitors (as well as at-sea observers) could be subject to negotiation between processors and harvesters with outcome partly dependent on relative bargaining power. There are also other, associated costs that could devolve to processors. These costs may relate to accommodation of shoreside compliance monitors (e.g., designating a workspace, purchase of approved scales) and any agreed upon cost sharing that may be a part of ex-vessel price negotiations. The DEIS does acknowledge on page 433 that shoreside tracking and monitoring requirements, including the use of shoreside compliance monitors, could add to processor operating costs.

Comment 72: The conclusion in Section 4.6.3.4 (Table 4-28, DEIS pp 339-349) that a 25 percent allocation of nonwhiting groundfish to processors would allow them to capture the entire market for certain species is unsupported by the analysis.

Response: Table 4-28 simply illustrates a reasonable premise: that an allocation to processors is likely to give them an advantage in ex-vessel price negotiations, which may be substantial for species where market demand can be met with comparatively smaller quantities. This supports the conclusion that harvesters would be relatively worse off compared to alternatives where harvesters receive a larger proportion of the initial allocation (either 100 percent, 90 percent under the adaptive management provision, or 80 percent of the shoreside whiting allocation and 90 percent of the nonwhiting allocation, once the AMP is implemented, under the preferred alternative).

10.4.5 Communities, Income, and Employment

Commenters: Crab Boat Owners Association; Vince Doyle and Others; Ecotrust; Food and Water Watch; Radtke, Hans; Tommy's Marine Service; West Coast Seafood Processors Association

Comment 73: Use more recent employment/unemployment data in Table 3-74 and include nontrawl fisheries in the description of the Brookings port group as part of a reanalysis of port vulnerability rankings.

Response: Census data and other information used to characterize west coast ports were incorporated from other sources. Employment/unemployment information was drawn from a detailed compilation of 2000 decennial census data conducted as part of the environmental justice analysis contained in the 2005-2006 groundfish harvest specifications EIS (PFMC 2004a 916 /id /ft; Appendix A). (Detailed demographic information is generally not available for years between decennial censuses for the geographic scale of small coastal communities.) This information is included in the DEIS as part of the baseline description of west coast fishing communities. Updating the cited analyses was not part of the preparation of this FEIS. The time frame of the 2006 vulnerability analysis falls within the analytical time period identified for the baseline description as discussed in Section 4.1.2 (also see Table 4-1).

Comment 74: The socioeconomic impact analysis is deficient because it lacks net economic value modeling and relates fleet efficiency to vessel size, which is not supported by historical evidence.

Response: With respect to net economic value modeling, the DEIS uses a modeling exercise that suggests possible increases in harvesting vessel efficiency, which was published in a peer reviewed journal subsequent to publication of the DEIS ((Lian, *et al.* 2009a).

The commenter also states that vessel size, which is an important factor in the Lian et al. analysis, "is not a major indication of total ex-vessel revenue within a fishery" and presents several examples to suggest many factors that "make a length predictor unreliable." First, ex-vessel revenue is different from vessel efficiency, which affects the cost of harvesting. Second, the commenter's examples of factors affecting fleet size misconstrue the Lian et al. analysis and its use in the DEIS.

Comment 75: The socioeconomic impact analysis is deficient because the regional economic impact analysis is qualitative and not specifically associated with the impacts of the alternatives.

Response: The DEIS contains estimated region-wide income impacts presented for three scenarios positing different levels of bycatch reduction under trawl rationalization. The income impact estimates were derived using the modeling method found in other Council/NMFS environmental analyses and documented in the 2005-2006 Groundfish Harvest Specifications EIS (PFMC 2004a 916 /id /ft; Appendix D) The commenter asserts that there is enough information to make such estimates at the community level. We disagree. Given the uncertainties surrounding the regional distribution of effects of trawl rationalization, presenting income impacts estimates at a finer scale would lead to a false sense of precision. Presenting numerical estimates at the community level could be more misleading than informative, because of the specific assumptions that would have to be made about factors affecting the distribution of income at this scale. Information presented in Section 3.14 (see for example Tables 3-70 and 3-71) is used to indicate the historical distribution of fishery-related income among west coast ports, which can be compared to the regional estimates to get a sense of the relative effects among communities.

It is also important to make the more general point that the analytical framework in the DEIS uses qualitative methods. This framework and approach is described in Section 4.1. The EIS discusses the

uncertainty in predicting outcomes (Section 4.1.6), and for that reason the analysts chose to disclose and discuss the range of potential impacts but could not specify the potential intensity of a given impact. Within this framework, several quantitative models were developed to explore and illustrate potential effects. Section 4.2 describes these models and how they are used in the analysis. Appendix C documents these models.

Comment 76: The socioeconomic impact analysis is deficient because the discussion of ex-vessel price negotiation (Section 4.4.3) cites an unpublished paper by Lian et al. that relies on outdated cost estimates. The commenter argues that the paper relies on 2004 cost estimates while more recent data cited in the DEIS shows that nonwhiting trawl revenue has subsequently increased.

Response: As noted above, the Lian et al. paper has been published in a peer-reviewed journal ((Lian, *et al.* 2009b). While gross revenues have increased, costs have also increased. The Lian et. al. paper illustrates the magnitude of the substantial benefits that might be expected from trawl rationalization under trawl rationalization, both with and without an accompanying expansion of harvest. For these reasons the general conclusions of the Lian et al. paper are still relevant.

Comment 77: The socioeconomic impact analysis is deficient because the DEIS does not contain a proper social impact assessment that would disclose the social costs of the loss to the general public of the asset value of QS. Generalizations about benefits should be removed from the analysis.

Response: The EIS analysis is intended to disclose both environmental and socioeconomic impacts of the proposed action. As noted in response to comment 75, a qualitative analytical framework was used, with certain potential impacts illustrated through the use of quantitative modeling. This qualitative analytical approach acknowledges data and predictive limitations.

Comment 78: The way in which the composition of the industry will change should be presented, especially the emergence of a rentier class of quota shareholders and brokers and fewer captain and crew. The EIS should discuss how this rentier class will derive unearned extra-competitive profits.

Response: The DEIS discusses capture of rents, which would otherwise be dissipated, by quota shareholders. These quota shareholders could be fishery participants or others who then lease quota to fishery participants. Appendix E contains a detailed analysis of the impacts on the allocation of QS on the short- and long-term distribution of rents from the fishery. It discloses that the quota share owner benefits from the stream of rents thus generated and points out that under program rules a wide variety of entities, not just fishery participants, could acquire quota. In terms of change in composition of the industry, the DEIS discusses fleet consolidation and relative bargaining power between harvesters and processors, as well as the possibility that QS might be owned by non-participants. The DEIS also discusses the potential effects of the program on captain and crew, acknowledging the program is likely to result in fewer such jobs and will likely shift the compensation scheme from one based on a share system to a wage system.

Comment 79: Section 3.14 excludes ports where groundfish fisheries are part of a broader "portfolio strategy," ports with nongroundfish fisheries that are likely to experience spillover effects, and ports historically active in the groundfish fishery. The communities are likely to experience adverse impacts that are not accounted for in the DEIS.

Response: Section 3.14 provides a general view of the characteristics of west coast ports by region. It provides information in tables and narrative that indicates the relative importance of groundfish fisheries

to the overall fishing economy of these regions and ports. Section 3.8.3 provides baseline information on nongroundfish fisheries. Section 4.14 considers impacts to nontrawl communities.

Comment 80: The socioeconomic impact analysis is deficient because the identification of vulnerable communities is outdated; an update would change resilience scores and the designation of some ports from not vulnerable to vulnerable.

Response: The analysis underlying the identification of vulnerable communities was part of the 2007-2008 groundfish harvest specifications EIS ((PFMC 2006). It used 2005 landings data to evaluate ports' engagement in fishing and dependence on groundfish. Census and other socioeconomic data were used to determine community resilience. Because of the time frame during which the EIS has been prepared, the most recent fishery data used comes from 2007 (fishery data is used for measures of dependence and engagement). Census and other data used to determine resiliency is generally not available at the geographic scale of ports for years more recent that the 2000 decennial census.[122] The 2006 vulnerable communities analysis uses data within the baseline time period (2004-2008) used for the analysis. The DEIS incorporates this information by reference; the assessment of community vulnerability was conducted separately from the DEIS analysis. For these reasons, the cited vulnerable communities analysis provides a reasonably accurate assessment of community status consistent with the baseline time frame used in the EIS.

Comment 81: The socioeconomic impact analysis is deficient because Section 3.14.6 does not include information about community-based entities engaged in the acquisition of fishing-related assets.

Response: Information on these community-based entities was not available an,d as noted elsewhere the baseline description of west coast fishing communities, takes a synoptic view. The Council discussed program provisions related to community fishing associations (CFAs; see comment response Section 10.1.5) and decided to implement such provisions through a trailing action. Therefore, inclusion of information about existing entities with similar purposes does not bear directly on the range of alternatives considered in the EIS.

Comment 82: The role processors play in providing critical fishery-related infrastructure in ports is not discussed in Section 3.9.3.

Response: Section 3.9.3 presents information on the flow of groundfish among west coast ports and processing centers. As the commenter acknowledges, the role of processing infrastructure is discussed in other sections of the DEIS. The commenter notes that such a discussion would illuminate shifts in processing center locations and its effect on other fisheries. There is substantial discussion in Section 4.14 of the potential effects of changes in the regional distribution of landings and the effects of fleet consolidation.

Comment 83: Reductions in fishery-related employment related to the proposed action are not considered or quantified in the context of impact on the general public in Section 4.5.5.

[122] Inter-decennial census data, such as the U.S. Census American Community Survey is not available for geographic areas with less than 20,000 population and estimates at this scale are only available as 3-year averages. The first 5-year estimates, which will contain data at sufficiently large scale, will not become available until later in 2010. Most of the ports are too small to obtain demographic characteristics directly.

Response: As explained in the DEIS, the general public environmental component is defined as nonconsumptive users and nonusers of the resource. Fishery-related employment is not relevant in this context. Fishery-related employment is addressed elsewhere (e.g., Sections 4.7, 4.12-4.14).

Comment 84: Amendment 20 will severely impact Fort Bragg fishermen, their families, and suppliers.

Response: The DEIS discloses potential adverse impacts to Fort Bragg and other fishing communities.

10.4.6 Regulatory Impact Review (RIR) and Initial Regulatory Flexibility Analysis (IRFA)

Commenters: Ecotrust, West Coast Seafood Processors Association

Comment 85: The RIR/IRFA analysis (Appendix H in the DEIS) is inadequate. The analysis needs to take into account impacts on the full range of affected entities. Considering effects at the scale of the whole nation for determining whether impacts are significant is not supported by EO 12866 or the Regulatory Flexibility Act. The evaluation of alternatives should include the additional alternatives proposed by the commenter elsewhere in their letter. The RIR/IRFA analysis is inadequate for the same reasons the commenter claims the impact analysis in Chapter 4 of the DEIS is inadequate.

Response: The RIR/IRFA analysis in Appendix H of the DEIS is preliminary. The RIR/IRFA analysis is tied to the regulatory process and its inclusion in the EIS is not required, but the EIS is frequently used as a way of disseminating this information to the public. Furthermore, the contents of the DEIS overlap with many, but not all, of the required elements of the RIR/IRFA analysis. However, the RIR/IRFA analysis has specific analytical requirements, such as cost-benefit analysis, that is not required in an EIS (40 CFR 1502.23). At the time the DEIS was published, the development of implementing regulations for Amendment 20 had not proceeded to a point where the RIR/IRFA analysis could be fully developed. A revised RIR/IRFA analysis has been prepared as part of Federal rulemaking and is included in this FEIS.

10.5 Policies, Legal Standards, and Requirements

10.5.1 Public Trust and Privatization

Comment 86: The commenter favors status quo and opposes Alternative 4b (the Council recommended alternative) citing concerns that Alternative 4b does not collect any resource rent and is chiefly concerned with putting anti-competitive measures in place so that the "winners" can extract extra-competitive profit. Alternative 4b provides access privileges with most of the attributes private property rights, exclusivity, tradability, and effective perpetuity. The Pacific coast limited entry trawl fishery, as with all other U.S. fisheries, should be maintained as a valuable public trust asset and not be doled out to private interests for free and forever.

Response: The policy recommended by the Council is one that balances several objectives. Imposition of the collection of resource rents without a phase-in process would be highly disruptive and likely result in the acquisition of harvest privileges by large well-funded entities with "deep pockets." The Council considered a provision that would phase in the collection of additional resource rents through an auction. While the Council deferred further deliberation on this provision until the first 5-year review, it put the public on notice that such provisions would be considered. Congress and the Council

have both been clear and explicit that what is being granted is a privilege that is modifiable and revocable at any time without compensation to the privilege holder (see Section A-2.3.4 of the EIS).

Under status quo, the fishery resource is held in the public trust until sometime after it is captured and brought on board a vessel, at which point it becomes the private property of the vessel. Under the proposed alternative, the situation will be no different. What changes is how the harvest is controlled. Under status quo, those with trawl permits compete with one another on the fishing grounds to harvest the trawl allocation. Under trawl rationalization, those with trawl permits will compete with each other, crew, communities, processors and others in the private market place to determine who is willing and able to pay the most for the harvest privileges. This process is expected to result in an efficient outcome and convert currently wasted resources into profits. It is not clear why the commenter believes these measures to be anticompetitive. The profits will be captured by the holders of the harvest privileges who: will pay taxes on any capital gains (benefiting the public), will pay directly or indirectly for the costs of the program, and may at a later time be asked to pay additional rents or royalties. The public trust nature of the resources will not change; the harvest privileges are not given out completely freely; and the nature of what is being given out is not necessarily fixed even over the next several years, much less so "forever."

Comment 87: The commenter voiced concern that the gifting of a valuable public asset worth many hundreds of millions of dollars is not accounted for and specifically asks: How much is this asset worth? Who is getting this asset? Is the public even aware that its asset is being given away for free and essentially forever? Has the PFMC made any effort to assess public sentiment over this giveaway of public wealth? How much annual resource rent (that could be used for better management and habitat restoration) is being forgone?

Response: The asset worth is assessed in Section A-2.1.1.a of the DEIS. The trawl permit holders would receive 90 percent of the nonwhiting QS, 80 percent of the whiting QS, and all of the mothership whiting and catcher processor allocations. The identities of these permit holders are a matter of public record available from the NMFS Northwest Region Limited Enter Permit Office. The 20 percent of the whiting QS going to first receivers is expected to be distributed among 11 companies listed on the Council website. The Council's policy deliberations are a matter of public record, noticed in the Federal register, announced through the Council web site and mailing lists, and reported on frequently by the press. The issue of whether these assets are being given away free forever is discussed in the previous response. With respect to assessment of public sentiment, the Council has received considerable public comment and is considering policies authorized by Congress, one of the main authorities for determining public interest. The amount of annual resource rent is directly related to the value of the long-term harvest privilege, discussed in Section A-2.1.1.a.

Comment 88: Anti-competitive protections for the catcher processor whiting, and other whiting and nonwhiting sectors should be removed from the preferred alternative. The catcher processor sector is a LAPP and should be subject to LAPP requirements.

Response: The measures this commenter terms "anti-competitive" are part of the status quo program (under Amendment 6 and Amendment 15, participation in the trawl sectors of the fishery was limited). The Council reconsidered its policy at its April 2010 meeting and recommended to NMFS that co-op permits be required for mothership catcher vessel and catcher-processor co-ops, with the understanding that this modification would clearly subject these sectors to LAPP requirements.

10.5.2 Magnuson-Stevens Act, Including National Standards

Commenters: Crab Boat Owners Association, Ecotrust, West Coast Seafood Processors Association

Comment 89: We believe that the action alternatives do not successfully meet the national standards for fisheries management in Section 301(a) of the MSA. We also believe that the action alternatives do not successfully meet the national standards for fisheries management in Section 301(a) of the MSA.

Response: Specific issues are addressed below. During Secretarial review, NMFS will review the Council's recommended alternative to determine whether it complies with the MSA's National Standards.

Comment 90: National Standard 2 requires the use of the best scientific information available. The DEIS makes the assertion that the analyses contained within constitute that information. Given the flaws discussed at length above, we disagree.

Response: As explained in responses above, in response to public comment, descriptions of some of the information presented in the EIS have been revised. NMFS will review the entire record supporting the Council's recommended action to determine compliance with National Standard 2 and all National Standards.

Comment 91: National Standard 5 prohibits management measures that have economic allocation as their sole purpose. Note the discussion on Section 1.3.1 above (Analysis of need for action).

Response: National Standard 5 does prohibit measures that have economic allocation as their sole purpose. The trawl rationalization program is not such a prohibited measure. The need for trawl rationalization arises from a complex set of challenges relating to biological, social, and economic concerns. This action addresses the challenge of addressing bycatch in a complex multi-species fishery in which management requirements for several overfished stocks are constraining the ability of the fishery to achieve OY on other stocks. By giving individual participants more flexibility, accompanied by greater individual accountability, the action is expected to better allow for achieving OY while rebuilding overfished stocks.

The stated purpose for the action reflects the range of biological, social, and economic concerns:

> Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.

NMFS notes that Sections 303(b)(b) and 303A of the MSA specifically authorize the establishment of limited entry and LAPP programs.

NMFS will review the proposed action to determine its consistency with National Standard 5 prior to making a final decision.

Comment 92: Individual quota programs are economic programs and they do not work without allocation when different sectors compete for the same fish but only one of those sectors is proposed to be rationalized.

Response: Section 2.6 of the analysis explains the Council's rationale for recommending the IFQ program. As stated in Section 2.6, the purposes of Amendment 20 are not merely economic but pertain to bycatch reduction and catch accounting as well. While allocations play an important role in implementation of an IFQ program, such allocations could be made through the biennial specification process under the current status quo without formalizing them in the FMP. The Council explores these alternatives in the context of Amendment 21.

Comment 93: National Standard 7 speaks to minimizing costs and duplication. Since the DEIS contains no real analysis of the monitoring program and its effects, we will base our comments on reports provided to the Council by enforcement bodies.

Response: The DEIS evaluates the potential impacts of the proposed action and its alternatives on the quality of the human environmental. In this context, it includes a broad level discussion of anticipated program costs. A more precise cost assessment is contained in the RIR/IRFA accompanying this FEIS. NMFS will evaluate compliance with National Standard 7 prior to making a decision.

Comment 94: The monitoring program contemplates the use of observers, rather than the existing electronic monitoring, on whiting trawl vessels – at a much higher cost. Fish in both the whiting and nonwhiting fishery will be observed by a federally-trained observer as it is hauled aboard a vessel and again when it is landed on shore in a processing facility, this time by a different federally-trained monitor. Specifics of the fish (weight, species, etc.) will be recorded on a fish ticket and in a production report, both of which will be made available to state and federal enforcement entities. Duplication and costs will run rampant.

Response: National Standard 7 states that "[c]onservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication." The monitoring requirements in the proposed trawl rationalization program are necessary for the effectiveness of the program. Under the IFQ program, the nature of fishing activities will not change, but *incentives* will. There generally will be enhanced incentive to avoid detection of overfished species due to the level of individual accountability. Current electronic monitoring may not be sufficient to detect throwing overboard of infrequently caught constraining bycatch. For catcher vessels in the mothership sector it may be important to have observers on board in case there are any situations in which codends must be bled for fish is otherwise spilled before it is transferred to the mothership. Moreover, it is important for the integrity of the program that fishermen believe that everyone is complying.

At-sea observers would perform different functions from shoreside monitors. The primary role of at-sea observers includes recording fishing effort and estimate total, and discarded catch weight by species. The function of the shoreside monitors includes verifying all shoreside deliveries of catch share species, ensuring that species are sorted to Federal species or species groups, and recording and submitting catch/landing data daily.

With respect to the requirements for both fish tickets and production reports, NMFS acknowledges that there may some duplication at the beginning of the program. This is due to the need for both the state and the Federal government to have access to the information and the different formats currently in use. However, it is possible that this situation can be improved during the initial phases of the rationalization program in a manner similar to how reporting in the Oregon whiting fishery has been resolved. In the Oregon whiting example, both the state and Federal government required access to information, and through cooperation they were able to develop one reporting instrument that met both needs. Thus, while there may be some duplication at the start of the program, the hope is that this will be reduced as the program develops.

NMFS, the states, and the Council intend to continue working collaboratively on data collection programs to meet both state and Federal purposes without duplication and in the most efficient manner.

NMFS will review the proposed action for compliance with National Standard 7 prior to making a final decision.

Comment 95: National Standard 8 requires minimizing effects on communities. The action alternatives will potentially increase unemployment, remove fishing facilities (vessels and processors) from "at risk" communities, and reduce income from local taxes and purchase of goods and services.

Response: National Standard 8 requires consideration of impacts on communities, but recognizes the higher priority of National Standard 1. Specifically, National Standard 8 states that "Conservation and management measures shall, consistent with the conservation requirements of the Magnuson-Stevens Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to: (1) Provide for the sustained participation of such communities; and (2) To the extent practicable, minimize adverse economic impacts on such communities."

Chapter 4.14 of the analysis describes anticipated impacts on communities and acknowledges a possibly profound impact on communities that depend on trawling. This is due to the nature of rationalization which results in fewer fishery participants and likely geographic shifts. The goal of attaining a sustainable fishery as a whole requires some impacts to individual communities. However, the Council also recommended measures that should mitigate these impacts.

For example, the program would allow communities to purchase quota or permits to keep some of the fishery in the community. In addition, the AMP is intended for use in ameliorating impacts on communities.

NMFS will review the proposed action for compliance with National Standard 8 prior to making a final decision. See also response to comment 105 below.

Comment 96: National Standard 9, reduction in bycatch, can be met equally well by the status quo alternative as by the action alternative.

Response: Chapter 4.17.2.2 provides information indicating that the proposed trawl rationalization program would be expected to be more effective at reducing bycatch than maintaining the status quo. See also responses to comments on the need for action, and responses to comments in Section 10.2 on the need for action 35.

NMFS will review the proposed action for compliance with National Standard 9 prior to making a final decision.

Comment 97: The proposed Program would elevate fishing efficiency and economic objectives over objectives dealing with environmental stewardship. This approach inverts the priority of the standards adopted by Congress to guide management plans. Under Congress' scheme, it is the standard on fishing efficiency that must be considered (National Standard 5), while the standard on fisheries conservation (National Standard 1) has primacy.

Response: NMFS does not agree that the order of the wording in the stated goal of the proposed program is intended to elevate any parts of the stated goal above others. NMFS notes that the MSA uses

a similar ordering of issues in defining OY as MSY as reduced by any relevant economic, social, or ecological factors. NMFS concurs with the statement that National Standard 1 takes primacy over certain other considerations in the MSA. The analysis contained in Chapter 6 indicates that the proposed program would comply with National Standard 1 by improving the ability of the fishery to achieve OY while preventing overfishing and achieving rebuilding. The MSA also mandates the consideration of economic efficiency, allows allocations to the extent that they are not the sole purpose of a management measure, and specifically authorizes the establishment of limited entry programs and LAPPs.

As discussed in Section 1.2.2 of the EIS, since the initiation of scoping for action, the Council has identified the interrelated issues of bycatch and fleet stability as key problems, and the Council has been committed to increasing accountability for bycatch. Amendment 18, which focused on bycatch, identified IFQ as an appropriate approach for bycatch reduction (pp. 3-4 of EIS).

NMFS will review the proposed action for compliance with the National Standards prior to making a final decision.

Comment 98: The Program's only concrete contribution to fishery conservation is the proposed full observer and camera coverage at sea and dockside and related reporting.

Response: Amendment 20 is expected to promote achievement of OY, reduce bycatch, and improve information available for use in managing the fishery. The analysis identifies numerous potential benefits, as well as potential adverse impacts, from the proposed action. The Council considered these impacts and concluded that the benefits outweigh potential adverse effects. Section 2.6 of the EIS explains the Council's rationale for recommending the actions in Amendment 20. NMFS will review the proposed action for compliance with applicable laws prior to making a final decision.

Comment 99: If implemented as planned, this aspect of the Program should yield information useful for improving fisheries management.

Response: The observer coverage and monitoring requirements are intended to yield useful information.

Comment 100: This potential gain is overshadowed, however, by the considerable negative impacts of the Program. The DEIS does not give an adequate accounting of these impacts. Additionally, it contains significant errors in the information and analysis that are provided.

Response: The DEIS evaluates the potential impacts of the proposed action and its alternatives on the quality of the human environmental. In this context, it includes a broad level discussion of anticipated program costs. As noted above, in some cases the EIS has been revised to provide a better description of the some of the information and its limits.

After considering potential positive and negative impacts of the proposed program and its alternatives, the Council determined that the proposed approach is the best way to achieve the stated goals as described in Section 2.6 of the analysis.

Additional economic information is provided in RIR/IRFA in this FEIS (see Appendix H). This additional information describes costs along with estimates of the distribution of these costs between the Federal government and the private sector NMFS will evaluate compliance with National Standard 7 prior to making a decision.

Comment 101: The program lacks the incentives needed to encourage harvesting the full optimum yield of higher biomass species while avoiding lower biomass species, thereby not meeting National Standard 1.

Response: Section 4.17.2.2 provides information indicating that the proposed trawl rationalization program would be expected to be more effective at reducing bycatch than would be maintaining the status quo. Section 2.6 explains the Council's rationale for recommending Amendment 20. See also response to comments in Section 10.2, the need for action.

NMFS will review the proposed action for compliance with National Standards 1 and 9 prior to making a final decision.

Comment 102: The program's allowance of non-fishing ownership and QS leasing will diminish fishers' incentive for stewardship, undercutting the ability to meet National Standard 1.

Response: Appendix A-2.2.2.3.b (p.A-225-230) describes alternatives the Council considered, but rejected, that would have modified the eligibility to own requirements. This section of the analysis sets forth costs and benefits of different eligibility requirements. For example, the council considered restricting eligibility to "stakeholders" or limited entry permit holders, but identified concerns about cost and administration of such restrictions. The council also identified benefits of allowing broader eligibility such as encouraging the highest value use of the resource. See also response to comments 25 and 28.

Comment 103: The allocation of 90 percent of the groundfish quota to a nonselective gear with high levels of habitat destruction and bycatch makes the action inconsistent with National Standard 1.

Response: National Standard 1 states that "Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield (OY) from each fishery for the U.S. fishing industry." The MSA defines OY as "the amount of fish which (A) will provide the greatest overall benefit to the Nation, particularly with respect to food production and recreational opportunities, and taking into account the protection of marine ecosystems; (B) is prescribed as such on the basis of the maximum sustainable yield from the fishery, as reduced by any relevant economic, social, or ecological factor; and (C) in the case of an overfished fishery, provides for rebuilding to a level consistent with producing the maximum sustainable yield in such fishery."

Thus, National Standard 1 pertains to an amount of fish rather than to a gear type's impact on habitat. The analysis does discuss the rationale for focusing management measures on trawl gear in Section 2.6.1. Currently, for a number of species (especially flatfish and slope species) trawl gear is the only gear capable of commercially viable harvest in the amounts in which the species are available—see the response above under comment 47 in Section 10.4.2 for more discussion. The fishery is already subject to rebuilding plans that comply with the mandates of National Standard 1.

In addition, it is important to recognize the ongoing nature of fishery management under the MSA. As management needs arise, the Council and NMFS respond to them. Recently, Amendment 19 addressed habitat issues in the fishery, and established extensive habitat protections. Amendment 20 maintains those protections while specifically addressing a separate management need for rationalization as described in the purpose and needs statement. While FMP amendments must comply with the broad array of policy objectives in the MSA's National Standards and within the FMP, not every FMP amendment will thoroughly address every management need in the fishery simultaneously. NMFS and

the Council will continue to review the best available information regarding habitat needs and develop additional management measures if necessary and appropriate.

The goal of Amendment 20 is to "[c]reate and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch." Within the context of achieving this goal, the EIS acknowledges impacts caused by trawl gear. For example, the impacts of trawl gear are discussed in a section on eco-labeling in Chapter 3 (p.100). While Amendment 20 is not focused on habitat remediation, as discussed in responses to comments in Section 10.4.3, Amendment 20 may allow for an increase from the status quo in the use of nontrawl gear in the trawl fishery. See also Section 2.6.1 of the EIS. Also, as noted in response to comment 47,, the allocations in Amendment 21 would limit the trawl share of harvest to a slightly lower level than status quo. NMFS will review the proposed action's compliance with all National Standards prior to making a final decision.

Comment 104: Although the intersector allocation process has been deferred to Amendment 21 (improperly, as discussed in our comments above on segmentation), the intended allocation to the trawl sector is clear on the record of Amendment 20. The preferred alternative has ignored available studies and reports showing the adverse effects of trawl gear on bottom habitat and overfished stocks, thus not addressing National Standard 2.

Response: The commenter's position regarding segmentation of Amendment 21 and 20 are addressed below. And, as noted in response to other comments, no allocation or management scheme is "permanent." the MSA requires periodic review of actions and the Council recommends modifications frequently. To the extent that the comments address the allocation scheme of Amendment 21, those comments are beyond the scope of this action.

The focus of Amendment 20 is rationalizing the trawl fishery and reducing bycatch. As discussed in responses above to comments addressing habitat concerns, especially the response to comment [5.2.4], Amendment 19 developed a suite of habitat protections that would continue under the Amendment 20 regime. The DEIS for Amendment 20 recognizes the impacts of trawl gear (for example, see page 100) and incorporates by reference information from the Amendment 19 EIS (see Section 4.20.3.3, p. 603). Amendment 20 would not modify the protections implemented pursuant to Amendment 19. We do not agree that relevant information has been ignored.

NMFS will review the proposed action for compliance with National Standard 2 prior to making a final decision.

Comment 105: The proposed Program fails to meet the National Standard 4 standards for allocation fairness and equitability in several ways. The Program's failure to provide for fishing community participation is especially troubling in light of the statutory provisions for inclusion of communities in initial allocations and a record of Congressional concern over this issue. Senate Report 109-229 on Senator Stevens' original limited access privilege bill, S 2012 in 2006 which, with changes not relevant here, was enacted into law. The report specified that allocation of harvesting privileges to fishing communities was to be allowed and that small vessel and entry-level participants as well as communities were to be included in any plan to rationalize a fishery.

Response: The cited legislation does not require initial allocations to communities or any other community specific provisions but does require that effects on communities be considered and taken into account. As stated in Section 2.5 of the EIS, the Council considered initial allocation alternatives,

including to communities but heard from local governments that they were not interested in the cost and burdens of administering a community quota program.

Appendix A provides additional discussion of the Council's consideration of communities at Section A-2.1.1.a, and lists alternative means by which Amendment 20 addresses community needs, including:

- Maintenance of a split between the at-sea and shoreside trawl sectors.
- Broad eligibility for ownership.
- A temporary moratorium on the transfer of QS to ease the adjustment period and allow for adaptive response.
- Specification of vessel and control limits to spread QS among more owners and potentially more communities.
- Inclusion of a community advisory committee as a formal part of the program performance review process.
- The Adaptive Management set-aside.

While initial allocations of quota would be limited based on qualifying criteria, after the first two years, the proposed program would allow both ownership of privileges by communities and acquisition by entry level participants. In addition, parties, including communities, desiring to receive initial issuance would be able to purchase limited entry permits such as The Nature Conservancy has done and receive initial issuance. Appendix A Sections A-2.2.2.d and A-2.2.3 describe entry level opportunities and transfer provisions.

NMFS will review the proposed action for compliance with National Standard 4 prior to making a final decision. See, in addition, response to comment below.

Comment 106: Given evidence that QS programs result in consolidation of fishing power in relatively large operations, the NS 4 (C) prohibition on acquisition of excessive shares under National Standard 4 may be violated along with National Standard requirements.

Response: National Standard 4 requires that allocations be "reasonably calculated to promote conservation," and that they be "carried out in such a way that no particular individual, corporation or other entity acquires an excessive share."

Chapter 4, particularly 4.17, describes the anticipated effects of the proposed program, and the expected conservation benefits for fish stocks, including increased speed of management information, elimination of the race for the fish, and reduction in bycatch and rate of bycatch. Section 2.6 sets forth the Council's rationale for recommending Amendment 20.

Limitations on accumulation and use are included in the program to prevent accumulation of excessive shares or excessive consolidation. These protections would include potential divestiture at the initial issuance stage.

Additional information on accumulation and use limits is provided in the response to comments 28 and 29.

NMFS will review the proposed action for compliance with National Standard 4 prior to making a final decision.

Comment 107: Congress intended that communities and small vessels be allocated harvest privileges (see, for example, Senate Report 109-229 on Senator Stevens' original limited access privilege bill).

Response: While initial allocations of quota would be limited based on qualifying criteria, after the first two years, the proposed program would allow both ownership of privileges by communities and acquisition by entry level participants. See response in Section 10.1.5.

Comment 108: The proposal runs counter to decisions of Congress in 1996 to strengthen laws promoting sustainable fishing and weaken National Standard 5 by replacing "shall promote" with the present "shall consider" efficiency.

Response: As stated above in response to comment 91 above, National Standard 5 does prohibit measures that have economic allocation as their sole purpose. The trawl rationalization program is not such a prohibited measure. The need for trawl rationalization arises from a complex set of challenges relating to biological, social, and economic concerns. This action addresses the challenge of addressing bycatch in a complex multi-species fishery in which management requirements for several overfished stocks are constraining the ability of the fishery to achieve OY on other stocks. By giving individual participants more flexibility, accompanied by greater individual accountability, the action is expected to better allow for achieving OY while rebuilding overfished stocks.

The stated purpose for the action reflects the range of biological, social, and economic concerns:

> Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.

NMFS notes that Sections 303(b)(b) and 303A of the MSA specifically authorize the establishment of limited entry and LAPPs.

NMFS will review the proposed action to determine its consistency with National Standard 5 prior to making a final decision.

Comment 109: In elevating economic objectives over statutory standards that provide for the sustained participation of fishing communities, the DEIS misconstrues the relationships among the standards and fails to exhibit consistency with NS 8.

Response: We reiterate the multi-purpose goal of Amendment 20 which is to "[c]reate and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch."

Economic considerations are an important component of a rationalization program and redistributive impacts are unavoidable. As discussed in the responses in Sections 10.1.5 and 10.4.5, the DEIS fully considers impacts on communities and Amendment 20 includes provisions to mitigate these impacts to the extent practicable.

NMFS will review the proposed action for compliance with the MSA and its National Standards prior to making a final decision.

Comment 110: Nothing in the DEIS indicates that the Program will actually minimize bycatch to the extent practicable, as called for by NS 9.

Response: Section 4.17.2.2 provides information indicating that the proposed trawl rationalization program would be expected to be more effective at reducing bycatch than would be maintaining the status quo. See also comment responses in Section 10.2, especially the response to the first comment.

As discussed above in response to comment 114, Amendment 20 does not allocate between the trawl and nontrawl fleets. The decision on that allocation will be made pursuant to Amendment 21. See response to comment 101.

NMFS will review the proposed action for compliance with all National Standards prior to making a final decision.

Comment 111: The claim of increased safety is unsubstantiated and contrary to reported results from other IFQ fisheries.

Response: This comment relies on one example and refers back to the leasing argument as the driver for that impact. The proposed Pacific program is structured differently than the BC program. The degree of quota divisibility in the Pacific program alters the effect of leasing by allowing new entrants to purchase small amounts over time while also serving as crew. This is a different mechanical structure than BC where huge chunks of quota must be purchased to "enter," so the new entrant has leasing as the only viable option.

Second, Pacific trawl vessels are currently in a relatively poor state as a result of the economics of the fishery. They also currently have a large incentive to fish in the winter due to the fishing opportunities present there via the trip limit regime. The proposed rationalization program would eliminate or reduce that structure and that corresponding incentive to fish in the winter.

Third, with regard to the whiting fishery, this program replaces the interim Amendment 15 provisions that restricted participation in the shoreside and at-sea sectors to vessels that met the specific eligibility criteria. Amendment 15, which was approved by the agency in 2008 and implemented in 2009 (see the final rule published March 10, 2009, 74 Federal Register 10139), contained no provisions for replacement vessels. Under the rationalization program, participation is no longer tied to a vessel but to a permit with a whiting endorsement. Permits can be transferred to different vessels, with some restrictions. This increases safety significantly over the Amendment 15 vessel limitation where aging vessels could not be replaced.

Last, most fisheries under IQs have shown an improvement in safety at sea. This is supported by the findings of the NRC.

NMFS will review the proposed action for compliance with the MSA and its National Standards prior to making a final decision.

Comment 112: Can you say, "Who's your Banker?" Catch shares also allowed investors who've never been in the business to control large quantities of our nation's fish resource. Some people would rather worship fish than eat them.

Response: Under Amendment 20, entities who are not currently fishermen would be able to acquire QS. The Council's rationale for this recommendation is set forth in Appendix A-2.2.3.a. See also response to comment above.

With respect to large quantities of quota, there would be accumulation limits in place.

The Council considered adding a use-or-lose requirement, but the tracking and monitoring requirements would have been untenable. The Council did add measures to try and ensure that quota is transferred to fishermen, including the requirement that all QP be transferred to quota account within a year, and the requirement that QP can only be transferred to a vessel. The 5-year review will allow NMFS and the Council to revisit this issue and determine whether additional management action is warranted.

10.5.3 Groundfish FMP Goals and Objectives

Commenters: Ecotrust, West Coast Seafood Processors Association

Comment 113: We believe the action alternatives are flawed and, in fact, do not meet the Groundfish FMP goals and objectives and specifically Goal 2, maximize the value of the groundfish resource as a whole, and Goal 3, promote the year-round availability of seafood to the consumer among other things.

Response: It is important to note that none of the FMP goals and objectives, nor any of the MSA National Standards, should be viewed in isolation. Both the FMP and the MSA contain a variety of competing policy objectives which must be considered and balanced whenever developing fishery management measures. In both the FMP and the MSA, some of the policies take priority over the others, such as the National Standard 1 mandate to achieve OY while preventing overfishing. As discussed in Chapter 6, the FMP contains three broad goals and 17 objectives to promote achievement of the goals. The three goals are enumerated in order of priority and the FMP specifies that they must be considered in conjunction with the MSA's National Standards. The first goal, and first priority, for the FMP is to "[p]revent Overfishing and rebuild overfished stocks by managing for appropriate harvest levels and prevent, to the extent practicable, any net loss of the habitat of living marine resources."

Thus goals 2 and 3 are secondary to the FMP's primary management goal.

Goal 2 of the FMP is to "[m]aximize the value of the groundfish resource as a whole." The concept of maximizing value does not pertain to bestowing value on any particular group or groups, but rather on maximizing value as a whole consistent with National Standard 1. Nevertheless, the analysis does extensively consider potential effects on processors and harvesters. See, for example, Chapter 4.6, describing impacts on harvesters, 4.9 addressing impacts on processors, and 4.14 addressing impacts on communities. The analysis identifies a variety of potential impacts on processors that would include both positive and negative potential impacts. Chapter 2.6 of the EIS explains the reasons for and considerations underlying the Council's recommendation. In addition, Appendix A contains detailed information on these considerations.

With respect to goal number 3, the FMP states that:

> Within the constraints of overfished species rebuilding requirements, achieve the maximum biological yield of the overall groundfish fishery, promote year-round availability of quality seafood to the consumer, and promote recreational fishing opportunities.

As stated in the EIS, the goal of trawl rationalization is to:

> Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.

Underlying this goal is the need to address management of bycatch in a complex multi-species fishery in which management requirements for several overfished stocks are constraining the ability of the fishery to achieve OY on other stocks. By giving individual participants more flexibility, accompanied by greater individual accountability, the action is expected to better allow for achieving OY while rebuilding overfished stocks. The Council and NMFS analyzed alternative approaches for meeting this management objective in context of the FMP's broader goals and objectives as well as the MSA's National standards.

In this context, the FMP's objective of a year-round fishing season is of lower priority than preventing overfishing, rebuilding, allowing for appropriate harvest levels, and preventing to the extent practicable, any net loss of habitat. The proposed measures in Amendment 20 would affect both whiting and nonwhiting fisheries. While the shoreside nonwhiting sector currently operates on a year-round basis, the whiting sectors do not. The reference in the analysis to extending the fishing season pertains to eliminating the "race for the fish" in the whiting sectors. By replacing regulatory seasons with greater individual catch accountability, the different sectors of the fishery will be able to operate according to the schedule that makes the most sense to them. For example, one reason for maintaining year-round fishery for groundfish is that it holds the fishery together between seasons for other species, such as crab. It provides flexibility to keep operations going/provides year-round fishing activity in coastal communities and for processing plants. The IFQ system will provide greater flexibility to maintain year-round operations. Thus a key reason for this objective is to maintain year-round "fishing" activity, not just year-round "groundfish" activity. There is an underlying concern for stable employment in the fishing community.

Comment 114: The Program with its 90 percent allocation to the habitat—damaging trawl sector would undermine FMP goal 1, net loss of marine habitat is to be prevented to the extent practicable.

Response: Amendment 20 would not allocate between the trawl and nontrawl fleets; the decision on that allocation will be made pursuant to Amendment 21. The allocations in Amendment 20 pertain only to allocating within the Limited Entry trawl fishery. With respect to the shoreside IFQ sector, the proposed program would initially allocate the shoreside whiting trawl quota as follows: 80 percent to limited entry trawl permits and 20 percent to processors. It would initially allocate the nonwhiting shoreside trawl species covered by the program as follows: 90 percent to limited entry trawl permits and 10 percent to an adaptive management program.

While Amendment 20 is not focused on habitat remediation, as discussed in responses to comments 1.8.1, 1.8.2, and 4.2.5, Amendment 20 may allow for an increase from the status quo in the use of nontrawl gear in the trawl fishery. See also Chapter 2.6.1 of the EIS. Also, as noted in response to comment 4.2.5, the allocations in Amendment 21 would constrain trawl harvests to a slightly lower level than status quo.

It is important to recognize the ongoing nature of fishery management under the MSA and that not every amendment will address every management need in the fishery simultaneously. As management

needs arise, the Council and NMFS respond to them. Amendment 19 established extensive protections for habitat. Amendment 20 maintains those protections while specifically addressing a separate management need for rationalization as described in the purpose and needs statement. While FMP amendments must comply with the broad array of policy objectives in the MSA's National Standards and within the FMP, not every FMP amendment will thoroughly address every management need in the fishery simultaneously. NMFS and the Council will continue to review the best available information regarding habitat needs and develop additional management measures if necessary and appropriate.

Comment 115: The Program does not comply with FMP objectives 14 through 17 with respect to impacts on small entities. The AMP cannot be relied upon in evaluating the impacts of the preferred alternative.

Response: As stated in response to the first comment in this section, the FMP's goals and objectives should not be considered in isolation, but as components of a complex framework of competing considerations.

Objectives 14 – 16 read as follows:

> Objective 14. When considering alternative management measures to resolve an issue, choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and the environment.
>
> Objective 15. Avoid unnecessary adverse impacts on small entities.
>
> Objective 16. Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.

Chapter 2.6 of the EIS explains the reasons for and considerations underlying the Council's recommendation. In addition, Appendix A contains detailed information on the Council's rationale for each of the alternatives recommended. Factors considered include degree of disruption, impacts on small entities, and impacts to communities. The analysis does recognize potential negative impacts on harvesters not receiving sufficient initial allocations of quota. See for example Table A-12 setting forth considerations for allocating to processors. See also, Table A-15 describing potential impacts on harvesting and processing sectors, Section A-2.1.3.a setting forth considerations for allocation formulas, Section A-2.1.1.a discussing the initial split of QS and particularly the discussion of impacts on communities, and Section A-2.2.3.b describing considerations on transferability and eligibility to own.

With respect to FMP objective of considering communities, the analysis documents the Council's consideration of communities and efforts to minimize economic impacts to the extent practicable. Due to the nature of the allocation program, it is not possible to control how participants will consolidate or what geographic shifts may take place. See response to comment 5.2.1 above as well as additional responses to comments regarding communities throughout this chapter for more discussion of measures recommended to address impacts on communities.

Amendment 20 contains a 10 percent set-aside of the nonwhiting shoreside trawl quota for AMP, to begin in the third year of the program. Prior to that time, the Council will develop the infrastructure and

program components for use with the AMP through adaptive management, NMFS and the Council will be able to develop appropriate response measures as the program is implemented and actual impacts begin to be manifested.

10.5.4 Segmentation of a Major Federal Action

Commenters: Crab Boat Owners Association; Daspit, William; Ecotrust, Food and Water Watch; West Coast Seafood Processors Association

Comment 116: As acknowledged in the DEIS, this action (Groundfish Amendment 20) and Groundfish FMP Amendment 21, which establishes under the FMP allocations between the groundfish trawl sector and other sectors of the groundfish fishery, are closely related actions. Commenters argue that NMFS and the Council impermissibly segmented what they claim is in fact a single major Federal action by producing separate EISs for Amendment 20 and Amendment 21. Two commenters additionally argue that Groundfish FMP Amendment 22 should also be considered part of this action. Amendment 22 establishes a new vessel registration requirement for vessels targeting groundfish but not registered to a Federal groundfish limited access permit.

Response: CEQ regulations at 40 CFR 1508.25(a)(1) describe connected actions, which "are closely related and therefore should be discussed in the same impact statement. Actions are connected if they:

(i) Automatically trigger other actions which may require environmental impact statements.
(ii) Cannot or will not proceed unless other actions are taken previously or simultaneously.
(iii) Are interdependent parts of a larger action and depend on the larger action for their justification."

Furthermore "[p]roposals or parts of proposals which are related to each other closely enough to be, in effect, a single course of action shall be evaluated in a single impact statement" (40 CFR 1502.4(a)).

We do not agree with the commenters' view that these actions are connected such that they should have been evaluated in one EIS. As described below, the Council made reasonable judgments about what should be analyzed separately.

Does either amendment "automatically trigger" implementation of the other amendment? Nowhere in either proposal is there a mechanism that triggers implementation of the other action.

Would it be impossible to implement either amendment if the other were not implemented (one cannot proceed without the other)? If Amendment 21 were not implemented, the trawl fishery could still be managed with IFQs and co-ops under Amendment 20. While an allocation is required to determine the conversion of QS to QP, such allocations could be determined and implemented through the Council's biennial groundfish harvest specification process. Although pre-established allocations such as the trawl allocation in Amendment 21 could simplify the biennial process, it is not accurate that Amendment 20 cannot be implemented without them. Likewise, Amendment 21 can be implemented without implementing Amendment 20. If that were the case, the Council would continue to manage the groundfish trawl fishery with status quo measures (cumulative trip limits and whiting quotas/seasons). Furthermore, as mentioned previously, the biennial harvest specifications process benefits in any event from the allocations established in Amendment 21, because the amount of decision-making required is reduced.

Are the two actions so interdependent as to rely on each other for their justification? The rationale for Amendment 20 does not flow from the fact that allocations are established and similarly trawl rationalization is not justified by the allocations adopted under Amendment 21. Conversely, Amendment 21 is justified independent of Amendment 20, because, as stated above, it will help to simplify the biennial harvest specifications process no matter what measures are used to manage the groundfish trawl fishery. The Council has made allocation decisions in the past that are not tied to trawl rationalization and Amendment 21 is another step in establishing allocations under the Groundfish FMP. The Groundfish FMP Section 6.3 lays out a framework for establishing allocations in reference to criteria described in Section 6.2.3 and FMP goals and objectives. The purpose and need for Amendment 21, as described in that EIS, identifies support of trawl rationalization as one of three purposes for establishing the allocation scheme, the other two being to streamline the biennial harvest specifications process and to address bycatch of Pacific halibut. These purposes are consistent with the Groundfish FMP.

Commenters assert that segmenting these two actions into separate EISs masks the adverse habitat impacts stemming from continuing to allow a large proportion of the catch to be made by trawl vessels and prevents the public from fully understanding that a large proportion of fishing opportunity will be directed to the groundfish trawl sector in the form of harvest privileges. The goal of Amendment 20 is to "[c]reate and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch." Within the context of achieving this goal, the EIS acknowledges impacts caused by trawl gear in Section 4.20. As discussed in responses to comments in Section 10.3 and comment 114, the proposed trawl rationalization program may allow for an increase from the status quo in the use of nontrawl gear in the trawl fishery. Also, as noted in response to comment 114, the allocations in Amendment 21 would constrain trawl harvests to a slightly lower level than status quo. Not every amendment will address every management need in the fishery simultaneously. The Council recently addressed habitat issues in Amendment 19, and will continue to review relevant information and recommend additional management measures if necessary and appropriate.

Commenters further assert that segmenting the action "deprived some people and communities of their ability to participate in a process of importance to them" and masked the extent of a plan that the public would have otherwise found "very unappealing to a public weary of both industrial-scale trawl fishing and corporate welfare." However, as the commenters themselves point out, the DEIS discloses the linkages between these two actions and in the impact analysis Amendment 21 is considered an external action contributing to the cumulative effects of trawl rationalization. Both of these actions were developed in the same decision-making forum—the Pacific Council—allowing the public to track the development of both in a fairly straightforward way and comment on them in the same venue. Given the common setting for the two actions, it is not the case that nontrawl groundfish fishery participants were burdened (noting their participation in the Council process through the Groundfish Advisory Subpanel, for example), nor did it "thwart public comprehension."

The original proposal upon which Amendment 22 was based outlined various options for creating a limited access framework for the "open access" (i.e., not Federal license limited) fishery targeting groundfish. However, the Council action only established a vessel registration requirement. The Council has not submitted the Amendment to NMFS for consideration and possible implementation. Commenters imply a linkage between the two actions, because of the effects of trawl rationalization on nontrawl fishery participants in the open access fishery. However, the fact that the open access fishery may be affected (as disclosed and discussed in the DEIS) does not create a necessary connection between the two actions. As noted elsewhere, the trawl rationalization proposed action focuses squarely on the groundfish trawl fishery and the Amendment 22 proposed action is well outside its scope.

Comment 117: Amendments 20 and 21 should be reconsidered as a single amendment and a 90-day comment period should be allowed for the related DEIS, because 45 days offers insufficient time to obtain the documents, read through them, and draft comments.

Response: For the reasons discussed above, the Council and NMFS did not combine Amendment 20 and 21 into a single action. The DEIS was available on the Council's website when completed (and somewhat in advance of publication of the NOA initiating the 45-day public comment period). Furthermore, because of the nature of the Council process, earlier drafts of the document were made available to the public for review. For example, a "decision document," substantially similar to the DEIS in form and content, was made available in October 2008 in support of the Council's choice of a preferred alternative in November 2008. CEQ Regulations require a 45-day comment period on a DEIS (40 CFR 1506.1(c)). The comment period on the DEIS was consistent with the CEQ regulations.

10.5.5 Commitment of Financial and Staff Resources by NMFS

Comment 118: For the last several years, NMFS has provided substantial financial and staff resources to the Council for the sole purpose of developing a trawl individual quota plan. It is clear that NMFS has committed those resources with a particular intent in mind, which calls into question the validity of the comment process in which we are engaged. The commenter notes that regulations at 40 CFR 1502.2(f) prohibit an agency from committing resources prejudicing selection of alternatives before making a final decision.

Response: NMFS has committed staff to the analysis of the development of a trawl rationalization program and to the drafting of the proposed regulations to implement the program. These are statutory requirements of the MSA. However, NMFS has not selected or implemented a final alternative. In addition, per 40 CFR 1503.2(f), NMFS has not committed resources that would prejudice the selection of alternatives prior to making a final decision on implementation of the trawl rationalization program.

10.6 Other Comments

Commenters: Bean, Brandon; Campbell, Bruce; Jensen, Charlie

Comment 119: Three comments not related to the proposed action were received. They discussed issues related to commercial whaling, collapse of the ocean food chain in the Pacific, and use of materials containing toxic materials.

Response: These comments do not relate to the proposed action or its effects.

10.7 Implementation Recommendations

Commenters: Department of Interior, Environmental Defense Fund, Tommy's Marine Service

Comment 120: The following comments were made related to implementation of the trawl rationalization program:

- **Prioritize available funds for program implementation according to recommendations made by Environmental Defense Fund and others in a joint comment letter.**
- **Provide funds for transition assistance at the outset of the program.**
- **Develop an electronic, web-based IFQ transfer and tracking tool based on the principle that this automated tool should result in cost savings.**
- **The Department of Interior recommends that the U.S. Fish and Wildlife Service's trust anadromous species be reported to the Service if they are caught as bycatch.**

Response: The comments do not relate directly to the description of the proposed action and the evaluation of impacts contained in the EIS. NMFS has taken these comments into consideration as part of the rulemaking and program implementation process.

Comment 121: One commenter cannot support moving forward toward the January 1, 2011, implementation date.

Response: The Council and NMFS note the commenter's recommendation but have decided that implementing the program at the earliest practicable date best serves the public interest. The commenter states that "problems [cannot] be solved through 'trailing amendments' or on the fly after the program starts." We disagree that delay is necessary. Although a broad range of issues have been anticipated and addressed in program design, inevitably there will be unforeseen effects and the program may not perform as expected. Beyond the future implementation of the AMP, which will allow the allocation of 10 percent of QP per year to address unforeseen and unintended effects, the Council and NMFS recognize that the program as a whole may need to be adapted to changing circumstances over time; for this reason, a 5-year review is part of the program. Modifications will be accomplished through future Council actions, related FMP amendments, and regulatory adjustments.

10.8 Environmental Protection Agency Comments

EPA assigned a rating of "LO" (Lack of Objection) to the Pacific Coast Groundfish DEIS, Amendment 20. They did, however, offer some suggestions for the FEIS.

Suggestion: EPA recommends a comprehensive monitoring and mitigation program that incorporates adaptive management to the extent possible in order to address community impacts, impacts on tribes, and potential increases in bycatch of protected and overfished species. These actions should be identified in advance of the implementation of the action, and preferably be identified in the FEIS.

Response: NMFS appreciates the suggestions brought forward by EPA. Regarding an AMP, as suggested by EPA, the DEIS describes the Council designed AMP that sets aside 10 percent of the shoreside nonwhiting individual fishing quota two years after initial program implementation. This quota set aside will be used to address unforeseen impacts on coastal communities, consistent with EPA recommendations. During the first two years of the program, the Council, working with NMFS and the states, will develop the infrastructure and program components necessary to effectively administer this mitigation program in the future.

Regarding bycatch of protected and overfished species, the DEIS describes one of the most important components of this IFQ program. The IFQ program will implement a 100 percent observer requirement as a prerequisite to participation in the program, which means all catch will be observed. The responsibilities of the observers include catch monitoring and enumeration of target as well as overfished species. NMFS fully expects this IFQ program to facilitate the rebuilding of overfished

species in the west coast groundfish fisheries. A secondary responsibility of these onboard observers is to identify and record incidental interactions with protected species. NMFS fully expects that potential impacts or interactions with protected species, which is currently minimal, will decrease under the new IFQ program.

Suggestion: Tribes may be represented on the Council, but DEIS is unclear if NOAA has actually consulted in accordance with the requirements of *Executive Order 13175, Consultation and Coordination with Indian Tribal Governments.* If consultation has taken place, describe in EIS. If not, NOAA should initiate consultation and include information as appropriate in the final EIS.

Response: Tribal participation in the development of this rationalization program for west coast groundfish fisheries through the Council process has been significant, and will continue to be a priority of the agency. For *EO 13175*, NOAA is currently developing internal procedures and requirements to be followed nationwide, thereby ensuring compliance. Although not specifically related to the trawl rationalization program, NMFS has recently restated their offer of government to government consultation on fishery management issues, including groundfish, on the west coast.

CHAPTER 11 AGENCIES, ORGANIZATIONS, AND PERSONS TO WHOM COPIES OF THIS STATEMENT WERE SENT

The Council makes both the DEIS and FEIS available on its website, so anyone with computer access may download an electronic copy. Electronic copies on CD-ROM and paper copies are made available upon request. The Council distributes a notice of availability for the DEIS and FEIS through its electronic mailing list, which include state and Federal agencies, tribes, and individuals. Copies of the FEIS are sent to anyone who comments on the DEIS. In addition, NMFS distributes copies of the FEIS to the following agencies:

Willie R. Taylor
Office of Environmental Affairs
Department of Interior
1849 "C" Street, N.W.
Washington, D.C. 20520
(1 hardcopy and 11 CDs)

U.S. Coast Guard, Commander Pacific Area
(1 CD)

William Gibbons-Fly, Director
Office of Marine Conservation
Department of State
2201 "C" Street, N.W.
Washington, D.C. 20520
(1 CD)

Timothy Ragan, PhD, Acting Executive Director
Marine Mammal Commission
4340 East-West Highway
Bethesda, MD 20814
(1 CD)

Pacific States Marine Fisheries Commission
205 SE Spokane Street, Suite 100
Portland, OR 97202
(1 CD)

Angela Somma
F/PR3; Endangered Species Division
Angela.Somma@noaa.gov
(Send documents electronically and/or inform of website location)

Dale Jones
F/EN; Enforcement Division
Dale.Jones@noaa.gov
(Send documents electronically and/or inform of website location)

Galen Tromble
F/SF3; Domestic Fisheries Division
Galen.Tromble@noaa.gov
(Send documents electronically and/or inform of website location)

Mr. Gordon White, Program Manager
Shorelands and Environmental Assistance Program
Department of Ecology
P.O. Box 47600
Olympia, Washington 98504-7600
(1 CD)

Mr. Bob Bailey
Ocean and Coastal Program Manager
Department of Land Conservation and Development
635 Capitol Street NE
Salem, Oregon 97301
(1 CD)

Ms. Anne McMahon
Acting Federal Programs Manager
California Coastal Commission
45 Fremont Street, Suite 2000
San Francisco, California 94105-2219
(1 CD)

Mr. Will Travis, Executive Director
San Francisco Bay Conservation and Development Commission
50 California Street, Suite 2600
San Francisco, California 94111-4704
(1 CD)

Table A-13. Some of the reasons given for allocating to permit holders. A-40
Table A-14. Some of the reasons given for allocating to processors. A-41
Table A-15. Explanation of Terminology: return on investment, profits, and rents. A-47
Table A-16. Summary of influences of the IFQ program and the initial allocation on the flow of QS with a focus on the harvesting and processing sectors. A-56
Table A-17. Summary of analysis of stewardship effect A-60
Table A-18. Effects on processor returns to investment resulting from the transition from status quo to an IFQ program. A-65
Table A-19. Estimated Catcher Vessel Permit values in March 2004 (Based on Dockstreet Broker Report on $/point). A-68
Table A-20. Estimated value of nonwhiting QS to be issued. A-69
Table A-21. Estimated nonwhiting QS value per permit, based on permit landing history, assuming the FPA (90 percent allocation to permits and with equal sharing of buyback history). A-70
Table A-22. Estimated nonwhiting QS value per permit, based on permit landing history, assuming 100 percent allocation to permits and no equal sharing of buyback history. A-71
Table A-23. Estimated nonwhiting QS value per permit, based on permit landing history, assuming 75 percent allocation to permits and no equal sharing of buyback history. A-71
Table A-24. Estimated nonwhiting QS value per permit, based on permit landing history, assuming 100 percent allocation to permits with equal sharing of buyback history. A-72
Table A-25. Estimated nonwhiting QS value per permit, based on permit landing history, assuming 75 perc ent allocation to permits with equal sharing of buyback history. A-72
Table A-26. Estimated ex-vessel value of shoreside whiting per permit for the FPA (80 percent to permits and equal sharing), based on QP issued for permit landing history (does not take into account net profits or expected future revenue that would be reflected in QS value) (total annual QP value is assumed to be $13.7 million). A-73
Table A-27. Estimated ex-vessel value of shoreside whiting per permit, based on QP issued for permit landing history (does not take into account net profits or expected future revenue that would be reflected in QS value) (total annual ex-vessel value associated witH QP is assumed to be $13.7 million). A-73
Table A-28. Estimated ex-vessel value of mothership whiting per permit, based on QP issued for permit landing history (does not take into account net profits or expected future

revenue that would be reflected in QS value) (total annual ex-vessel value associated witH QP is assumed to be $6.9 million). A-74
Table A-29. Indications of vessels leasing permits. A-74
Table A-30. Effect of the IFQ program on a firm's economic status with respect to capital investment, depending on QS price (rows) and whether or not it is still making payments on existing capital investments (columns). A-91
Table A-31. Number of processors categorized by number of permits delivering to different classes of processors based on average annual 2004 to 2006 ex-vessel value of deliveries received by the processor. A-100
Table A-32. Distribution of nonwhiting QS allocations and estimated value of associated QP, by QS owners' residence and/or head office (note the allocation formulas provided as examples here do not include a processor recent participation screen, the recent participation screen would substantially reduce the number of communities listed). A-105
Table A-33. Description of categories of buying and processing activities and, for each option for attributing history, whether the fish handled in those activities would be included or excluded in the allocation formula calculations. A-117
Table A-34. Count of permits participating in each catcher vessel sector, by sector combinations for 1994 to 2003 participation. A-120
Table A-35. Number of permits not meeting recent participation requirements for a variety minimum participation periods and numbers of years of participation required during the participation period (buyback permits not included) A-121
Table A-36. Percent of permits with some shoreside nonwhiting landings during 1994 to 2003 (N=163) not meeting recent participation requirements for a variety minimum participation periods and numbers of years of participation required during the participation period (buyback permits not included). A-121
Table A-37. Percent of 1994 to 2003 shoreside nonwhiting landings by permits that did not meet the indicated minimum participation requirements A-121
Table A-38. Effect of a recent participation requirement on the amount of equal share-based QS allocation a permit receives (assuming on average 44 percent of the QS is allocated equally among permits and 80 percent of the QS goes to permits). A-121
Table A-39. Number of permits and amount of landing history screened out by not meeting a 1998 to 2003 recent participation requirement with nonwhiting or shoreside whiting or mothership whiting deliveries. A-122
Table A-40. Number of permits with some shoreside whiting landings during 1994 to 2003 that did not have shoreside whiting landings during the 1998 to 2003 qualifying period in the indicated number of years (buyback permits not included). A-122
Table A-41. Percent of permits with some shoreside whiting landings during 1994 to 2003 (N=59) that did not have shoreside whiting landings during the 1998-2003 qualifying period in the indicated number of years. A-123
Table A-42. Percent of 1994 to 2003 shoreside whiting landings by vessels that did not have landings during the 1998 to 2003 qualifying period in the indicated number of years. A-123
Table A-43. Shoreside whiting permits and history screened out by not meeting a 1998 to 2003 recent participation requirement with nonwhiting or shoreside whiting deliveries. A-123
Table A-44. Number of permits with some mothership whiting landings during 1994 to 2003 that did not have mothership whiting landings during the 1998 to 2003 qualifying period in the indicated number of years (buyback permits not included). A-124
Table A-45. Percent of permits with some mothership whiting landings during 1994 to 2003 (N=32) that did not have mothership whiting landings during the 1998 to 2003 qualifying period in the indicated number of years A-124
Table A-46. Percent of 1994 to 2003 mothership whiting landings by vessels that did not have landings during the 1998 to 2003 qualifying period in the indicated number of years. A-124
Table A-47. Catcher–processor permits with some activity during 1994-2006. ..... A-125

Table A-48. Mothership companies with some activity during 1994-2006. ..... A-127
Table A-49. Number of shoreside nonwhiting buying firms by maximum number of years of participation from 1998 through 2003 at indicated annual participation levels and those firms' share of the total 1994 to 2003 history (gray cells indicate firms do not meet the criteria of recent participation options). A-130
Table A-50. Number of shoreside nonwhiting buyers operating within each state and active during the indicated periods (1998 to 2003 and 1994 to 2003) and either meeting or not meeting the indicated criteria. A-130
Table A-51. Number of buyers and deliveries screened out by recent participation requirement options, by state A-131
Table A-52. Number of shoreside whiting buying firms by maximum number of years of participation from 1998 through 2003 at the indicated annual participation levels and those firms' share of the total 1994 to 2003 history (gray cells indicate firms that do not meet the criteria of recent participation options). A-132
Table A-53. Number of shoreside whiting buyers in each state active during the indicated periods (1994 to 2003 and 1998 to 2003) and having a maximum of the indicated number of years of participation during that period (note: Option 1 requires at least 1 year >0). A-132
Table A-54. Quantity (in mt) by state and share of state total, 1994 to 2003 receipts, for shoreside whiting buyers screened out by whether or not they whiting during a 1998 to 2003 recent participation period recent participation criteria. A-133
Table A-55. Number of shoreside whiting buyers in each state active during the indicated periods (1994 to 2003 and 1998 to 2003) and having a maximum of the indicated number of years of receiving at least 1 mt in the year (note: Option 2 requires at least 2 years >1 mt each). A-133
Table A-56. Quantity (in mt) by state and share (%) of state total buying history (1994 to 2003) for shoreside whiting buyers screened by the number of years they received at least 1 mt of whiting during the 1998 to 2003 recent participation period A-133
Table A-57. Unspecified rockfish as percent of all remaining rockfish by year and state. A-136
Table A-58. Number of fish tickets with unspecified rockfish by year and state (1994-1999). A-137
Table A-59. 1994 to 2003 Aggregate Landing history Shares (percent) for *Buyback Permits*. A-141
Table A-60. 1994 to 2003 Aggregate Landing history (mt) for *All non-CP Limited Entry Trawl Permits (Buyback + Remaining)*. A-142
Table A-61. Annual ex-vessel revenue equivalent per permit for QP which could be received through equal allocation (assuming 2004 to 2006 average prices and landing levels and 169 permits receiving an initial allocation).* A-143
Table A-62. Rationale for periods considered for various qualifying and allocation period provisions during development of the IFQ and co-op alternatives. A-147
Table A-63. Periods used in various qualifying and allocation provisions that remain as options in the trawl rationalization program alternatives A-148
Table A-64. Shoreside nonwhiting sector: comparison of 2005 ex-vessel revenue from selected groundfish species under different drop year allocation options using allocation based on relative history (Council's final preferred alternative) and absolute pounds). A-154
Table A-65. Latitudinal strata considered for the allocation of overfished species. A-158
Table A-66. Bycatch rates used for the allocation of overfished species, by latitudinal area and shoreward and seaward dept stratifications A-162
Table A-67. Number of permits receiving more under the indicated method as compared to the alternative method (data summarized from Figure A-36 through Figure A-42). A-165
Table A-68. Species for which the OY varies by geographic area A-196
Table A-69. Illustration of relative lb "weights" (sector catch in year 2003 divided by annual catch): 1994 to 2004 ..... A-206
Table A-70. Relative weight of landing history for each year of the allocation period using 2003 as the base year (2003 value = 1.0) and comparative histories and QS allocations

using pounds (Abs) and relative history (Rel) for actual permits with histories categorized as strong early, strong late, and consistent..... A-207
Table A-71. Distribution of nonwhiting ex-vessel value from 2004 to 2006 compared to distribution of QP value, based on zip codes reported for the businesses that would receive the QS allocations assuming an 80/20 permit/processor split, equal allocation of buyback landing history, and a grandfather clause for initial allocations over the control limits ($ thousands)..... A-209
Table A-72. Allocation to catcher processor permits using 1997 to 2003 landing history (relative history) and no-drop years. A-211
Table A-73. Allocation to mothership companies using 1997 to 2003 processing history weighted (relative history) and no drop years. A-213
Table A-74. Comparison of shoreside nonwhiting receivers, 200 to -2006: all receivers versus new entrants with zero history during 1994 to 2003 (mt). A-216
Table A-75. Comparison of shoreside nonwhiting receivers, 2004 to 2006: all receivers versus new entrants with zero history during 1994 to 2003 (revenue)..... A-216

Figure A-6. Hypothetical cost structures and debt positions for 5 firms at a set level of production. A-66
Figure A-7. QS allocations for FPA (90 percent initial allocation of QS to harvesters, 10 percent to adaptive management, with equal allocation of buyback shares, and with opportunity to divest) (QS amounts are entire initial allocation) compared to QS allocations for PPA (80 percent of initial allocation for harvesters, 20 percent for processors, with equal allocation of buyback shares and no grandfather clause) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right. A-78
Figure A-8. Annual ex-vessel value estimated for QSs allocated to entities that only harvester (left) and those that process (right) in the shoreside nonwhiting sector under the PPA allocation formula (PPA: 80 percent harvester – 20 percent processor initial allocation of QSs, equal allocation of buyback shares, and no grandfathering for initial allocations over the accumulation limits) compared to average 2004 to 2006 ex-vessel revenue of landings for each entity. A-79
Figure A-9. QS allocations for formula with 100 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for QS allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right. A-80
Figure A-10. QS allocations for formula with 100 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and no grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right..... A-81
Figure A-11. QS allocations for formula with 100 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and a grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right..... A-82
Figure A-12. QS allocations for formula with an 80 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right. A-83
Figure A-13. QS allocations for formula with an 80 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel

revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right. A-84
Figure A-14. QS allocations for formula an 87.5 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and no grandfather clause for initial allocations over the accumulation limits compared to the PPA. A-85
Figure A-15. For whiting, the annual ex-vessel value of QSs allocated to entities that only harvester (right) and entities that processors (left) in the shoreside whiting fishery under the PPA allocation formula (PPA: 80 percent harvester – 20 percent processor initial allocation of QSs, equal allocation of buyback shares, and no grandfathering for initial allocations over the accumulation limits) compared to average 2004 to 2006 ex-vessel revenue of landings for each entity. A-85
Figure A-16. For shoreside whiting, comparison of the FPA to the PPA, and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right. A-86
Figure A-17. For shoreside whiting, comparison of the PPA allocation formula to one with 100 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits. A-87
Figure A-18. For shoreside whiting, comparison of the PPA allocation formula to one with 50 percent initial allocation of QSs to harvesters, 50 percent initial allocation of QSs to processors, equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits..... A-88
Figure A-19. For shoreside whiting, comparison of the PPA allocation formula to one with an 80 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits. A-88
Figure A-20. For mothership sector whiting, the annual ex-vessel value of QSs allocated to harvesters and processors in the at sea mothership whiting fishery (under an allocation formula using 80 percent harvester – 20 percent processor initial allocation of QSs, equal allocation of buyback shares, and no grandfathering for initial allocations over the accumulation limits) compared to average 2004 to 2006 ex-vessel revenue of landings for each entity. ..... A-i
Figure A-21. For mothership sector whiting, comparison of the PPA allocation formula to one with a 100 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits. A-90
Figure A-22. The ex-vessel value of nonwhiting QP going to processor-permit relationships under two allocation formulas as compared to 2004 to 2006 ex-vessel revenue for those relationship (notes: each point represents a processor and the permits delivering to it; lower panels are a magnification of the upper panels; these formulas include a grandfather clause, but no equal sharing). A-99
Figure A-23. Comparing a 100 percent allocation to permits to a 75 percent allocation to permits: ex-vessel value of nonwhiting QP going to processor-permit relationships (notes: each point represents a processor and the permits delivering to it; lower panels are a magnification of the upper panels; these formulas include a grandfather clause but no equal sharing). A-100
Figure A-24. The ex-vessel value of nonwhiting QP going to processor-permit relationships under the FPA as compared to 2004 to 2006 ex-vessel revenue for those relationship (notes: each point represents a processor and the permits delivering to it; lower panel is a magnification of upper panel; the FPA formulas include equal sharing and no grandfather clause, but a divestiture opportunity)..... A-101
Figure A-25. Comparing the PPA to the FPA: ex-vessel value of nonwhiting QP associated with the QS going to processor-permit relationships at time of initial issuance (notes: each

point represents a processor and the permits delivering to it; lower panel is a magnification of the upper panel; these formulas both include equal sharing, and neither has a grandfather clause, but the FPA allows QS to be issued in excess of control limits and then divested). A-102
Figure A-26. The ex-vessel value of nonwhiting QP going to processor-permit relationships under the PPA as compared to 2004 to 2006 ex-vessel revenue for those relationships (notes: each point represents a processor and the permits delivering to it; lower panel is a magnification of upper panel; the PPA formulas include equal sharing and no grandfather clause). Acronyms and Abbreviations

Acronym	Definition
ABC	allowable biological catch. The ABC is a scientific calculation of the sustainable harvest level of a fishery and is used to set the upper limit of the annual TAC. It is calculated by applying the estimated (or proxy) harvest rate that produces maximum sustainable yield to the estimated exploitable stock biomass (the portion of the fish population that can be harvested).
ACL	annual catch limit
ACT	annual catch targets
AMP	Adaptive Management Program
ARID	allocations to permits using area identifiers
Bycatch EIS	The Pacific Coast Groundfish Fishery Management Plan Bycatch Mitigation Program Final Environmental Impact Statement
CFA	Community Fishing Association

Organization of Appendix A

Each section starts with a restatement if the provision and option being analyzed. A rationale is then provided, followed by an explanation of the interlinked elements and an analysis of the provision.

In the provisions a "►" indicates an option that is part of the Pacific Fishery Management Council's (Council's) preliminary preferred alternative (PPA).

Interlinked elements include the following measures:

- Directly dependent on one another (e.g., if quota pounds [QP] did not have to be placed into a vessel account in order to be used, we would have to change the way the use-or-lose provision is specified)
- Those that, if changed, would substantially alter the impact or decisions made on other provisions (for example, if only vessel owners are allowed to own quota shares [QS]/QP, we would have to rethink many of the provisions and rationales related to how we are addressing the needs of communities and crewmembers).

The following text outlines the individual fishing quota (IFQ) program. Table A-1 provides an overview of the organization of the sections of the program.

Table A-1. Organization of the IFQ alternative program elements and options from Appendix A.

A-7	***Gear Conversion (Option)***
A-8	***Regional Landing Zones (Option)***

In the detailed description below, where the Council chose an option as part of the preferred alternative, the choice is indicated by a "►" symbol. Program elements without options are adopted as described unless otherwise noted. Elements and options that are not relevant under the preferred alternative are so noted and provided in boxed text. For example, program elements relating to IFQs for the at-sea sector are not relevant under the preferred alternative. Appendix D is a detailed, stand-alone description of the entire program adopted by the Council.

A-1 TRAWL SECTOR MANAGEMENT UNDER IFQS

A-1.1 Scope for IFQ Management, Including Gear Switching

❖ *Provisions and Options*

QP will be required to cover catch of all groundfish (including all discards) by limited entry (LE) trawl vessels with certain gear and gear exceptions.

Gear Exceptions: For trips delivered **shoreside**

Option 1: QP is required for LE trawl vessels using any directed commercial groundfish gear0F[1] EXCEPT

LE fixed gear when the vessel also has an LE permit endorsed for fixed gear (longline or fish pot) AND has declared that they are fishing in the LE fixed-gear fishery.

► Option 2: QP is required for LE trawl vessels using any gears EXCEPT

exempted trawl,1F[2]	salmon troll
gear types defined in the coastal pelagic species (CPS) fishery management plan (FMP)	crab pot
gear types defined in the highly migratory species (HMS) FMP	LE fixed gear when the vessel also has an LE permit endorsed for fixed-gear (longline or fish pot) AND has declared that they are fishing in the LE fixed-gear fishery.

Species Exceptions:

For trips delivered **shoreside** QP is not required for

Option 1: No species exceptions.

► Option 2: For trips delivered shoreside QP is not required for

Longspine South of 34°27'	California Scorpionfish
Minor Nearshore Rockfish N	Cabezon
Minor Nearshore Rockfish S	Kelp Greenling
Black Rockfish (WA)	Shortbelly
Black Rockfish (OR-CA)	Other Rockfish
	Other Fish

[1] For the purpose of the trawl rationalization alternatives, "directed commercial groundfish gear" is defined as all legal commercial groundfish gear including limited entry gear and commercial vertical hook and line, troll, and dinglebar gear.

[2] California halibut gear of 7.5" or greater used in state waters would be exempted.

Option 3: Same as Option 2 but provide an exception for spiny dogfish and not for "Other Fish"

For trips delivered **at-sea** QP is not required for

Option 1 (similar to status quo):	any species other than whiting and widow, darkblotched, and canary rockfish
Option 2 (extended List)	same as Option 1 plus add slope rockfish, yellowtail rockfish shelf rockfish, lingcod, POP, and sablefish to the list of covered species.
Option 3 (all bycatch exception)	any species other than whiting.

See Section A-5 for an alternative specification of scope for whiting trips that would not require QP for any bycatch species (i.e., QP would be required only for whiting).

This definition of the scope allows a LE trawl vessel to switch between trawl and nontrawl groundfish gears, including fixed gear, for the purpose of catching their QP ("gear switching"). It also allows a nontrawl vessel to acquire a trawl permit, and thereby use trawl QP to catch the LE trawl allocation using nontrawl gear.

An option was added to allow "gear conversion" (the permanent switch from trawl to some other legal groundfish gear). **This option is described in Section A-7**.

❖ *Rationale and Policy Issues*

Coverage of Landings and Discards

Coverage of landings and discard is expected to be consistent with several aspects of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the Groundfish FMP, and the Council's goals and objectives for Amendment 20. Accountability for landings and discard is expected to increase the certainty managers have regarding fishing mortality, and this in turn is expected to foster the rebuilding of overfished species (consistent with MSA – 303A(c)(1)(A). Furthermore, the increased observation necessary to monitor landings and discard is expected to increase the information flow on the status of the fishery as the fishery occurs (consistent with the Groundfish FMP objective 1). Finally, responsibility of landings and discard – and the monitoring necessary for that type of management – is expected to increase accounting ability and result in changes to fishing behavior, which include a reduction in the bycatch rate of constraining stocks and an elimination, or reduction, in the need for regulatory discarding. These changes are expected meet Council objectives 1 and 3 of Amendment 20, which speak to total catch accounting, reducing bycatch, and reducing discard mortality. Coverage of total catch is also consistent with the bycatch mitigation program (Amendment 18).

The reduction in bycatch rates for constraining overfished species will allow harvesters to increase their harvest of currently underutilized target species and thereby increase the value of the groundfish fishery. Such an increase in value is consistent with the Groundfish FMP objective 6 (attempt to achieve the greatest net economic benefit to the nation), with Groundfish FMP objective 2 (maximize the value of the groundfish resources as a whole).

Species Coverage

The coverage of species with quota is intended to act as a catch control tool to ensure that management targets are adhered to, that other sectors are not affected by higher than expected catch levels in the trawl fishery, or both. One rationale is that the lack of IFQ coverage (or some other management tool) of some species may lead to a case where trawl vessels target uncovered species in unchecked quantities. However, this is not necessarily the case, especially for those species that may be inaccessible to groundfish gear, or for those species that are constrained by the catch of other species. Implicit in this concept is that not every species in the Pacific Ocean that may be encountered by commercial groundfish vessels has to have catch managed through a catch control tool in order to stay within management targets. Many species may be encountered in such small volumes that their management through IFQ could be unnecessary and lead to administrative costs that are not necessary for successful management of fishing mortality. Species where it may not be necessary to cover catch with quota include infrequently encountered nongroundfish species such as sardines, Ocean Sunfish, and Albacore tuna. However, it may also be unnecessary to cover many groundfish species with quota because the amount of those species encountered by trawl vessels is small relative to management targets.

In addition to the idea of whether it is necessary to cover such species with quota in order to stay within management targets is the idea that for some species, their coverage with quota may lead to a case where the market does not act in an efficient manner. This could be due to relatively infrequent encounters of such species and the relatively infrequent trades that occur on the market (often called thin market conditions). Infrequent trades make it difficult to effectively price transactions on the market because there is relatively little historic information on the trading price of those species. This means that prices may be determined more by negotiation skill than market conditions and the implications are an over-inflated, or deflated, price of the quota.

The species covered with IFQ (shown in the table above) would be different for the shoreside whiting sector depending on whether three versus four trawl sectors are established. If three sectors are established, the shoreside whiting and nonwhiting sectors would be combined, whereas if 4 sectors are established, the shoreside whiting sector would be responsible for the same species as found in the at-sea portion of the table. This is due to the fact that, if a three-sector option is established then shoreside whiting and nonwhiting would be able to trade quota with one another. In order for this to occur, both sectors would need to hold quota for the same species. If four sectors are established, the shoreside whiting and nonwhiting sectors would be separated, and it would not be necessary for them to hold quota of the same species. The four-sector option may make the shoreside whiting fishery responsible for the same species as the at sea sectors because the mix of species caught by shoreside whiting vessels is similar to that of vessels in the at sea fishery.

For the shoreside sector, the Council considered whether to include "other fish" within the IFQ program. There has been some substantial trawl harvest of some species within the "other fish" category in recent years, unlike most of the other species that are excluded from the IFQ program in Species Exceptions Option 3, however, some of these species are not targeted and historical catch data for them is sparse. As the Council is transitioning from its traditional method of setting harvest specifications (i.e., allowable biological catch [ABC] and optimum yield [OY]) to the new federal program using overfishing levels (OFL), annual catch limits (ACL) and, potentially, annual catch targets (ACT), it seemed appropriate to delay consideration of adding the "other fish" category to the IFQ program until after that process is complete. In addition, the Council explicitly excluded dogfish from the IFQ program, which is a component of the "other fish" category. Because dogfish are not assessed and are typically not retained in the fishery, it is difficult to determine the amount of dogfish to break out of the larger "other fish" category. Therefore, given that the other species in that category are taken

in relatively small quantities, the Council chose to treat the entire category based on its concerns with respect to dogfish. With respect to dogfish, the council was concerned that it is taken in practically every fishery—groundfish and nongroundfish—across all sectors, including recreational fisheries. While there is currently no assessment for this species, one is anticipated in the next assessment cycle (2011). This assessment will provide the Council with a better understanding of the status of the stock. Additionally, the Council also did not feel it had a good understanding of the amount of bycatch of dogfish in the trawl fishery or other fisheries. This makes it difficult to assess what the trawl fishery needs would be for the IFQ program and the potential effects to other fisheries if the trawl catch were accommodated. The Council's intent would be to collect that information through the IQ program with 100 percent observer coverage.

Gears and Fisheries Covered and Gear Switching

The IFQ program allows gear switching, meaning that vessels with a LE trawl permit can use gear other than trawl gear to prosecute their IFQ. Some complexities arise when a LE trawl endorsed vessel is participating in another fishery. In the current groundfish fishery, when trawl vessels use a nontrawl gear, their groundfish catch is attributed to the trawl sector. This does not constrain the harvest activity of vessels engaging in nongroundfish fisheries as those vessels can simply discard groundfish caught incidentally that may be in excess of trip limits and continue fishing in that nongroundfish fishery. Under an IFQ program where discards and landings are counted against IFQ, groundfish catch in nongroundfish activity could have the potential of constraining nongroundfish activity for LE trawl licensed vessels if that groundfish continues to count against the trawl sector. In light of this possibility, several gears were considered for exclusion from the trawl IFQ program, meaning that if a trawl licensed vessel were using one of these excluded gears, they would not be required to cover their incidental groundfish catch with IFQ. The reason for excluding certain gears from the IFQ program is that some gears are almost exclusively used in nongroundfish activity and the amount of groundfish catch occurring with these nongroundfish gears is minor.

The proposed scope implicitly allows gear switching and would not prevent a vessel from converting[3] to a nontrawl gear; however the vessel could reverse the gear switch or transfer IFQ back to a trawl vessel if conditions warranted it. There is also an option for permanent gear conversion (Section A-7.0). Under the gear conversion option, in certain circumstances, IFQ would be permanently converted away from trawl gear and restricted from switching back. In addition to resolving the management complexities mentioned in the previous paragraph, a scope that allows gear switching may generate some conservation benefits if the gears to which harvest is switched generate smaller habitat impacts or have selectivity that increases stock productivity (e.g., disproportionately remove from the biomass fish that are of a less productive age or size class). Gear switching also provides vessels with an increased amount of flexibility in determining the most efficient mix of harvest strategies (as compared to a scope that includes only catch taken with groundfish trawl gear).

Gears that are excluded under the program include exempted trawl (such as pink shrimp, ridgeback prawn, and California halibut gear in certain areas), gears defined in the CPS FMP, gears defined in the HMS FMP, salmon troll gear, crab pot gear, and LE fixed gear when the vessel also has a LE permit endorsed for fixed gear (longline or fish pot) and has declared that they are fishing in the LE fixed-gear fishery. These gears were excluded from the program because catch of groundfish in these fisheries and gears is small. Therefore, requiring that trawl licensed vessels using these gears fish under the requirements of the IFQ program (such as carrying observers) is unnecessary

[3] Converting means permanently switching harvest to a nontrawl gear. In contrast, gear switching implies the ability to switch back.

❖ *Interlinked Elements*

Alternative Scope – Section A.5 provides an alternative scope that allows QS for whiting only and no QS for bycatch species in the shoreside whiting sector. While this alternative scope would effectively change the species for which whiting vessels are individually responsible, and is, therefore, a replacement to much of the analysis in this section rather than an interlinked element, it is useful to consider this alternative program scope while considering the analysis in this section.

Gear switching/gear conversion – Based on the logic that the risk of yelloweye rockfish encounters should be minimized, and that hook and line gear encounters yelloweye much more frequently than trawl gear: "for trawl vessels fishing IFQ with longline gear, Rockfish Conservation Areas (RCAs) may need to be more conservative."

Gear conversion – In addition to gear switching, which is part of the scope of Amendment 20, a gear conversion provision (A-7) was added as an option for Council consideration. The gear conversion option would add to the scope of the trawl rationalization program, if adopted as part of the preferred alternative, and there may have to be some alteration of the gear-switching portion of the scope.

Fishing restriction while in deficit – The scope of Amendment 20 defines which gears and fisheries are participating in trawl rationalization, but Section A-2.2.1, lists which fisheries trawlers may or may not have access to when in violation (e.g., IFQ overage). This provision would further refine the scope of the program.

Tracking and Monitoring Program – Observer coverage is a necessary element for the trawl rationalization program, and Amendment 20 could not be implemented without the tracking and monitoring provision.

Although not a provision of Amendment 20, the inter-sector allocation process is necessary to define the trawl sector allocation, which in turn is necessary for issuance of individual and cooperative shares.

❖ *Analysis*

In general, imposing a rationalization program on the LE trawl sector is expected to result in some substantial changes to the fishery. Much of the expected effect of a rationalization program is discussed in Chapter 4 and is, therefore, only briefly summarized here where appropriate. The general effects of rationalization on the west coast trawl fleet include a variety of effects such as fleet consolidation; elimination of derby-style fishing in the whiting sectors; and increased landings of currently underutilized species, among others. The reader is referred to Chapter 4 for a more detailed description of generalized effects of rationalization.

Coverage of Landings and Discards

Requiring that vessels be held individually responsible for both catch and discard is a departure from the status quo approach of holding vessels individually accountable for landings but the fleet accountable for landings and discards. Holding vessels responsible for both landings and discard is expected to result in some substantial changes in behavior, especially in the case of overfished species encounters. Under status quo conditions, managers attempt to craft regulations that limit the amount of fishing effort occurring in areas where overfished species are relatively abundant. This is necessary because discard mortality is 100 percent in many cases, so holding vessels accountable for landings is not sufficient alone to control total mortality. Holding vessels accountable for both landings and discard shifts the

burden of catch control to those engaged in the harvesting of groundfish resources, and the expected outcome is one where vessel operators engage in techniques that avoid depleted species and/or fish in areas where they are less abundant.

Conservation

Key to the IFQ program is holding vessels accountable for their landings and discards. Because of the incentives to under-report and discard IFQ species in order conserve QP, 100 percent at-sea monitoring is required. A side benefit of the monitoring program will be the increased certainty that managers have about total fishing mortality. This will improve their control of total mortality as well as improve the information used in stock assessments. The improved information will help to sustainably manage all stocks and, in particular, assist in the successful implementation of rebuilding plans.

Individual vessel responsibility for total mortality is expected to encourage fishermen to reduce their incidental catch rates (and decrease their incentive to discard incidental catch). Empirical information suggests that the outcome of imposing responsibility for both landings and discard on vessels can result in substantial changes in the amount of bycatch of depleted species. As illustrated in Chapter 4, the Washington Arrowtooth Flounder Exempted Fishing Permit (EFP) was conducted in a manner that held vessels responsible for both landings and discard and the result was one where bycatch rates of constraining overfished species decreased substantially relative to status quo management. It is likely that the same result would occur in a rationalized trawl fishery.

The implication of reducing bycatch rates of constraining overfished species means that there is likely to be increased access to currently underutilized target species. In other words, many species are not accessed fully under status quo conditions because managers limit access to those stocks in order to rebuild depleted stocks. If harvesters reduce the encounter rate of such constraining species under rationalized fishery conditions, they will in turn be able to leverage more target species that were not being fully accessed under status quo. From a biological perspective, increased removals may mean a lower biomass level for those species that experience higher mortality levels. However, as shown in Chapter 4, the estimated increase in mortality levels is not expected to result in any species falling within the precautionary zone within the 20-year time period analyzed.

Economic Effects

A fishery rationalization program that holds individuals accountable for their discards will induce reductions in the bycatch rate of constraining overfished species. Since fishermen are then accountable for bycatch mortality, managers no longer have to impose regulatory constraints to control bycatch. For example, if an IFQ system were developed that covered landings only, managers would have to reduce the amount of QP issued for target species in anticipation of the average incidental catch rates for overfished species. As covered in the section on conservation, making fishermen responsible for their discards gives them the incentive to reduce unwanted incidental bycatch in order to increase the harvest of currently underutilized target species, thus increasing the value of the groundfish fishery. The result is an increase in economic activity associated with fishing through higher landings, higher ex-vessel revenues, and increased processing among other things. These impacts have positive effects on objectives related to net benefits, efficiency, sector health, labor, and communities.

Program Costs and Effectives

One of the main implications of the decision to require QP to cover discards is the need for 100 percent at-sea monitoring. The costs of this monitoring program are covered in Section A-3.1.

Species Covered

Three options exist for species coverage with IFQ. Option 1 would cover all species in the Council's ABC/OY table, while the second and third options would cover a sub-set of those, leaving a number of species that are rarely encountered by trawl vessels out of the program. Options 2 and 3 differ only in that Option 3 also excludes the "Other Fish" category of groundfish.

Requiring that all species be covered with IFQ introduces a factor of risk to harvesters engaged in IFQ activities with minimal conservation benefit. For those species that are rarely encountered, it is likely that there will be a small allocation made to the trawl sector. Two sources of risk exist from a species that is rarely encountered and with a small allocation. A rarely encountered species is likely to have IFQ that is "thinly" traded, meaning that IFQ for these species will be traded infrequently. The implication of infrequent trading is the lack of a clear price signal to both the buyer and the seller and the end result is a traded price that is often based more on personal relationships and negotiation skill than supply/demand conditions. Depending on the skill of the buyer, the buyer may end up paying a large cost for acquiring shares of these species. This potential means there is a possibility that harvesters in the trawl sector that need to acquire shares of those species will pay a large cost.

A second source of risk is derived from the small sector allocation. In many markets, supply will rise to meet demand. However, in a trawl IFQ program, the QP of each species are fixed, but it is entirely possible that harvesters could catch more than the total amount of QP available to the fishery. In cases where allocations made to the sector are relatively small and catch events are highly uncertain and variable, it is not unreasonable to expect that a single trawler could take a substantial portion of the sector allocation on one trip. If that amount is enough to put the total sector catch over the allocation, then that harvester will not be able to acquire additional QP, requiring that vessel be tied up for a period of time (the actual period of time, and the factors determining that time period, is to be determined, see Section A-2.2.1). This tie-up provision imposes risk to that harvester because he must forego some future fishing opportunity. However, the potential of exceeding the sector's allocation means that there is also a collective risk to the entire sector. If the sector allocation is exceeded, NMFS may respond by closing areas of the west coast where that species is found, and this is likely to prevent harvest of certain target species found in the same areas. This effectively eliminates future harvest opportunity for some target species for all harvesters, creating a risk that is collective to the entire sector. If the risk of this event occurring is great enough, and harvesters in the fishery know that risk is relatively great, then a gradual tendency toward a derby fishery may begin to develop as harvesters effectively "race for bycatch."

From an empirical basis, the trawl sector currently harvests relatively small amounts of some rarely encountered species (such as cabezon, kelp greenling, and nearshore rockfish). In 2005 and 2006, the trawl fishery harvested 1 mt and 5 mt of black rockfish respectively, relative to a 2008 OY of 1,262 mt. If, hypothetically, the trawl sector had been allocated 3 metric tons of black rockfish in 2006, the sector would have exceeded its allocation by 2 metric tons. If that occurred in an IFQ fishery, the economic implications to harvesters in the trawl sector could be fairly large, but the implications to the stock (and by extension, to other recreational and commercial fisheries) would be essentially unnoticeable. Instances like this suggest that the cost of covering rarely encountered species that are not overfished with IFQ may be large to the trawl sector, but with little or no benefit to management, to other fishery sectors, or to the status of the stock.

Table A-2. Catches of selected nearshore species by trawl sectors, 2005–06.

	2006		2005		2008 OY
	Nonwhiting Trawl	Whiting Trawl	Nonwhiting Trawl	Whiting Trawl	
Black rockfish	5	0	1	0	1,262
Other Nearshore rockfish N	3	0.1	1	0	142
Other Nearshore rockfish S	0	0	0	0	564
Cabezon	0	0	0	0	69
Kelp greenling	0	0	0	0	NA

The Councils final preferred alternative excludes: longspine south of 34°27', minor nearshore rockfish north and south, black rockfish, California scorpionfish, cabezon, kelp greenling, shortbelly, "other rockfish" and other fish. Many of these species are found in nearshore areas where trawlers do not, or cannot, operate and for the most part are managed through state-based regulations. Species affected by the state management described above include the following: cabezon, black rockfish, kelp greenling, California scorpionfish, and the various species making up the nearshore rockfish group (including deeper and shallow nearshore). Gear switching should be considered alongside the types of species covered in the program. While trawl vessels do not harvest many types of species under status quo measures, the ability for those vessels to switch gears may provide for some opportunities to harvest different species. As illustrated in Chapter 4, some species are not caught with trawl gear, but are caught with nontrawl gear. In particular, longspine 34 degrees 27 minutes North latitude are caught with nontrawl gear. However, based on information from industry representatives, fixed gear vessels do not actively target longspine thornyheads because the price is too low to justify targeting on that stock (Richter, 2008. Personal communication). Therefore, the fixed gear landings of these species are almost certainly incidental to efforts spent catching shortspine, sablefish, slope rockfish, or another deep water species. Longspine south of 34 degrees 27 minutes North latitude are found in areas not accessible to trawl gear. When combined with the fact that fixed gear vessels do not target longspine thornyheads, it may be reasonable to exclude longspine south of 34 degrees 27 minutes North latitude from the IQ program because the catch of that species is likely to be small. Shortbelly is similar in that markets are not available for this species and the OY is large relative to the amount of incidental catch. "Other rockfish" and other fish are somewhat different. The catch of "other rockfish" is small and is constrained by catch limits on other species. "Other fish" are also constrained to some degree by the catch of other species, though targeting does occur on species making up this complex such as skates and dogfish.

The "other fish" stock complex contains all the unassessed Groundfish FMP species that are neither rockfish (family *Scorpaenidae*) nor flatfish. It includes dogfish (Table A-3). While there have been proposals in the past to remove dogfish from the "other fish" category it remains part of that category. Dogfish is a major component of the "other fish" catch (Table A-4). Landings in the "other fish" category and landings of dogfish have been relatively stable across sectors with the exception of a recent increase in tribal fisheries (Table A-5 and Table A-6).

Table A-3. Groundfish species included under "Other Fish."

The choice of whether or not to include "other fish" under the IFQ program has a number of impacts. With respect to conservation objectives, protection for any species within the complex is somewhat limited because the "Other Fish" OY is under harvested and there is substantial potential to shift targeting among species within the category. If it is determined that an undesirable amount of shifting within the category is occurring, it might be possible to impose cumulative limits on the species experiencing excess targeting. This is true whether the group is managed with IFQs or under status quo. Currently, the Council's ability to impose trip limits requires identification of a conservation concern for a species for which there is an OY. The justification for the current landing limits that are in place for dogfish is based on the need to control incidental catch of overfished species, which occurs when dogfish are targeted. Ultimately, whether managed with IFQs or under status quo, with 100 percent monitoring on trawl vessels the fleet will be held fully accountable for its catch and conservation objectives will be achieved.

One or all species in this group could be brought under the IFQ program later. The possibility for this to occur could create a competition for harvest history if the group is left outside the IFQ program. The potential for that competition might be a conservation concern. To address this possibility the Council indicated that for this group it would likely use 1994-2003 permit landings history as the basis for its initial QS allocation should it become necessary. See Section A-2.1.6 for additional discussion and analysis of this provision.

Inclusion of "other fish" under the IFQ program could impose a major constraint on the fishery if the correct amount of dogfish is not allocated to the fishery. Because of the ubiquitous and variable nature of the occurrence of dogfish in bycatch, the Council was particularly concerned about the difficulty of setting the trawl allocation amount properly. Improper setting of the trawl allocation for this species could seriously constrain harvest, reduce net benefits, and adversely impact the harvesting and processing sectors, labor, and communities. Leaving the group under status quo management allows the Council more latitude for adjusting management measures to account for the needs of both trawl and nontrawl sectors.

The main disadvantage of leaving the "other fish" out of the IFQ program is that if markets do begin to develop and constraints have to be imposed, these constraints (two-month limits) could substantially reduce benefits from a developing fishery, as compared to the management options available under IFQ management. To address this possible negative impact, "other fish," or dogfish as a separate category, could be brought under the IFQ program later.

Coverage of species with IFQ is expected to be consistent with several aspects of the MSA, the Groundfish FMP, and the Council's goals and objectives for Amendment 20. Covering species with IFQ means that harvesters are responsible for the catch of those species. When combined with monitoring requirements envisioned to be necessary to support a total catch IFQ program, the coverage of overfished species with IFQ is expected to help foster the rebuilding of those stocks, which is consistent with MSA – 303A(c)(1)(A). This consistency exists because of increased catch certainty associated with IFQ coverage of those species. This increased catch certainty exists because of the type of monitoring associated with a total catch IFQ program (monitoring is expected to be more timely than status quo conditions) and the fact that vessels must stop fishing when reaching their quota. For these same reasons, the coverage of species with total catch IFQ promotes conservation of those stocks, which is consistent with MSA – 303A(c)(1)(C)(ii).

For some species that may be infrequently encountered, the conservation benefit associated with covering those stocks with quota may be minimal. However, the cost and risks associated with covering those stocks with quota could be quite large. When considering this effect next to MSA standards, FMP and Amendment 20 objectives, the coverage of infrequently encountered species with quota may be contrary to the Groundfish FMP objective 15, which states "avoid unnecessary adverse impacts on small entities." This could occur if a vessel falling under the definition of a small entity catches an unexpected quantity of a relatively infrequently encountered species. The cost of covering that catch with quota could be high because of the limited amount of quota available on the market. Additionally, that vessel may incur an enforcement action (if unable to cover that catch with quota) which could be costly. Relative to the OY of infrequently encountered nearshore stocks, the catch occurring in the trawl sector is small. This means that the possible cost to a vessel encountering an unexpected amount of catch of one of these species may be "unnecessary" for the successful management and conservation of the stock while also having an "adverse impact" on that vessel. Furthermore, for reasons outlined in paragraphs above, a catch event could be large enough to affect the entire trawl sector and trawl dependent communities while having little to no effect on the status of the stock or other fishery sectors.

Alternative Scope (A-5)

One option exists that would require whiting vessels to be individually responsible for whiting, but not be individually responsible for the catch of other species. Under this form of management, it is envisioned that bycatch limits would continue to be used for the three whiting sectors (either collectively or at a sector level). The effect of this type of management was discussed in Chapter 4, Section 4.6.2.4, therefore, the reader is referred to that section for additional discussion that may not be contained here.

This alternative scope has two principal effects. One effect deals with risk management by quota holders in an IFQ program. The other effect is related to management complexity. Under status quo measures, bycatch limits are used to manage the bycatch of select species in the whiting fishery. Beginning in 2009-2010, bycatch limit management is applied on a sector-specific basis. It is envisioned that this type of management would continue under the alternative scope, meaning that managing the bycatch of the three whiting sectors would not change from status quo if one or more sectors of the fishery were managed with IFQ. This means that management of bycatch in the whiting fishery is not likely to add to administrative complexity of the program of this alternative scope is adopted.

Harvesters under an IFQ program face a degree of risk based on the species for which those harvesters are responsible, and whether they are responsible for those species collectively or individually. As stated in Chapter 4, holding harvesters individually responsible for bycatch species may create a relatively high amount of risk to individuals, but a relatively low amount of collective risk. Individual

risk is defined as one where individuals face a relatively high cost of some form if they catch greater than expected amounts of bycatch species and are responsible for covering that catch with quota individually. This is a relatively high individual risk because, if a harvester incurs a "disaster tow," that harvester would be responsible for purchasing enough quota to cover that catch event by themselves and this may prove quite costly. A collective risk is one where the actions of one harvester can affect the opportunities to another harvester, potentially leading to a break down in rational fishing behavior and race for fish conditions via a race for bycatch even though the fishery may be "rationalized." Such an outcome could occur if a bycatch limit is applied at a sector or fishery level and participants in that sector or fishery do not believe that they can successfully manage that bycatch collectively. When participants stop believing that successful bycatch management is a possibility, the likely outcome is one where they begin to race to catch their target species before the bycatch limit is reached.

The alternative scope described in this section would effectively trade some individual responsibility for some collective responsibility, and decrease individual risk while potentially increasing collective risk. The degree to which individual risk is traded for collective risk depends on the level of bycatch management and whether bycatch is managed at a fishery level or a sector level.

Gears and Fisheries Covered and Gear Switching

Gears and Fisheries Covered

The Council's motion on gears and fisheries covered states the following:

> If a vessel has an LE trawl permit and groundfish is caught by any gear, IFQ must be used, with the following exceptions: exempted trawl, California halibut trawl (in California state waters), CPS gear, HMS gear, salmon troll, and crab pot.

The Council's decision to eliminate these gears from the program is based on the notion that such gears do not encounter volumes of groundfish that would justify the measures necessary to fold their use into the IFQ program. To help illustrate this point, the following information was developed. This information shows landings of groundfish by fishery, and this information is useful for illustrating the potential amount of groundfish catch that occurs in each of the fisheries. Based on this information, the California halibut, pink shrimp, fish pot, Pacific halibut, salmon and set net fisheries take the most groundfish (Table A-7.). However, the catch of groundfish in the pink shrimp fishery has declined dramatically since the introduction of fish excluder devices and that fishery now takes some of the smallest amount of groundfish relative to other nongroundfish fisheries. Of the previously listed fisheries it is primarily the California trawl and pink shrimp fisheries that have substantial crossover with the groundfish trawl fishery, and some participation in the California halibut fishery is considered part of the overall fishing strategy by vessels participating in the LE trawl fishery off Central California. Outside of the California halibut, fish pot and Pacific halibut fisheries, the ex-vessel revenue from groundfish contributed less than 3 percent of the value of the total catch in these open access fisheries (Table A-8).

Of these listed fisheries, California halibut trawl and sea cucumber trawl use gear defined as "legal groundfish gear." Pacific halibut uses anchored longline, fish pot uses anchored fish pot gear, and set net and California halibut hook and line use gear often described as groundfish gear. Gears used for pink shrimp, ridgeback prawn, spot prawn, CPS, crab pot, HMS, salmon, and sea urchin are not typically considered gears that are used to prosecute groundfish.

Table A-7. Federal groundfish landings in incidental fisheries, 1998-2006, including averages.

Fishery	1998	1999	2000	2001	2002	2003	2004	2005	2006	AVG

1/ spot prawn trawling prohibited in California starting April 2003. Incidental landings allowed with ridgeback prawn landings

Association with the Inter-Sector Allocation Process

Requiring that a vessel with a LE trawl permit cover groundfish catch in nongroundfish fisheries with quota is consistent with existing provisions that applies groundfish landings made by a vessel with a LE permit in a nontrawl sector to that vessel's trawl cumulative limit. This effectively limits groundfish catch by a trawl vessel to its cumulative limit regardless of which fishery that vessel may have harvested groundfish and expands the trawl sector allocation to participation in fisheries other than the trawl fishery. Exceptions do exist however, such as when a trawl vessel with a LE fixed gear permit participates in the sablefish tier fishery. Under this circumstance, the catch of a vessel with a trawl permit associated with it in the sablefish tier fishery is not applied to the trawl cumulative limit.

If groundfish catch made by LE trawl licensed vessels that are participating in a nontrawl fishery are not included under the scope of the trawl rationalization program, then the inter-sector allocation process may have to consider that decision. One method of dealing with this issue is to attribute groundfish catch in fisheries not covered under the scope of the rationalization program toward the nontrawl sector. This could be done by developing estimates of groundfish catch made by licensed trawl vessels participating in fisheries not covered under the scope of the program and applying that estimated catch to the allocation made to the nontrawl sectors. Another approach for some legal gears that take a very small amount of groundfish quota would be to estimate the expected mortality preseason and deduct it from the trawl allocation before allocating out the QP. Adjustments would be made from year to year if the actual take were greater or smaller than the estimates but given the low harvest levels, deviations from the estimates would be unlikely to have a significant conservation impact.

Gear Switching

Gear switching is an implied result of the definition of the program scope. Gear switching may be used to balance catch accounts (because different gears have relatively different catch rates), take advantage of differing market opportunities, or to respond to public relations issues. Although difficult to predict, some information suggests that there are harvesters located in different sections of the west coast that are more likely to engage in gear switching on a permanent basis. Harvesters located in the central and southern-central California coast have expressed a desire to switch from trawl gear to groundfish fixed gear (longline and pots) in recent years because of public relations issues and because consumers in central and southern California appear to prefer nontrawl caught fish. In addition, harvesters that have typically relied on areas with relatively high rates of constraining species bycatch may be more likely to switch to a nontrawl gear to avoid those constraining stocks since many types of fixed gear have lower bycatch rates of overfished stocks than trawl gear (though not always as is evidenced by the comparative bycatch rates of yelloweye rockfish). This may encompass harvesters located in northern Washington and some harvesters in southern Oregon ports. Other factors may cause harvesters temporarily to use nontrawl gear to prosecute fishing activities during certain times of the year. This may be due to market conditions where there is a noticeable differential in the prices paid for groundfish species caught with one gear versus another. This is particularly the case for sablefish. The figure below shows that there is a substantial price differential between fixed-gear-caught sablefish and trawl-caught sablefish. If the trawl sector harvests 10 percent of the trawl allocation with fixed gear, this would increase ex-vessel revenues by approximately $600,000. If 20 percent of the trawl allocation was caught with fixed gear, ex-vessel revenues may increase by $1.2 million.

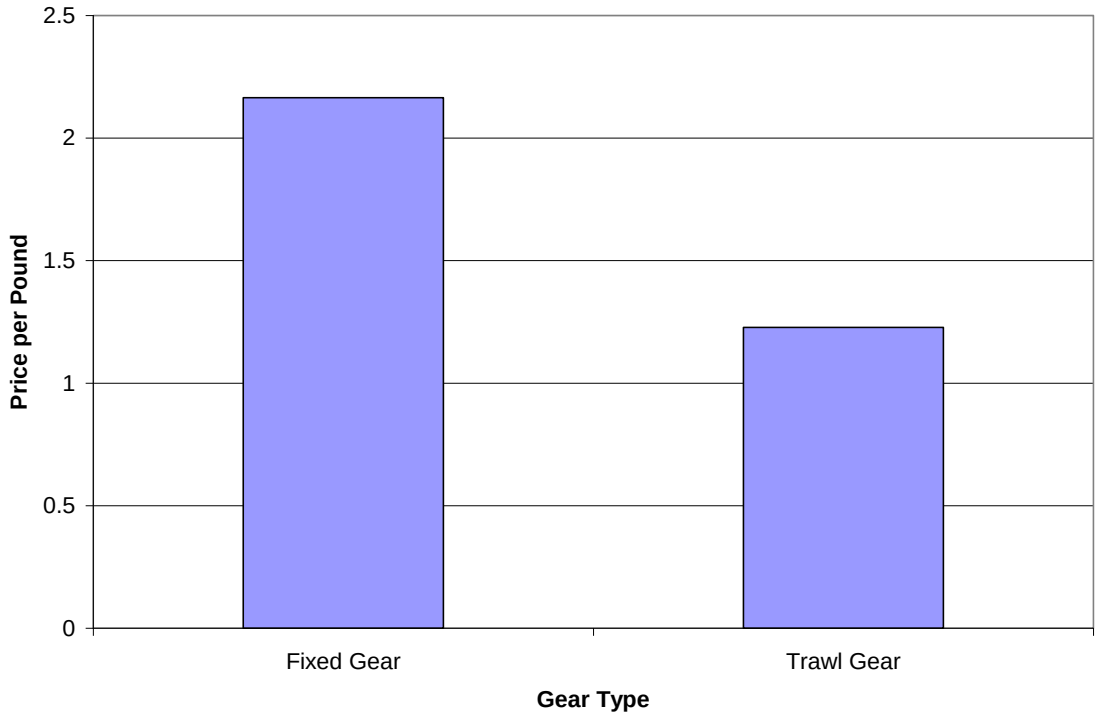

Figure A-1. Average price per pound for sablefish by gear type (2004 to 2007).

Another factor influencing gear switching, aside from the price differential, is the ability to harvest some types of groundfish with trawl gear that cannot be caught with nontrawl gear. Harvesters in many areas are not likely to abandon trawl gear completely because doing so would mean giving up the catch of many species of flatfish, which are not easily caught with nontrawl gears. In other words, in many areas of the coast, harvesters may use nontrawl gear to target species such as sablefish during certain times of the year and use trawl gear to prosecute Petrale sole, Dover sole, and other flatfish during other times of the year. The relative catch rate—under status quo conditions—for bottom trawl and fixed gear is shown in Table A-5. This information shows that fixed gear is successful at catching sablefish, shortspine thornyhead, and arrowtooth to some degree, but is not productive for catching many types of flatfish. Trawl gear on the other hand is capable of catching all of the species listed in the table. One reason these flatfish are not successfully caught with hook-and-line gear is because of their feeding patterns. While many longline fishermen may use herring with large hooks for example, several of the flatfish shown below feed on small prey, like worms, and have mouths too small to be caught with many of the hook sizes currently used. This information implies that large-scale gear switching may result in several species of flatfish being left unharvested.

Table A-9. Catch of select groundfish by gear type, mt (2006).

Species	Nonwhiting trawl	Fixed Gear
Sablefish	2,654.3	3,119.3
Shortspine	648.7	178.1
Longspine	821.3	21.2
Dover sole	7,475.5	4.6
Petrale sole	2,690.1	4.1
English sole	1,291.4	0.0
Arrowtooth flounder	2,817.6	78.8
Other Flatfish	1,854.9	4.1

Gear switching in an IFQ program addresses several aspects of guidance related to rationalization. Gear switching is related to conservation, net benefits, and sector health. The MSA at 303A(c)(1)(C)(ii) states that limited access privilege programs (LAPPs) shall promote fishery conservation and management, while the Groundfish FMP objective 5 specifies the objective of minimizing adverse impacts on essential fish habitat (EFH). Gear switching is expected to result in a wider use of gear types some of which may have a smaller impact on habitat than bottom trawl gear. However, this is not necessarily always the case, especially in cases where fixed gear can access high relief substrate and trawl gear cannot. If gear switching results in increased fishing pressure in areas where trawl gear currently cannot access, the result may be a greater impact on habitat than under status quo. In other areas (those that are accessible to trawl gear), the impact may be a reduction in the impact on habitat. A reduction in habitat impacts is expected to have an indirect effect on fish stocks and in this way influence fishery conservation.

[i] Longnose skate has since been moved out of the "Other Fish" category.

A-1.2 IFQ Management Units, Including Latitudinal Area Management

❖ *Provisions and Options*

QS will carry designations for the species/species group, area, and trawl sector to which it applies (see A-1.3 for the list of trawl sectors). The QP will have the same species/species group, area, and sector designations as the QS on the basis of which the QP was issued. QP will not be used in a trawl sector other than that for which it was issued, unless specifically allowed, and will not be used in a nontrawl sector (i.e., by vessels without trawl permits).[4] QP will not be used in a catch area or for a species/species group other than that for which it is designated.

For those species within the scope of the program, the, species groupings and area subdivisions will be those for which OYs are specified in ABC/OY table that is generated through the groundfish biennial specifications process.

Geographic Subdivision **Option 1:** Additionally, for species or species groups for which the OY is not geographically subdivided (i.e., there is only a coast wide OY), the QS will be subdivided geographically at the 40°10' N latitude line. Existing geographic lines for other species will be maintained. [If this option is not adopted, area divisions will be as specified for OYs in the biennial ABC/OY table, unless changed by the Council.]

► Geographic Subdivision **Option 2:** Additionally, there will be area subdivisions for those species for which there is an area specific harvest policy.

OR

See Section A-8 for an alternative approach to addressing concerns about geographic shifts: "regional landing zone restrictions." Regional landing zone restrictions would not alter the IFQ management units.

QS for remaining minor rockfish will be aggregated for the nearshore, shelf, and slope depth strata, as per Table A-82, Control and Vessel Limit Options.

After initial QS allocation the Council may alter the management units by changing the management areas or subdividing species groups. Section A-2.1.6 provides methods for reallocating QS when such changes are made after initial implementation of the program.[5] *Hereafter, all references to species include species and species group, unless otherwise indicated.*

❖ *Rationale and Policy Issues*

The IFQ units would be matched to the ABC/OY table species and species complexes in order to allow managers to control trawl harvest with respect to the annual ABC/OY management targets.

The option to provide a further geographic subdivision of those categories is intended to spread out effort to decrease the likelihood of localized depletion of fish species/populations and to disperse landings to sustain a variety of coastal communities. Managers of both British Columbia groundfish and IPHC halibut employ area management.

[4] Not withstanding this provision, a vessel with a LE trawl permit may catch the trawl QP with a nontrawl gear, as per Section A-1.1.

[5] Such changes in latitudinal area management may occur as a result of changes in the management areas for species/species complexes in the ABC/OY table or as a result of separate Council action to change the trawl QS by area. In either case, specific Council action will be required to change the management areas, and such action will be accompanied by appropriate supporting analysis and public comment opportunity.

The GMT recommended in June 2007 that status quo area management measure be applied as a precautionary measure under both status quo and rationalization management systems.

> As evidenced by the March 2007 groundfish inseason action, increasingly complex spatial management measures may be necessary within the existing management framework. Intersector allocations (ISAs) and the implementation of trawl individual fishing quotas (TIQ) may further increase the need for spatial management, perhaps in a manner different than status quo….
>
> Spatially explicit management has proven to be critical to meeting conflicting management goals and objectives, such as maintaining fishing opportunities on healthy stocks while reducing incidental catches of rebuilding species, and meeting habitat protection requirements. Furthermore, there is a growing appreciation of the significance of heterogeneity in population structure for most marine organisms, as well as for the potential interaction between population structure and fishing behavior, that scientists and managers alike will find increasingly necessary to confront in population models and management measures….
>
> The GMT recommends incorporating current area management tools within the TIQ program, recognizing the limitations, and continuing to pursue research and data that may further inform spatial management. As data become available, area management within the TIQ program is expected to evolve and adapt.

A further explanation of how north-south trawl IFQ allocation would work is provided below.

1. Allocation of QS would be based on landings by area north and south of the 40° 10’ N latitude area management line. The area to the north sums to 100 percent, and the area to the south sums to 100 percent.
2. Division of trawl allocation between north and south areas could be based on average landings over a series of years (1994 to 2003 was suggested by the GMT; 2004 to 2006 is the status quo years used in the analysis). The Council has not selected a period of years.

Currently, and in the past, permits could be sold coast wide. There is a possibility that, if a permit was sold to a different part of the west coast, the permit would not get an initial allocation of QS that match the present-day location of the vessel, but rather match the history of the permit. For example, if someone in California wanted to sell their permit to someone fishing in Washington, that vessel might qualify, based on fishing history, for southern QS, but not northern. That vessel would have to acquire northern QSs to fish by a different means than initial allocation, such as buying or trading.

The goals and objectives addressed by the Area Management provision include the following: promote fishery conservation (MSA 303A(c)(1)(A)); consider biological stock structure and minimize localized concentrations of fishing effort (Amendment 20 Constraint 3); address concerns over excessive geographic consolidation in the harvesting or processing sectors (MSA 303A(c)(5)(B)(ii)); and promote sustained participation of fishing communities and address concerns over excessive geographic consolidation (MSA 303A(c)(5)(B)).

Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
X			X				X			

A process option to form a group to address area management was considered but rejected. Furthermore, the Council adopted (as part of the PPA) area management and Regional Landing Zones as dual preferred alternatives. Both were not adopted as the Final Preferred Alternative. Some factors leading to the decision not to adopt area management as a Final Preferred Alternative include the fact that little scientific information was available to support the decision on where boundaries might be drawn to support such area subdivisions and whether implementing such measures would be necessary for conservation of groundfish resources given the life history characteristics of groundfish caught in the trawl fishery.

❖ *Interlinked Elements*

General Management and Trawl Sectors –The north-south division of coast wide OYs would not apply to the shoreside whiting fishery if managed by IFQs, as it occurs entirely to the north.

Stock distribution vs. distribution of trawl sector allocation – The north and south distribution of trawl sector allocation, if based on past landings amounts, may not match up with future groundfish locations and centers of abundance. The percentage of the north-south OY split is typically based on biological considerations, is part of the biennial specifications process, and would not necessarily be indicated under Amendment 20. IFQ area management units are related to decisions to be made under the ISA and/or 2011-12 groundfish harvest specifications EISs.

Reallocation with changes in management area – There are specific formulas proposed in the program provision alternatives that describe how reallocation would occur if there were an area subdivision, area recombination, area line movement, or species group subdivision.

❖ *Analysis*

Area management units would have both a biological effect and a socioeconomic effect. Under a rationalized fishery, it is anticipated that harvest privileges will be more fluid than under status quo. Under status quo, permit owners can sell their permit, or lease their permit to another individual that fishes that permit. However, IFQ is anticipated to be more fluid because it is divisible, and one individual's quota can be spread throughout several different active vessels or stacked on one vessel. Because of this envisioned fluidity, fishing effort is likely to be much more concentrated in areas where economic conditions (including catch per unit effort and species mix in the catch) are most favorable (assuming area management restrictions do not exist). This may have the effect of shifting fishing and delivery activity away from some areas and toward others, resulting in an overall shift in location in which fishing activity occurs.

Assuming area management units do not exist, from an economic standpoint, this shift can be viewed as favorable to some as quota owners are best able to capitalize on favorable economic conditions. In the case of coastal communities, the effect is largely distributional. Those communities that lose fishing

activity stand to be adversely affected while those communities that gain fishing activity stand to be positively affected.

From a biological standpoint the issue is somewhat mixed. On one hand, if short-term economic conditions dominate the decision of where fishing effort will be concentrated, then stocks present in areas with an increase in fishing effort may experience more mortality than under status quo. However, if those stocks become less abundant, harvesters may elect to move and fish in areas where stocks are more abundant, allowing stocks in the first area to recover while harvesters fish in the area of more abundant stocks. Even so, if costs are lower in a particular port or region of the coast, or the travel distance to the fishing grounds shorter, QP may tend to flow to vessels in those locations even though the CPUE is lower due to localized depletion.

If area management restrictions exist, this is likely to temper the geographic shift effect. In general, trawling effort has been becoming increasingly concentrated in areas off Oregon and northern California and less concentrated in areas off central and southern California. If an area management boundary is put in place at 40° 10' N latitude (just south of Cape Mendocino), it is expected that the shift in concentration of fishing to the north of that latitude line will be halted/reversed, and more fishing activity will take place to the south compared to a case where no area management restrictions exist. Implementing this area restriction may have the effect of spreading the distribution of fishing activity across a wider number of communities. However, quota owners may be less able to capitalize on favorable economic conditions and the fluidity of QS will be reduced.

In November 2007, the GMT proposed a north-south QS split based on average fleet harvest history in the two areas during the 1994 to 2003 period. In Table A-10 below, trawl caught average percentages north and south for 1994 to 2003 are compared to more recent years (2004 to 2006 averaged) for certain species.

Table A-10. Share of Trawl Landings North and South of 40° 10' N latitude Line averaged for the years 1994 to 2003 and 2004 to 2006.

	1994-2003		
	All Permits	**Nonbuyback**	**2004-2006**
Sablefish			
North of 40-10	82.34%	80.78%	86.96%
South of 40-10	17.66%	19.22%	13.04%
Shortspine Thornyheads			
North of 40-10	72.77%	68.26%	71.39%
South of 40-10	27.23%	31.74%	28.61%
Longspine Thornyheads			
North of 40-10	75.39%	71.10%	54.37%
South of 40-10	24.61%	28.90%	45.63%
Dover Sole			
North of 40-10	71.73%	66.82%	81.92%
South of 40-10	28.27%	33.18%	18.08%
Petrale Sole			
North of 40-10	81.99%	77.26%	86.08%
South of 40-10	18.01%	22.74%	13.92%
Other Flatfish			
North of 40-10	56.25%	44.66%	77.02%
South of 40-10	43.75%	55.34%	22.98%

For some species, such as other flatfish, Petrale sole, and Dover sole, the more recent years show the trawl catch is greater in the north. Using 1994 to 2003 would not reflect the current trawl effort as well as more recent years would, but using the older years would spread the effort out more between northern and southern areas. For other species, such as sablefish, there is less of a discrepancy between using an

older data set and more recent years. The Council may wish to split the north and south QS for shortspine and longspine thornyheads to disperse the trawl effort on those species. However, the provision as it is currently written would have to be changed to include the thornyheads, because the current provision only applies to species that have no OY management division. Thornyheads have a management division at the 34° 27' N latitude line, which has little application to the trawl fishery.

The status quo management of some species' OY currently divides fishing effort to the north and south of 40° 10' N latitude, such as minor nearshore, shelf and slope rockfish. Other species have an OY management division at a different line of latitude, such as shortspine and longspine thornyhead, and 34° 27' N latitude. Most groundfish species, such as whiting, Dover sole, Petrale sole, and widow rockfish, have a coast wide OY with no specified area management. Below is a table (Table A-11) that lists every west coast groundfish stock and stock complex with a specified OY and whether that OY is coast wide or has a division. Those species with no OY division would have the 40° 10' N latitude management line applied to them under rationalization.

Table A-11 furthers the analysis by commenting on the potential biological effect of creating a management division at 40° 10' N latitude. In general, species that are found further off-shore, e.g., on the continental slope, have a life history that involves broadcast spawning, a higher level of adult mobility, and a higher level of genetic mingling than species found on the continental shelf and nearshore. Adult nearshore species tend to have higher site fidelity, are less likely to colonize new habitats, have lower levels of genetic mixing, and, therefore, have higher levels of genetic specialization and diversity. Nearshore species are more vulnerable to intense and localized fishing effort because they tend to be more adapted to a specific area than slope species. If concentrated fishing effort occurred on slope species, there is a lower risk of localized population depletion because other individuals in the population are genetically similar and could migrate to repopulate the depleted area. Localized depletion would have a greater effect on species occurring on the shelf and nearshore, because in general their life history characteristics tend to include low larval dispersal, high geographic loyalty, and high genetic diversity.

In addition to the generalized differences in life characteristics of slope versus shelf species, there are other considerations that bear on whether or not the management division at 40°10'N latitude would apply in a useful way. For example, some species range entirely above or below 40°10'N latitude, are not caught in either the north or the south, and a management line at that location would not help spread out the catch effort (i.e., arrowtooth flounder, Pacific ocean perch, and Pacific cod, which all primarily occur in the northern area). Some species have an unknown distribution, and still other species are so rarely caught by the bottom trawl fishery that an area management line would have little biological implication.

Creation of a line for species that are abundant coast wide but present in relatively small quantities south of Cape Mendocino may risk problems similar to those described in Section A-.1.1 with respect to species that are generally caught in small quantities by the trawl fishery (e.g., cabezon and black rockfish). See Species Covered in Section A-1.1 for a discussion of the implications of requiring IFQ for species that are rarely encountered and for which the available QP is very limited.

Minor effects of the area management provision, would include additional tracking, monitoring, and enforcement of QS harvest location. North and South categories of QS would be created and tracked to make sure that QS are fished and traded/sold in the correct area. Likewise, if adaptive management QS are part of the rationalization program, those QSs would also be designated North and South.

In summary, an OY management division at 40° 10' N latitude would result in a more precautionary management measure for some of the species currently lacking north/south area management divisions, would be more effective for certain species than others depending on life history traits, would help ensure some communities retain some amount of historical fisheries commerce, and would restrict coast wide tradability of QS.

Table A-11. West coast groundfish stocks and stock complexes with harvest specifications (overfished stocks in CAPS.)

Stock	Geographic Extent of Specified Optimum Yields (OYs)	Potential Biological Benefit of Separate OYs N and S of 40°10' N lat. (if current OY is coast wide)?	Comments
Lingcod	Coast wide	Likely	Southern sub-population has different pop. dynamics and is more depleted
Pacific Cod	Coast wide	Unlikely	Rare S of 40°10' N lat.
Pacific Whiting (U.S.)	Coast wide	Unlikely	Highly migratory with majority of fishing pressure in the north
Sablefish	Separate OYs N and S of 36° N lat.	N/A[6]	
PACIFIC OCEAN PERCH	Coast wide	Unlikely	Rare S of 40°10' N lat.
Shortbelly Rockfish	Coast wide	Unlikely	Negligible exploitation
WIDOW ROCKFISH	Coast wide	Unknown	Stock differences along west coast unknown
CANARY ROCKFISH	Coast wide	Unknown	Stock differences along west coast unknown
Chilipepper Rockfish	S of 40°10' N lat.	N/A	Managed under the minor shelf rockfish complex in the north
BOCACCIO	S of 40°10' N lat.	N/A	Managed under the minor shelf rockfish complex in the north
Splitnose Rockfish	Coast wide	Unknown	Stock differences along west coast unknown
Yellowtail Rockfish	N of 40°10' N lat.	N/A	Managed under the minor shelf rockfish complex in the south
Shortspine Thornyhead	Separate OYs N and S of 34º27' N lat.	N/A	
Longspine Thornyhead	Separate OYs N and S of 34º27' N lat.	N/A	
COWCOD	S of 40°30' N lat. (Con. and Mon. areas)	N/A	
DARKBLOTCHED	Coast wide	Unlikely	Slope species: genetic diversity likely low along west coast due to broad larval dispersal
YELLOWEYE	Coast wide	Unknown	Stock differences along west coast unknown; sedentary life history may lead to stock differences
Black Rockfish	Separate OYs N and S of WA-OR border	N/A	
Minor Rockfish North	N of 40°10' N lat.	N/A	
Nearshore Species	N of 40°10' N lat.	N/A	
Shelf Species	N of 40°10' N lat.	N/A	
Slope Species	N of 40°10' N lat.	N/A	
Minor Rockfish South	S of 40°10' N lat.	N/A	
Nearshore Species	S of 40°10' N lat.	N/A	
Shelf Species	S of 40°10' N lat.	N/A	
Slope Species	S of 40°10' N lat.	N/A	
California scorpionfish	Coast wide	No	Ranges S of 37° N lat. and rare N of 34°27' N lat.
Cabezon	OY for CA only	N/A	

[6] Not Applicable (N/A). The 40°10' N lat. management line would not be applied to species with a previously specified management division.

Table A-12 cont. West coast groundfish stocks and stock complexes with harvest specifications (overfished stocks in CAPS.)

Stock	Geographic Extent of Specified Optimum Yields (OYs)	Potential Biological Benefit of Separate OYs N and S of 40°10' N lat. (if current OY is coast wide)?	Comments
Dover Sole	Coast wide	Unlikely	Stock differences along west coast unknown, but long larval period (2 yrs) and offshore larval transport prob. contribute to low genetic diversity
English Sole	Coast wide	Likely	Stock differences along west coast unknown, but inshore larval dispersal may contribute to higher genetic diversity
Petrale Sole	Coast wide	Likely	Stock differences along west coast unknown, but inshore larval dispersal may contribute to higher genetic diversity
Arrowtooth Flounder	Coast wide	Unknown	Stock differences along west coast unknown, but deeper shelf spawning and 4 week larval period may contribute to higher genetic diversity
Starry Flounder	Coast wide	Likely	Stock differences along west coast unknown, but nearshore distribution prob. contributes to higher genetic diversity
Other Flatfish	Coast wide	Likely	Mix of species including nearshore species with probable high genetic diversity
Other Fish	Coast wide	Unknown	Mix of species with disparate life histories; Though stock differences along west coast unknown there may be some trawl-caught species with higher genetic diversity
Kelp Greenling	HG for OR only	N/A	
Longnose Skate	Coast wide	Unlikely	Stock-specific OY specified starting in 2009; Highly migratory with prob. low genetic diversity

A-1.3 General Management and Trawl Sectors

❖ *Provisions and Options*

Unless otherwise specified, status quo regulations, other than trip limits for species within the scope of the IFQ program, will remain in place. If individual vessel overages (catch not covered by QP) make it necessary, area restrictions, season closures or other measures will be used to prevent the trawl sector (in aggregate or the individual trawl sectors listed here) from going over allocations.[7] The IFQ fishery may also be restricted or closed as a result of overages in other sectors. There will be:

►**Option 1:** three trawl sectors: shoreside, mothership, and catcher-processors.
Option 2: four trawl sectors: shoreside nonwhiting, shoreside whiting, mothership, and catcher-processors.

Allocation among trawl sectors to be determined in the intersector allocation process.[8]
Trawl vessels fishing IFQ with nontrawl gear will be required to comply with the RCA lines applicable for that gear. Such restrictions, as necessary, will be determined in a separate process.

❖ *Rationale and Policy Issues*

Within a rationalization program, the more transferability allowed among vessels the more efficient the use of the fishery resource and hence the greater the potential total economic benefits of the program. However, in an attempt to preserve certain characteristics of a fishery that may be considered desirable, limits on IFQ transfers among sectors may be adopted despite being less economically efficient overall.

The Council, at the recommendation of the Trawl Individual Quota Committee (TIQC), eliminated the one trawl sector option from further analysis. By not differentiating between trawl sectors, the single trawl sector option would maximize potential transferability among trawl fisheries. However, with one sector, the market may not fully capture all the important social and economic effects, particularly if some IFQ buyers in the market benefit from both harvesting and processing profits while others only harvest or only process. It is anticipated, therefore, that a single sector would lead to migration of quota to the more vertically integrated catcher-processor sector. Such expected consolidation would likely result in disruption of other sectors in the fishery and a change to its current landscape, including loss of small-boat/owner-operator businesses that could be out-competed in both the shoreside and mothership

[7] The Council authority to establish or modify RCAs will not be changed by this alternative.

[8] The allocation among trawl sectors will be determined as part of the intersector allocation process. The TIQC recommended a number of options for determining the allocation among trawl sectors. One of these would have based the allocation on fleet history, but would not have included in the fleet history the history of any vessel not meeting the recent participation requirement. The Council rejected this application of a recent participation requirement to a determination of fleet history. The remaining TIQC options recommend that the division of allocation among trawl sectors be based on the fleet history over the same time periods used to allocate QS. The TIQC further recommends that if different periods are used for different trawl sectors, either (1) calculate the share for each sector based on its IFQ allocation period, then adjust all percentages proportionately such that they sum to 100 percent; OR (2) use the shortest period common to the allocation formula for all sectors.
If bycatch in the whiting sectors is not managed with IFQs and is pooled at the overall whiting fishery or sector level, allocations of bycatch will be determined through the intersector allocation process. The TIQC recommends allocation among the whiting sectors based on Option 1: pro rata in proportion to the whiting allocation, or Option 2: weighted historical catch formula (for example, in projecting bycatch in the whiting fisheries prior to the start of the season, the GMT uses a four-year weighted average starting with the most recent year: 40 percent, 30 percent, 20 percent, 10 percent).

fleets. Such situations would conflict with the objective to minimize adverse effects on fishing communities to the extent practical and the MSA mandate to consider the basic cultural and social framework of the fishery (303A(c)(5)(B).

While less economically efficient in theory, the options of three sectors or four sectors would better protect communities and regions once the fishery was rationalized. Multiple sectors would allow the Council to make explicit decisions about how to allocate QS between the sectors in order to incorporate some of the socioeconomic values that might not be captured by a market driven allocation.

Four sectors represent the current groundfish fishery and its diversity.

Under a three sector fishery, the shore-based harvesting sector would share one pool of whiting and other groundfish, and this could allow for more flexibility to move harvest opportunity between shoreside whiting and nonwhiting trips to address the fishery's needs. This would relieve some of the Councils allocation tasks and result in more economically optimal distribution, particularly with respect to the consideration of the shoreside whiting and nonwhiting fisheries needs for bycatch, which would be addressed through market-based mechanisms rather than regulatory, administration-based mechanisms.

❖ *Interlinked Elements*

IFQ or cooperatives as the catch control tool: If the nonwhiting sector is managed with IFQ, and the shoreside whiting sector is managed with cooperatives, the fishery must be managed with four trawl sectors.

❖ *Analysis*

Number of Trawl Sectors

It has been hypothesized that if one sector of the fishery has more financial capability of purchasing quota than another sector, then establishing a single shoreside sector may tend to result in a flow of quota from one group of harvesters to another. If overfished species IFQ flows from one sector to another (because one sector has greater purchasing power), the sector that loses the overfished species IFQ may see their ability to access target species reduced (because of the constraining nature of overfished stocks). Alternatively, if there are four sectors, the separation would tend to preserve the amount of species available to each sector. It is important to note that this argument is theoretical. Available information suggests that both shoreside sectors will see profits improve under a well-designed rationalization program. However, having a single shoreside sector will tend to make it easier for trades to occur, while having two shoreside sectors will tend to maintain two fairly distinct sectors (though some vessels may participate in both).

The number of trawl sectors established will likely influence the flexibility that harvesters have in either sector. By creating three trawl sectors and bundling both shoreside sectors into a common allocation, the trading of quota can occur between both sectors in a manner that creates flexibility in harvesting activity because of the ability to acquire and sell quota as needed. The establishment of four trawl sectors imposes risks to harvesters because it reduces the amount of QP available to each sector and creates a firm set of allocations that could cause a sector to close if one or more of those allocations were met. For example, if the incidental catch of Pacific whiting in the nonwhiting sector is higher than anticipated, nonwhiting harvesters could end up being constrained by Pacific whiting and would not be able to purchase whiting quota from shoreside whiting harvesters to alleviate some of that constraint. This division of quota between the shoreside sectors could restrict the ability of nonwhiting harvesters to prosecute fishing activity if some species become unexpectedly constraining, because it establishes

boundaries and restrictions on fishing activity without a mechanism for harvesters to work around those restrictions. Alternatively, the establishment of four trawl sectors implies that a set-aside or allocation of non-target species will be necessary for the whiting fishery. Such a set-aside may be a target species for the nonwhiting fishery. Setting firm allocations for separate trawl shoreside sectors may mean a loss of economic opportunity in years where the whiting fishery does not need that entire set-aside, thus jeopardizing the ability of the trawl sectors to achieve their allocation. Sablefish is one example of a species where catch in the whiting fishery has varied from year to year and for which allocations necessary to establish four sectors may result in lost potential or produce a constraining species. In years where the catch of sablefish is low in the whiting fishery, that catch will reflect a lost economic opportunity to nonwhiting harvesters if that quota cannot be transferred to them. Figure A-2 shows sablefish catch in the whiting fishery over the past several years. This figure shows that the catch of sablefish has varied substantially. Interestingly, the largest source of variation is in the shoreside whiting fishery. In years where sablefish bycatch is low, the inability to transfer that catch to the nonwhiting sector (because of the establishment of four trawl sectors) represents a lost opportunity.

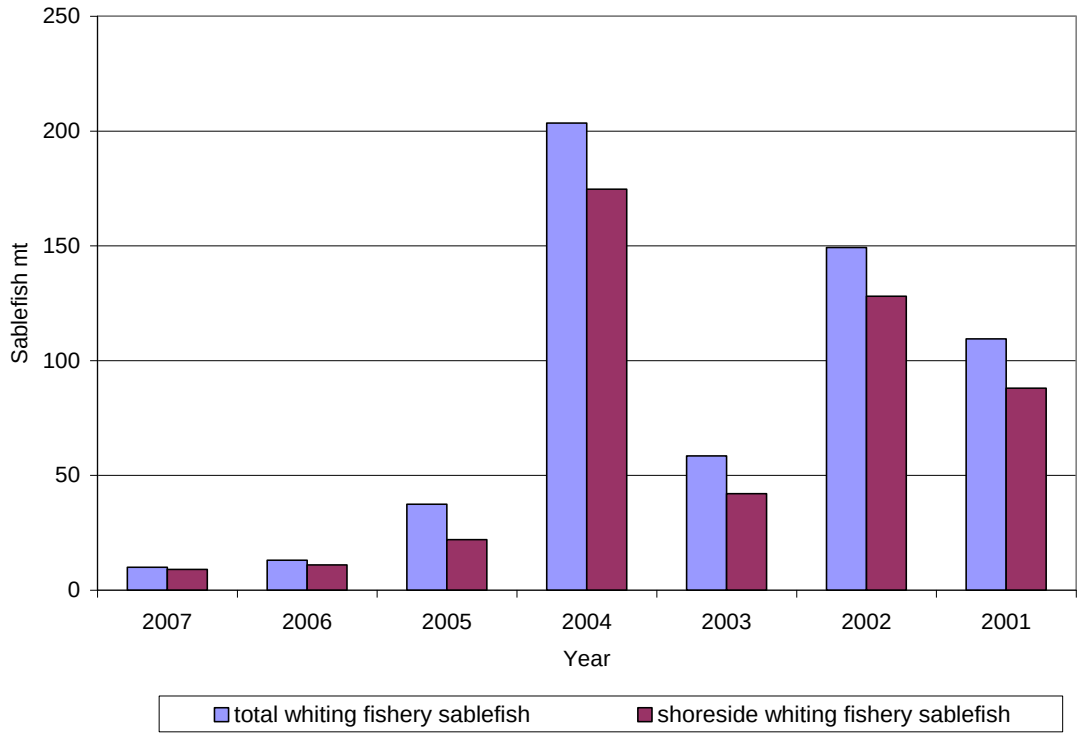

Figure A-2. Bycatch of sablefish in the Pacific whiting fishery (2001–2007).

Measures used to Prevent Exceedance of Allocations

Closing portions of the fishery through area restrictions, season closures, or some other measure to prevent the trawl sector from going over an allocation, or implementing those measures because another sector has exceeded its allocation, is likely to mean the preemption of some fishing opportunities to harvesters in the trawl sector. Many target species are only available in certain areas, such as shelf flatfish. If, hypothetically, an overage of yelloweye rockfish occurs in the trawl sector or another sector that requires depths less than 150 fathoms be closed to trawl activities, several species of flatfish will be inaccessible (such as sand sole, sanddabs, and English sole, among others). This area-based closure would mean that the sector would not be able to harvest these target species, and revenues in the fishery

would be lower than expected. In other cases, some vessels may not have the capacity to fish deeper than 150 fathoms even if target species are available at those deeper depths. However, because of the transferability provisions of a rationalization program, harvesters not able to fish in those other areas can transfer quota to a vessel that does operate in areas remaining open and in this way continue to participate in the fishery.

If measures were not used to prevent overages from the trawl sector or from other sectors, the outcome may mean the exceedance of a management target such as an OY. In the worst-case scenario, the belief that another sector or another harvester can affect the opportunities of trawlers in a rationalized fishery can lead to behavior that resembles race for fish behavior. This is most likely to occur for bycatch species or cases where catch potential is large relative to the management target. Not implementing a restriction, such as an area closure, in a case where a management target is met or exceeded may mean that rebuilding plans are jeopardized or over-fishing occurs. Area closures could also be used to slow the harvest of some species if the Council identifies the need for additional tools to achieve various goals for managing the fishery that are not being achieved by the rationalization program itself. Therefore, while implementing a restriction on the trawl sector to prevent an overage in the trawl sector, or as a result of an overage in a nontrawl sector, may restrict economic opportunity, it is likely to assist in the long-term health of groundfish stocks.

A-1.4 Management of Nonwhiting Trips

❖ *Provisions and Options*

> Nonwhiting trips are those with less than 50 percent whiting. No changes to management measures, other than those identified in Section A-1.3, have been identified at this time.[9]

Nonwhiting trips are those where whiting comprises less than 50 percent of the groundfish catch.

No management measures other than those identified in Section A-1.3 have been identified at this time.

A-1.5 Management of Whiting Trips

❖ *Provisions and Options*

> Whiting seasons will not be changed under the TIQ program, and so the current spring openings will be maintained to control impacts on Endangered Species Act (ESA)-listed salmon.[10]
>
> When the primary whiting season for a sector is closed (see section A-1.3 for options on the number of trawl sectors)
>
> - ► If there are 3 sectors: for shoreside deliveries, cumulative whiting catch limits will apply and shoreside QP will be required to cover whiting incidental catch. Deliveries will be prohibited for at-sea sectors during at-sea closures.
> - If there are 4 sectors: whiting sectors will be prohibited from delivering.

❖ *Rationale and Policy Issues*

Maintaining the existing season structure of the whiting fishery is intended to accomplish several objectives. One objective is to continue to minimize interactions with salmon and in this way continue to meet ESA requirements over salmon management. The reason for continuing to maintain different start dates for the at sea fishery and the shoreside fishery is that many mothership catcher vessels also deliver to shoreside processors. Having the fisheries timed differently is expected to minimize conflicts between the mothership sector and the shoreside sector over catcher vessel participation in both sectors. By maintaining different start dates for this fishery, catcher vessels can participate in the mothership sector in May and early June, and motherships can expect those vessels to deliver catch without concern that catcher vessels would unexpectedly move to the shoreside sector. The inverse is also true. By maintaining a different start date, shoreside processors do not have to have much concern that catcher vessels will unexpectedly move to the mothership sector.

---

[9] For the nonwhiting fishery there is a potential that a vessel might make a targeted whiting trip by accumulating whiting QPs provided to cover whiting bycatch in the nonwhiting fishery. This could create a problem if it occurred during a time when the whiting fishery is closed to control for impacts on ESA-listed salmon. Other than that, whiting-targeted trips using whiting QP intended for whiting bycatch in the nonwhiting fishery might not create a problem. Restrictions might be imposed on whiting catch in the nonwhiting fishery as needed to address concerns ESA concerns.

[10] The current process for changing the whiting fishery opening dates involves a regulatory amendment developed under the FMP through a framework process. Implementation of an IFQ program should not change this process.

For a management system in which the various whiting sectors would be managed under separate IFQ systems, the Council considered an option that would allow unused whiting QP to be rolled from one sector to another. This option was rejected early on in favor of maintaining the separation among sectors or allowing the market to handle redistribution of whiting QP by managing the fishery as a single sector under IFQs. Under the final preferred alternative, rollover of QP was not a consideration because the at-sea sector is managed with co-ops.

❖ *Interlinked Elements*

Sector management (three versus four sectors) - Under the four-sector option, the directed whiting sectors would be prohibited from delivering whiting when the fishery is closed. Under the three-sector option, QP and cumulative limits would be used for managing shoreside whiting outside the whiting season.

❖ *Analysis*

The existing start date for the at sea portion of the Pacific whiting fishery was established as a mechanism to minimize the take of salmon. Historical information suggests that salmon bycatch is higher in months prior to May. It can be reasonably inferred that changing the start date of the fishery to an earlier period would, therefore, result in more salmon bycatch than would otherwise be the case.

The effect of the existing start date has economic implications in addition to biological implications. The existing timing of the fishery allows participants in the at sea fishery to engage in fishing opportunities before moving to the Bering Sea Pollock fishery or to the shoreside whiting fishery. This allows participants to engage in multiple fishing opportunities throughout the year and generate greater revenues compared to a case where no differentiation in the timing of fishing opportunities existed. While rationalization may make differential season start dates less necessary for those harvesters that desire to participate in multiple fisheries, it still has the effect of minimizing conflicts that may arise between various processors over catcher vessel deliveries and the timing of those deliveries. Since shoreside processors and motherships use many of the same catcher vessels, maintaining a differential start date minimizes the conflict shoreside processors and mothership may have over when those catcher vessels should engage in at sea activity or shoreside activity.

A-1.6 Groundfish Permit Length Endorsements

❖ *Provisions and Options*

Option 1: Length endorsement restrictions on limited entry permits (LEP) endorsed for groundfish gear will not apply for vessels using LE trawl gear. (This action will not change the application of length endorsement restrictions for vessels using LE longline or pot gear).

- **Option 2:** Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained; however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e., length endorsements will not change when a trawl-endorsed permit is transferred to a smaller vessel).

❖ *Rationale and Policy Issues*

Elimination of the groundfish permit length endorsement is being considered because rationalization of the fishery is expected to eliminate the incentives for "capital stuffing" and increasing capacity in the fishery beyond what is necessary to harvest the available catch. In a race for fish fishery where vessels compete with one another for catch, there is a large incentive to increase the capacity and

competitiveness of vessels by increasing speed, hold capacity, equipment capacity, etc., because increasing this type of capacity makes it more likely that a vessel will out-compete other vessels in a fishery and assume a large percentage of the available harvest.

Since rationalization eliminates the need for vessels to compete with one another, it also eliminates the incentive vessel owners and operators have for capital stuffing. The incentives created by rationalization lead toward capital that is able to maximize revenue given the opportunities in the fishery, but this can only be done if the market is able to indicate the correct incentives toward fishery participants. The elimination of the length endorsement is intended to allow fishery participants the ability to optimize their fishing capital relative to their fishing opportunity.

The option of retaining the length endorsement but not requiring that the length endorsement declines if it is transferred to another vessel is intended to accomplish a couple of different factors. Vessels in the trawl fishery are built to specifications that make them consistent with the length endorsement for the permit that is registered to that vessel. Since there are limited numbers of permits that fall under any given size category, the value of many vessels is artificially inflated to some degree. If the length endorsement were to be eliminated, it is possible that vessels that fall under a relatively inefficient size category would become less valuable as vessels of that size category are no longer needed to harvest the resource, and instead the fleet can instead become made up of efficient vessels. Inversely, if the length endorsement is retained, the fleet will continue to be made up of vessels of varying sizes according to the permit length endorsements and, therefore, the fleet must continue to be comprised of some relatively inefficient vessels. The requirement that the fleet continue to be made up of at least some relatively inefficient vessels means that some relatively inefficient vessels will continue to have value.

The option of not requiring that the length endorsement declines if the permit is transferred to a vessel of a smaller size recognizes that a reduction in fleet capacity is accomplished through fleet consolidation in a rationalized fishery rather than through a decline in the size of vessels in the fishery (which may tend to happen if the permit length endorsement declines if traded to a smaller vessel). In other words, the implementation of rationalization allows entities essentially to stack their fishing privileges on to fewer vessels, resulting in fleet consolidation. Under status quo that is not possible.

❖ *Interlinked Elements*

No provisions of Amendment 20 appear to be substantially interlinked with length endorsement.

❖ *Analysis*

Retaining a vessel length endorsement on a LEP is expected to result in some inefficiency. The effect of retaining the length endorsement may very well mean that vessels of an inefficient size category will remain in the fishery, increasing the aggregate cost of harvesting groundfish, and decreasing the economic efficiency of the fleet. If a length endorsement is retained, some permits and associated vessels may have a greater asset value if their associated length endorsement is of the size necessary to prosecute fishing activities efficiently.

However, before drawing conclusions about whether vessels and permits will retain value if the permit length endorsement is relaxed, it is important to view the count of permits in each size category and compare that to the expected amount of fleet consolidation. The following figure illustrates the existing count of LEPs by size category. From this figure it is apparent that nearly 80 permits exist that fall under the "efficient" size category identified by Lian, Weninger, and Singh (2009). When compared to the expected amount of fleet consolidation, it appears that there will be sufficient numbers of permits in the efficient category to handle the number of boats in the fishery. This means that, contrary to some

arguments made for retaining the endorsement, retaining the length endorsement is likely to do very little in terms of retaining the asset value of permits or associated vessels. However, as the number of permits in the efficient category is still somewhat limited, there may still be some small effect of retaining that endorsement. Furthermore, if the efficient vessel size changes over time through technological change, retaining the length endorsement would mean that vessels and permits would retain some additional asset value if the length endorsement is retained.

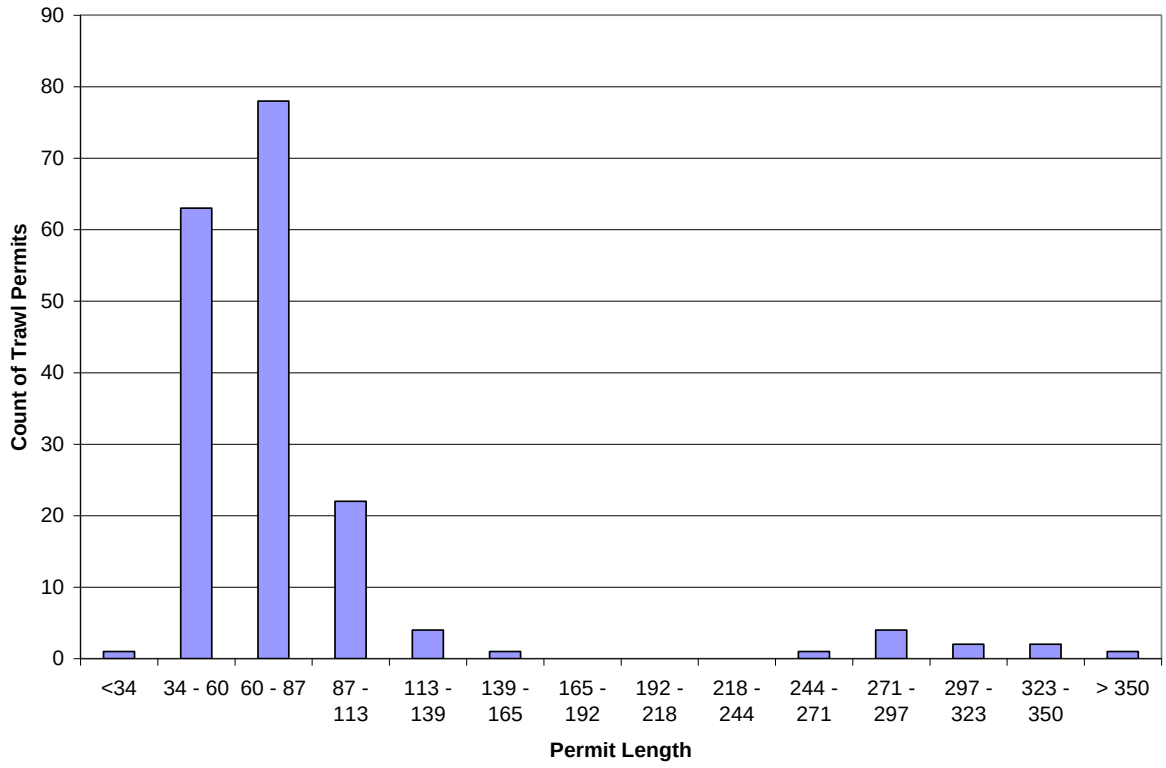

Figure A-3. Count of limited entry trawl permits by size category.

A-2 IFQ SYSTEM DETAILS

A-2.1 Initial Allocation and Direct Reallocation

The Council began its development of the IFQ alternatives under the guidance provided in the MSA as reauthorized by the Sustainable Fishery Act of 1996 and completed the design pursuant to the requirements of the 2006 reauthorization of the MSA. Under the Sustainable Fisheries Act, Councils developing IFQ programs were required to take into account an NRC study (NRC, 1999) on the topic. The NRC recommended that "the councils consider a wide range of initial allocation criteria and allocation mechanisms in designing IFQ program . . . and more broadly consider . . . (1) who should receive initial allocation, including crew, skippers, and other stakeholders (councils should define who are included as stakeholders); (2) how much they should receive; and (3) how much potential recipients should be required to pay for the receipt of initial quota (e.g., auctions, windfall taxes)" (NRC 1999) (pg. 203). Councils should "avoid taking for granted the option of 'gifting' QSs to the present participants in the fishery, just as they should avoid taking for granted that vessel owners should be the only recipients and historical participation the only measure of what each deserves. Councils should consider using auctions, lotteries, or a combination of mechanisms to allocate initial shares of quota" (NRC 1999) (pg. 207). This section covers most of the initial allocation topics raised by the NRC[11] as well as the requirements of the MSA, as reauthorized in 2006 (Table A-12). Specifically, this section covers the following issues related to initial allocation of IFQ as QS:

Eligible Groups

- What groups will be eligible to receive an initial allocation of QS (A-2.1.1.a)?
- How much of the initial allocation will go to each group (A-2.1.1.a)?
- What criteria must be met for membership in each group and how might the attributes that meet those criteria be passed on or accrue to successors in interest (A-2.1.1.b, c, and d)?

Recent Participation

- Should recent activity or membership in the group be required to receive an initial allocation? (A-2.1.2.a, b, and c)

Allocation Formula

- What amounts of QS should be allocated to each of those qualifying for an initial allocation? (A-2.1.3, a, b, c, and d) The following are considered in addressing this allocation question:
    - Should there be an equal allocation element in the allocation formula?
    - Should there be a landing history element in the allocation formula?
    - What time periods should be used for allocation?
    - Should the allocation formula take hardships into account?
    - Should the same credit be received for a given amount of catch, regardless of the year in which it is harvested?

Initial Recipients vs. Eligible to Own

The question "Who should be eligible to receive an initial allocation of IFQ?" is separate from a similar question "Who should be eligible to acquire IFQ after the initial allocation?" The latter question is covered in Section A.2.2.3. The initial allocation does not tell us which groups (permit owners, crew, processors communities or others) will come to hold the quota shares over the long run.

[11] The primary exception is the amount that initial recipients might pay to receive their initial IFQ allocation See Sections A-2.3.2 and A-6 for discussion of issues related to fees and auctions.

- Should overfished species be allocated on basis different from that used for other species?

Exceptional Situations

- With respect to the allocation formulas, how should various exceptional situations be addressed (e.g., credit for EFP landings in excess of trip limits)? (A-2.1.4)

Appeals

- What process should be provided to address disagreements about applications of the provisions and unusual situations that may arise that are not otherwise addressed? (A-2.1.5)

Direct Reallocation and Future Allocation after Initial Issuance

- If after QS is issued direct reallocation appears to be needed to address the redefinition of management units[12] or if there are substantial changes in the status of a species, how would those reallocations be achieved? How would an initial allocation be made for a groundfish species not currently within the scope of the IFQ program? (A-2.1.6)

Policy guidance on allocation actions is provided in the MSA (National Standards and 303A provisions pertaining to LAPPs), the goals and objectives of the Council's groundfish FMP, and those specified for this amendment. Guidance related to initial allocation has been grouped into categories in the summary shown in Table A-12. In the following sections, we will draw on this guidance to focus our evaluation of various initial allocation provisions.

[12] For the IFQ program, a management unit is defined by the species or species group, area, and trawl sector (e.g., shoreside, mothership, or catcher-processor) for which QS is issued.

Table A-13. Policy guidance on allocation decisions from the MSA, as reauthorized in 2007) and Council goals and objectives.

Guidance	Reference
Conservation	MSA - National Standard 4(b)
Allocations reasonably calculated to promote conservation.	
Net Benefits and Efficiency	
Consider efficiency	MSA - National Standard 5
Reduce capacity	MSA - 303A(c)(1)(B)
Attempt to achieve the greatest net economic benefit to the nation	GF FMP Obj 6
Provide for a[n] . . . efficient groundfish fishery.	A-20 Obj 2
Disruption (Efficiency and equity implications). Accomplish change with the least disruption of current domestic fishing practices, marketing procedures, and the environment (NOTE: this objective also has implications for efficiency and net benefits).	GF FMP Obj 15
Excessive Shares (Efficiency and equity implications). Control of excessive shares (including geographic concentration)	MSA - National Standard 4(c) MSA – 303A(c)(5)(B)(ii) MSA – 303A(c)(5)(D) A-20 Constraint 6
Fairness and Equity	MSA - National Standard 4(a) GF FMP Obj 13
Establish procedures to ensure **fair and equitable** initial allocations, including consideration of (i) **current and historical** harvests; (ii) **employment** in the harvesting and processing sectors; (iii) **investments** in, and dependence upon, the fishery; and (iv) the **current and historical participation** of fishing communities;	MSA – 303A(c)(5)(A)
Fishery Participation. Allocate IFQ to persons who **substantially participate** in the fishery	MSA – 303A(c)(5)(E)
Market Power. Avoid provisions where the primary intent is a change in marketing power balance between harvesting and processing sectors.	A-20 Constraint 5
Sector Health	
Provide for a viable, profitable . . . groundfish fishery.	A-20 Obj 2
Promote measurable economic . . . benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.	A-20 Obj 6
Labor: Crew, Processing Plant Workers Etc.	
Include measures to assist, when necessary and appropriate, . . . captains, crew	MSA – 303A(c)(5)(C)
Promote measurable . . . employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.	A-20 Obj 6
Communities	
Consider importance to communities (in order to provide sustained participation and to the extent practicable minimize adverse impacts).	MSA - National Standard 8
Consider promotion of sustained participation by fishery dependent communities.	MSA – 303A(c)(5)(B)(i)
Include measures to assist, when necessary and appropriate, entry level and small fishing communities.	MSA – 303A(c)(5)(C)
Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.	GF FMP Obj 17
Minimize adverse effects from an IFQ program on fishing communities and other fisheries to the extent practical.	A-20 Obj 5
Small Vessels, Small Entities, and New Entrants	
Consider promotion of sustained participation by small owner operators.	MSA – 303A(c)(5)(B)(i)
Include measures to assist, when necessary and appropriate, entry level and small vessel owner-operators	MSA – 303A(c)(5)(C)
Avoid unnecessary adverse impacts on small entities.	GF FMP Obj 16
General Public: Auctions – must be considered	MSA – 303A(d)

A-2.1.1 Eligible Groups

A-2.1.1.a Groups and Initial Split of QS

Eligible Groups

- What groups will be eligible to receive an initial allocation of QS (A-2.1.1.a)?
- How much of the initial allocation will go to each group (A-2.1.1.a)?

❖ Provisions and Options

Eligible Groups The initial allocation of QS will be made either only to permit owners or to permit owners and processors. *Some QS or QP may be set aside to support adaptive management.*

	Nonwhiting Sector QS		Whiting Sector QS	
	Amount to Permits	**Amount to Processors**	**Amount to Permits**	**Amount to Processors**
Option 1	100%	0%	100%	0%
Option 2	87.5%	12.5%	75%	25%
Option 3	75%	25%	50%	50%
Option 4 (10% ***QP*** for Adaptive Management)	100%	0%	100%	0%
Option 5 (10% ***QP*** for Adaptive Management)	75%	25%	50%	50%
Option 6a (10% ***QP*** for Adaptive Management)	80%	20%	80/20 split of whiting 100/0 split for all other species	
Option 6b (10% ***QP*** for Adaptive Management)	80%	20%	80%	20%
	Nonwhiting QS		**Whiting QS**	
	Amount to Permits	**Amount to Processors**	**Amount to Permits**	**Amount to Processors**
►**Option7** (10% ***QS*** for Adaptive Management)	← 90%	0%	80%	20%

Due to limitations on available documentation, fish "receivers" may be used as a proxy for the "processors" (see A-2.1.1.d). After initial allocation, trading will likely result in changes in the distribution of shares among permit owners and processors. Additionally, entities that are neither permit owners nor processors may acquire quota shares (see below: "IFQ/Permit Holding Requirements and IFQ Acquisition").

Rationale and Options Considered, but not Included

The NRC report on IFQ program design (NRC 1999) contained the following recommendations with respect to groups for which an initial allocation of QS might be considered.

NRC Recommendations for Allocation Groups (Other than Vessel Owners)	
Skippers and Crew Allocations	Consider where appropriate. Lack of detailed catch data are not a reason to forgo this option as equal allocation is an option. It may be less appropriate in industrial fisheries that do not involve crewmembers as co-venturers in the same sense as other fisheries.
Processor Allocation	No compelling reason to include or exclude processors from an initial allocation.
Communities	Consider initial allocations of IFQ to communities. Some communities may be heavily dependent on fishing for social, cultural, and economic values and/or are lacking in alternative economic opportunities.
Public	Consider auctions, lotteries or combinations of mechanisms to allocate initial shares. Avoid taking for granted the option of "gifting" IFQ.

With respect to vessel owners, the NRC report notes that they are usually the recipients of initial allocations. Initial allocation to "permit owners," as a group, was not considered in the NRC report. This may have been because the permit owner was considered analogous to the vessel owner. The permit owner generally tends to be the vessel owner, but not always. Since establishment of the groundfish license limitation system, permit owners (not vessel owners) have been the recipient of new LE allocations (the fixed gear sablefish endorsement and fixed gear tier system). Criteria often mentioned in connection with this issue include compensation for those whose asset values are most adversely affected by the new program and minimizing disruption (PFMC, 1998). During scoping, public comments also recommended consideration of allocations to crew and captains, vessel owners, communities, lottery entrants, and auction. Of these, the TIQC recommended that consideration be given to allocation to current owners of LE permits, vessel owners, processors, or combinations thereof, as well auctions. However, in the final set of program alternatives the TIQC recommended to the Council it included only options for allocating to holders of LE permits and processors.

- Consideration of Vessel Owners

The TIQC recommended against allocation to vessel owners rather than permit owners, because once the LEP system was established, everyone understood that the permit represented the access privileges for the fishery and much of the value of the fishery was capitalized into the value of the permit. Thus, permit values will be more directly affected by a change in the nature of the access rights. At the same time, it is recognized that the fleet consolidation will indirectly diminish the value of a vessel, to the degree alternative uses of surplus vessels generate less net revenue for the vessel owners. Splitting the allocation between vessel and permit owner was discussed but considered overly complex.

- Consideration Individual History as an Owner (Personal History)

The TIQC recommended not considering allocation to the owner of a vessel or permit at time of landing (i.e., personal history) because it could result in allocations going to individuals who no longer participated in the fishery and would inhibit entry and exit during the development of the program. Allocation to the current owner of assets in the fishery is a way in which current participation is taken into account.

- Consideration of Skippers Crew

Direct allocation to skippers and crewmembers was discussed and the costs and complexity of identifying vessel workers and determining whether they participated on vessels while those vessels

were fishing in the groundfish trawl fishery were noted. Complexities include the fact that crewmember-licensing requirements vary between states and in some cases crewmembers are not required to have permits. Multiple alternative sources of information would have to be considered in determining crewmember eligibility for an initial allocation.

With respect to relative impacts of an initial QS allocation on different classes of fishery participants, it was noted that for a crewmember dislocated because of the IFQ program there would likely be a greater number of economic alternatives available, as compared to a fishing permit or vessel. Additionally, since crewmembers move between fishing operations, an allocation to crew could reduce the initial allocation available to a harvester in comparison with its recent operation levels, leaving fixed capital assets without significant production opportunities. While harvesters receiving less than their needs would be able to acquire additional QS through purchase, the need to make such purchases would likely mean a greater disruption during initial implementation of the program.

● Consideration of Communities

In the fall of 2005, the Council received a report on potential measures to address community concerns. Included among the measures considered was direct allocation to communities. Among other issues, it was noted that it would be difficult to determine what body within the community might represent that community and receive the initial allocation. For most of the process, communities expressed little if in any interest in receiving an initial allocation; community leaders voiced concern over the administrative costs and political difficulties that would be entailed in managing an allocation of QS to communities and distributing it within the communities. As the Council reached its final decision, some public interest was expressed in creating criteria for community fishing associations (CFAs) and providing CFAs with an initial allocation. The Council is considering a trailing amendment that might create criteria for CFAs (see Section A-9) and provide them with some degree of an exemption from accumulation limits. However, the Council chose not to consider a direct initial allocation of QS to CFAs but instead to rely on the following:

- The QS set-aside for adaptive management as a potential source of quota to address adverse impacts on communities (Section A-3)
- A number of other provisions that are expected to benefit communities

Other measures in the program intended to address community needs (in addition to the QS set aside for adaptive management) include the following:

1. Maintenance of a split between the at-sea and shoreside trawl sectors (options for a single sector had been considered) (Section A-1.3)
2. Specification of a broad class those eligible to acquire QS, including communities (Section A-2.2.3.a)
3. Inclusion of a temporary moratorium on the transfer of QS to ease the adjustment period and allow for adaptive response (Section A-2.2.3.c)
4. Specification of vessel and control limits to spread QS among more owners and potentially more communities. (Section A-2.2.3.e)
5. Inclusion of a community advisory committee as a formal part of the program performance review process (Section A-2.3.4)

Additionally, any community that owns or acquires a permit prior to the initial allocation would be eligible to receive an initial allocation as a permit owner.

Consideration was also given to area management (Section A-1.2) and a landing zone requirement (Section A-8), both of which would have some effect in maintaining a distribution of landings along the coast, but the latter of which would be most directly targeted to maintaining a distribution of landings among communities. A number of other provisions to address community concerns were considered at the November 2005 Council meeting but rejected. Rejected measures included the right of first refusal before QS is transferred out of a community, an owner on board requirement, a partial prohibition on leasing, and redistribution of QS to new entrants, including nonprofit community organization. These rejected measures are discussed further in Section A-11.

- Consideration of Permits and Processors

Many reasons have been given for allocating to permits and allocating to processors. The following tables list some of the reasons that are contained within the records of the Council deliberations.

Table A-14. Some of the reasons given for allocating to permit holders.

Reasons to Allocate to Permit Holders	Reasons Given for Not Allocating All QS to Permit Holders
The management problem to be resolved with IFQs is the management of harvesting not processing.	The problem of managing the harvest is still resolved if some of the QS is given to processors.
It is the harvesters who have become overcapitalized as a result of the management system.	The processing sector is also overcapitalized either as a result of participating in the race for fish or as a result of reductions in harvest.
Compensation for reduced permit value and compensation to those who are squeezed out in the consolidation process.	Long-term compensation should not be given for a short term problem.
The language of the MSA strongly indicates an emphasis on the allocation to harvesters (e.g., National Standard 4). Permit holders are fishery participants that are invested and dependent on the fishery (303A) and have made contributions to the development of the fishery.	Permit holders may not be operating the harvesting business. They may be leasing to the vessels. Further, they are often owned by corporate entities, not the fishermen themselves.
Harvesters cannot operate without QS or QP to support their harvest.	Harvesters can acquire QS/QP through the market and by partnering with processors.
A harvesting operation not receiving an initial allocation of QS/QP will be in a position of greater financial risk than a processing operation without QS/QP.	Processors may be at financial risk if harvesters get all the QS, gain market power, and reduce processor profits.
The allocation of QS to harvesters will correct a current imbalance in market power between the two sectors.	If processors receive no QS as part of the initial allocation, a market power imbalance will be created in favor of harvesters.
There is a greater conservation benefit if the QS is in the hands of the fishermen, including the reduction of bycatch of overfished species. An allocation to fishermen clearly puts responsibility on them.	Permit holders will not necessarily be the fishermen and may lease the QP to harvesters. If the system allows processors to acquire QS then conservation concerns should not be a reason for not giving it to them as part of the initial allocation. Earlier analysis indicated there was not a difference between allocations to harvesters and processors with respect to conservation effects.
If QS is given to processors they will have less incentive to ensure that it is used optimally than if they have to buy it.	Regardless of how they receive it, they will still lose benefits if the QS/QP is not used optimally.
Processors will benefit in other ways and, therefore, do not need that additional compensation. For example, the total volume of product may increase.	Harvesters will also benefit from the increase in total product volume.
The history of development of this program encompasses the identification of a continued harvester overcapacity problem and conception of the buyback program in 1996, the groundfish strategic plan, and the bycatch reduction amendment. The success of this long-term effort requires protection for those established in the fishery in order to increase the economic stability for all.	For stability, harvesters need a stable processing sector to sell to.

Table A-15. Some of the reasons given for allocating to processors.

Reasons to Allocate to Processors	Reasons Given for Not Allocating to Processors
Compensation for stranded capital	Stranded capital will not occur for processors. Long-term compensation should not be given for a short term problem.
Processors are fishery participants that are invested and dependent on the fishery (303A) and have made contributions to the development of the fishery.	National Standard 4 says allocations, when necessary, should be to "fishermen." No precedence for allocating IFQ to processors
Keep balance of market power and flow of product to existing plants	Will create a market power imbalance.
Facilitate communication and coordination of fishing activity between plants and vessels, including management of total harvest, bycatch, and participation among co-ops.	Such communication and coordination occurs under status quo and processors do not need an initial allocation to continue. If processors do not receive an initial allocation they can still participate in co-ops by acquiring QS in the market place.
There is a conservation benefit whether you give QS to permit holders or processors.	Degrades conservation benefit.
Maintain diversity and competition in the processing sector.	The processing sector will be consolidated and new entry will become more difficult.
Processor buy-in is needed to move the program forward.	
Since processing plants are more tied to communities than vessels are, an allocation to processors will stabilize the distribution of harvest across communities.	The major processing companies are active in multiple ports and may move allocations between ports. It is not clear that an allocation to processors will address concerns about geographic redistribution.
If processors do not receive an initial allocation existing working relationships will be disrupted.	Long established relationships between processors and harvesters will continue to exist, there will not be widespread disintegration and relocation of these relationships.
	Consolidation among permit holders not associated with processors will increase, reducing the number of participants in the fishery that are not linked to processors.
	An allocation to processors does not take into account the permit owner's obligation to repay loans from the buyback program. Those loans bought up permits representing nearly 50% of the fleets landing history.
	There is not a large disadvantage to processors if they do not receive an initial allocation.
	An initial allocation to processors may lead to greater than desirable consolidation, particularly if there is a grandfather clause.
	The processing sector as a whole, will receive some allocation because they hold permits.

An option to allocate nonwhiting groundfish evenly between permit owners and processors (50 percent each) was rejected. The following is the rationale provided by the TIQC and Groundfish Allocation Committee (GAC) in its recommendations for removal of this option.

Rationale for removing the 50/50 option for nonwhiting groundfish:

- TIQC members raised concern that with a 50 percent allocation to processors, the quota initially allocated to a trawl permit may not be enough to allow for fishing. One TIQC member opposed to removal of the 50 percent allocation option noted that analysis of impacts has not been completed and so the suggested impacts are only assumed (2/2007 TIQC meeting).

- The majority of GAC members believed that a 50 percent initial allocation to processors would create an imbalance of power. They cited as examples the lack of power that vessel owners have had in negotiating crab prices and the potential for the number of alternative buyers to be more restricted within smaller geographic regions than it is coast wide. GAC members also noted concern that the initial allocation would only be the starting point with respect to the amount of shares controlled by processors and that they would expect processors to acquire additional shares, subject to accumulation limits. Some processor/permit owners may also receive shares for both their processing activity and permits they own. In general, there was a perception that there is a current imbalance in favor of the processors and that a 100 percent allocation to harvesters would not create an imbalance in favor of harvesters. On that basis, they recommended that the analyzed range be narrowed by reducing the maximum amount that might be allocated to processors while maintaining the option of a 100 percent allocation to permit holders. A minority of GAC members wanted to see the analysis of a 50/50 split before making a decision. It was noted that analysis has not yet been produced to demonstrate that an imbalance would result from a 50/50 initial allocation, though question arose as to the extent that a quantitative analysis could provide insight on this issue (12/2006 GAC meeting).
- During discussion, concern was also expressed that vessels fishing IFQ provided by processors might not have the same incentive to minimize bycatch as it would for its own IFQ. Others countered that the processor and vessel would both have incentive to minimize bycatch in order to maximize their ability to harvest and process target species (12/2006 GAC meeting).

Initial rationale for including a 50/50 option:

- Part of the original rationale for the 50/50 option, when the TIQC developed it, was that it was the closest legal alternative to a two-pie system.

Rationale for the Council's final decision on the allocation split between permit owners and processors:

During Council discussion it was noted that the MSA LAPP provisions in Section 303A(5) require that the Council ensure fair and equitable initial allocations, including consideration of (1) current and historic harvests, (2) employment in the harvesting and processing sectors, (3) investments in and dependence on the fishery, and (4) the current and historical participation of fishing communities. Congress specifically instructed that the Council fully analyze alternative program designs, including the allocation of limited access privileges (LAPs) to harvest fish to fishermen and processors. Much of the Council's discussion about an allocation to processors revolved around the impact of both status quo and trawl rationalization on market power. It was noted that the U.S. economy relies on competition and on individuals and businesses acting in their own self-interest for growth, innovation, price setting, and the allocation of resources. There was a sentiment that government should not interfere in business competition unless it is necessary for the public benefit. It was noted that the Council interferes with harvesting businesses because of problems identified relative to conservation and management both in the nonwhiting and whiting fishery. When the Council intervenes in harvesting, it cannot help but also interfere with the processing businesses by changing the basic bargaining dynamics in the raw fish product market. While ex-vessel price negotiations have to be left to the harvesters and processors, the Council felt it could not ignore how fishery management actions might influence those negotiations. Some Council members opposed any allocation to processors because they believed it would have an adverse effect on market power (increasing market power for processors) and that there were ways to address concerns about community stability, other than by allocating to processors. They noted that even if processors received no QS, after initial allocation processors would likely be in a position to acquire additional shares and achieve the balance of power they want. The real issue of concern in this

regard may be the control limits, to make sure the balance does not get out of hand. Others were concerned about small processors and expressed concern that not to allocate to processors might cause more consolidation and a further decline in the number of buyers, increasing the power of remaining processors. In its PPA, the Council recommended giving processors 20 percent of the shoreside allocation of QS for all species except bycatch taken in the shoreside whiting fishery. Council members noted the difficulty of determining the correct percentage for a possible QS allocation to processors. The option for a 50 percent allocation of whiting QS to processors seemed like far too much. When a 20 percent option was proposed, some Council members felt that when the 20 percent allocation to processors was combined with a 10 percent allocation for adaptive management, and considering that some processors would receive QS for the permits they hold, the amount remaining for harvesters would be insufficient. In selecting its PPA Council members noted that the case for providing QS to whiting processors seemed to be relatively clear but it was less clear for nonwhiting processors. For whiting processors, the switch from a derby fishery would immediately result in some of the processing capacity becoming surplus. The shift from two-month cumulative limits to IFQs would not affect the nonwhiting processors in the same way. However, with respect to nonwhiting processors there was concern for small processors' ability to compete with larger processors. The 20 percent approach chosen for the PPA was believed by some to be a fair middle ground for public review and comment.

In its final preferred alternative, after further review of the analysis and public testimony, the Council recommended giving processors 20 percent of the QS only for shoreside whiting and no QS for shoreside nonwhiting. In taking this action, Council members expressed their concern that an initial allocation of QS to nonwhiting processors would add too much to the market power of shoreside nonwhiting processors. They noted that there was already considerable consolidation among processors, particularly relative to the number of vessels operating in the fishery. Providing processors with an initial allocation would be expected to further increase consolidation and market power. Additionally, the argument that the larger processors also held vessel permits that would provide them with QS held more sway. At the same time, Council members continued to be concerned with the impact of the program on smaller processors. It was noted that if an allocation of nonwhiting QS to processors were to be made, that the appropriate amount might be 10 percent of the QS. Instead, the Council favored providing a 10 percent allocation for adaptive management. The adaptive management program (AMP) could be used not only to provide some amount of certainty and security to the larger processors, but also to provide flexibility to tailor a program that would provide some protection to smaller processors. In making its decision, the Council specified its intent that the AMP be constructed in a manner to ensure that the program accomplishes this as one of its objectives.

With respect to the decision to allocate 20 percent of the whiting QS to processors, differing conditions between the whiting and nonwhiting sectors were noted. In particular it was noted that the size of the shoreside whiting fleet was expected to be very small (only 20 vessels), providing the fleet with greater market power relative to the three major whiting buyers than would be experienced by the nonwhiting fleet relative to the major buyers of nonwhiting species. While the shoreside whiting fleet position would be strong, the analysis predicted that, with the move from a whiting derby fishery to an IFQ program, the amount of processing capital needed in the whiting fishery would decline by 30 to 50 percent,[13] and that competition among whiting processors would tend to increase in order to continue to attract deliveries to their facilities, leading to a decrease in their market power. In contrast to whiting, the nonwhiting trawl fishery is not a derby style system; it is managed with two-month cumulative trip limits. Therefore, the shift to IFQs will not create a sudden increase in the amount of excess processing capacity. Even with a 20 percent allocation of whiting QS to processors, the Council believed it may be uncertain whether the initial allocation of whiting QS to processors will offset whiting harvester gains in

[13] Processors invest in excess capacity to compete with other processors for deliveries by being able to handle peak volumes during the derby fishery. When the derby is over, much of the capital then remains idle. The move to an IFQ program will slow the pace of the fishery resulting in substantial unneeded processor capital.

market power, relative to status quo. An initial allocation of whiting QS to processors functions as a means of guaranteeing supply for processors, granting processors some leverage in bargaining power as they can "hold out" against harvesters, and providing an incentive to make necessary capital investments to increase product recovery yield.

- Option 6a and 7 (FPA) for Whiting

At its June 2008 meeting, the Council added an option that would allocate QS for whiting to processors but not QS for bycatch species in the whiting fishery. This option provides another variation on the initial allocation balance between harvesters and permits and provides a different result with respect to the distribution of wealth and control generated by the initial allocation. Because this variation was added late in the process, it is analyzed separately at the end of the analysis section (page A-107).

- Allocation of QS or QP for the Adaptive Management Program

At its November 2008 meeting, the Council decided that, rather making an allocation of IFQ for adaptive management by setting aside QP, it would set aside an amount of QS, thus creating Option 7 for the eligible groups provision. While QS is set aside for adaptive management, the associated QP for the program may distributed among those holding non-set-aside QS in proportion to their QS holdings (i.e., a pass-through). For at least the first two years of the program, all QP associated with the set-aside for adaptive management will be passed through to those holding non-set-aside QS. Allocating IFQ for adaptive management in the form of QS rather than QP was believed to provide more of an opportunity to make multi-year commitments of adaptive management quo and to increase the assurance that the use of the adaptive management quota will not be usurped for other purposes.

When the Council specified Option 7, it also indicated that the 10 percent set-aside would apply for all nonwhiting species. Since the shoreside nonwhiting and whiting sectors are to be managed as a single shoreside sector, this meant that 10 percent of the nonwhiting species that would otherwise go for bycatch for whiting vessels would be allocated for the AMP that is focused primarily on the nonwhiting fishery. The 10 percent reduction in the initial QS allocation to whiting vessels to cover their bycatch needs would likely be covered by the equal allocation component of the allocation formula (except with respect to overfished species).

❖ *Interlinked Elements*

The following elements of the IFQ program interact with the decision on groups to which an allocation will be made.

- Number of Trawl Sectors (Section A-1.3)

The Council's preferred alternative combines the shoreside whiting and nonwhiting harvest into a single sector. Creating a single shoreside sector has implications for the effects of Option 6a, which would not allocate bycatch species for whiting history to processors. With a single shoreside sector, processors receiving a whiting allocation will have a larger market to go to if they want to acquire QS for the bycatch species needed to harvest whiting.

- Moratorium on Trading (Section A-2.2.3.c)

At the start of the program, the Council's preferred alternative will include a two-year moratorium on QS trading. This moratorium will make it more difficult for processors receiving only whiting (Option 6a) to adjust by either acquiring the needed bycatch species QS or divesting themselves of whiting.

Until they are able to balance their whiting QS holdings with bycatch species, in years when bycatch species limit whiting harvest, they may find themselves with whiting QPs that have little value.

● Grandfather Clause Exemption for Everyone (Section A-2.2.3.e)

There are four options:

- To provide a full grandfather clause exemption, allowing those who would qualify for an initial allocation of QS in excess of the accumulation limits to keep that allocation (Grandfather Clause Option 1).
- To provide an grandfather exemption for up to twice the vessel accumulation limits. Any QS over twice the limit would be redistributed to the remainder of the initial recipients (Grandfather Clause Option 2).
- To provide no grandfather exemption. Any QS over twice the limit would be redistributed to the remainder of the initial recipients (Grandfather Clause Option 3).
- To provide no grandfather exemption but allow those qualifying for an initial allocation of QS in excess of accumulation limits a period to divest themselves of those QS (Grandfather Clause Option 4).

Depending on which of these grandfather clause options is implemented, the initial allocation results may be substantially altered. The balance of allocation between harvesters and processors will not be affected but the distribution between larger and smaller entities will be affected. In general, the amounts of QS allocated to larger producers will likely be less than the shares of harvest the larger producers have taken historically. If larger harvesters have been producing at levels above those facilitated by accumulation limits then their only opportunity to have a chance to stay close to those levels would be through the grandfather clause, such as that provided in Grandfather Clause Options 1 and 2 (and Option 4 on a temporary basis). As the amount of allocation that goes to processors increases, the initial allocations going to harvesters will decline reducing the effectiveness of the grandfather clause in allowing the continuation of larger harvest operations. The degree to which increasing the allocation to processors diminishes the effectiveness of the grandfather clause for harvesters will depend on where accumulation limits are set. For processors, the accumulation limits and initial allocations will not constrain production. Higher accumulation limits would reduce the impact of the presence or absence of a grandfather clause and the interaction with the decision on the initial QS split among groups.

● Additional Measures for Processors (Sections A-2.4 and A-3)

The key decision for eligible groups and initial split (A-2.1.1.a) is whether or not processors will receive an initial allocation of IFQ and if so how much. The following elements are contingent on initial allocation of QS to processors to address concerns about adverse impacts of IFQ program on processors. While addressing this impact, these options would issue QS to processors that differs in character or is for a different duration than the QS issued to LE permit holders.

A-2.4. Additional Measures for Processors. There are options in Section A-2.4, all of which are interlinked with the options of Section A-2.2.1. The options are not mutually exclusive.

Option 1 (Limited Duration QS): QS issued to processors based on buying history will expire after a certain period (to be determined as part of final Council action). When they expire, all remaining QS would be increased proportionally to sum to 100 percent. The rationale for this provision is based on the idea that, if an initial allocation to processors is intended to provide an adjustment period and compensate processors for potential harm, this intent can be fulfilled by issuing QS that has shorter duration than those issued based on harvesting history.

Option 2 (No Grandfather Clause for Processing History): Any QS issued for processing history would not be subject to the accumulation limit grandfather clause (i.e., processors would be

held to the accumulation limits except with respect to landing history issued for any LE permits held by the processor). The rationale for this provision is that processors need not be grandfathered in above accumulation limits in order to receive sufficient compensation for adverse impacts of the IFQ program.

Option 3 (Adaptive Management Program Modification): The AMP will be used to compensate processors for demonstrated harm by providing them witH QP. This provision provides processors relief one year at a time only after harm has been demonstrated.

A-3. Adaptive Management. Under the AMP (without the modification specified in A-2.4 Option 3), 10 percent of the QS would be eligible for use to benefit processor stability, among other objectives.

❖ *Analysis*

The following are the key questions to be covered in this section of the analysis.

1. How does the initial allocation affect who holds the QS over the long term?
2. How does who holds the QS at any point in time affect achievement of goals and objectives, including market power and equity effects related to who receives the initial financial benefit (wealth) from the initial allocation?

The answer to the first question determines the duration and timing of the effects covered under the second question. The sections in which each of the goals and objectives will be discussed are identified in the following table. The section on the effect of the QS allocation on the long-term distribution is extensive and covers topics of relative efficiency, vertical integration, market power, and access to capital. For that reason, a full analysis of that issue is provided in a separate appendix (Appendix E), and a summary is provided here.

Impact of QS Allocation on Long Term Distribution	A-48 -A-56	X	X	X	X	X	X	X	X	X	
Impact on Conservation (Resource Stewardship)	A-57	X									
Impact on Sector Health											
Buyers/Processors	A-60			X			X			X	
Harvester Sector—Permits	A-74			X			X				
Harvester Sector—Vessels	A-92			X			X			X	
Labor—Harvester	A-93							X			
Labor—Processors	A-93							X			
Impact on Net Benefits	A-96		X								X
Impact on Equity	A-104				X	X					

Note: The general public is affected by many if not all of these impacts. For example, reduced net benefits have an effect on the general public, but indirectly though the effect on the economy. Here the emphasis is on the direct effect (e.g., paying for administrative costs related to allocation).

Table A-15 provides an explanation of some of the economic terms that are used in this analysis.

Table A-16. Explanation of Terminology: return on investment, profits, and rents.

General Term and Description of the Concept	Economic Term
Return on Investment: Profit that goes to compensation for capital investment (to compensate the owners of capital). For industries that involve greater risk, greater return is required to compensate or attract capital investment. If the industry profit level is not enough to compensate capital, there will not be new investment.	Quasi Rents
Relative Efficiency Profits: Profits earned by firms that are more efficient than others.	Intramarginal Rents
"Reasonable" Profit Level: Income necessary to pay for all labor, supplies, capital, and entrepreneurial expertise used by a firm at going market prices. This includes compensation for capital (quasi rents).	Normal Profits (Zero Economic Rent or Zero Economic Profit)
Extra Profits (Abnormal Profits): Any earnings above normal profits are considered "economic profits" or "economic rents." Economic profits or rents attract new entrants.	Economic Rents (Above Normal Profits)
Value/Cost of the Resource: Amount paid for the use of a raw resource. In open access fisheries management, no one pays for access to the resource; what might otherwise be paid for fishing privileges shows up as extra profit. The extra profit attracts new entrants until efficiency decreases to the point that only normal or less than normal profits are earned. What would have been paid for the resource goes instead to excess capacity.	Resource Rents

Key Findings

1. The initial allocation may have a substantial effect on how the QS is distributed over time (with initial recipients being more likely to accumulate additional QS, up to accumulation limits).
2. Market conditions under rationalization will vary from status quo thus changing the market power dynamics.

Under status quo, the following occur:

- Harvesters and processors negotiate with one another in an attempt to capture the profits that are associated with the resource (resource rents).
- Harvesters, and possibly processors, are overcapitalized, putting them in a position where they are willing to accept unsustainable prices over the shorter term, giving up some of their returns to capital in order to continue operation (operating at a long-term loss).

Under a rationalized system, the following occur:

- Profits that are associated with resource rents will be captured by whoever owns the QS/QP,
- Rationalization will result in more appropriate levels of capitalization and substantially reduce a business' willingness to accept unsustainable prices (operate at less than normal profit levels).
- Under such circumstances and assuming well functioning markets, holding the QS/QP does not give any additional leverage in determining price for the raw product. [If a harvester holds the QS/QP, it would be expected to receive a payment for its fish that reflects a normal profit level and may receive, as part of that transaction, an additional amount reflecting the value of the QS/QP. If a processor holds the QS/QP, the harvester would be expected to receive a payment for its fish that reflects a normal profit level and no more or less.]

However, the result for the rationalized system may change to the degree to which there are other nonrationalized fisheries with surplus capital that is readily adaptable to the West Coast groundfish trawl fishery. Under such circumstances, more of a status quo situation may hold, one in which harvesters (for example) are willing to deliver to a processor witH QP at a price that gives them lower than normal returns, giving up some of their returns to capital. The ability of the competing harvesters to enter depends on the surplus LEPs that are expected to be available after fleet consolidations.

Without such a surplus, there would not be an opportunity for surplus vessels from nonrationalized fisheries to enter the West Coast groundfish fishery.

Before discussing how the initial allocation affects distribution over the long term and the impacts resulting from allocation of QS to different groups, it is useful to have a brief discussion about the entities composing those groups.

● Who: Nature of the Entities and Group Membership

As we consider the groups to which allocations are made, we should take into account that some entities may qualify as members of a variety of groups. For example, when we talk about vessel owners or permit owners, they may also be processors. People have a variety of roles in the harvesting and buying sectors including the following.

- Permit ownerVessel owner
- Vessel operatorCrewmember
- Fish buyerFish buyer/processor
- Fish buyer/processor employee

Individual or business entities may combine a mix of roles to create a business or income earning strategy. As summarized below, these strategies vary in profit generation and risk exposure. Specific criteria for membership in the groups to which allocations might be made are described in Section A-2.1.1.b and c.

● Summary of the Impact of QS Allocation on Long-term QS Distribution

Appendix E contains a detailed analysis of the relationship between the initial and long-term distribution of QS among groups. The results are summarized here. The main dynamic driving the long-term distribution is that more profitable entities are more likely to acquire the QS than less profitable entities; and initial recipients of QS are likely to have a period of greater profitability than those who do not receive QS or receive less QS. This initial advantage may, to some degree, be self-perpetuating. In considering relative profitability, both the total financial profits and the level of risk must also be taken into account. This analysis examines a firm's financial profitability as it is affected by the following factors:

- The firms relative operating efficiency (what it costs to produce)
- The firms vertical integration (which affects both operating efficiency and market power)
- The firm's ability to exert market power to capture above normal profits (what it earns)
- the firms cost to access to capital (what it costs to acquire capital)

Market power is defined as the ability to influence prices in order to obtain above normal profits for a sustained period. Exerting market power requires the existence of barriers to entry. Within the framework of these considerations, Table A-16 on page A-56 provides this section's main conclusions on the following:

- Status quo conditions
- The influences of the IFQ program on QS distribution (regardless of the initial allocation)
- The effect of initial allocation on the long-term distribution of QS

♦ *Summary of the Analysis in Appendix E*

The main points made in each section of Appendix E that support the conclusions in Table A-16 are presented below.

RAW FISH MARKETS AND RESOURCE RENT DISSIPATION OR CAPTURE UNDER STATUS QUO

(Section E.2)

This section describes how prices and quantities produced are determined in a typical market. The main points are as follows:

1. The yield constraint in fisheries (usually an OY or allocation) results in a gap between the minimum price harvesters are willing to fish for and the maximum price that processors are willing to pay.
2. The gap between these two values is the potential resource rents (amounts that could be collected for use of the resource).
3. Both sides will try to use bargaining power to capture a portion of those rents.
4. Instead of being captured, the competition to harvest more fish increases costs; money that could have been paid for the resource is instead committed to the harvest operations (and in some cases the processor operations). However, this result requires that the raw fish market be competitive (both buyers and sellers accept a going market price with little deviation based on negotiations, such that neither side exerts market power).
5. If participants on one or both sides of the market are able to exert some market power,[14] competition is reduced, and some resource rents may be saved from dissipation and preserved as private profit.

QP MARKETS AND INTERACTION WITH RAW FISH MARKETS

(Section E3)

The following assume a competitively functioning market, except as noted:

1. Under an IFQ program, the QP will represent an additional key input. The need to hold QP becomes an additional cost of providing the raw fish.
2. Costs of production, excluding the cost of the QP, are expected to decline by an amount that will be offset by the price of the QP.
3. In most circumstances, the QP holder is expected to capture the difference between the minimum price for which harvesters are willing to fish (excluding the cost of the QP) and the maximum that processors are willing to pay, i.e., the resource rents.
4. The reported transaction price for raw fish costs (reported ex-vessel value) will depend on who provides the QP for the transaction and the terms under which they are provided (e.g., a processor might provide the QP to a vessel at no charge, and the reported price will be the minimum price for raw fish the vessel is willing to accept (its costs plus a normal return of profit), or the vessel might provide the QP, and the price will include an amount that covers the vessels costs, as well as normal profit for the vessel, and the cost of the QP.
5. With respect to the QP owner's ability to exert market power,

[14] Note that for item 3 the term "bargaining power" was used rather than market power. Bargaining power is a short term concept. It may enable a firm to establish an above normal price. Marketing power requires that the above normal price be sustainable. Unless there is a barrier to entry, the higher price established through bargaining power will be dissipated as high profits invite competition.

a. Assuming a fully rationalized fishery, the QP holder will only be able to exert market power to the degree that there are not enough independent harvesters and processors in the market to establish effective going market prices for raw fish (to the degree that markets are not sufficiently competitive). However, even if such prices are established, inevitably, there will be opportunity to express some market power due to transaction costs such as convenience and search times or the linkage of groundfish with other fisheries (i.e., because of costs associated with finding a new buyer or seller, even in a competitive situation there may be some room for price negotiation). Ability to use market power to leverage higher prices will be limited by the fluidity of the QP and raw fish markets.
b. It will likely be difficult for a QP holder to increase the profits associated with its QP holdings through the use of market power to achieve QP prices substantially above those that reflect the value of the resource (resource rents). This is because, in the absence of overcapitalization (for the sector as a whole or within a locally isolated market), harvesters and processors will be unwilling to take prices that do not allow them to cover costs and normal returns on investment. It is the prices the harvesters and processors are willing to accept that determine the value of the QP (the potential resource rents). For example, if harvesters hold all the QP, they collect all of the resource rents but are not in a strong position to extract additional profits from processors, except possibly during the transition period during which the processors are overcapitalized. The same would be true if the processors held all the QP, assuming that the harvesting side is rationalized and not overcapitalized. However, surplus LEPs and the potential for excess capital in nonrationalized fisheries to seek employment in the West Coast groundfish fishery may provide an opportunity for processors witH QP to exert market power due to the availability of alternative harvesters, forcing harvesters to accept lower than normal returns.
c. Once the QS have been bought and sold at prices based on expected profits then, like the harvesters and processors, the QS holders offering QP for sale will have a price they must receive to compensate them for their investment in the QS purchase. Under such circumstances and assuming no excess capacity and competitive markets, no party to the transaction should be able to exert more market power during negotiations than is seen in any other competitively functioning sector of the economy.

QS FLOW AMONG GROUPS (INDEPENDENT OF THE INITIAL ALLOCATION)

(Section E.4)

In this section, we look at dynamics affecting the flow of QS among groups independent of the initial distribution. These dynamics affect the flow of QS through their impact on willingness and ability to pay for the QS (the center box in Figure A-4.) Topics addressed are as follows:

- Relative efficiency
- Vertical integration
- Market power
- Access to capital

These topics are represented by the hexagons in Figure A-4. Factors to be considered for each of these topics are provided in the related squares, and each square is accompanied by a note box indicating the nature of the dynamic or affect.

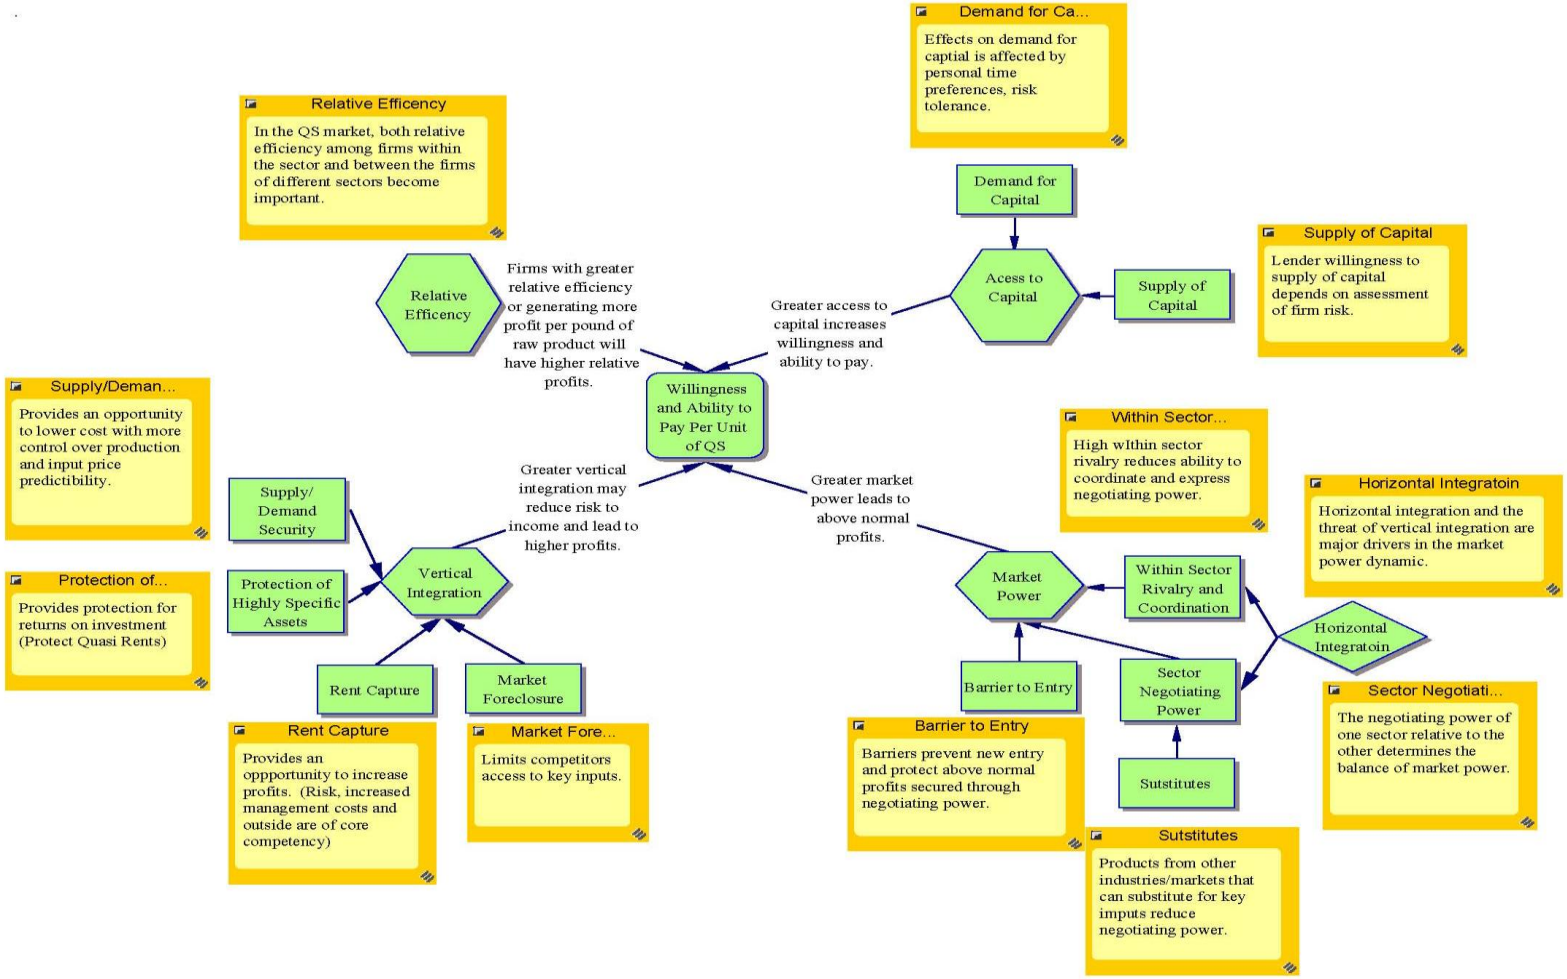

Figure A-4. Factors influencing QS flow among groups.

Relative Efficiency

(Section E.4.1)

This section of Appendix E explains the concept of relative efficiency within a sector with respect to profits per unit of raw product. Key points are as follows:

1. Those firms with greater relative efficiency are more likely to acquire QS over the long term.
2. There may be overcapitalization in both the harvesting and processing sectors, and the possibility that over the short term, IFQ management may provide more mechanisms for harvesters to increase efficiency than processors.
3. Firms with identical efficiency could have substantially different levels or profit per unit of raw product. A firm that generates more profit (including returns to capital) than another for the same amount of raw product will be more likely to accumulate QS. These differences may occur within a sector or across sectors. If harvesters tend to have the same efficiency per unit of raw product as processors but generate more profit per unit of raw fish, they will be willing to pay more for QS and will likely accumulate it over time, or vice versa.

Vertical Integration, Return on Investment (Quasi Rents), and Above Normal Profits (Economic Rents)

(Section E.4.2)

1. Under status quo, most vertical integration occurs through processor ownership of vessels and/or permits. There has been relatively little harvester participation in ownership of processors, though some has recently developed in the at-sea mothership fishery, and catcher-processing vessels are by definition vertically integrated.
2. The IFQ program provides processors a new opportunity to vertically integrate by acquiring QS, but acquisition of QS does not provide harvesters an opportunity to control processing operations. Therefore, vertical integration by harvesters is discussed under the section on market power.
3. There are a number of reasons to expect processor vertical integration, including supply security, profit protection, and capture and expansion of market share by preventing competitors from accessing a key input (raw fish), i.e., foreclosing competitor access.
4. Typically, vertical integration also involves certain management expenses and additional risks. QS provides an opportunity to exert control over harvesting operations at substantially less management expanse and risk than entailed in vessel ownership.
5. Firms that are already vertically integrated through ownership or control of vessels will have more profits per unit of raw product to protect with QS than firms that are not vertically integrated, and will, therefore, be more likely to accumulate QS over time.
6. Not applicable to the FPA (the FPA does not place a control limit on QP): If there were a control limit on QP, the opportunity for individual processors to vertically integrate would be limited by the control limits. If there is no grandfather clause provision for QP control limits, some processors could have found themselves in a position of needing to divest themselves of vessels in order to stay within the limits.
7. The opportunity for the sector as a whole to vertically integrate through acquisition of QS will depend on the total number of active processors and the accumulation limits. For example, with a 10 percent control limit on a particular species, if there were 10 large processors, all QS for that species could be controlled by processors (as would be the case if 10 harvesting companies controlled all the vessels).

Market Power, Horizontal Integration, and Consolidation

(Section E.4.3)

As a reminder, in this section of Appendix E we evaluate effects of the IFQ program on market power **independent of the effects of the initial QS allocation.** Using this approach we can then focus on the initial allocations incremental effect on market power separately from the effect of creating the IFQ program.

1. If a firm or sector is able to exert market power, it will be more willing and able to pay for QS. Exertion of market power implies markets are less competitive.
2. An adaptation of a widely used market power model (the Porter 5 Forces Model) specifies criteria for evaluating the following factors:
    a. Rivalry and coordination within a sector (Forces 1 and 2: situations for selling sector and buying sector)
    b. Relative bargaining power across sectors (between harvesters and processors, including the threat of substitutes)[15] (Forces 3 and 4: relative bargaining power and substitutes)
    c. Barriers to entry (Force 5)
3. Rivalry and coordination. The more rivalry there is within a sector, the more difficult it will be for members of the sector to exert market power. Ten criteria are used for this evaluation, including concentration of production within the sector and the presence of an active industry shakeout process.
    a. Under status quo, there are many reasons to expect high rivalry for both harvesters and processors. However, license limitation may constrain high rivalry among harvesters. For processors, previous industry shakeouts, the small number of firms handling most of the product, and the threat of the effects of another shakeout may reduce rivalry.
    b. Under IFQs, a shakeout among **harvesters** is expected, followed by a period of reduced rivalry with fewer total participants. The need to acquire QP may stimulate rivalry in the QS/QP market, but higher costs (e.g., observer costs) may stimulate cooperation among harvesters in their negotiations with processors over raw fish prices. Local markets will become more closely linked by the ease of transfer of QP across geographic distances. For **processors**, the low cost of moving QS/QP across geographic areas and the link between the QS/QP and raw fish markets will increase competition by decreasing the geographic isolation of local markets for raw fish. This will expand the number of processors that effectively have a role in competition for a particular harvest commitment (prior to catch). Rivalry may increase if processors attempt additional consolidation as a means of defending against the possible exercise of harvester market share. Rivalry will also increase because the expansion by any processor will require the direct and immediate contraction of processing by another processor (as compared to the current lag, which occurs as an expansion by a particular processor works itself out in the bimonthly trip limit based management system and marketplace).
4. Bargaining Power. Bargaining power of one sector with respect to another is an important element of market power. There are seven criteria for evaluating bargaining

[15] The 5 forces model separates the bargaining power of each side and the threat of substitutes into three separate market forces.

power (including ability to threaten vertical integration and ability to switch to a different processor or different harvester.

a. Under status quo, nearly all of the criteria favor processors.
b. Under IFQs, **harvester** bargaining power may increase. Harvesters with QS cooperate and use it to support their own processing facility or encourage a new entrant. Consolidation will leave fewer harvesters for processors to deal with. **Processor** bargaining power may increase or decrease. Processors may be able to vertically integrate at a lower cost than under status quo.[16] Liquidity of QP will expand the geographic area from which buyers with an interest in a potential QP/raw-fish sale may be drawn. This will increase the number of potential participants in the transaction, encouraging development of a market that functions well enough to establish "going prices," thereby reducing bargaining power. However, it may also increase pressure for further consolidation. This within-sector consolidation may be hampered by QS control limits, but pressures for consolidation may be strong enough for it to occur in spite of the control limits.

5. Barriers to entry are necessary to preserve any market power advantage that is achieved. Five criteria were used to evaluate barriers to entry, including government regulation and economies of scale.
    a. Under status quo, license limitation provides the barrier for harvesters and economies of scale may create barriers for processors.
    b. Under IFQs, the entry barrier for **harvesters** will be greater because of greater fixed costs related to compliance with program regulations and the need to acquire QS or access to QP to reach efficient scales of production. There may also be an increase in the entry barriers for **processors.** The increase in compliance costs for processors is likely to be relatively small compared to harvesters. If some processors experience higher profitability through receipt of an initial allocation of QS, their costs will be lower than later entrants who would have to buy QS to attain a similar level vertical integration and the associated advantages.

Access to Capital (Demand) – Discount Rates

(Section E.4.4)

1. The price of QS represents the present value of a stream of current profits.
2. Individuals who place a relatively high value on current income (as compared to future income) have what is called "high time preferences" and will not be willing to pay as much for QS as those with "low time preferences" (those who are relatively indifferent between receiving income now or in some future period).
    a. There are indications that fishermen may have high time preferences relative to others.
    b. Those with relatively low incomes also tend to have high time preferences. Crewmembers may fall into this category.

   If those in the harvest sector have higher time preferences than processors, then this factor may influence the flow of QS toward processors, regardless of the initial allocation.

[16] Under an option in which control limits apply to QP (not the FPA), vertical integration for larger processors would be limited by accumulation limits. Some larger firms may have had to reduce existing levels of vertical integration (depending on accumulation limit rules).

Access to Capital (Demand – Planning Horizon and Investment Recovery)

(Section E.4.5)

The length of time over which one anticipates receiving a benefit will also affect how much one is willing to pay for QS. However, the opportunity to sell the QS and fish-related businesses at the end of a personal planning horizon diminishes the importance of the planning horizon, with certain exceptions; for example, the QS owner who has special skills enabling him/her to generate levels of profit that subsequent owners are unlikely to anticipate will find it difficult to capture the profits associated with those special skills when he/she sells his/her QS. On this basis, we would expect QS to flow toward those with higher than normally expected skills or profitability and a longer planning horizon than similar individuals with shorter planning horizons. At the same time, those with higher skill levels may be tempted to remain in the fishery longer because of their inability to sell the QS for an amount that reflects their potential earnings over a longer period.

Access to Capital (Supply)

(Section E.4.6)

1. In determining risk, lender considerations include size of the firm, its diversification, assets that may be used as security, and the value of those assets outside the industry in which the firm participates. The cost of loans is lower for entities with lower risk profiles.
2. Harvesting firms tend to be smaller than processing firms, and less of the capital may be useful in other sectors, making it more expensive for harvesters to access capital as compared to processors (on average).
3. The IFQ program will decrease the risk profile for harvesters that remain after consolidation.
4. If it is anticipated that harvesters will be able to exert market power, there may be a perceived increase in risk to processor profits. There also may be a transition period during which processor profits are reduced prior to the exit of excess processing capital from the industry.
5. Harvesters and processors that acquire QS are likely to reduce risk and the cost of their access to capital as compared to firms that do not have QS.
6. A harvester without QS will be viewed as a substantially greater financial risk than a processor without QS because harvesters without QS cannot catch fish, while processors without QS are still able to buy.

SUMMARY AND EFFECT OF THE INITIAL ALLOCATION

(Section E.5)

Table A-16 summarizes the conditions for the harvesting and processing sectors with respect to each of the four major influences on willingness and ability to pay for QS. The first column provides the conditions under status quo and the second the expected influence of the IFQ program, as described above. The third column summarizes the effect of the initial allocation on the long-term

Table A-17. Summary of influences of the IFQ program and the initial allocation on the flow of QS with a focus on the harvesting and processing sectors.

	Status Quo	IFQ Program	Initial Allocation
Relative Efficiency: If there is an efficiency differential between the sectors, IFQ will flow to the more efficient sector (See Section E.4.1)			
	Given the nature of fishery management and imperfections in the function of markets, one sector may have greater relative efficiency than the other.	• If there is an efficiency differential between the sectors, IFQ will flow to the more efficient sector. Even the efficiency of the sectors is identical, profits per pound may vary and product will be an important driver of IFQ flow. • Over the short term, there are more mechanisms by which harvester sector efficiency may be enhanced than for the nonwhiting-processing sector.	The capital infusion represented by the initial allocation will provide an opportunity for harvesters and processors that receive an initial allocation to increase their efficiency. Increased efficiency will increase ability to accumulate QS.
Vertical Integration: Firms integrate vertically for market security, asset protection, rent capture, and market foreclosure. IFQs will increase vertical integration incentive (See Section E.4.2)).			
	Processors tend to be more vertically integrated than harvesters.	• Harvesters' vertical integration (acquisition of processing capacity) will not be constrained by accumulation limits. • As harvesters become more profitable, they could become more of a target for vertical integration by smaller processors (rent capture). • QS provides processors a less expensive way to vertically integrate harvesting activities and a new way to foreclose market opportunities of competitors. • Processor vertical integration could be constrained by control limits if such control limits are applied to both QS and QP.	• Initial allocations will enhance the recipient's resources for vertical integration. • If control limits are applied to QP, processor vertical integration would be constrained, and those processors grandfathered in at levels above the control limits would have a long-term advantage over those receiving less than those limits.
Market Power: QS will likely flow toward those with more market power because of their higher profits (See Section E.4.3))			
	Incentives for processor and harvester rivalry may each be constrained. There are more indicators that processors are likely to be able to exert bargaining power than there are for harvesters (this is not a statement as to whether or not either sector has in fact exerted market power) Barriers are necessary for long term-preservation of market power. Indicators of potential bargaining power favor processors and indicators of entry barriers may favor harvesters.	For harvesters • Rivalry is expected to decrease after an initial shakeout, • Bargaining power increase through consolidation and opportunity to vertically integrate, and • Entry barrier increase For processors • Rivalry is expected to increase, • Possible bargaining power decrease because QP liquidity increases the distance from which potential buyers may be drawn, • The result for entry barriers is more uncertain.	***As amount allocated to processors increases*** For harvesters: • Increased rivalry in QP and raw fish market including increased strategic stakes in the outcome • Latent permits may become active to handle processor QP • Fewer assets to support using the threat of vertical integration as a lever during price negotiations For processors: • Reduced exit barrier would tend to decrease rivalry • Increased assets to support vertical and horizontal integration • Processor-held QP can be used to activate latent permits, increasing processor bargaining power • A greater entry barrier (including a temporary scale advantage by larger processors) will help protect any negotiating advantages that are established.
Access to Capital: QS will flow to those with greater demand for and cheaper access to capital. (See Sections E.4.4–.4.6)			
	Harvesters may be less willing to pay for capital because of their high time preference. Processors may have access to cheaper capital because of they present a lower investment risks.	• Industry stability is expected to increase (particularly for harvesters), potentially decreasing the cost of capital. • QS may be of tenuous value as an asset for securing a loan. • Firms with cheap access to capital are more likely to acquire QS and grow. • The risk of lending to processors may increase, if the IFQ program increases harvester opportunity to exert market power.	• Initial recipients will receive an infusion of wealth that may give them cheaper access to capital (lower interest rates). • Harvesters not receiving enough QS to support their business plan will have a less secure income flow and, if financially distressed, may have a hard time securing loans for QS/QP acquisition or other capital investments. • For processors, QS/QP is not needed for operation, but an initial allocation will increase the security of their access to raw product, reducing risk and, therefore, lowering capital costs.

● Impact on Conservation (Resource Stewardship Effect)

Resource stewardship is a term often used to describe actions that are taken to benefit conservation of the resource. It has been proposed that IFQ programs generate a "resource stewardship effect" as a result of privatization of the opportunity to harvest fish. A recent study of IFQ systems worldwide showed that, even after taking into account factors such as the intensity of management, fisheries under IFQs appear less likely to be overfished (Costello, *et al.* 2008). We will look at four factors related to the degree to which an IFQ program might generate a resource stewardship effect and examine influence of the initial allocation on the likelihood that a resource stewardship effect is realized:

1. Degree of exclusivity of access
2. Discounted value for future benefits (i.e., delayed gratification)
3. Ethical action
4. Control over what happens on the vessel

♦ *Exclusivity*

Ownership of QS gives individuals a direct interest in the productivity of the resource as a whole, a portion of which cannot be impinged upon by others. However, it does not give them control or access to specific fish. Therefore, any action that a QS owner undertakes that either benefits or harms the resource is still shared proportionally with all other QS owners (NRC 1999, pg 36), as well as those sectors relying on the resource which are not under IFQ management. Nevertheless, the approximation of sole ownership is greater under IFQs than under license limitation or open access management. Under license limitation and open access, a fisherman is not even certain of receiving a share of the available harvest.

It may be that collective stewardship action (e.g., fishermen's associations working to benefit the resource) is encouraged by IFQs more than individual stewardship action. For example, Nova Scotia fishermen worked with managers to develop stronger conservation measures. At the same time, there were anecdotal reports that individual actions for personal benefit continued, even though they adversely affected the resource (high grading and under-reporting catch) (NRC 1999) (pg 106).[17] Collective actions (or collective restrictions) ensure that all participants are contributing to a particular outcome and make it more likely that the individual will receive a benefit commensurate with his or her contribution. Collective actions where the commitments are made up front will be most easily enforced (for example, an association of fishermen might invest in research to support a stock assessment). Other types of collective actions motivated by economic incentive require participants to trust one another to contribute to the collective good, resting on the belief that violators will be detected and penalized.

Sole ownership (i.e., exclusivity) may be a necessary condition for "stewardship" motivated by economic incentives alone; however, it does not guarantee a stewardship result. For example, economically driven stewardship may require that the returns available from harvesting all the fish and putting the net proceeds in the bank be less than the growth rate of the fish stock. This issue is addressed in the following section.

[17] Highgrading problems have appeared to have escalated in the Icelandic ITQ fishery where there is not full observer coverage. For other programs, such as those in New Zealand and the Alaska halibut fishery, it is reported that under reporting of catch appears to be minimal. There are some questions as to whether or not there may have been problems in the Alaska sablefish fishery (NRC 1999). Highgrading also occurred in the Alaska red king crab fishery after rationalization.

♦ *Discount Rates*

Assuming that someone is relatively certain of gaining the return from their investment in stewardship, one must still ask whether the return they will receive is enough to compensate them for incurring a cost and waiting for that return. The term associated with this concept of "delayed gratification" is discount rates. Discount rates are discussed more fully above and in Appendix E. If the stock growth/improvement rate is greater than the individual's discount rate, then it will make sense for the individual to make an investment in anticipation of the greater return. If it is difficult for humans to take into account returns that take longer than a generation to be realized (e.g., longer than 30 years), or longer than the remaining span of their lifetime, then economically driven stewardship incentives for some of the slowest growing west coast rockfish species may be limited. Thus, if QS holder discount rates are high and resource condition improvement rates are slow, even if a fishermen were relatively certain of reaping the benefits from his conservation action, there may not be sufficient incentive for fishermen to make the investment that stewardship actions require, purely based on economic incentives. An additional factor to consider is that the trawl sector is not the only sector reliant on the resource. So for example, assume that trawlers (collectively or individually) take some kind of extra action to help conserve the resource and other sectors take no extra actions. If that action results in improved stock productivity, the trawler would likely have to share that benefit with all the other sectors that rely on those species for which improvement is achieved. This reduces the future return from any present action.

♦ *Ethical Action*

Stewardship based on ethical action may occur even if the action does not make "economic sense" when we consider only exclusivity and discount rates. There is much research showing that fairness and reciprocity are strong determinants of human behavior (Falk, *et al.* 2002) Under the models in this body of research, individuals value an outcome both for its effect on themselves and on others. Game theory experiments developed by Falk, et al. classified participants into those strongly motivated by reciprocity and those motivated primarily by personal economic gain. They observed that institutional rules determined the observed outcome, i.e., determined whether the outcome in the human system is driven by reciprocity or solely by economic self-interest. If there is not an institutional rule that either externally forces cooperation or provides the possibility that participants will find ways to sanction one another, a non-cooperative outcome is more likely to result. Falk, et al. (Falk, *et al.* 2002) state "In a sense, institutions select the type of player that shapes the final result." The following section identifies some ways in which the structure of the institutions (i.e., rules on who is allowed to hold QS) may affect the opportunity for development of informal sanctions for non-cooperation.

Falk, et al. (2002) also identify other theories for outcomes that are not solely economically driven, including "moral norm activation" (Stern, *et al.* 1999). Under this theory, if people accept a value (e.g., fishery conservation), believe that things important to that value are threatened (e.g., that excess harvest could damage the status and productivity of a stock), and that they can take actions which will help alleviate the threat, they will take those actions.

♦ *Control over Activities on the Vessel*

If we assume that through economic or noneconomic values there is a potential for sufficient incentive to encourage stewardship behavior, then the question is who is in the best position to control such behaviors. In this discussion, we will assume that the QS holder has the greatest incentive for stewardship, due to combined economic and noneconomic values. Dawson reviews the issue of control over production from the perspective of transaction costs associated with contract formation and

contract enforcement (Dawson 2003). He identifies that specifying the exact behavioral deliverables in a contract, monitoring that behavior, and enforcing the contract become more difficult as the relational distance between the parties to the contract increases. For example, establishing standards, monitoring, and control are much easier with an employee than with a contractor. Following this line of thought, it appears that in terms of vessel operations the following would be a reasonable ranking of those with greatest control over stewardship behavior to those with the least such control.

- Crewmembers (most control if stewardship actions have to do with how individual fish are handled on deck)
- Vessel operator (most control for stewardship actions having to do with where the vessel fishes, length of tow, etc)
- Vessel owner/lessee (most control for stewardship actions having to do with gear and vessel equipment)
- Processor/permit owner
- Other entities

On this basis, if the Council wants to place maximum emphasis on the likelihood that the IFQ program will lead to stewardship behavior (possibly diminishing achievement of other objectives), the program should be designed to encourage ownership consistent with the priorities in the above list. Moreover, the decision on which groups will be allowed or encouraged to own QS could be part of the design of an institutional framework that supports a stewardship ethic, as discussed in the Ethical Action section (page A-58). This design may include consideration of the ability of QS holders to observe other QS/QP holders and harvesters and ability to impose sanctions. Those with the greatest ability to impose sanctions within a harvesting operation may be the owners of such operations. Those with the greatest ability to monitor the activities may be vessel operators and crewmembers.

♦ *Summary*

The initial allocation among groups is just that, an initial distribution. It does not determine where the QS will end up over time. However, those receiving an initial allocation will receive a leg up by the capital infusion represented by the allocations and will be in a better position to maintain their QS and acquire additional QS in the future.[18] Table A-17 summarizes the results with respect to each of the above sections. With respect to the potential stewardship effect, those present on the vessel will be able to most effectively act on the stewardship incentive (i.e., be able to implement stewardship actions at the least cost). This is consistent with Clark's finding that fishermen who lease will have little incentive to conserve because they do not have long-term access (Francis, *et al.* 2007).

[18] Up to QS control limits.

Table A-18. Summary of analysis of stewardship effect.

Exclusivity	QS owners have limited exclusivity because the benefit/cost of any action they take individually may be shared by all other QS owners as well as other sectors that rely on the same resource. Yet there is more exclusivity than under open access or license limitation.
Discount Rates	Even if individuals have some exclusivity, if they have a high discount rate, the increase in benefits over time may not be sufficient to compensate them for the near-term sacrifices. Fishermen have been reported to have relatively high discount rates.
Ethical Action	Ethical action may override (or act in concert with) action based solely on economic incentives. Therefore, lack of complete exclusivity or discount rates higher than benefit return rates does not mean there will not be a stewardship effect. Institutional design can affect whether or not ethical considerations dominate behavior. External sanctions or ability for participants to sanction one another may enhance the expression of a stewardship ethic. Buy-in on the problem and potential for individual action to help alter the outcome are important.
Control	Crewmembers and vessel operators may be in the best position (have the lowest cost) to monitor and control stewardship behavior.

- Impact on Sector Health

  - *Buyers/Processors*

There is an overlap between buyers and processors in that some businesses act only as buyers, some buyers act as processors (buying only for themselves), and some buyers act as processors but also buy raw fish for other processors. The set of all businesses functioning as buyers is of concern because it is they who interact with harvesters in the raw fish market. Those buyers acting as processors are of concern because of their larger capital investment in the fishery and the over investment that may have been caused by the regulatory regime. In Section A-2.1.1.d, we will discuss whether the Council allocation to "processors" would be to actual processors or to buyers (as a proxy for processors) and the implications of that choice on the results of the analysis. In order to minimize confusion between the terms used in the analysis and those used in the alternatives (e.g., allocation to processors), in the following discussion we will use the term "processors" to refer to both buyers and processors, unless otherwise noted.

COMPETITIVENESS

There are a number of aspects of sector competitiveness to consider:

1. Competition in negotiations with harvesters
2. Competitiveness within the sector (smaller processors vs. large processors)
3. Competitiveness in wholesale markets

Negotiations with Harvesters. In Appendix E, on market power, one of the focuses was on competitiveness within the sector in the context of the processing sector's interactions with harvesters in the raw fish market. There we found the following indicators:

- Processors are in a strong position to exert market power under status quo (whether they do or not) and may have cheaper access to capital than harvesters.
- An IFQ program under which processors do not receive an initial allocation would weaken that position.
- Even if weakened, processors could regain some strength through the acquisition of QS, but only up to accumulation limits (see Appendix E for a list of indicators of factors affecting the flow of QS among groups independent of the initial allocation).
- An initial allocation of QS would give them a stronger bargaining position than if they did not receive an initial allocation.

- If there are well-established market prices for QP and raw fish, it is then implied that strength of bargaining position will be less important in establishing market prices. To the degree that there are transaction costs associated with moving between one buyer and another (or from one seller to another), however, it will still be possible to use bargaining power to influence the price away from average market prices.

Specifically, an initial allocation of QS would do the following:

1. Provide a capital infusion that may allow processors to employ one of a number of different strategies to grow and increase their efficiency (e.g., acquisition of additional QS, horizontal integration, etc.).
2. Diminish the exit barrier (liquidation of QS would allow a firm to exit the industry with less debt or greater gains).
3. Initially provide processors with greater bargaining power (as compared to their initial situation under IFQs if they did not receive an initial allocation), useful mainly if the market is not competitive enough to strongly establish going market prices.
4. Create a greater barrier to new entry.
5. Create an even greater barrier to entry if there is a control limit grandfather clause (not part of the FPA).
6. Decrease the cost of processor access to capital.

The initial capital infusion may have a long-term affect on the distribution of wealth in the industry. The effect of the IFQ program on processors' ability to remain in business is discussed below in the section on investments (page A-62).

Effect on Smaller Processors. If there is not an initial allocation to processors, smaller processors may be at a disadvantage relative to larger processors. At this time, most of the LEPs that are owned by processors are owned by larger processors. Therefore, smaller processors would have to acquire QS or operate at a lower profit level (processors owning trawl permits will earn levels of returns for the QS granted to them that will not be available to those who purchase later). Either way, whether they choose to acquire QS or not, compared to those granted QS because they own permits, those without permits would be at a competitive disadvantage within the sector. Anecdotal information has indicated that those processors in the IFQ system in British Columbia who did not own vessels or were not closely partnered with vessels had a financially difficult time competing because of their need to make payments on capital borrowed for their QS acquisitions. This is consistent with reports from New Zealand that indicate lower economic satisfaction for later entrants who have to buy QS to enter the fishery (as compared to those receiving an initial allocation) (Dewees 2006). An initial allocation of QS would give smaller processors some QS to work with, and, if there is no QS control limit grandfather clause, it could substantially even the distribution of QS among processors. If there is a QS control limit grandfather clause, an initial allocation of QS would probably still leave smaller processors at a significant disadvantage in QS holdings as compared to the larger processors.

Effect on Larger Processors. If there is an initial allocation to processors, some larger processors will likely be at the control limits. If they are at the IFQ control limits, and the limits apply to both QS and QP, they would have no ability to extend their vertical integration (expanding their harvesting activities). If there is no grandfather clause, they may have to reduce their level of vertical integration. However, the FPA applies control limits only to QS and not QP. Once processors reach QS control limits, expansion of their shares of the market would have to occur without the support of QS. Whether large processors are more likely than small processors to expand their market share would depend on the relative profitability of adding an increment of production to a large-scale processor without the support of QS, as compared to adding the same increment of production to a small-scale processor with the support of QS.

Competition in the Wholesale Market. One factor to be considered is how the IFQ program may affect the competitiveness of west coast seafood processors in the wholesale market. While west coast processors may participate and have an advantage in local niche markets, many of the fish products currently produced in the west coast groundfish fishery are sold into a wholesale market in which there is global competition.

It has been argued that processors need to receive an initial allocation of QS and be able to accumulate larger volumes of QS in order to be competitive in the world market. However, processors do not need QS to process fish, and, if they cannot sell the available product, then fishermen or QP holders will be forced to lower their prices to move the available product. If fishermen are already accepting their minimum price (covering costs including normal profit), then the value of the QP will diminish. If the fishermen are at their minimum prices, and marginal QP values near zero, then it is likely that some fish would go unharvested. However, overall, the IFQ program will likely reduce operation costs and make west coast products more competitive on the global market thus increasing the volume of what processors are able to sell at a normal profit level even if processors do not receive an initial allocation.

An initial allocation to processors would improve individual processor marketing flexibility and profits. Individual processors would have more direct control over the price they pay for the quota (what they pay themselves for QP) and more immediate flexibility to respond to marketing opportunities with price adjustments rather than having to wait for the changing price signals to work their way through the QS and raw fish markets.

INVESTMENT, DEPENDENCE, AND DISRUPTION

Dependence on the groundfish trawl fishery is a function of the degree of investment in the fishery and the ability to employ the assets representing those investments in activities outside the groundfish trawl fishery. Thus, dependence on the groundfish trawl fishery implies that, absent an opportunity to earn income from this fishery, there would not be sufficient returns to compensate those making the original investments. The investments we will focus on in this section are primarily investments in physical capital, but there may also be investments in human capital (e.g., specialized knowledge or labor skills). The IFQ program will change the management system and markets, potentially disrupting a firm's ability to recover returns on fishery dependent investments and affecting a firm's ability to sustain participation in the industry. In this section, we will assess the conditions and mechanisms under which a firm's ability to recover returns on fishery-dependent investments and sustain participation will be adversely affected. We will also look at some qualitative indicators of the degree of that effect.

When the IFQ Program is implemented, those holding QSs are expected to capture the difference between the maximum price for raw fish processors are willing to pay and the minimum price at which vessel owners are willing to harvest, as resource rents. In question is whether QS/QP holders (whether they be harvesters or independent QS/QP holders) might also capture a portion of the processor's earnings needed to cover capital investments (their quasi rents).

Under status quo, if there is no processor overcapitalization, we would expect that the market would allow processors to cover their average total costs (i.e., earn enough to pay for their variable operating costs and earn a normal return for their fixed/capital costs). However, if there is more capital than is necessary to utilize the available raw product, some processors will produce at less than their optimal output, until the excess capital leaves the fishery. In Section 4.9, we identify that the nonwhiting processing sector could be overcapitalized due to the recent contraction in the fishery and that processors in the shoreside and mothership sectors may be overcapitalized due to their need to compete for vessel deliveries during the Olympic-style whiting seasons.

- Given an overcapitalized situation, processors will compete with one another to reach, as close as possible, their optimal level of output. In that competition, processors may bid away some of the profit that would otherwise go to return on their capital investment.

The following text box provides a technical explanation of this point.

Text Box: Technical Explanation of Dissipation of Returns to Capital when the Processing Sector is Overcapitalized

Figure A-5 illustrate the economic choices. The diagrams show a price or dollar cost per unit on the vertical axis and a quantity on the horizontal axis. The curves shown are supply curves for a single firm. Three curves are shown in each figure: the top curve shows average total cost (including capital investments), the lower curve shows average variable costs, and the curve crossing the other two shows marginal costs. The amount paid for raw fish is an input that affects the height of the curves. As the price of raw fish increases, all three curves move up. The difference between the left figure and the right figure is that the right-hand figure reflects a higher price for the raw product.

In order to achieve a normal profit, a firm must cover its variable and fixed costs (total costs). In the left-hand figure, a price of P1 for processed product would allow the firm to achieve a normal profit with the production of about 25 units. Twenty-five units represents optimum capacity for this firm; however, if the industry is overcapitalized, not all firms will be able to achieve optimum capacity. Assuming that wholesale prices are fixed (that the wholesale market is competitive), as a firm's production decreases, it can be seen that it will no longer achieve normal profits (in the left-hand figure the revenue line, P1, is below the total cost line when production is less than 25 units). At around 5 units of production, the firm would no longer cover variable costs and would cease production over the short term. Between 5 units and 25 units, the firm will continue to produce over the short run but over the long run it will not be able to replace capital as it wears out. Excess capacity in the sector means that some processors will face producing at levels at which they cannot cover total costs and will compete to reach as close to their optimal production levels as possible. In this example, assume there are only 50 units of harvest available and five companies, each with a cost structure identical to that described here. Each company will strive to maintain as close to 25 units of production as possible, using whatever leverage it has available to acquire product. For example, a company might vertically integrate, link its willingness to accept deliveries to other products for which there is not a surplus in processing capacity, guarantee its ability to receive a vessel's product during an Olympic fishery, or offer higher ex-vessel prices. If a processor must attract product by raising the ex-vessel price it offers, the company raises its cost curves. A $15 per unit increase results in the cost curves shown on the right. If this increase is enough for the company to win 22+ units of production, it will stay in business over the short term (i.e., cover its variable costs), but will not cover much if any of its fixed costs (i.e., its return on investment, quasi rents, will have been dissipated).

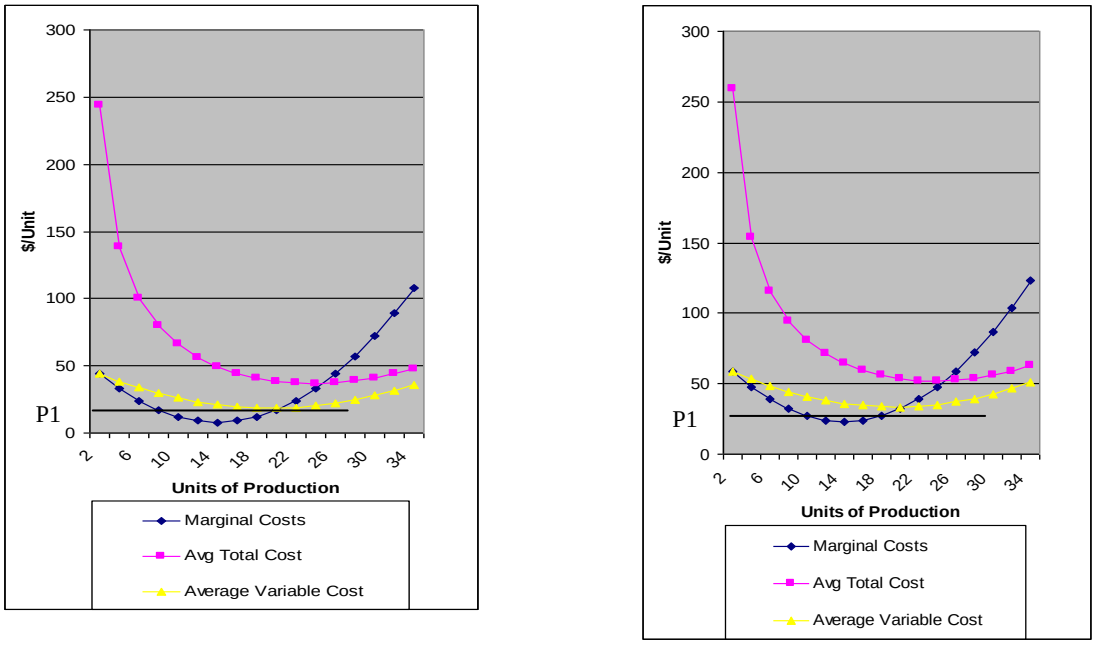

Figure A-5. Comparison of cost curves before (left) and after (right) an increase in the cost of a key input.

If there is overcapitalization in the processing sector, and the sector is fully competitive under status quo, processors will already be bidding away some of their rents in the competition for the limited amount of raw product available. The IFQ program will reduce flexibility to turn to alternative harvesters, which might further increase the competition and hence price for raw product. These processors may find their situation somewhat improved if the IFQ program results in an increase in total landings (through bycatch avoidance), provides processors an opportunity to reduce costs (most likely in the whiting fishery), or provides processors an opportunity to seek higher wholesale prices. Even so, until excess capital is dissipated, they may bid away any improvement as part of the competition for landings,[19] similar to their situation under status quo.[20] Capital will leave the fishery either as it wears out or as other markets are found for it. If a processor is covering its variable costs, but can get a higher return on investment from liquidation of its capital assets than it can from continuing to produce, it may choose to liquidate rather than remain in the fishery.

If processors are overcapitalized but able to compete for deliveries at least partially through their ability to handle volume (i.e., not solely based on prices offered for raw product), then they might be earning some return on their capital investments that may, after the transition to an IFQ program, be bid away in the competition for raw fish deliveries. This may be the situation for processors in the catcher vessel sectors of the whiting fishery.

If the processing sector does exert market power, then so long as they are able to continue to do so after implementation of the IFQ Program, QS holders will not be able to capture the processors' investment return-related profits. If the processing becomes competitive after implementation of the IFQ program, then it is possible that the QS holders will be able to capture some of the investment return-related profits so long as the sector remains overcapitalized. If the processing sector is not overcapitalized, it is less likely that the QS holders will be able to capture investment-related profits from the processing sector. Table A-18 provides a summary of the effects on processor return on investment as it varies by the degree of competitiveness in the sector under status quo.

[19] Unless there are means other than by offering to pay higher prices through which buyers ensure they have access to sufficient raw product.

[20] Since the nonwhiting fishery is already run at a slower pace, the opportunity for processing cost reduction or revenue increases may be relatively limited compared to the whiting fishery.

Table A-19. Effects on processor returns to investment resulting from the transition from status quo to an IFQ program.

Processing Sector Capitalization	Processing Sector Competitiveness		
	Market Power Exerted	**Processors Compete for Product Based on Price**	**Processors Compete for Product Based on Ability to Handle Capacity**
Fully Capitalized	Normal or above normal returns under status quo. QS holders will, at most, be able to capture resource rents (will not be able to capture processor profits that would go to return on investment).		
Overcapitalized	In a situation where market power is exerted overcapitalization would not normally be expected. However, under status quo, there could be processor market power and overcapitalization as a result of historic conditions (e.g., the contraction in the available harvest). Under IFQs, processors would maintain their previous profit levels unless the sector becomes competitive after the IFQ program is implemented (i.e., their market power is overcome).	Under status quo, returns to capital dissipated. This continues under the IFQ program until no longer overcapitalized (unless the IFQ program allows processors to exert market power, i.e., transition to a less competitive situation)	Under status quo, processors may be earning some returns to capital. Under IFQs, processors would no longer compete based on their capacity to handle product. If they then compete based on price offered for raw product, QS holders may be able to capture the profits associated with the processor assets (unless the IFQ program allows processors to exert market power, i.e., transition to a less competitive situation).

Note: Market power in the harvester sector is not considered in this table. If that sector is able to exert market power, they would capture some of the rent that QS holders would otherwise capture.

Under an IFQ program, in a situation where some profits that would otherwise go to capital might be lost by processors offering higher prices in the competition for raw product, it is important to consider the degree and duration of that loss. We do not necessarily expect that every firm will bid away all or even most of its returns to capital in the transition. Whether a particular firm is affected and the degree of impact depend on the cost structure and debt positions of other firms in the industry. In particular, the position of the weakest firms will have a significant bearing on the amount of profit that other firms dissipate in bidding for raw product to serve an overcapitalized industry. Firms with higher average variable costs and firms for which a significant portion of the difference between average total cost and average variable cost is dedicated to payments on a loan will have less flexibility to weather price competition. If these firms drop out quickly in the price competition, there will not be so much of a need for remaining firms to bid away a portion of their profits. Some of the capacity within a firm may also drop out of production to the degree that it goes unused. Ultimately, the price that processors will bid for raw product will be just below the average variable costs of the most efficient of the excess units of capital. (The units of capital that are in excess are considered to be those that are less efficient. On this basis, the price paid will be slightly below the average costs of the most efficient of the set of lesser efficiency capital units.) Each unit of capacity remaining active will be able to capture the profit that corresponds to the amount by which the efficiency of that unit exceeds the efficiency of the most efficient unit of dropped out capacity. A visual example of this concept is illustrated in the two diagrams in Figure A-6 of the following text box.

The above discussion indicates that the following:

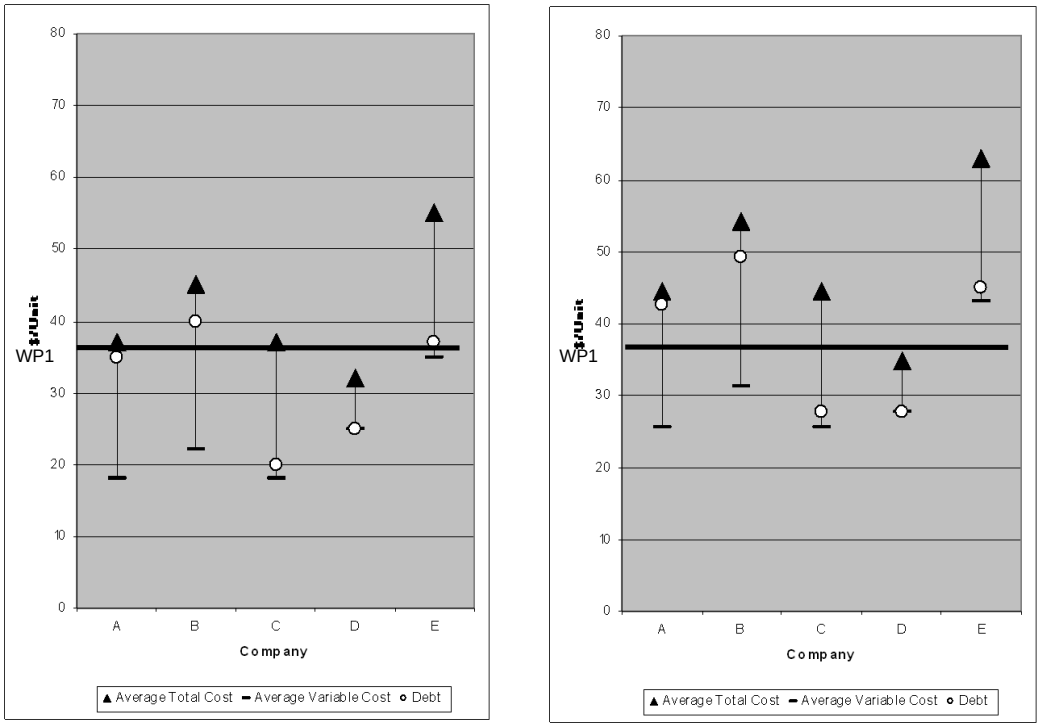
- Under status quo, if the processing sector is overcapitalized and unable to exert market power, it will likely already be bidding away returns to capital, unless it is able to compete for raw product through nonprice competition (e.g., to handle a large volume of product during a derby fishery).
- If the processing sector is overcapitalized and unable to exert market power under an IFQ program, it may bid away some of its returns to capital as increased prices offered raw product

- The price that must be paid for raw produce will only increase until enough capacity is left idle such that the remaining active capacity is just able to process the available product.
- When that price is reached, the financial return for units of capital remaining active may be diminished, however, it is unlikely that there will be a complete loss of returns to investment
- Once excess capacity has left the fishery, normal returns to capital will be restored.

Text Box: Visual Illustration of Elimination of Capacity and Retention of Some Returns to Capital

Five hypothetical firms are represented with different average total costs (top end of each bar), average variable costs (bottom end of each bar) and debt service (difference between the bottom of the bar and the circle in the middle of each bar). With a price of wholesale price of P1 on the left hand side, the following occurs:

Firm A:Covers average total costs, average variable costs, and makes payments on debt.



Firm B: Cannot cover average total costs but covers average variable costs (stays in business over the short run). Cannot make complete payments on debt.

Firm C: Covers average total costs, covers average variable costs, covers debt, and has some cash flow representing returns to capital (difference between total costs and debt payment plus variable costs).

Firm D: Covers average total costs, average variable costs, makes payments on debt, and has some earnings above total costs (above normal or economic profit)

Firm E: Cannot cover average total costs but covers average variable costs (stays in business over the short run and makes payments on debt).

If these firms now compete for raw product by raising ex-vessel prices, hence raising their average variable costs while revenues (P1) remain constant (figure on the right), firm E will drop out as soon as its average costs exceed P1. Firms A and B may also drop out if they cannot make arrangements for payments on their debt, and Firm C will remain for the short run, collecting some returns on capital investment, but if raw product prices do not drop back down, it will eventually have to exit as its capital wears out and has to be replaced. Firm D remains, covering its total costs. This figure illustrates the dynamics that may occur if firms have dissimilar cost structures and debts. If, instead, all firms have similar cost structures and debt, it would be more likely that production will be scaled back across the entire industry, with individual firms cutting out their least efficient units of production first. However, the same general rule would apply, with each unit of capacity remaining active capturing the profit that corresponds to the amount by which the efficiency of that unit exceeds the efficiency of the most efficient unit of capacity that drops out.

The right hand side figure assumes an increase in variable costs due to price competition for raw product deliveries.

Figure A-6. Hypothetical cost structures and debt positions for 5 firms at a set level of production.

Reduced Value of Processor Assets. Relative to status quo, processors are not expected to lose returns on their investment to QS holders unless processors are overcapitalized and either have been competing for raw fish deliveries based at least partially on something other than price (e.g., competition based on ability to handle volume), or have been able to exert market power to protect their returns to assets and lose that ability under an IFQ program (likely only under special circumstances, such as a somewhat recent contraction in supply). If processors are overcapitalized and under IFQs are unable to influence prices substantially away from a natural equilibrium (i.e., not able to exert market power), it does not necessarily mean that they will lose all of their returns to capital. They will still earn a return that is related to the difference in efficiency between their capital and the most efficient units of capital that drop out of production. Inability to exert market power does not necessarily mean that harvesters have exerted market power; it could also mean that both sides accept going market prices and are unable to use negotiating leverage to gain major deviations from those prices. To the extent that processor returns on irretrievable investment are diminished under IFQs, the allocation of QS to processors may provide them with an asset to compensate them for some of the loss. If processors are given an initial allocation of QS, one scenario is that the allocation may encourage more rapid rationalization of the processing sector by reducing the barrier to exit (making it easier for processors to recover capital losses).

SUMMARY

Compared to an IFQ program with no initial allocation of QS to processors, an initial allocation to processors may accomplish the following:

- Strengthen their bargaining position vis-à-vis harvesters in the raw fish market (to the degree that prices are influenced by negotiations rather than going market prices).
    - Over the short run (via the initial grant of an asset and via their ability to hold QS in excess of control limits)[21]
    - Over the long run, if they would not otherwise accumulate QS through purchase
- Under certain circumstances, compensate for partial losses of returns on investment.[22] [23]
- Possibly strengthen large producers relative to small producers (if there is a grandfather clause);
- strengthen small producers relative to large producers (if there is no grandfather clause and depending on relative efficiencies).
- *Not likely* affect competitiveness of west coast product in the wholesale markets but may allow individual firms to be more responsive to changes in marketing opportunities (to the degree that processors would not otherwise acquire the QS through purchase).
- Reduce exit barriers by providing compensation for capital losses by those who might seek to leave the fishery.

[21] Under FPA, however, this ability is limited to the first four years of the IFQ program, by the end of which time they must have divested themselves of their excess shares.

[22] If the processing sector is overcapitalized under status quo and unable to exert market power under an IFQ program, then it may experience a loss in the value of its capital if either (1) market power was being exerted under status quo, or (2) market power was not exerted under status quo, but at least some of the competition for raw product was on a basis other than price (e.g., the ability to handle a large volume of product in a timely manner). Note that under the latter condition the processors were likely already losing some of their return on investment under status quo (to the degree that price was a factor in the competition for raw product).

[23] Under IFQs, if processors are not able to exert market power, the amount of profit they bid away in the price competition is unlikely to be the full amount of profit related to return on investment.

♦ *Harvester Sector—Permits*

In this section, we will focus on the permit owner and the permit as an asset independent of harvesting activities.

INVESTMENT DEPENDENCE AND DISRUPTION

Dependence on the groundfish trawl fishery is a function of the degree of investment in the fishery and ability to employ the assets representing those investments in activities outside the groundfish trawl fishery. This is described more fully in the corresponding section above on processors (page A-62).

Under an IFQ Program, the LEP values are expected to decline substantially because of the following:

- The fleet is expected to consolidate down to a number of vessels that is less than half the current number of permits (Section 4.6).
- The permit by itself will not offer access to any amount of the groundfish trawl allocation.
- The permit has no alternative use (its value is entirely dependent on the access to groundfish that it allows).

While these permits were issued to qualified vessel owners at relatively low cost (a cost sufficient to cover administrative costs of issuing the permits) up to 65 percent of these permits have changed ownership since the implementation of the license limitation program (based on an examination of ownership information from the LEP office). Many of the exchanges are believed to have occurred at prices of several hundreds of thousands of dollars. Therefore, there are many owners who have made a substantial financial investment in the permits.

Table A-20. Estimated Catcher Vessel Permit values in March 2004 (Based on Dockstreet Broker Report on $/point).

Permit Length Category	Number in Category	Permit Length Endorsement	Points For Indicated Length	Permit Values Based on	
				$6,000/point	$10,000/point
Less than 40 feet	22	40 feet	6	$36,000	$60,000
40-50 feet	14	50 feet	10	$60,000	$100,000
50-60 feet	31	60 feet	16	$96,000	$150,000
60-70 feet	27	70 feet	23	$138,000	$230,000
70-80 feet	32	80 feet	32	$192,000	$320,000
80-90 feet	20	90 feet	43	$258,000	$430,000
90-100 feet	7	100 feet	56	$336,000	$560,000
>100	14				
Total	167*				

* Data on number of permits from summer 2009. Two permits were combined in 2008 and 2009, reducing the total number of catcher vessel permits from 169 to 167.

All of those who hold the permits, regardless of whether they purchased them or received them as part of the initial allocation, will experience a decrease in the value of that asset. Under status quo, all permits of a similar size class are of similar value in terms of the access they provide to the fishery (note: in the current climate, permits with similar size endorsements may trade at values related to their landing history because of speculation that QS will be given to permit owners). How a particular permit owner fares as a result of the IFQ program will depend on the amount of QS given to permit holders in aggregate (as opposed to the amounts provided to processors or for adaptive management), the formula for allocating among permits, and the amount of landing history associated with that particular owners

permit. It was estimated that annual resource rents for the nonwhiting fishery (the value of the QP) might run about $18 million per year (after subtracting $350/day for observer costs). QSs have been reported to trade for between 3.5 and 10 times the QP price. On this basis, the QS value might be expected to run between $63 million and $180 million. There are up to 169 permits that may qualify for nonwhiting sector QS. Therefore, on average these permit holders would receive between about $0.4 million and $1.0 million of QS per permit.

Table A-21. Estimated value of nonwhiting QS to be issued.

	3.5:1 QS:QP Ratio	10:1 QS:QP Ratio
Annual Value of Nonwhiting QP	$18,000,000	$18,000,000
Estimated Value of QS	$63,000,000	$180,000,000
Average QS per Permit	$387,000	$1,065,000

Note: A ratio of 3.5:1 has the same result as a discount rate of about 40 percent applied over 30 years. A ratio of 10:1 has the same result as a discount rate of about 10.5 percent applied over 30 years.

However, the owners of a permits which have relatively low landing history may experience a decrease in the value of their combined permit/QS assets (as compared to value of the permits before adding speculation about the IFQ program effects), even if 100 percent of the QS is given to permit holders (depending on other aspects of the allocation formula). For purposes of illustration, assume an average permit price of $200,000. Under the FPA, with 90 percent of the QS going to permits and an equal allocation component, if we assume a QS value of $180 million, no permits would be expected to receive QS in an amount worth less than $200,000 (Table A-21).[24] If a QS value of $63 million is assumed, then 44 permits (26 percent of all permits) would be expected to receive QS valued at between $100,000 and $200,000. Allocations that maximize amounts to any one permit (100 percent to permits with no equal sharing) are provided in Table A-22. Under such an allocation, there would be 38 permits (22 percent) receiving less than $200,000 worth of QS (assuming $180,000 as the value for all QS) (Table A-22). On the other hand, if only 75 percent of the QS goes to permits, and the QS is valued at $63 million, then 69 permits (41 percent) would receive less than $200,000 of QS (Table A-23). In Table A-24 and Table A-25, similar information is shown for 100 percent and 75 percent allocations, but with equal sharing. Comparing Table A-21 (the FPA—90 percent allocation to permits and equal sharing) to Table A-24 (100 percent allocation to permits and equal sharing) shows the effect of the 10 percent QS allocation for adaptive management. For example, if a $63 million value is assumed for QS, the 10 percent reduction increases the number of permits receiving less than $200,000 of QS from 36 to 44.

It is likely that some of those permits that would receive smaller amounts of nonwhiting QS would receive larger amounts of whiting QS or a co-op permit. Of the permits with nonwhiting history from 1994 to 2003, 58 also have some history in the shoreside or mothership whiting fisheries during that period. Unfortunately, we do not have a model available to estimate the increased efficiency and hence value of the QS that may be expected in the whiting fishery.

However, Table A-26 and Table A-27 provide the estimated ex-vessel value that might be taken witH QP issued for the shoreside whiting. It can be seen in Table A-27 that there are 110 permits with no shoreside whiting history. With equal allocation (and 80 percent allocation to permits), all permits would receive some amount of whiting QS, and half the ex-vessel value equivalent of the whiting QS would go to 22 permits that receive QS that might generate between $200,000 and $500,000 in annual ex-vessel value. With 100 percent of the allocation going to permits and no equal allocation, half the

[24] The calculation is based on applying the vessels share of all nonwhiting QS to the estimated value of the nonwhiting QS.

ex-vessel value equivalent of the whiting QS would go to 12 permits that receive QS that might generate between $500,000 and $1,000,000 in annual ex-vessel value. Because only 7 percent of the shoreside whiting QS is allocated equally among permits, most of the effect is probably the result of the 20 percent allocation to processors.

Table A-28 provides similar information for the mothership whiting fisheries. IFQs for the mothership sector are not part of the final preferred alternative.

Table A-22. Estimated nonwhiting QS value per permit, based on permit landing history, assuming the FPA (90 percent allocation to permits and with equal sharing of buyback history).

QS Value Per Permit	# Permits	% of Permits	% of QS Value

SUMMARY

- LEPs are highly specific assets, the value of which is likely to decline substantially with the implementation of an IFQ program.
- Owners of permits without much history may experience a decline in the value of their permits that is not fully offset by the value of the QS they receive.
- At most, 65 percent of the permits have changed ownership since the implementation of the program. The remainder of the permits continues to be owned by entities that received them at little cost as part of an initial grant.

♦ *Harvest Sector Vessels*

We will focus on vessels as the main unit around which the harvesting operation is organized. The permit owner and the vessel owner are believed to be the same about 87 percent of the time (based on a matching of permit owner and vessel owner addresses).

Table A-30. Indications of vessels leasing permits.

	Name of Vessel Owner and Permit Holder	Address of Vessel Owner and Permit Holder
Same	136 Permits (76%)	155 Permits (87%)
Different	42 Permits (0.24%)	23 Permits (0.13%)
Total	178 Permits*	178 Permits*

* When the initial data sets were drawn, there were 179 permits (including 10 catcher-processor permits). More recently, one permit has been combined with another. This table was developed from a more recent data draw.

Anecdotal information indicates that, in some cases where a vessel owner and permit owner information do not match, the permit is being purchased by the vessel owner, and transfer is scheduled to be completed when the final payment is made.

COMPETITIVENESS

Negotiations with Processors. In the sections of Appendix E on market power (summarized starting on page A-49),we focused on the harvesting sector's interactions with processors in the raw fish market. There we found the following indicators:

- Harvesters are in a weaker position than processors to exert market power under status quo.
- Access to capital may be more expensive for harvesters than processors because of the smaller size of their businesses and most of their primary assets have fewer alternative uses.
- There are more mechanisms through which harvesters may gain efficiency under an IFQ program than processors (over the long-term, both sectors will rationalize).
- If harvesters receive all the QS at the time of initial allocation, their bargaining position will be significantly strengthened; competition among harvesters initially will be isolated to the QS/QP market (processors may acquire QS over time), and there will be incentive for harvesters to cooperate in the raw fish market. Bargaining power is important to the degree that prices are influenced by negotiations rather than going market prices.[25] [26]
- See Table A-16 for a list of indicators of factors affecting the flow of QS among groups independent of the initial allocation).

Specifically, as the allocation of QS to processors increases as follows:

- The capital infusion to harvesters decreases.
- The exit barriers increase lengthening the IFQ program transition period.
- Harvester competition in the raw fish market will increase reducing their bargaining power.
- The cost of harvester access to capital would increase.
- The likelihood of harvester bankruptcies would increase.

The initial capital infusion may have a long-term effect on the distribution of wealth in the industry.

Competition within the Sector. Those vessels that have the advantage of receiving QS as part of the initial allocation will be better able than new entrants to compete in the raw fish market for the opportunity to deliver on processor held QP. As the amount allocated to processors increases, that advantage will be diminished due to the reduction in the initial allocation of QS going to vessels. If the QS control limits had been set lower than they were under the FPA and if there were a grandfather clause, the vessels qualifying for larger amounts of QS would have had an ongoing advantage over those receiving less than the control limits (the advantage of operating at a scale larger than allowed for those not grandfather in at levels above the control limits). An increase in the amount allocated to processors would have reduced this differential in the advantage for those receiving the most QS, by reducing the amount by which their initial allocation was in excess of control limits. Information on

[25] If there are enough participants acting independently on both sides of a local market then the sellers and buyers will tend to be price takers, and whoever holds the QS will receive the profits related to resource rents.

[26] Under the FPA, there is no grandfather clause, and QS control limits are generally set well above initial allocation levels. If there had been a grandfather clause and control limits were lower, providing processors with an initial allocation would have resulted in lower grandfathering levels for those individual harvesters that would have received QS in excess of accumulation limits. They would not be able to achieve the same harvest scale that they would have with a 100 percent allocation to harvesters.

amounts that will be allocated to permits, relative to accumulation limits, and under different permit/processor splits is provided in Section A-2.2.3.e on accumulation limits. If there were a grandfather clause, over time, as the grandfather clause expires, holdings of the largest QS owners would diminish to within control limits. There may be some advantage for those receiving QS in excess of control limits, but that advantage will not extend beyond year four, by which time divestiture is required.

INVESTMENT DEPENDENCE AND DISRUPTION

Dependence on the groundfish trawl fishery is a function of the degree of investment in the fishery and ability to employ the assets representing those investments in activities outside the groundfish trawl fishery. This is described more fully in the corresponding section above on processors (page A-62). The situation for vessels, vis-à-vis QS holders, is similar to the situation of processors, i.e., to the degree that there is overcapitalization and price competition, vessel owners will likely give up some (not all) of their return on capital by way of accepting lower prices for raw fish or paying more for QP (until the point is reached at which there is no longer surplus capacity in the fishery). If, over the short term (until excess capital is dissipated), harvesters give up returns on capital to QP holders, it is not expected that the amount given up will be substantially greater under IFQs than what is given up or dissipated under status quo.

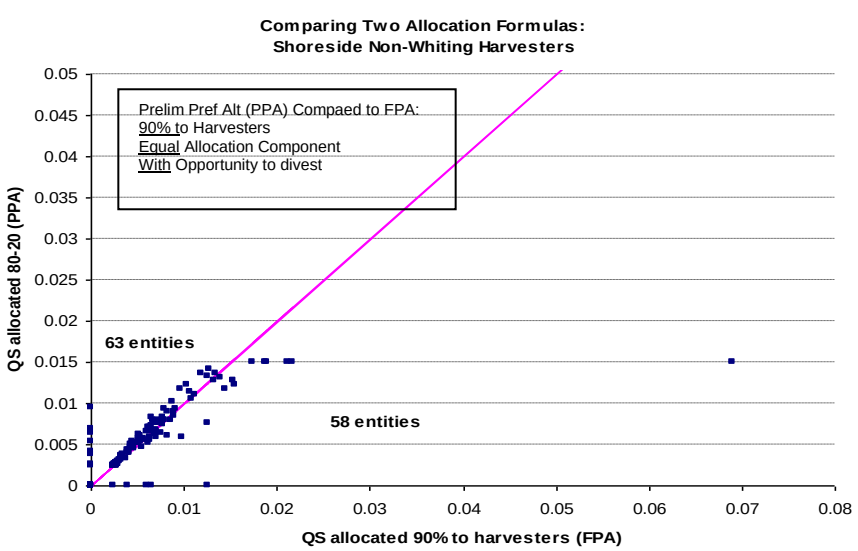
As with processors, the effect of the imposition of the IFQ program on returns to capital for vessel owners will depend on the degree to which those returns are already being given up or dissipated under status quo and the cost structure and debt positions of all firms in the sector. However, the new flexibility provided by the IFQ program may afford harvesters with more opportunity/necessity than processors to modify their operations rapidly, decreasing their total and average costs, particularly as compared to nonwhiting processors. If excess capacity leaves the harvesting sector more rapidly (the sector becomes rationalized), the period over which returns on investment are dissipated in bidding for QS could be shorter than that for processors. The illustrations provided above for processors (Figure A-5 and Figure A-6) can also be applied to harvesting operations in the nonwhiting and whiting fishery. The difference is that rather than bidding up the price of raw fish, the harvesters will increase their costs by bidding up the price of a different key input, the QP. A similar dynamic will ensue in which there will be opportunities for harvesters to reduce costs under an IFQ program as compared to status quo management, and relative cost structures and debt positions will determine how much of the potential profits are bid away to QP owners. The process by which vessels increase their economic efficiency as QS is consolidated and transferred from less efficient to more efficient producers. The process by which less efficient vessels leave the fishery is described in Section 4.6.2.1.

Harvesters must acquire QS or QP in order to harvest. The more of the QS that is given to harvesters as part of the initial allocation, the less they will continue to dissipate their returns on investment in bidding for a market for their raw fish or for QS/QP.

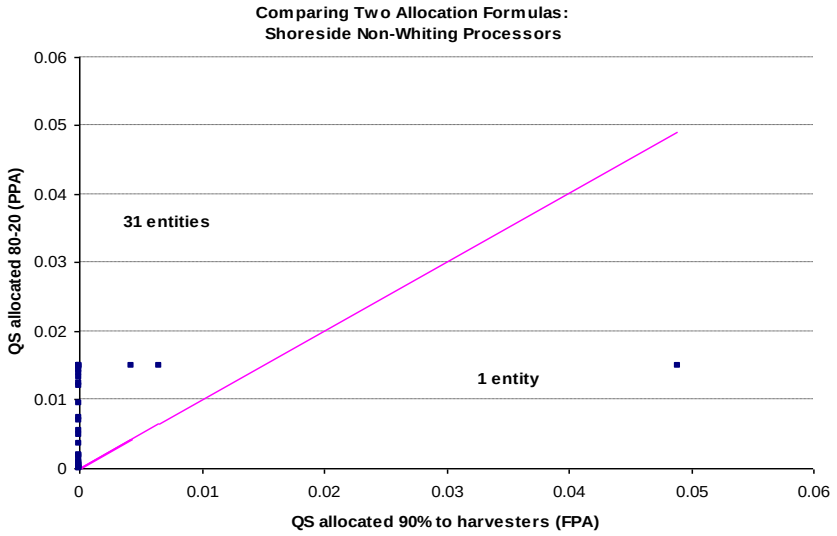
If 100 percent of the QS is given to permit holders, the need for harvesters to give up returns on capital in order to bid more for QS would depend on how the initial allocation matches up with their existing and optimal production levels. As the amount given to processors increases a harvester's need to acquire QS (or access to QP) in order to continue its operations increases.[27] The top half of Figure A-7 provides a scattergram showing how entities fare under the FPA as compared to the PPA. The left-hand side of the figure shows results for entities that only harvest (hold permits) and the right-hand side shows results for entities that process, some of which also hold permits. From this figure, it can be seen that, despite less total QS going to harvesters under the PPA, most harvesters (63) may have fared slightly

[27] Processors do not need QS in order to maintain their existing operations.

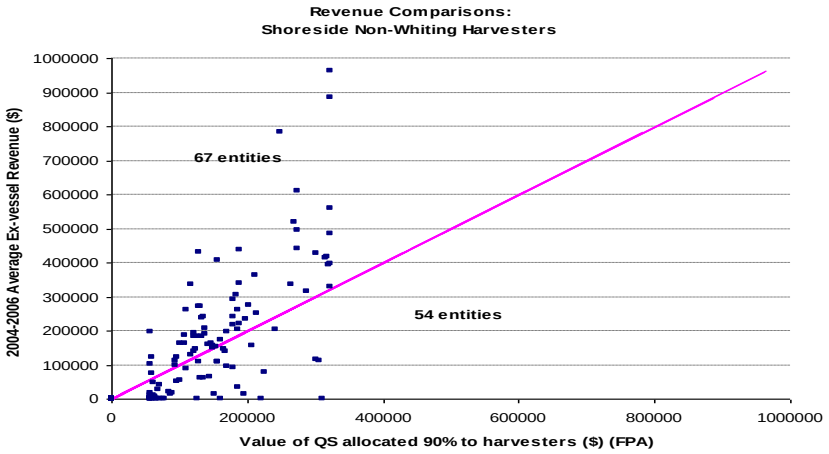
better with the PPA than under the FPA (58 fared better under the FPA). The reason for this is likely the effect of the grandfather clause provision, and this result may be somewhat misleading. First, the reason the PPA appears to perform better for many individual entities is that the initial allocations to any one entity are capped at 1.5 percent[28] of the nonwhiting QS. Looking along the horizontal axis, it can be seen that a number of entities are expected to receive well more than 1.5 percent of the QS (one at about 7 percent and several at between 1.5 and 2.5 percent). The amount of QS that these entities would not receive because of the assumed accumulation limit approaches 10 percent, and that amount has been redistributed to permit holders with initial allocations below the limits. Additionally, a number of other permit holders while not restricted by the aggregate limits were restricted by the individual species limits. Under the PPA, their allocations are reduced and redistributed to those who are under the control limits. Thus, for many, the increase in the amount of the initial allocation going to harvesters under the FPA is not enough to offset what they might have expected to gain under the PPA, which has no grandfather clause and no opportunity to divest.[29] These results may be misleading because there is a high likelihood that those entities expecting to exceed the control limits because of their ownership of multiple permits would divest themselves of some of their permits prior to the initial allocation in order to capitalize on the value of the QS represented by those permits prior to the time the QS is actually issued. Therefore, many of those who appear to gain under the PPA would not gain nearly as much, or might have a worse outcome under the PPA. The bottom half of Figure A-7 compares the revenue that permits might expect from their initial allocation of QS under the FPA to their recent revenue (2004 to 2006 average). Figure A-8 provides a similar comparison for the PPA. Figure A-9 through Figure A-14 compare the Council's PPA to other allocation formulas, varying various central elements.



With respect to shoreside whiting, the PPA and FPA are virtually identical because both allocate 80 percent to harvesters and 20 percent to processors. The QS control limits are not constraining, so the presence or absence of a grandfather clause does not have an impact on the initial distribution (Figure A-16). The largest producing harvesters would receive the most with a 100 percent allocation to harvesters and no equal sharing. A comparison of this option to the PPA is provided in Figure A-17. Under the FPA, 25 harvesters would receive less QS than they need to achieve their recent average (Figure A-16) as compared to 21 entities that would receive less under a 100 percent allocation to harvesters (Figure A-17).



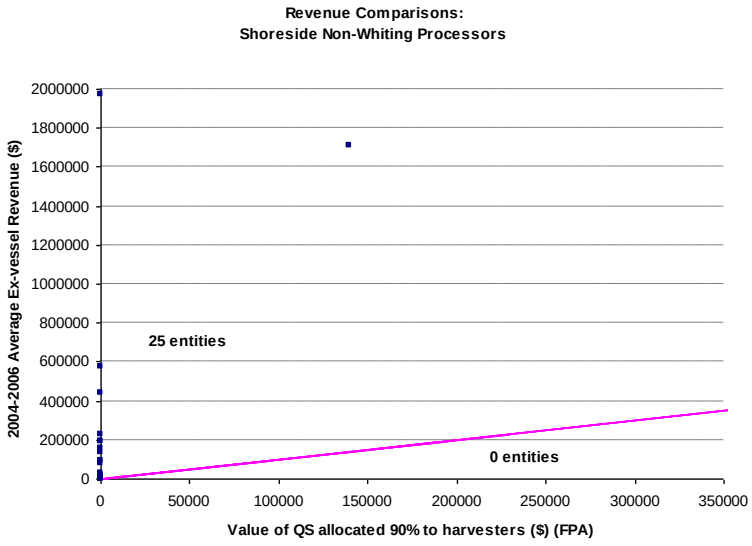
Additional comparisons are provided in Figure A-18 and Figure A-19. Figure A-18 compares the PPA to an allocation formula with 50/50 split between harvesters and processors. Figure A-19 compares the PPA to an allocation formula with no equal sharing. Both alternative allocation formulas also include a grandfather clause; however, because the QS control limit is not limiting for whiting, the presence or absence of the grandfather clause does not affect the results.



Similar information is provided for the mothership whiting fishery in Figure A-20 and Figure A-21. Under the FPA, the mothership sector would be managed with co-ops rather than IFQs.

[28] The 1.5 percent aggregate control limit was the most restrictive of the options considered by the Council and was selected for the analysis to illustrate the maximum effect of the grandfather clause provision.

[29] The FPA also does not have a grandfather clause, but, under the FPA, those over the control limits are allowed to receive their initial allocation and then sell it to others.



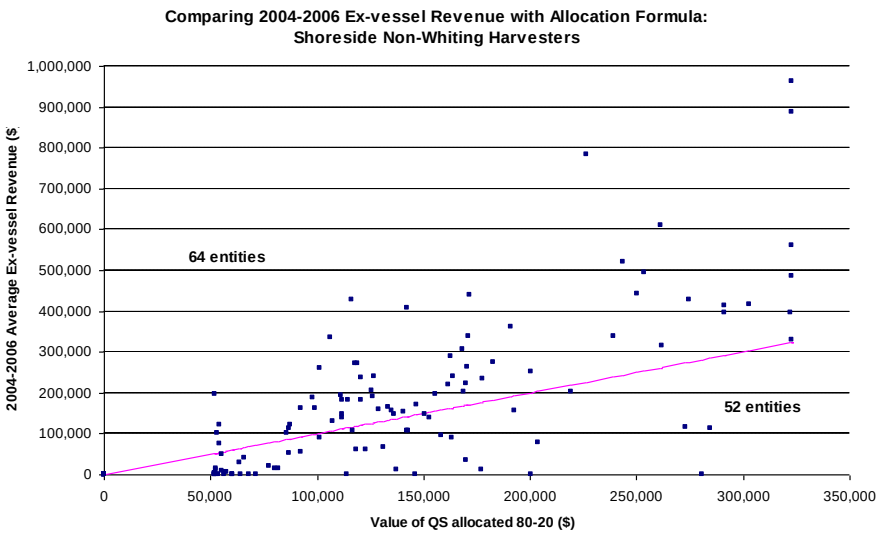


Figure A-7. QS allocations for FPA (90 percent initial allocation of QS to harvesters, 10 percent to adaptive management, with equal allocation of buyback shares, and with opportunity to divest) (QS amounts are entire initial allocation) compared to QS allocations for PPA (80 percent of initial allocation for harvesters, 20 percent for processors, with equal allocation of buyback shares and no grandfather clause) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right.

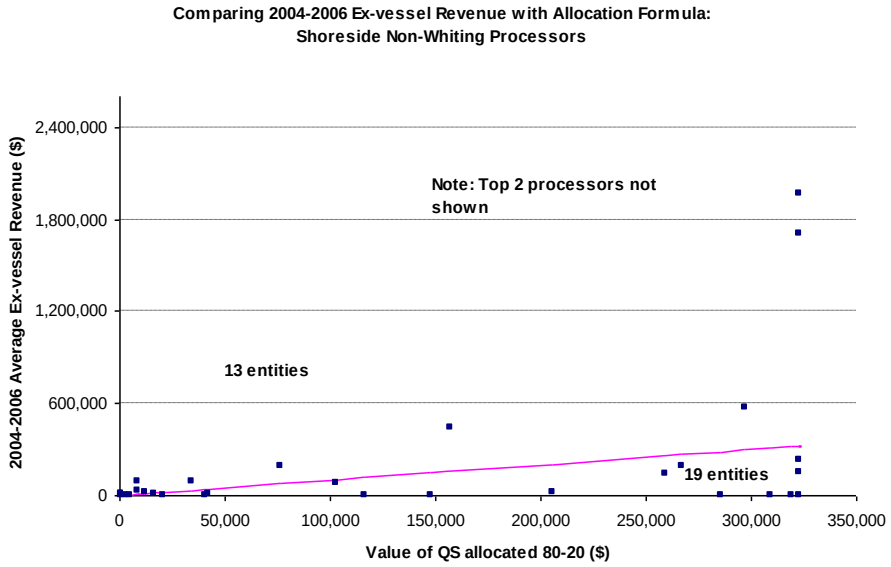

Figure A-8. Annual ex-vessel value estimated for QSs allocated to entities that only harvester (left) and those that process (right) in the shoreside nonwhiting sector under the PPA allocation formula (PPA: 80 percent harvester – 20 percent processor initial allocation of QSs, equal allocation of buyback shares, and no grandfathering for initial allocations over the accumulation limits) compared to average 2004 to 2006 ex-vessel revenue of landings for each entity.

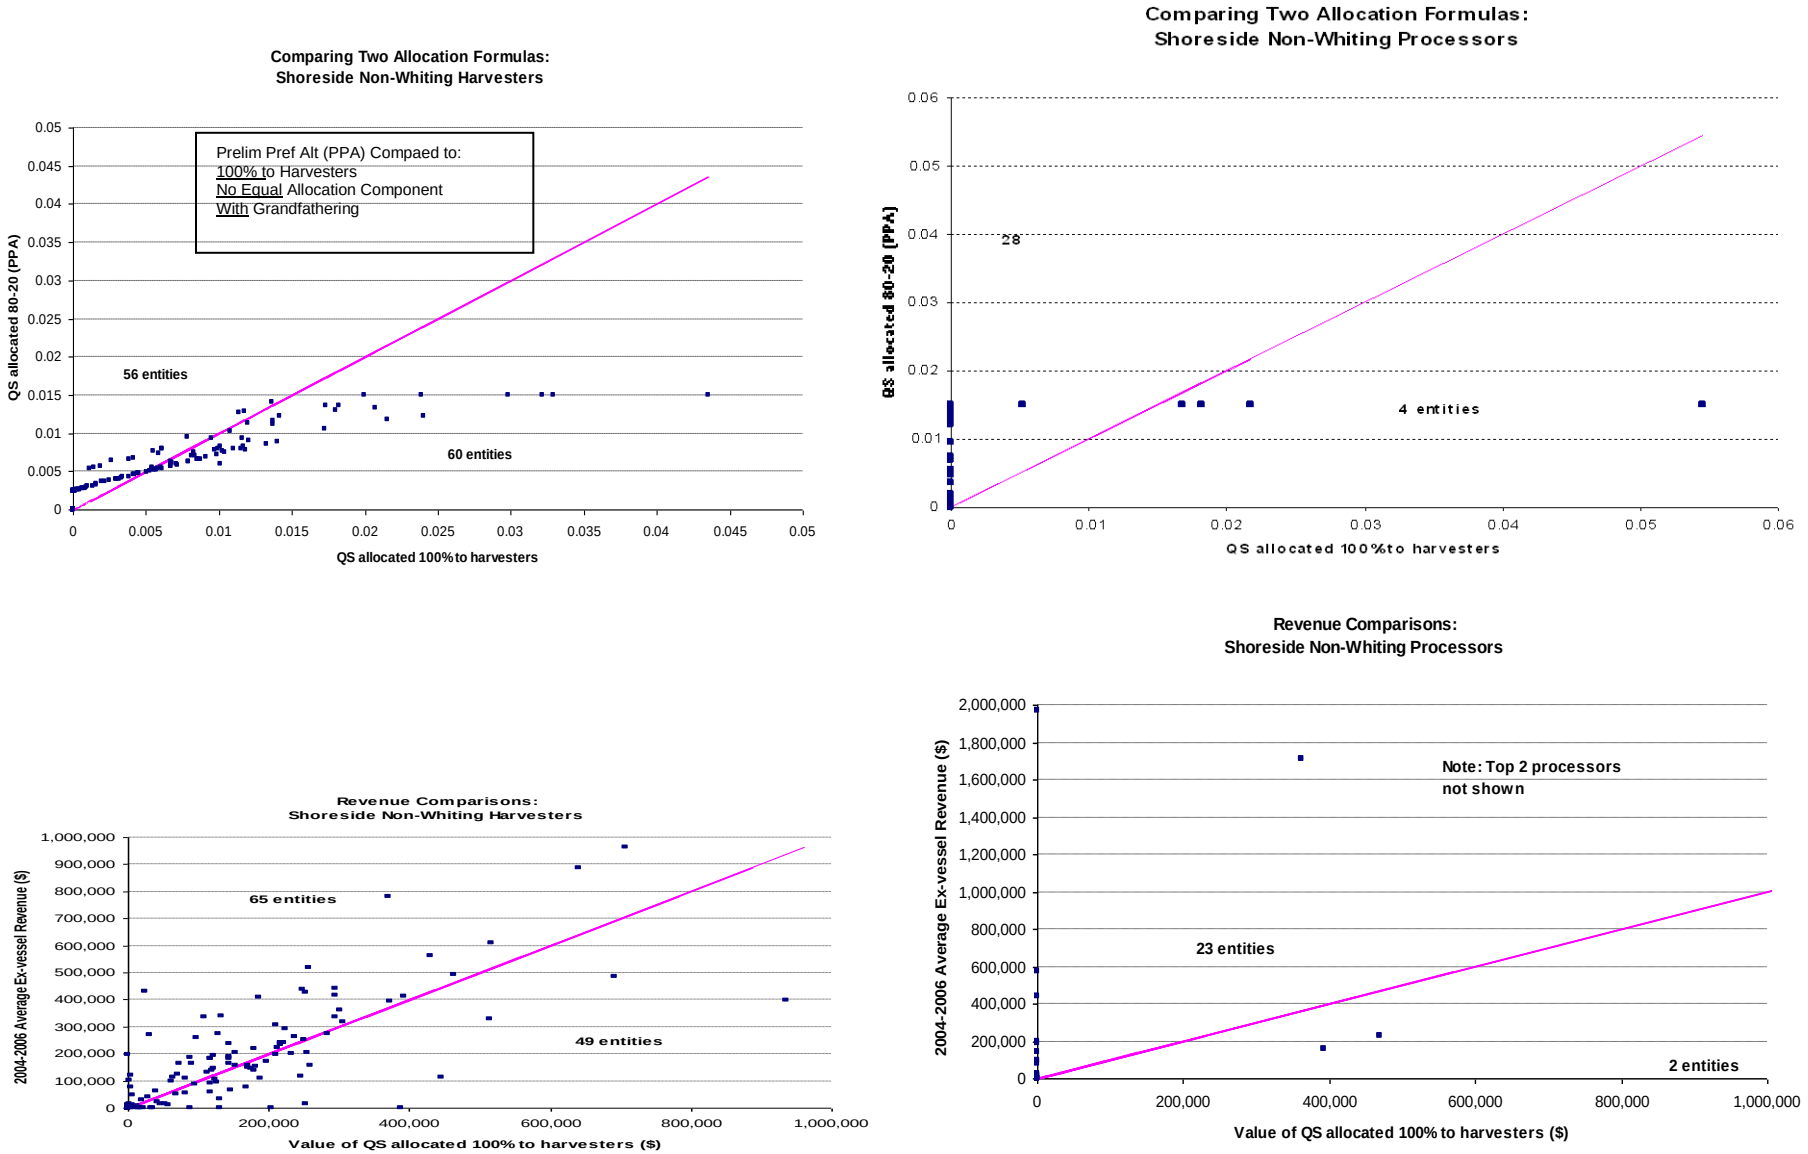

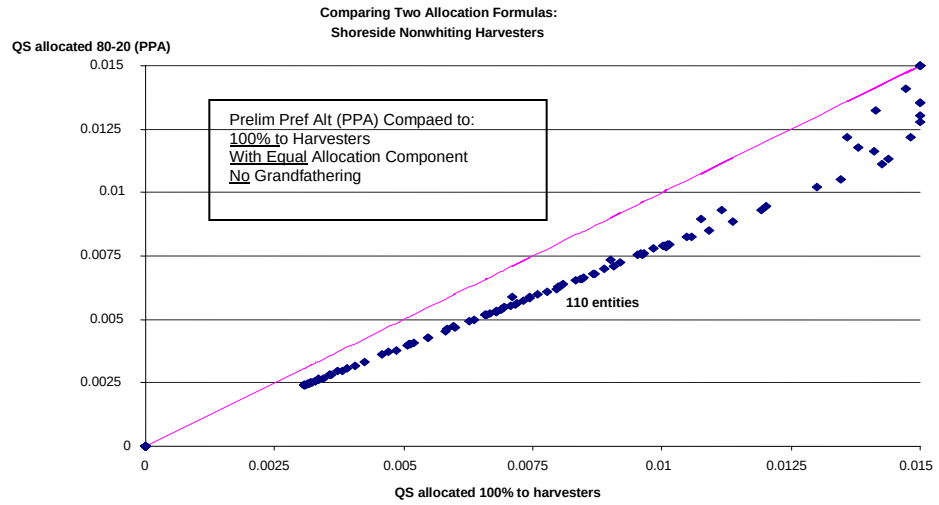

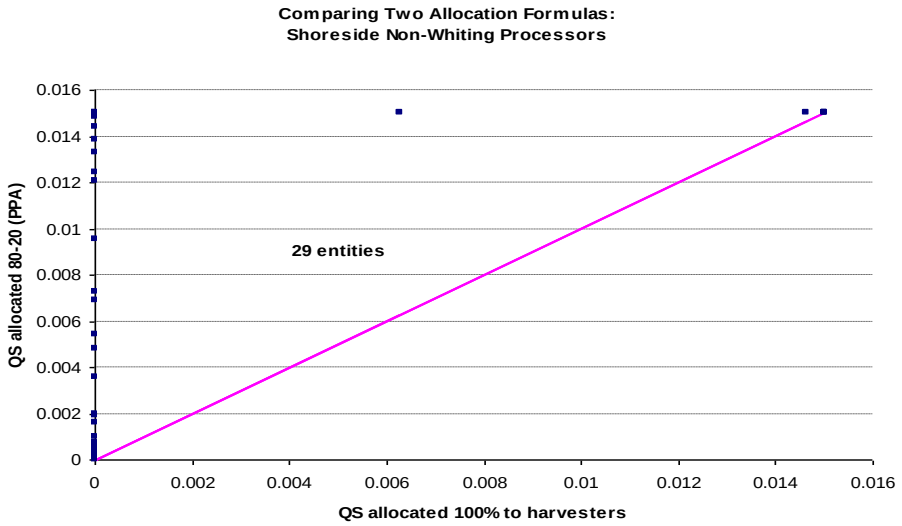

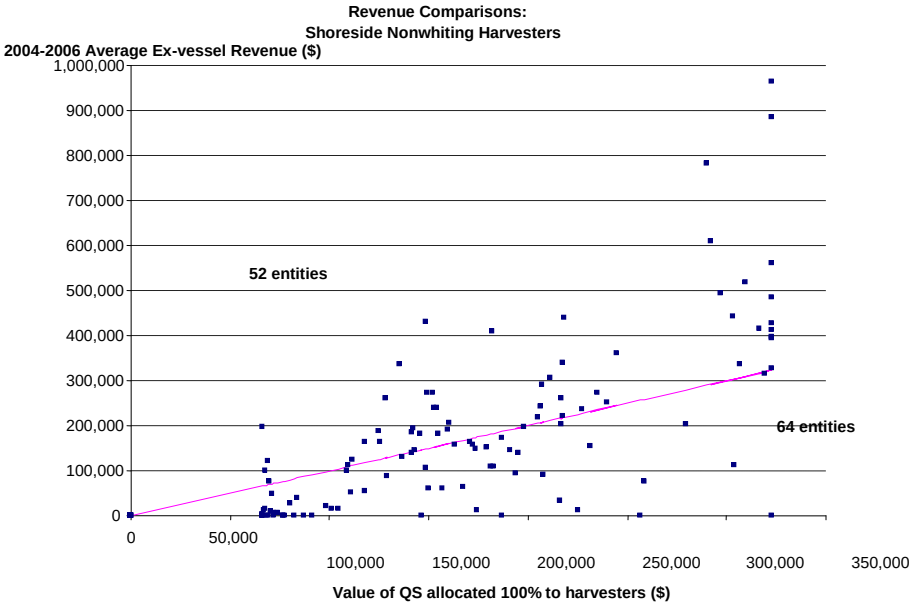

Figure A-9. QS allocations for formula with 100 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for QS allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right.

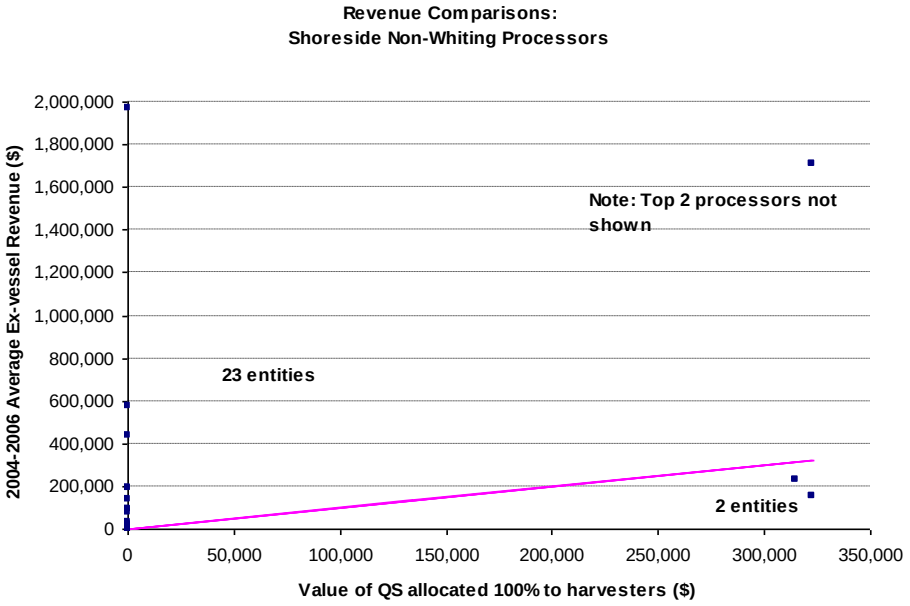

Figure A-10. QS allocations for formula with 100 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and no grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right.

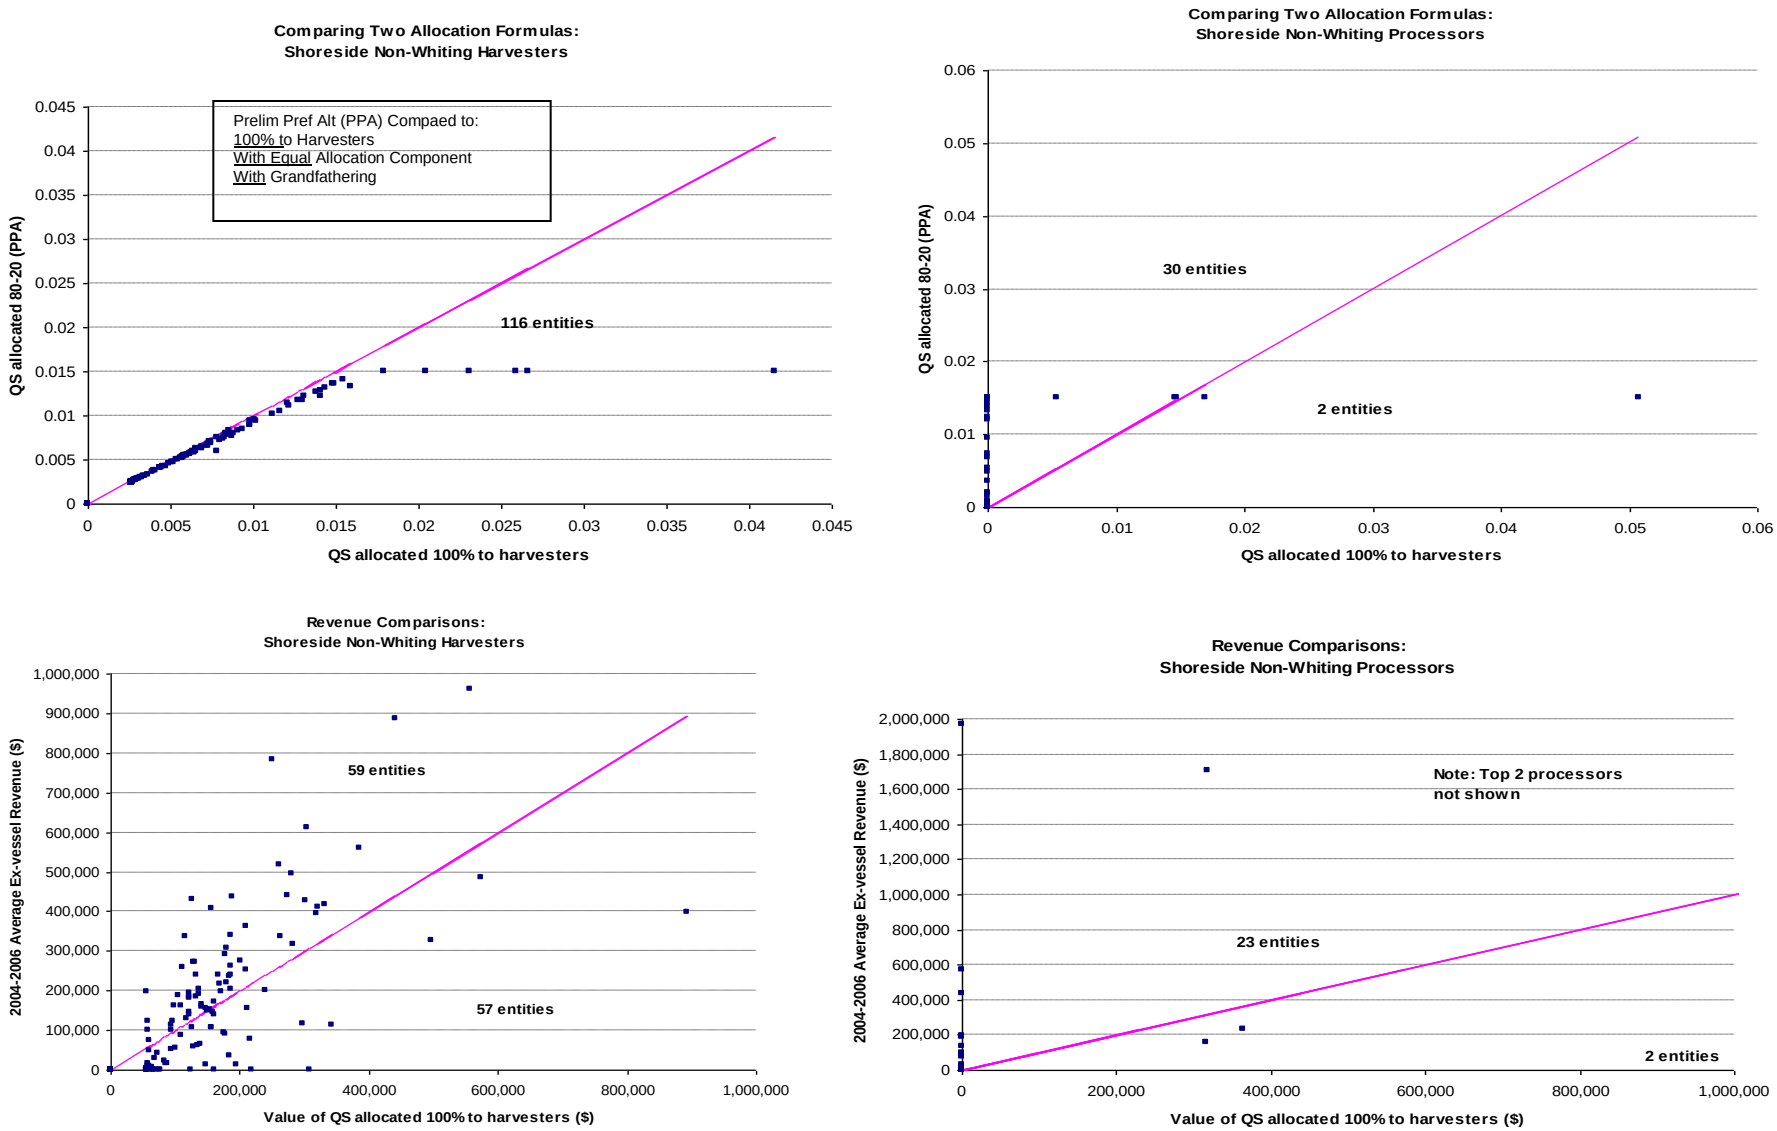

Figure A-11. QS allocations for formula with 100 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and a grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right.

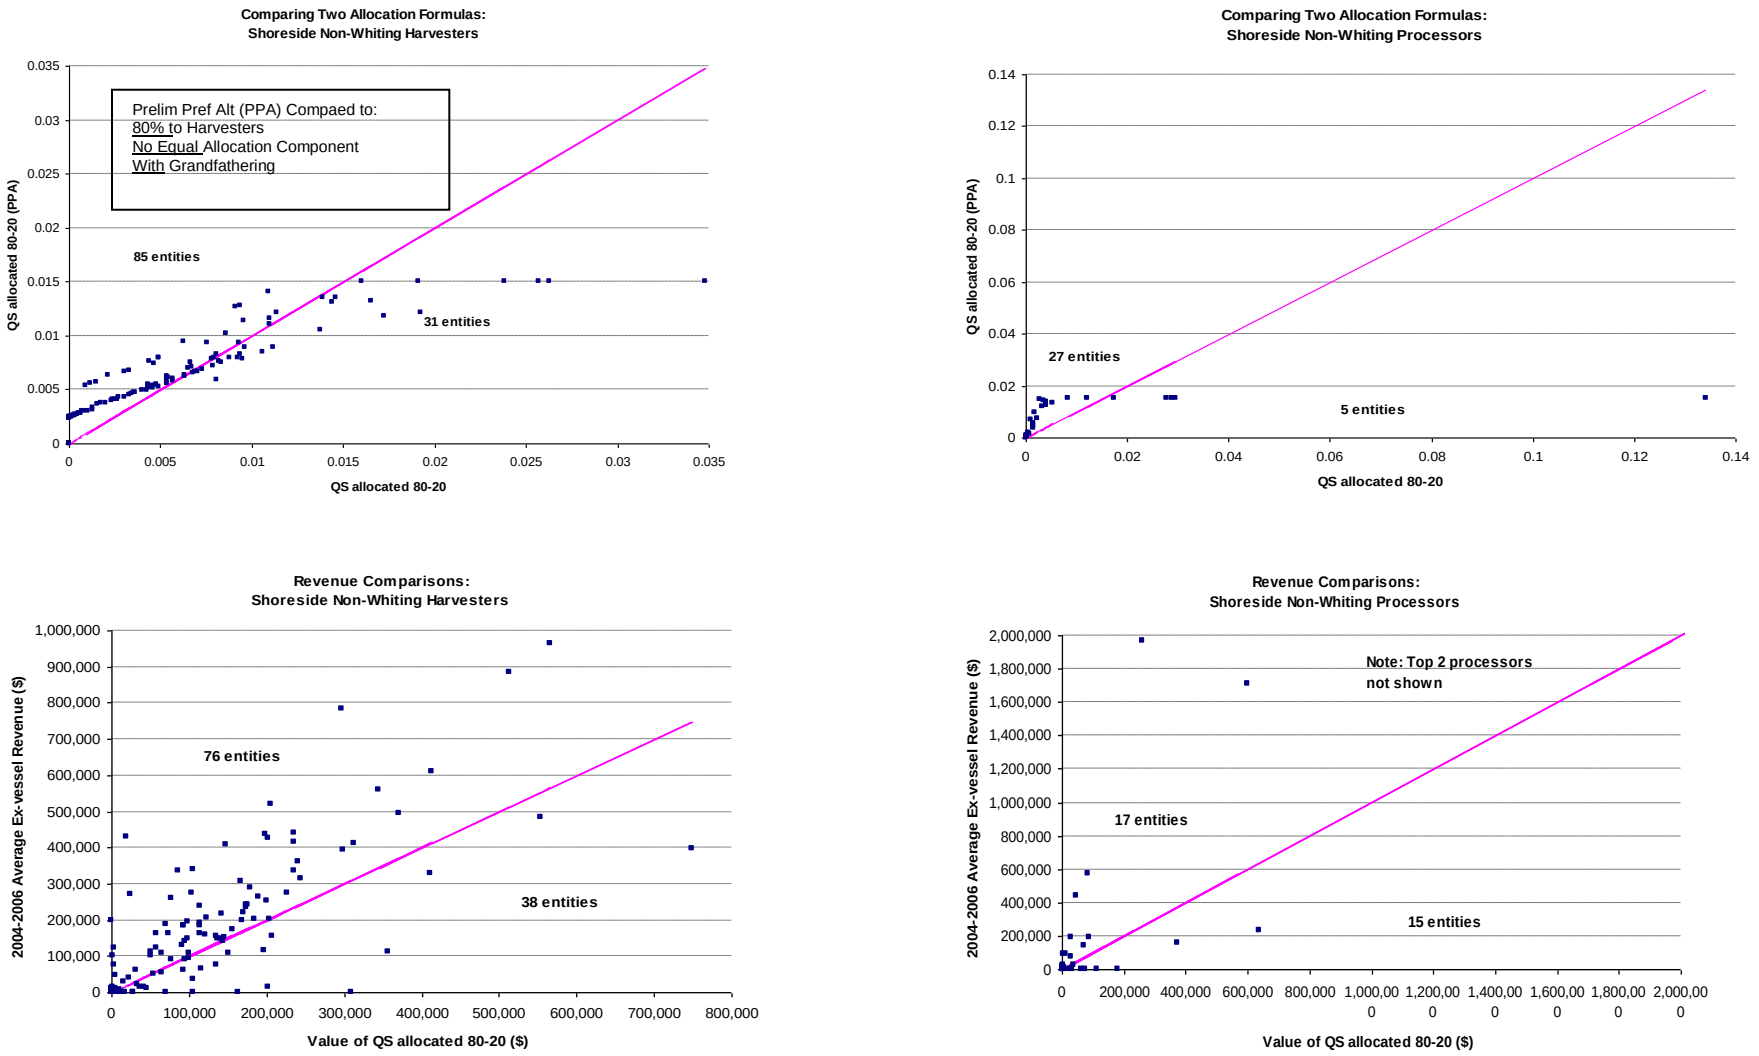

Figure A-12. QS allocations for formula with an 80 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right.

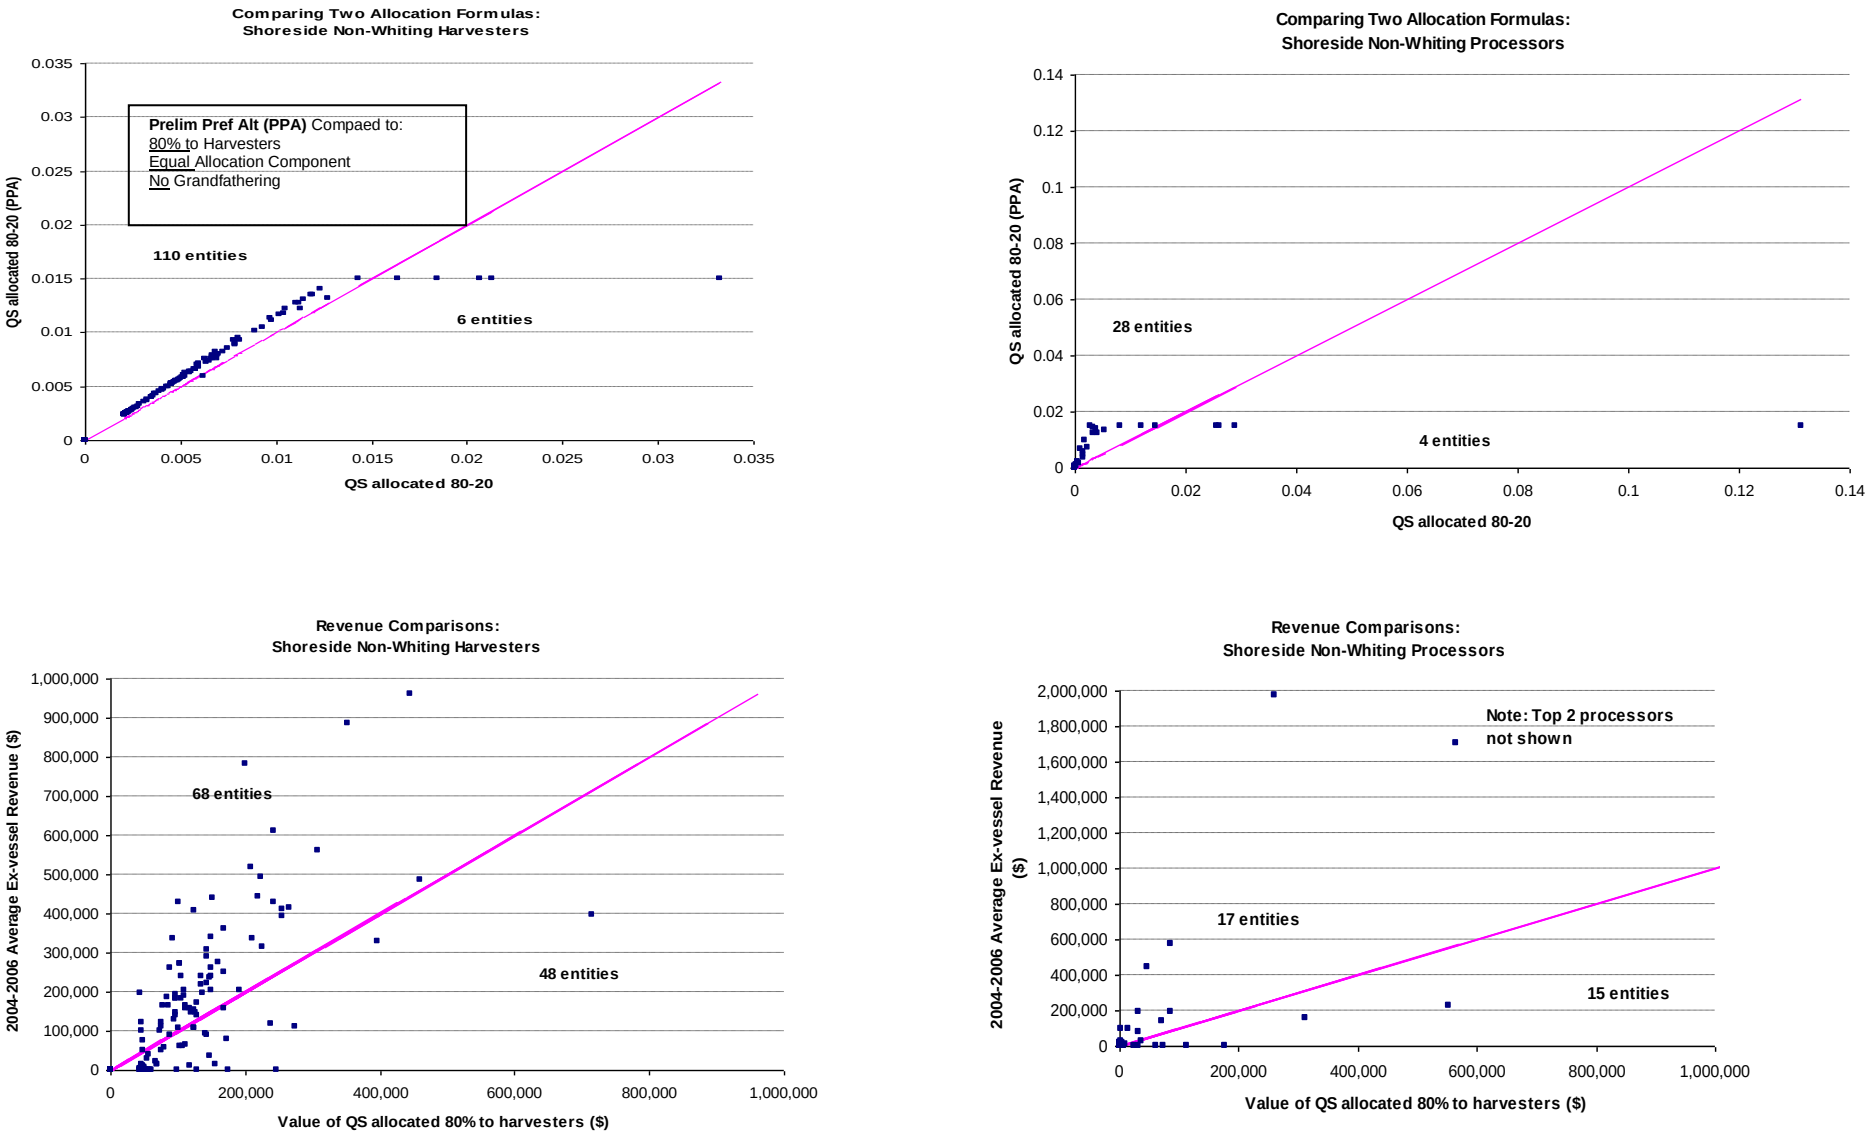

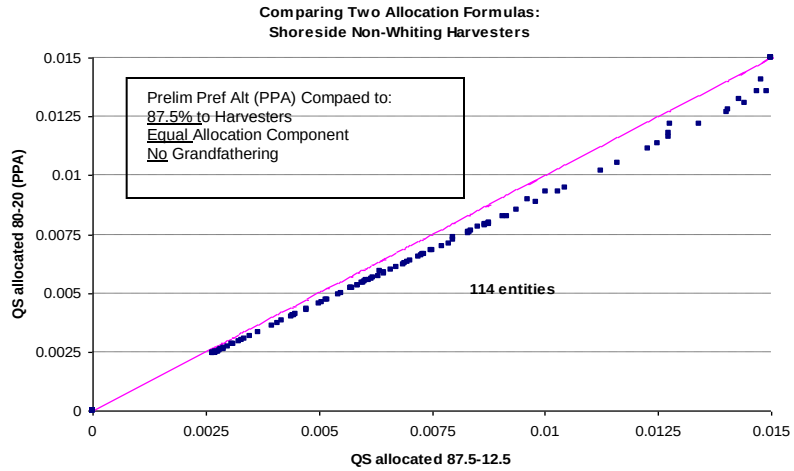

Figure A-13. QS allocations for formula with an 80 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits compared to QS allocations for PPA (top) and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right.

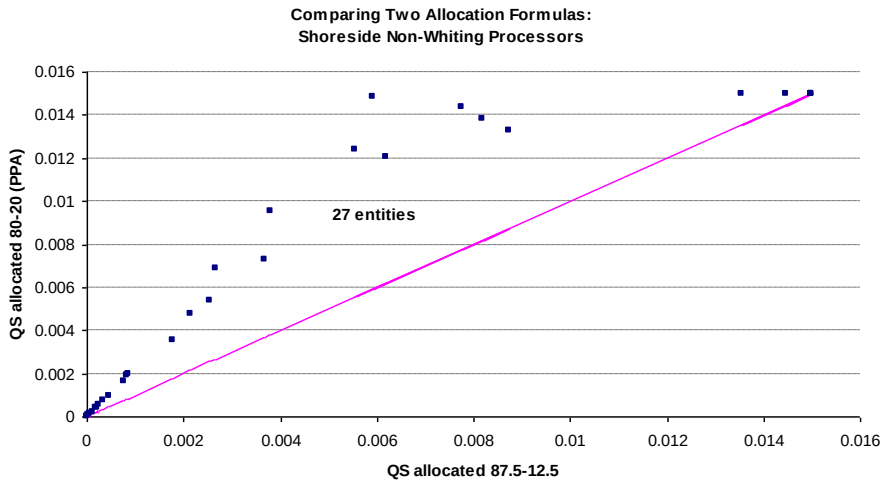

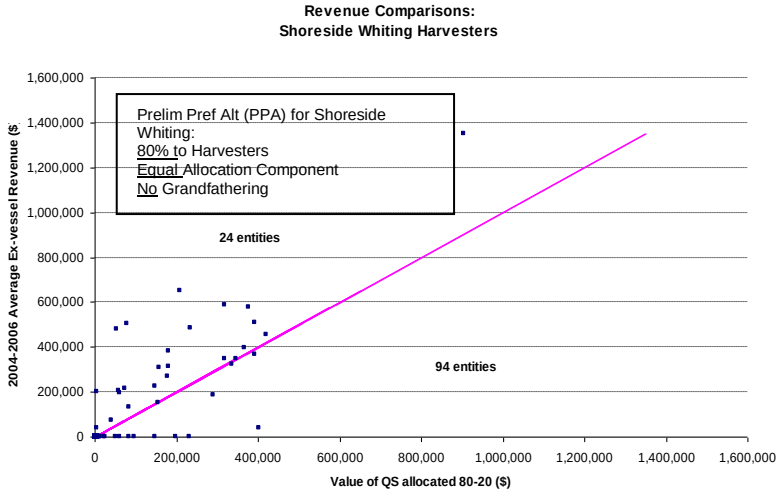

Figure A-14. QS allocations for formula an 87.5 percent initial allocation of QSs to harvesters, equal allocation of buyback shares, and no grandfather clause for initial allocations over the accumulation limits compared to the PPA.

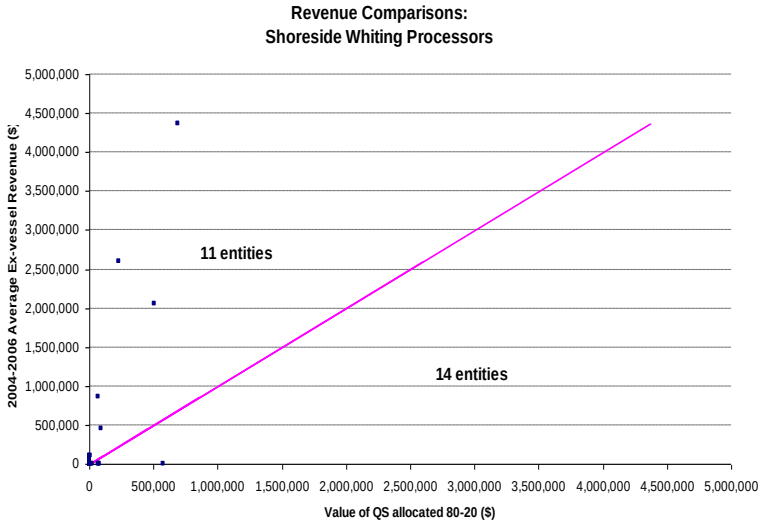

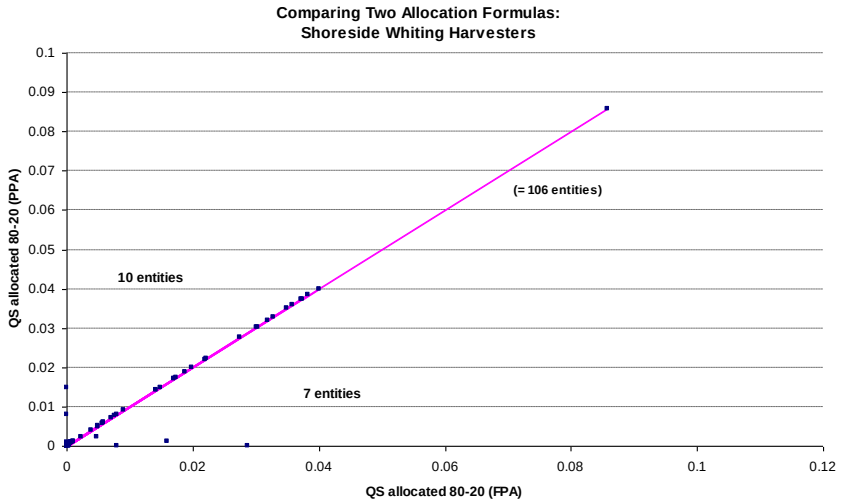

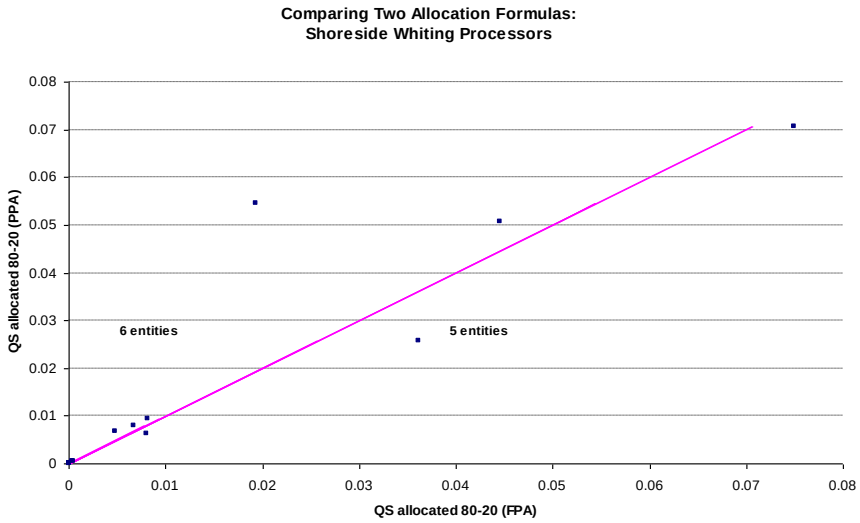

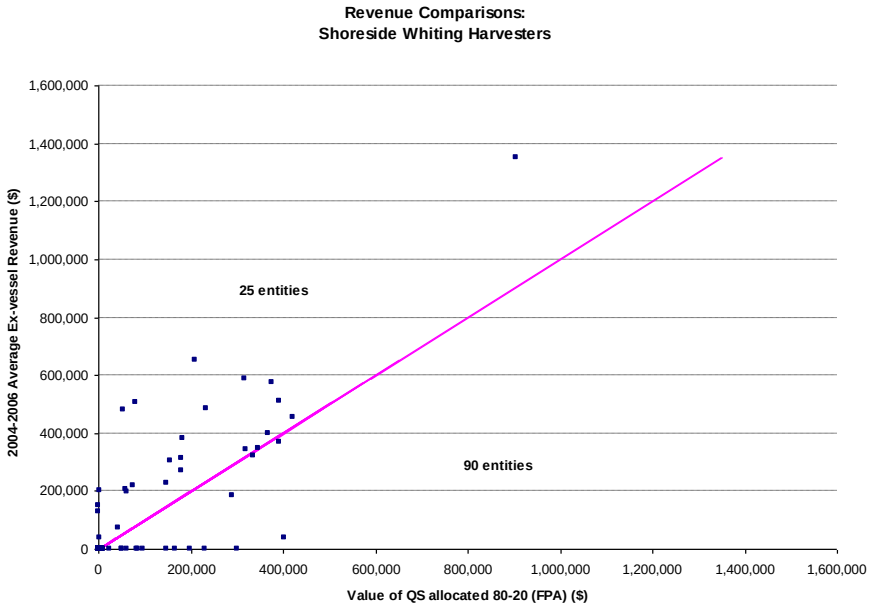

Figure A-15. For whiting, the annual ex-vessel value of QSs allocated to entities that only harvester (right) and entities that processors (left) in the shoreside whiting fishery under the PPA allocation formula (PPA: 80 percent harvester – 20 percent processor initial allocation of QSs, equal allocation of buyback shares, and no grandfathering for initial allocations over the accumulation limits) compared to average 2004 to 2006 ex-vessel revenue of landings for each entity.

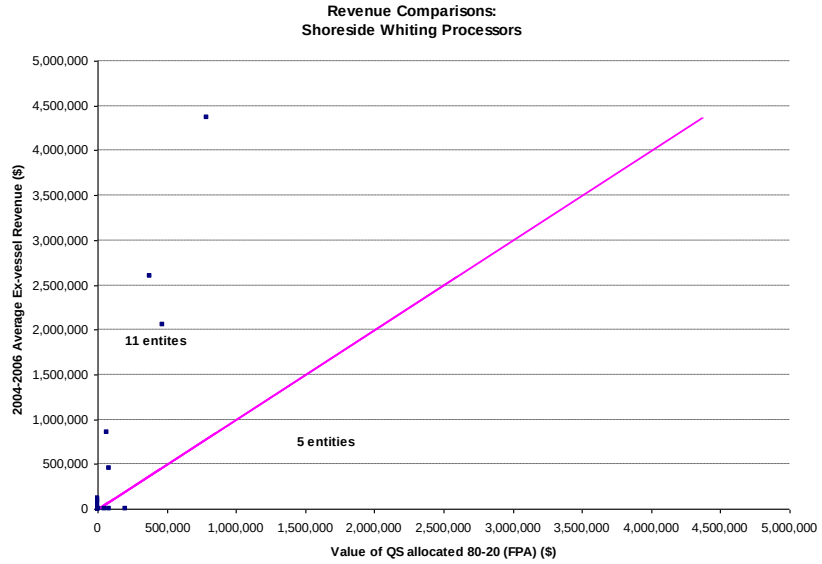

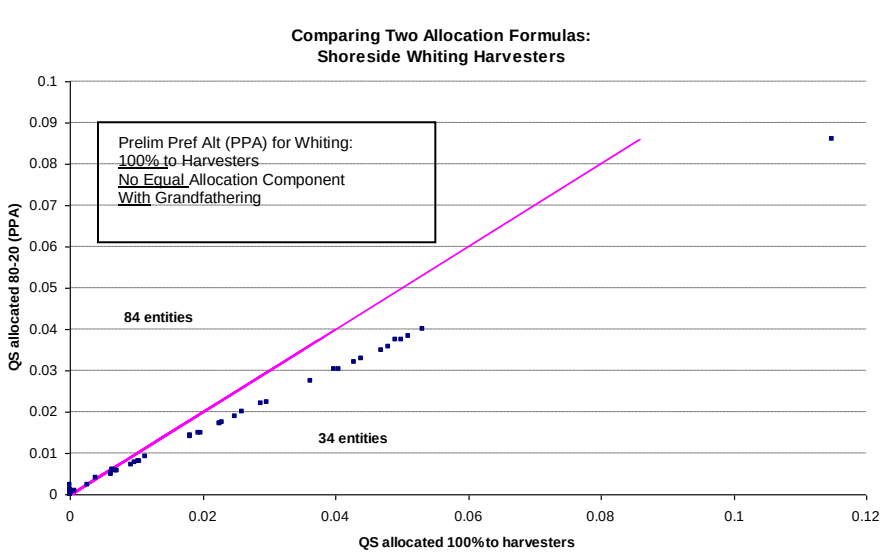

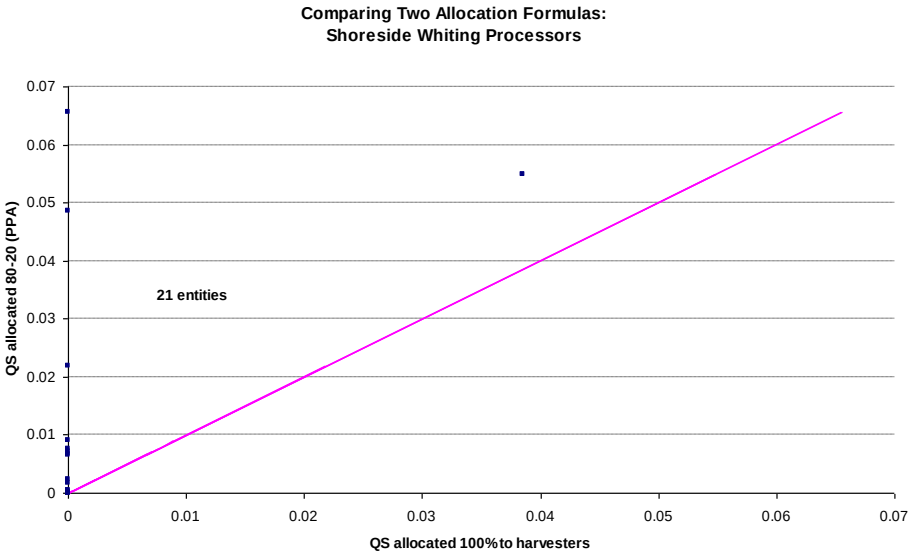

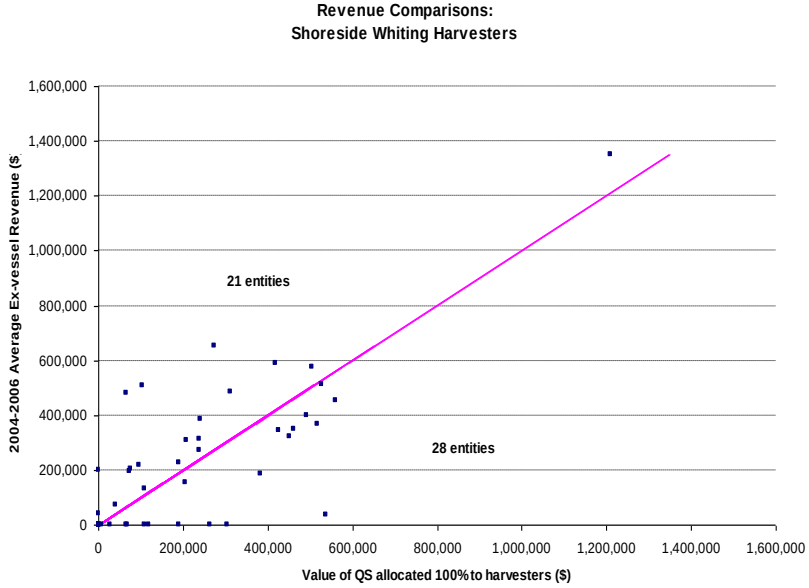

Figure A-16. For shoreside whiting, comparison of the FPA to the PPA, and converted to ex-vessel revenue and compared to average 2004 to 2006 ex-vessel revenue of landings for each entity (bottom)—entities that only harvest (left) and those that process (right)—any QS for processor-held permits is on the right.

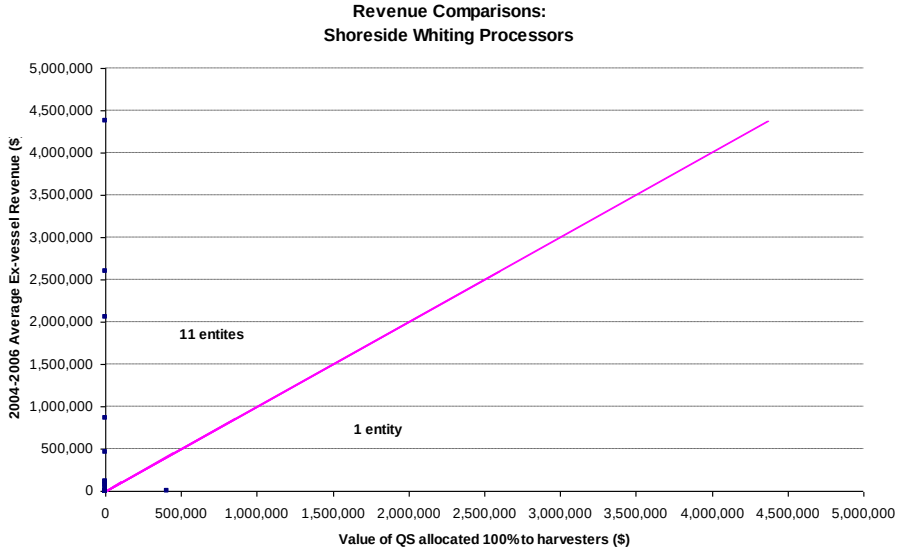

Figure A-17. For shoreside whiting, comparison of the PPA allocation formula to one with 100 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits.

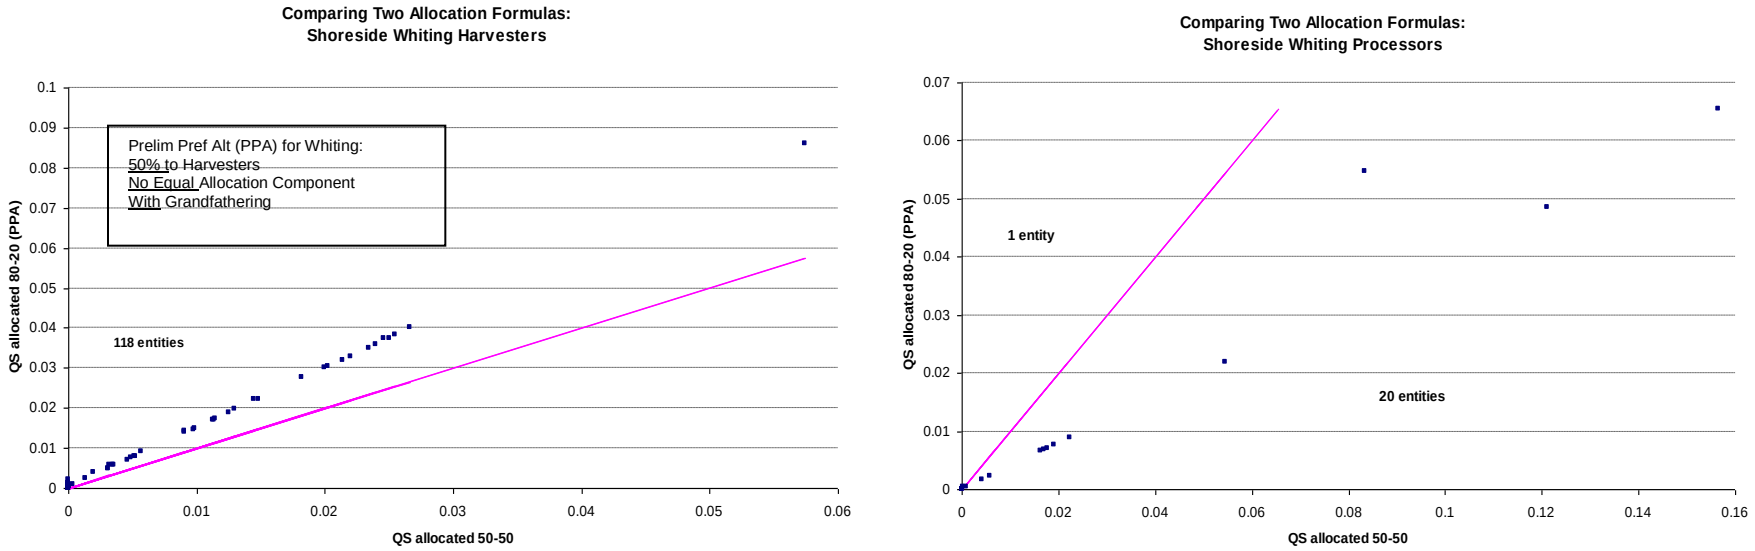

Figure A-18. For shoreside whiting, comparison of the PPA allocation formula to one with 50 percent initial allocation of QSs to harvesters, 50 percent initial allocation of QSs to processors, equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits.

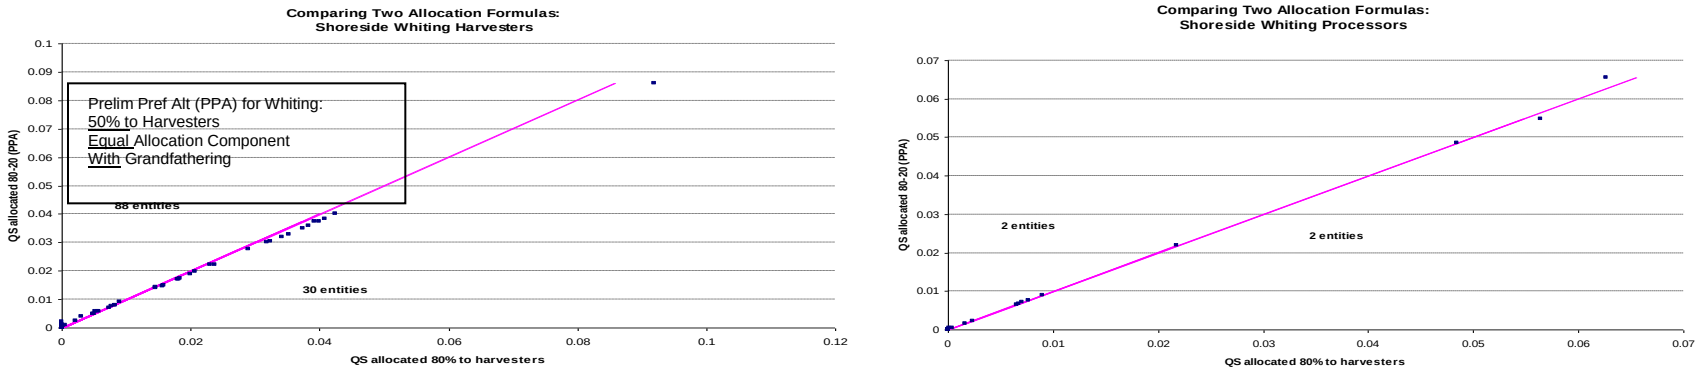

Figure A-19. For shoreside whiting, comparison of the PPA allocation formula to one with an 80 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits.

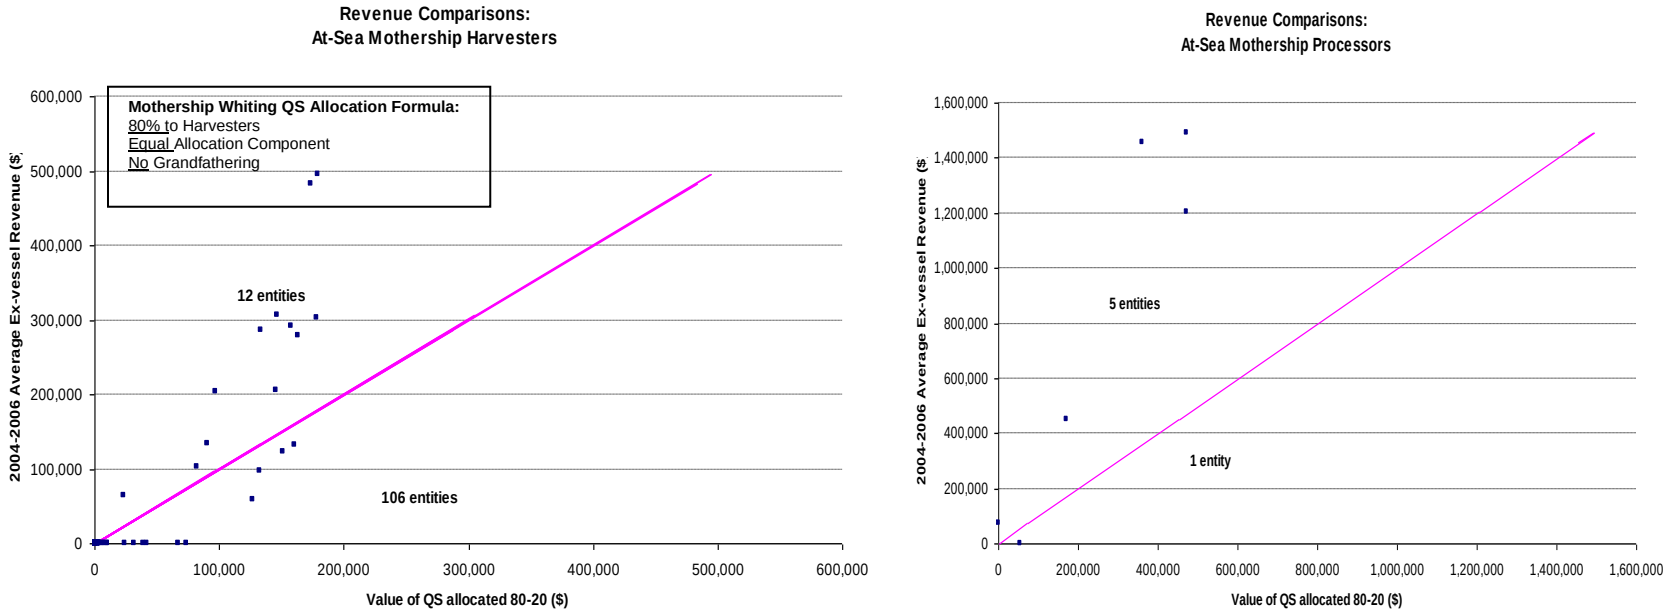

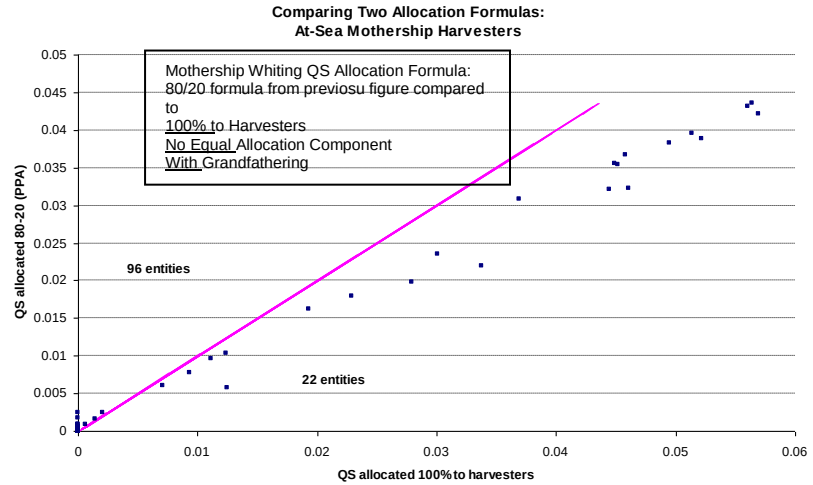

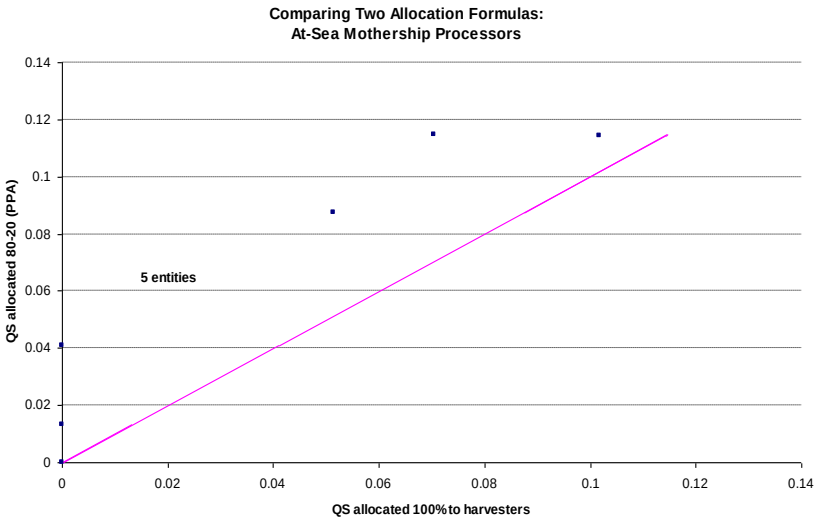

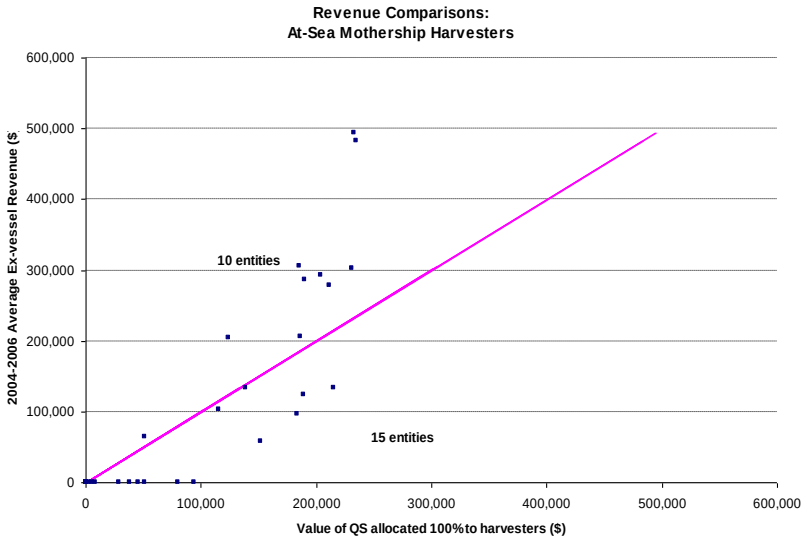

Figure A-20. For mothership sector whiting, the annual ex-vessel value of QSs allocated to harvesters and processors in the at sea mothership whiting fishery (under an allocation formula using 80 percent harvester – 20 percent processor initial allocation of QSs, equal allocation of buyback shares, and no grandfathering for initial allocations over the accumulation limits) compared to average 2004 to 2006 ex-vessel revenue of landings for each entity.

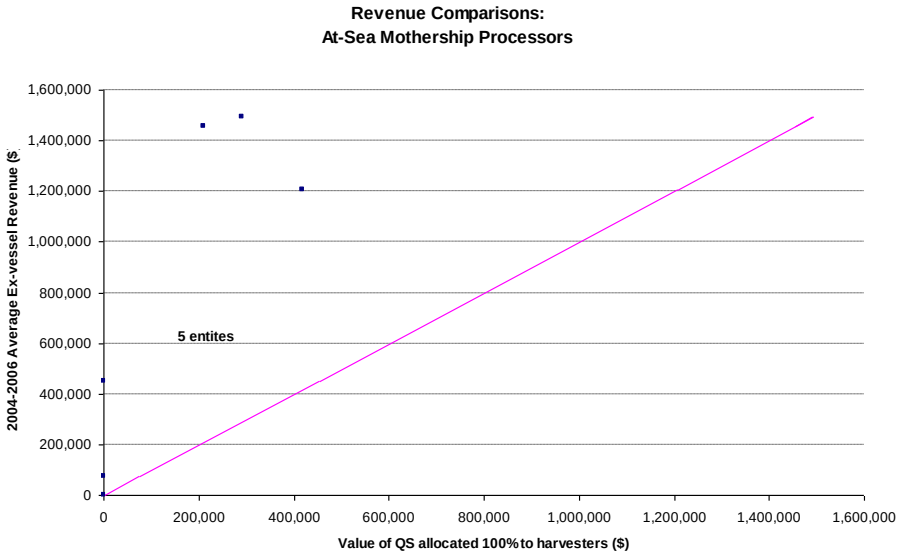

Figure A-21. For mothership sector whiting, comparison of the PPA allocation formula to one with a 100 percent initial allocation of QSs to harvesters, no equal allocation of buyback shares, and with a grandfather clause for initial allocations over the accumulation limits.

Vessel owners that are not permit owners (i.e., do not receive an initial allocation of QS) will be in a particularly difficult position with respect acquiring QS in terms of both their need and their ability to borrow money for QS acquisition. However, they will essentially be in the same position as a new entrant (Francis, *et al.* 2007) (except they will have already made substantial capital investments and have some expertise in the fishery). For harvesters already under some financial stress (in particular those which do not have much equity in their capital assets), the need to acquire QS or access to QP, combined with limited assets to provide as collateral for QS purchase will put them at a greater risk for bankruptcy or exiting the fishery, as compared to a processor in a similar financial situation that does not receive QS. Harvesters leaving the fishery are part of the rationalization process. To the degree that harvesters do not receive the QS they need for their operations, firms may leave the fishery more rapidly when the program is first implemented.

a. The relative position of harvesters receiving QS compared to those not receiving an initial allocation will be affected by the price of QS and whether or not the firm has recovered its previous capital investments or is still making payments (Table A-30). When the fishery is fully rationalized the price of the QS will represent the profits associated with resource rent. When it is overcapitalized, the price of the QS may also include some profits that would otherwise have gone to returns for capital investments. A firm may receive the QS free as part of an initial allocation, may be able to purchase QS at a price that represents the rent to the resource, or may have to pay a higher QS price (one that represents rent to the resource and some additional amount associated with the degree of overcapitalization in the fishery). Each of these situations are represented in the rows of Table A-30. The firm may come into this situation from one of two positions with respect to its capital investment, either at a time when it has fully recovered the cost of the capital investment (having repaid any loans taken to make the investment) or at a time when it is still making payments on the original investment (the columns of Table A-30). A firm that has existing debt and has to acquire QS (or access to QP) before the fishery is completely rationalized, may find it difficult to remain in the fishery (lower right hand cell of Table A-30).

Table A-31. Effect of the IFQ program on a firm's economic status with respect to capital investment, depending on QS price (rows) and whether or not it is still making payments on existing capital investments (columns).

	Status the Firm's of Capital Investment	
Cost of IFQs	**Recovered Capital Investment (Little Outstanding Debt)**	**Still Paying for Capital Investment (Outstanding Debt)**
Endowment Received at Minimal Cost, as Part of Initial Allocation	Excellent position for growth and competition. Endowment plus cash flow associated with already paid for capital and greater efficiency.	Increased ability to pay for capital with better efficiency under IFQs.
Purchase: QS Price Represents Resource Rent	Should be able to recover QS cost through profits, plus have some additional cash flow associated with already paid for capital.	Should be able to recover QS cost through profits.
Purchase: QS Price Represents Resource Rents and Some Profits That Would Otherwise Go to Returns to Capital Investment	Should be able to recover QS cost through profits and some of the cash flow associated with already paid for capital.	May have to exit fishery if the increase profits are not enough to compensate for the cost of the QS and make payments on capital investment.

In the section below on Current and Historic Harvests (page A-98), the effect of an allocation of QS to processors on existing permit-processor associations (based on 2004 to 2006 patterns) is evaluated. In that section, it shows that, assuming these associations would otherwise remain stable, an allocation of

QS to processors would increase disruption to these associations, in part because some processors would receive allocations that did not receive trawl landings from 2004 to 2006.

SUMMARY

Greater amounts of QS given to harvesters as part of the initial allocation will achieve the following:

- Strengthen their bargaining position compared to processors in the raw fish market (to the degree that prices are influenced by negotiations rather than "going" market prices).
- Provide more harvesters with amounts of QS that provide at least as much future harvest opportunity as they have taken in recent years.
- Reduce disruption that might result from the immediate departure of firms that receive substantially less than what they need to stay in business and that are unable to finance additional purchases.
- Result in lower exit barriers by providing compensation for capital losses by those who seek to leave the fishery.
- Decrease borrowing costs by providing harvesters security of an asset that can be used to demonstrate that they have a viable business model when seeking financing for further capital investment (there are indicators under status quo that harvesters are in a weaker position than shoreside processors to acquire access to capital).

♦ *Labor—Harvester*

The following summarizes the findings of Section 4.4.2 on the impacts of the IFQ program on crewmembers.

> In the harvesting sector, the number of crew and captain jobs are expected to decline, but more of the jobs are expected to be full time. Additionally, crew shares may decline but that decline may be offset by an overall increase in vessel earnings such that total earnings per remaining crew member increases. The nature of compensation may also change. Traditionally, crewmembers have taken part in the risk and reward of the harvest operations by taking their income as a share of the vessel revenue, and the share earned by a crewmember varies with their skill level. Under IFQs, there is sometimes a change from share-based compensation to wage-based compensation.

An initial allocation of QS to crewmembers would not necessarily prevent a shift from share-based to wage-based compensation, but would provide crewmembers who have some record of participation a more certain opportunity to maintain a larger share of the harvesting profits. This form of compensation would provide them an award in perpetuity (for the duration of the IFQ program or for as long as they decide to hold the QS, regardless of whether they continue to work as a crew member).

As with physical assets, labor also earns a return that will be affected by the creation of an IFQ program. Crewmembers who earn above average shares because of their development of particular skills may lose the advantage of those skills if they are forced to move into another occupation. However, humans are more malleable than physical capital in terms of their ability to take on different tasks.

The main source of new entrants to the fishery is captains and crewmembers. During Council deliberations on the effect of the program on crewmembers, it has been noted that new entry by crewmembers will be facilitated by the liberal eligibility requirements for owning QS (A-2.2.3.a) and the high degree of QS divisibility, which allows crewmembers incrementally to acquire capital and speed their accumulation of wealth. The IFQ program will make it more expensive to enter the fishery, but will provide a more stable industry for new entrants.

The balance of the allocation of QS among harvesters and processors will affect harvester labor through the speed of adjustment required, the geographic distribution of harvest operations, and the distribution of activity among vessels. As described for harvesters, as the allocation to processors increases, the speed of rationalization in the fishery is likely to increase. More rapid rationalization of capital will require a more rapid adjustment by labor. In addition to the duration and timing of jobs, the initial allocation will affect the locations and vessels on which there are opportunities. While over time, QS is expected to flow to ports that are able to support the most efficient complex of harvesting and processing operations,[30] due to transaction costs and other ways in which the economic system does not function in the ideal, the initial distribution will likely affect the short- and long-term geographic distribution of activities (and hence employment opportunities). The more QS that goes to processors, the more the location of harvest/landing activity will be initially directed by factors related to processing operation costs; and the more likely it is that jobs will be on processor owned vessels as opposed to vessels of independent harvesters.

SUMMARY

1. There is some reason to expect that compensation rates for crewmembers will decline. An initial allocation of QS to crewmembers would provide them with an opportunity to maintain a larger share of the vessel profits.
2. As allocation to processors increases, the speed of rationalization in the harvesting sector is likely to increase requiring more rapid adjustment by crewmembers.
3. Geographic distribution is likely to be affected by the initial allocation. The more allocated to processors, the more harvest/landing activities will be initially directed by factors relating to processing operation preferences and the more likely it is that jobs will be on processor-owned vessels as opposed to independent harvesting vessels.

♦ *Labor—Processor*

The main effect of the initial allocation of QS to processors is likely to be the geographic distribution of processing jobs. The types and numbers of jobs may also be affected by the relative size of the processing operations in the industry. The effect on size of processor operations is discussed in the section above on allocation to the processor sector. The effects on labor are discussed in Section 4.12 on processor labor.

● Impact on Net Benefits

The impacts considered in this section are closely related to the overall economic efficiency outcome (i.e., net benefits or social welfare).

We will look the impact of the initial allocation of QS among groups on net benefits as it is affected by the following:

- Price setting in markets
- Transaction costs
- Implementation costs

[30] Taking into account both travel costs to and from the fishing grounds and to distribution centers for wholesale products

♦ *Price Setting in Markets*

In an efficiently functioning market, neither buyers nor sellers are able to influence price because of the existence of competing buyers and sellers. Everyone in the market is a "price taker," accepting the "going" price. Bargaining power is, by definition, limited. Under certain circumstances, such as when there is a limited number of competitors (see Appendix E for additional discussion), the potential for participants in the market to exert market power increases.

If one side or the other in a market is able to influence price away from the market equilibrium, (i.e., exerts market power) there are generally two effects on economic welfare: (1) it redistributes income toward the side of the market with market power and (2) it reduces overall production in the economy (reduces net benefits). Here the concern is net benefits.

The discussion of the effects of the allocation on market power is summarized very generally as follows:

- Under status quo, there are more indicators that processors may be able to exert market power than harvesters.
- The creation of an IFQ program will likely increase to some degree the potential for harvesters to exert market power or resist processor market power independent of the amount of QS they are initially granted, to the degree that the fleet is rationalized and excess capacity removed. However, even with the main trawl fleet rationalized, there may be some excess capacity that remains, to the degree that vessels in nonrationalized fisheries can be adapted to participation in the groundfish trawl fishery. This opportunity to adapt capacity from other fisheries could adversely affect the fleet's ability to exert market power or resist processor market power.
- If market power, as defined here, exists under status quo, whoever receives an initial allocation of QS is likely to be in a better position to exert market power and accumulate additional QS, unless the creation of the IFQ program changes the system enough that all entities become price takers, for the most part accept the going price.

The IFQ program could potentially break down some of the local market isolation that may currently be limiting the number of effective participants in the market and providing them opportunity to exert market power. It could also both encourage consolidation among processors and encourage or discourage the entrance of new processors with an uncertain net effect on price competition among processors. Local market isolation and other factors that may change the nature of price setting as compared to status quo are discussed in Appendix E. If the markets change such that there are many more players on each side, everyone will become price takers and holding QS will not enhance one's negotiating power.

However, even if the IFQ program and initial allocation allows an entity to exert market power, the effect on net benefits is less clear than under standard economic theory. Under standard economic theory when there are a limited number or buyers or sellers, the exertion of market power can lead to a reduction in total production, reducing net benefits. [31] [32]However, in fisheries production, market power is constrained by government regulation of a key input (the amount of fish caught). Based on current production levels and demand, and the fact that the only costs for a QS holder to produce QP (release QP onto the market additional QP) are transaction costs, it does not appear likely that total annual production will be diminished, even if one side or the other is able to control market prices that total annual production will be diminished. Therefore, market inefficiencies related to reduced production would not be expected. Given that it is not likely that production will be affected by the exertion of monopolistic/monopsonistic (single seller/buyer) power or oligopolistic/oligopsonistic (very limited number of sellers/buyers) power, any market power established as one outcome of the IFQ program or initial allocation will affect the distribution of total net benefits rather than the amount of total net benefits.

♦ *Transaction Costs*

In order for QS to be used, the QP issued to the QS holders will have to be transferred to a vessel account. Transaction costs are those costs associated with the search for an input, the bidding and negotiation process, monitoring performance on the transaction contract, and transaction contract enforcement. The greater the distance in ownership between the QS holder and the vessel, and the more dispersed the ownership of the QS, the greater will be the transaction costs. The entity most certainly connected with the vessel is the vessel owner. Allocations to vessel owners are not being considered. The next entity that is most probably linked to the ownership of a particular vessel is the permit owner (about 87 percent of the permits appear to be owned by the vessel owner). Crewmembers are also associated with vessels but are probably more mobile between vessels and there are more crewmembers than vessels. Therefore, an allocation to crewmembers would involve the negotiation of more transactions and greater transactions costs than an allocation to vessels. Processors also have close connections to vessels (7 percent of permits, or 17 permits in total, are owned by processors). An allocation to processors would require fewer transactions, and would likely result in lower total transaction costs, than an allocation to crewmembers. However, except for processor owned vessels there would still have to be transfer of QP each year from QS owners to the vessel owners/operators.

---

[31] NMFS guidelines on LAPPs suggest that excessive control of QS might result in an individual operating as a monopsonist or monopolist in the QS market and that this would lead to a less efficient fleet (NMFS 2007).

[32] Exerting monopoly like control over prices in a QP market has some particular challenges.

- If a dominant QS holder releases QP in a manner that reduces fleet efficiency, the amount individuals would be willing to pay for QP would be reduced by the reduction in efficiency.
- QPs are nonperishable and highly liquid
- Any QP released may be held by the buyer, reducing the QS holder's market power.
- While there is an opportunity cost for not using QP, the production cost of QP is almost zero, and any QP not released to a vessel by the end of the year expires; therefore, it is likely that all will be released.

The main profits available through the exertion of market power are those that would otherwise go to the QP holder, unless the following occurs:

- Profits that would otherwise go to return on investment are captured (i.e., there is some excess capital in the fishery or within a local area),
- The power is used to affect prices in a transaction that does not include the QPs being used to establish the market power.
- The dominant QS holder is able to achieve price discrimination (charge each potential buyer the maximum he/she is willing to pay rather than a market price based on the release of a reduced quantity of QS, the more typical way a monopolist would extract additional rents).

On this basis, it appears that transaction costs will be lower with an allocation to permits than with an allocation to processors, with the exception of those processors that may operate their own vessels.

Another factor affecting transaction costs is how the QS are distributed compared to the recent distribution of catch among fishery participants. The greater the difference, the more transactions required to get the QS/QP into the hands of those who need it to continue their operations. If these transactions do not occur, higher costs will emerge as dislocation costs since those who have been recently catching the fish will no longer be able to do so, and those receiving the QS may ramp up to higher levels of production than they have experienced in the recent past. In the section below on equity, a quantitative assessment is provided of the difference between the distribution of QS among participants and the recent participation history of those participants (Current and Historic Harvests on page A-98). That section (Figure A-22) shows how QS would be distributed among associations of processors and harvesters (based on 2004 to 2006 landings activities). This figure shows that, there is a greater mismatch between recent production by processors-permit associations and the QS distribution to those processor-permit associations with a 25 percent allocation to processors.

♦ *Administrative Costs*

Each group to which an initial allocation is given will add to the administrative start-up costs of the program. The least expensive way to make an initial allocation would likely be through an auction that is open to all comers; however, such an option is not among those that have been identified for full analysis. Permit owners are a defined group; therefore, an allocation or auction to permit holders would likely be relatively in expensive, as compared to an allocation to crewmembers. While an allocation to crewmembers is not impossible, it would be difficult because crew licensing varies by state and data are not kept on the crewmembers working on each boat. Such an approach could require the development of complex rules for evaluating crewmember qualifications or simple rules that either do not allocate to the intended crewmembers, or allocate to substantially more people than the intended crewmembers. In either case, the costs of the initial allocation would increase substantially. An allocation to crewmembers is not being considered at this time. The other group for which the Council is considering an allocation is processors. The costs of allocating to processors will depend on the rules developed for the allocation. Information about buyers is included on every fish ticket, but there is no information on the ticket about whether the buyer (1) is a processor and (2) processed the fish documented on the fish ticket. The Council's intent is to allocate to processors, but an allocation to buyers was considered as a lower cost proxy for the allocation to processors. This is discussed in more detail in Section A-2.1.1.d. The administrative costs of the initial allocation will somewhat affect total net benefits, particularly at the start of the program, but the start-up costs will likely have negligible effects on net program benefits over the long run. Direct costs of the initial allocation will be covered by fees collected from the applicants.

♦ *Summary*

- Even if the initial distribution of QS results in some parties being able to exert market power, the effects are more likely to be distributional than to have an adverse impact on net benefits.
- As the amount of QS issued to processors increases, transaction costs will increase as QP issued to processors holding QS will have to transferred to vessels each year in order to be used (unless processors acquire vessels).
- As the amount of QS issued to processors increases, there is a greater mismatch between recent production by processors-permit associations and the QS distribution to those processor-permit associations.
- Program administrative costs increase with each additional group to which an allocation is made and costs will likely be higher for an allocation to those groups that are less well defined.

● Impact on Equity

Equity has various definitions, including "freedom from bias or favoritism" (Merriam-Webster dictionary) and conformity with rules or standards. Unlike net economic benefits, we do not have measures of equity that are commonly accepted standards against which we can evaluate the effects of an action. The best we can do is provide information on effects that are generally believed to have equity implications and rely on decision makers to balance the equity considerations with conservation and efficiency objectives for which there are more commonly accepted standards. With respect to equity considerations and initial allocation, the MSA directs that consideration be given to (i) current and historical harvests; (ii) employment in the harvesting and processing sectors; (iii) investments in and dependence upon the fishery; and (iv) the current and historical participation of fishing communities (Section 303A(c)(5)). Items (ii) and (iii) are explicitly covered above. Items (i) and (iv) will be covered under topics of this section. This section is organized around the following topics:

- Compensation for harm
- Excessive shares
- Current and historic harvests.

♦ *Compensation for Harm*

"Compensation for harm" is an equity rationale that has been proposed for guiding the initial distribution of QS. The potential adverse impacts of the IFQ program on capital assets and labor assets are discussed in the above section on "Sector Health." Potential adverse affects on communities is discussed in Section 4.14. These sections relate to the consideration of current and historical harvests for participants and communities in the context of the initial allocation.

♦ *Excessive Shares*

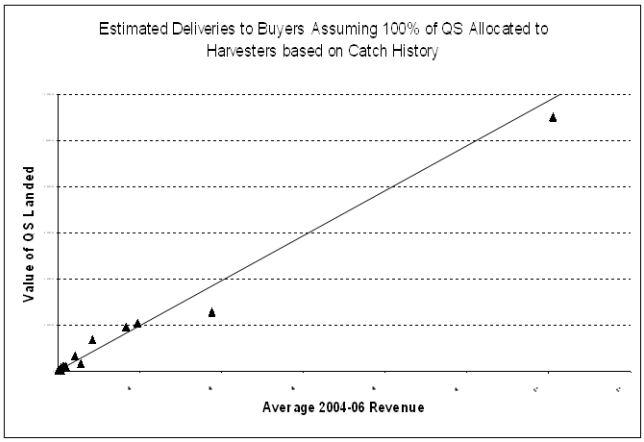
What constitutes **"excessive shares"** may be socially determined or economically determined. On an economic basis, an excessive share would be one that would be expected to result in a sector with market power. This concern is addressed above in the section on net benefit related effects. From a social policy perspective, concentration of ownership affects the social and community structure and the sense of equity that may, in part, be grounded in the history of fishery management, which has largely been based on common property concepts. In general, excessive shares will be controlled directly through QS control limits. The choice of the amounts of the initial allocation that goes to harvesters and processors affects whether there may be excessive shares only to the degree that there is a grandfather clause to the QS control limits. In the section on sector health, graphs are provided that show the expected concentration of QS in comparison to recent harvest levels for permits and processors for various permit/processor splits and for the presence or absence of a grandfather clause. As an example of the nature of the effect, with a 100 percent allocation to permits, no equal sharing, and no grandfather clause, the most QS that goes to a single entity that only harvests is about 4.3 percent, and the most that goes to a processor is close to about 5.5 percent (Figure A-9). If, instead, there is an 80 percent allocation to permits and a 20 percent allocation to harvesters, the most that goes to a permit is about 3.5 percent, and the most that goes to a processor is about 13.5 percent (Figure A-12). If there is not grandfather clause, then the allocation between permits and processors will not affect excessive shares because no one will be grandfathered in above the accumulation limits that any entity would be eligible to achieve through the acquisition of additional QS. The allocations illustrated in Figure A-9 and Figure A-12 would be capped at the amount of the initial allocation. Section A-2.2.3.e on accumulation limits (including QS control limits) and the grandfather clause includes tables that show the amounts of QS that would be allocated in excess of the accumulation limits, depending on the split of the allocation among harvesters and processors. Under the FPA, there will not be a grandfather clause, but individuals

will be allowed to receive QS in excess of limits and then given a period to divest of them (up to four years). Thus, while an entity would not be able to maintain an allocation above the QS control limit, it would still be able to benefit from selling that allocation. Because some processors also own permits (qualifying for both permit and processor history), the decision not to allocate nonwhiting QS to processors will likely result in a lower maximum initial allocation to any single entity than would result if an allocation were made to processors.

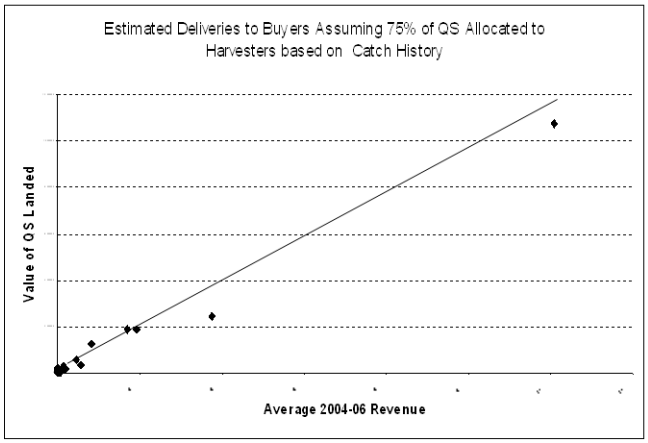
♦ *Current and Historic Harvests*

EFFECT ON QS AVAILABLE FOR RECENT TRADING RELATIONSHIPS

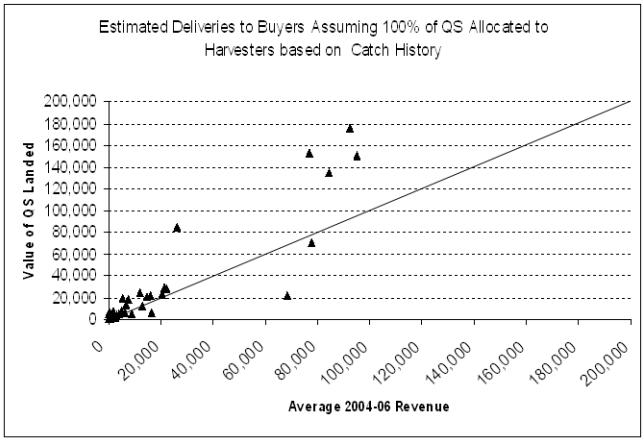
With respect to the question of the distribution of initial allocation between permits and processors, it is apparent that the distribution of more or less to permits and processors will proportionally affect the difference between what they receive and what they need to continue at production levels of the recent past. In the section on sector health, we compared the QS permits would receive to their 2004 to 2006 landings and the QS that processors would receive to their 2004 to 2006 landings (with the caveat that processors do not "need" QS to maintain their production levels). Here we will examine the effect of this decision on trading relationships.



The question to be evaluated is, "If permits and processors wish to maintain their historic practices with respect to the amounts of fish each permit delivers to each processor, how will the decision on the split of QS between these groups affect their ability to do so?" For the purpose of this evaluation, we looked at the pattern of deliveries among vessels and processors for 2004 through 2006. In Figure A-22 though Figure A-25, we plot amounts of landings and amounts of QS allocated to these trading relationships from the processor's perspective (i.e., summarize for each processor the amount of QS it received, together with that received by permits delivering to that processor.)[33] These figures show that when the amount of QS initially allocated to combinations of permits and processors is considered, the greater the direct allocation to processors, the more divergence occurs between the amount of QS going to participants in these relationships and the amount of recent landings that occurred within those relationships.



In Figure A-22, the QS allocations to each set of relationships are contrasted to the average 2004 to 2006 landings within each relationship (the amount of groundfish trawlers delivered to a particular processor). The figure on the left shows the results if 100 percent of the nonwhiting QS allocation goes to permits, and the figure on the right shows the results if 75 percent of the nonwhiting allocation goes to permits and 25 percent to processors. The top figures show the general distribution without showing the units. Points along the diagonal line from the origin are those at which the trading relationship (the harvesters and processors together) will receive an amount of QS that is comparable to its 2004 to 2006 deliveries. The bottom figures show the distribution among those trading relationships with less than $200,000 of QS and less than $200,000 of 2004 to 2006 landings history. The left-hand panel shows that with a 100 percent allocation to permits, there are some processor-permit associations that will receive little or no QS history relative to their 2004 to 2006 activities. For example, for a QS allocation based 100 percent on permit history there are five processor-permit associations (the top and bottom left hand panel combined) with more than $20,000 of history for 2004 to 2006 that will receive QS less than what would be needed to maintain their 2004 to 2006 average. If a 25 percent allocation is given to processors, the right-hand panel shows six or seven trading relationships in this category. The right-hand panel also shows that, if there is a 25 percent allocation to processors, seven trading relationships



[33] For a permit delivering to more than one processor, QS for the permit was distributed between processors in proportion to the 2004 to 2006 deliveries to those processors. The objective of the analysis is not to say whether these delivery patterns will be maintained, but rather will QS go directly to the entities that could maintain them if they choose to negotiate to maintain previous delivery patterns.

that had less than about $25,000 of 2004 to 2006 history will receive more than about $60,000 of QS. Figure A-23 shows a direct comparison of results with 75 percent going to harvesters (vertical axis) and 100 percent going to harvesters (horizontal axis). In this figure, it is seen that trading partnerships that involved more than $40,000 in ex-vessel value fared better under the 100 percent allocation to permits. To understand these results better, Table A-31 is provided. This table displays the number of permits delivering to processors based on the 2004 to 2006 deliveries. Most processors with less than $20,000 of 2004 to 2006 history received deliveries from only one or two permits. Of the 42 processors falling into this category, six received from between three and five permits and two from seven or eight permits and the remainder from on permit. Some permits deliver to more than one processor and so will be counted more than once in the table.

Figure A-24 compares the amount of QS trading relationships receive under the FPA to their 2004 to 2006 average. Thirty-nine trading relationships will receive QS that represents more QP than their 2004 to 2006 average revenue, and 27 would receive less QS. Figure A-25 shows that 40 trading relationships were better off under the PPA than under the FPA. However, the relationships that receive the most QS either do better under the FPA than under the PPA, or are relatively unaffected by the choice between the two.

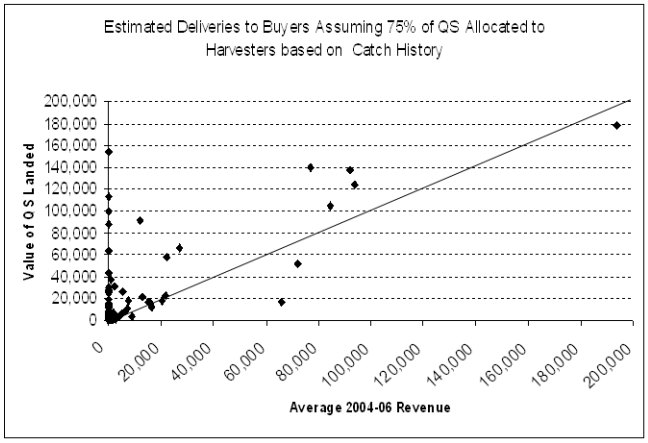


Figure A-22. The ex-vessel value of nonwhiting QP going to processor-permit relationships under two allocation formulas as compared to 2004 to 2006 ex-vessel revenue for those relationship (notes: each point represents a processor and the permits delivering to it; lower panels are a magnification of the upper panels; these formulas include a grandfather clause, but no equal sharing).

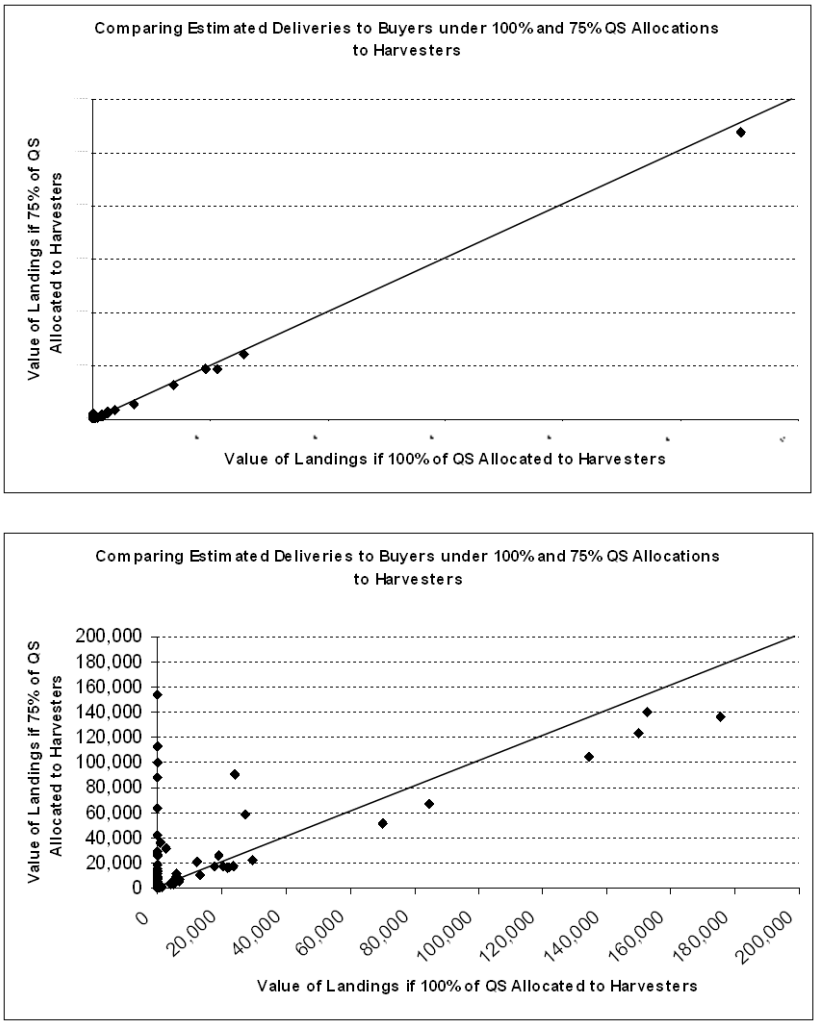

Figure A-23. Comparing a 100 percent allocation to permits to a 75 percent allocation to permits: ex-vessel value of nonwhiting QP going to processor-permit relationships (notes: each point represents a processor and the permits delivering to it; lower panels are a magnification of the upper panels; these formulas include a grandfather clause but no equal sharing).

Table A-32. Number of processors categorized by number of permits delivering to different classes of processors based on average annual 2004 to 2006 ex-vessel value of deliveries received by the processor.

Number of Permits Delivering	2004–06 average buyer purchases ($ ex-vessel payments)						Total
	<10,000	10,000-20,000	20,000-100,000	100,000-250,000	240,000–1 Million	>1 Million	
1	22	1	2	1	0	0	26
2	11	0	1	0	1	0	13
3	1	1	3	1	0	0	6
4-5	2	2	2	0	1	0	7
6-8	1	1	2	1	0	0	5
9-20	0	0	0	1	1	1	3
21-100	0	0	0	0	0	3	3
Total	**37**	**5**	**10**	**4**	**3**	**4**	**63**

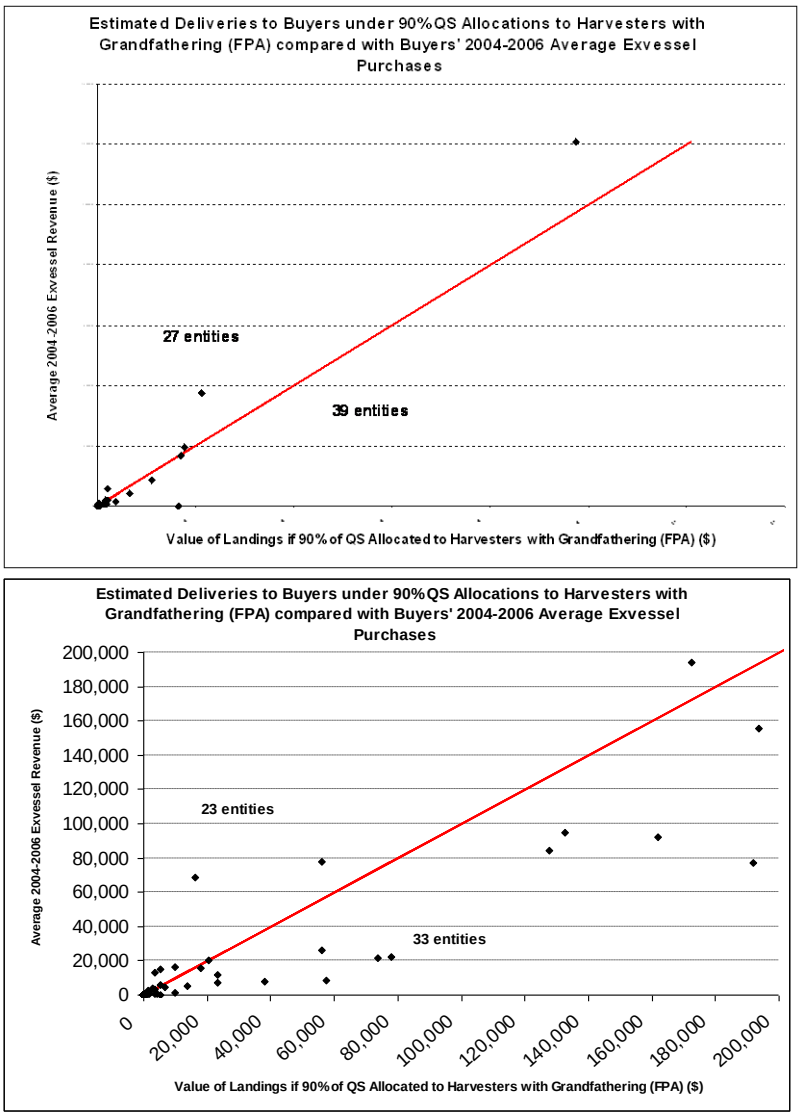

Figure A-24. The ex-vessel value of nonwhiting QP going to processor-permit relationships under the FPA as compared to 2004 to 2006 ex-vessel revenue for those relationship (notes: each point represents a processor and the permits delivering to it; lower panel is a magnification of upper panel; the FPA formulas include equal sharing and no grandfather clause, but a divestiture opportunity).

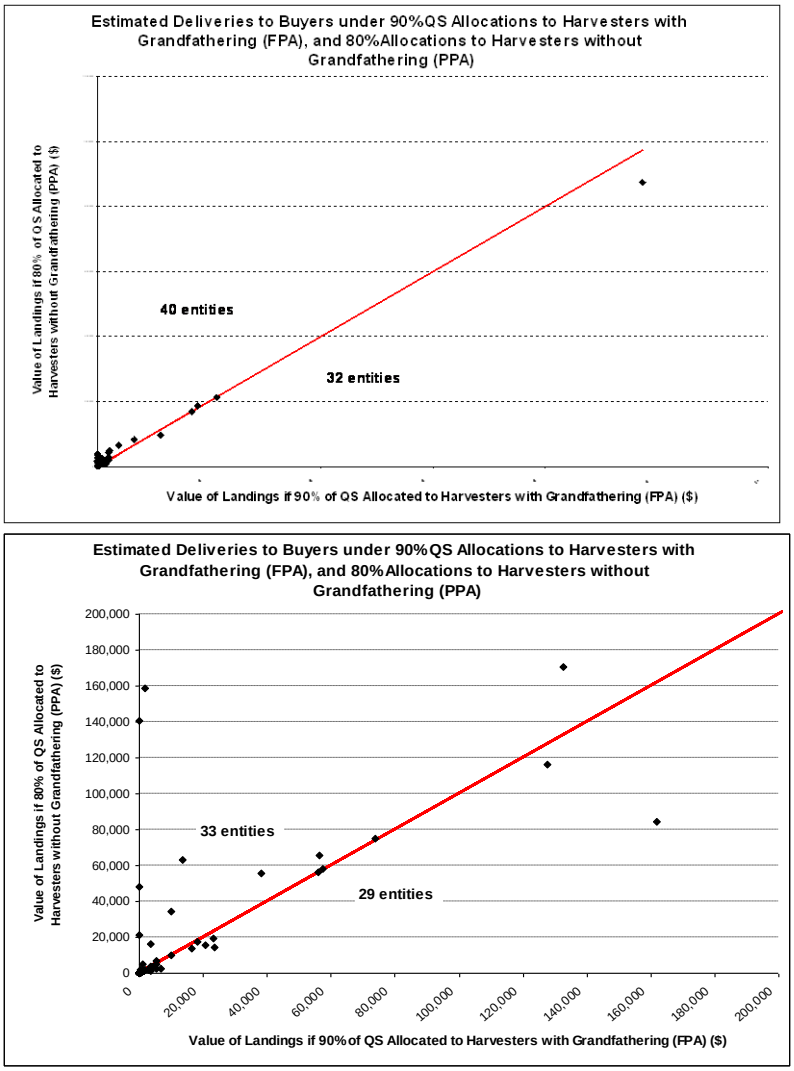

Figure A-25. Comparing the PPA to the FPA: ex-vessel value of nonwhiting QP associated with the QS going to processor-permit relationships at time of initial issuance (notes: each point represents a processor and the permits delivering to it; lower panel is a magnification of the upper panel; these formulas both include equal sharing, and neither has a grandfather clause, but the FPA allows QS to be issued in excess of control limits and then divested).

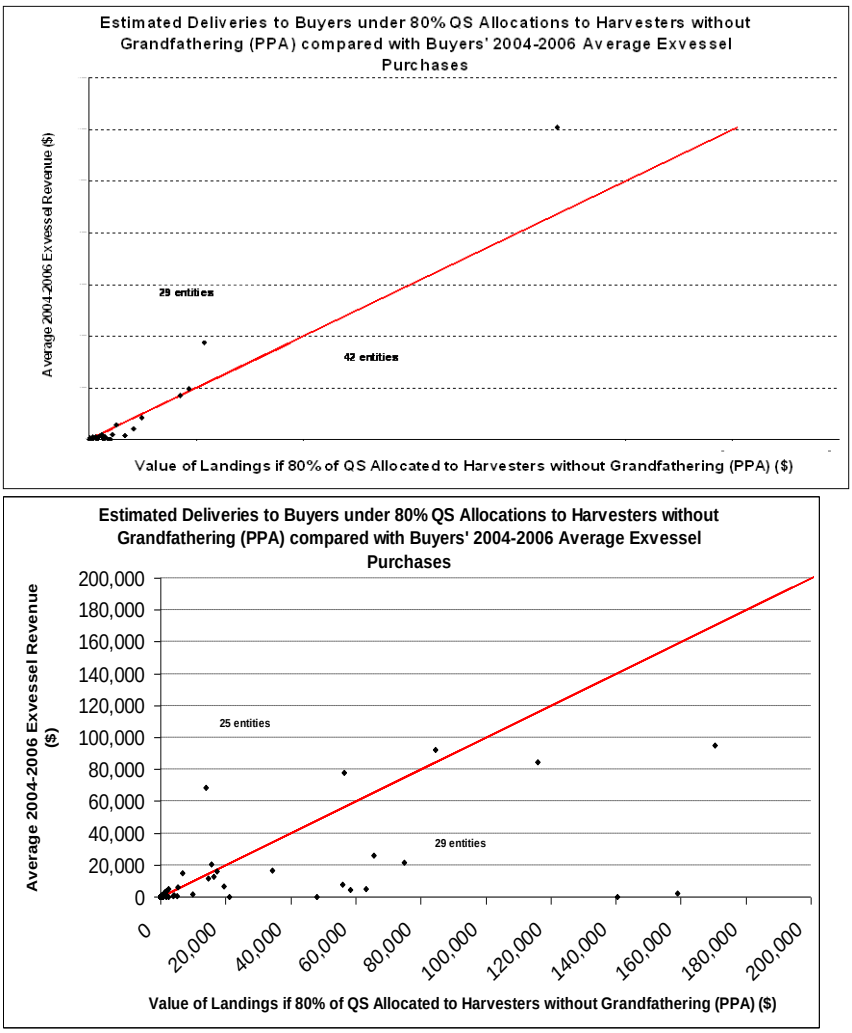

Figure A-26. The ex-vessel value of nonwhiting QP going to processor-permit relationships under the PPA as compared to 2004 to 2006 ex-vessel revenue for those relationships (notes: each point represents a processor and the permits delivering to it; lower panel is a magnification of upper panel; the PPA formulas include equal sharing and no grandfather clause).

Allocation Basis as a Means of Accounting for Current Participation

One way to take into account current harvests up to the date of the allocation is to attach the allocation criteria to an asset that is transferable as participants enter and exit the fishery (as opposed, for example, to attaching the allocation criteria to a person who may no longer be a participant in the fishery at the time of initial allocation). On the harvester side, the vessel (under Amendment 6) and the permits (under Amendment 8 [which was tabled], Amendment 9, and the sablefish tier system) have been used as the asset against which qualification criteria are measured. Anecdotal information suggests that fishermen have been relying on the permit to be the most likely vehicle that the Council would use for the allocation of QS. Allocation based on criteria related to other assets, such as the vessel or a processing facility, would be viewed as a change from past practices. For processors, it has not been necessary up until now to identify such a key asset (there have been no allocations to processors). In

Section A-2.1.1.d, consideration will be given to how historic participation criteria might be specified to take into account exit and new entry during the period that this program has been under deliberation.

SUMMARY

- **Compensation for Harm:** QS may be issued to those with assets that will be adversely affected by the IFQ program (see sections above on sector health). Rather than allocating QS to communities, the Council has ensured that communities can purchase QS if they desire and are included an AMP to address impacts on communities (Section A-3).
- **Excessive Shares**. If there is a grandfather clause (or no grandfather clause, but an opportunity to divest, as under the FPA), the maximum amount of QS initially allocated to those who receive the most increases as the allocation to processors increases. The effect of excessive shares on efficiency is discussed in the net benefits section. With respect to equity issues, determination of what constitutes an excessive share is a value judgment made by the Council.
- **Current and Historic Harvests.** Figures are provided comparing how processor-permit trading partnerships fare with and without an allocation to processors. In general, processor-permit trading partnerships to which more than $40,000 would be allocated (QS translated to QP using 2004 to 2006 landings and prices) fare better with a 100 percent allocation to harvesters than with a 75/25 permit/processor split.

● Impact on Communities

This issue of allocating to communities is discussed above in the section providing a rationale for not allocating to communities and the section on equity and compensation for harm. Here we focus on the effect of the choice of allocating among permits and processors on communities.

Recognizing the QS can easily be moved between communities, we can look at the locations of the home offices for permits and processors receiving an initial allocation and how the distributions among these locations would vary depending on choices made with respect to the amount allocated to processors and harvesters. This also tells us where the owners of QS most likely reside and the individuals who will be collecting and spending the profits from QS ownership. Table A-32 provides information on how nonwhiting QS shifts among communities as the balance of the initial allocation shifts between processors and permits. In this table, it can be seen that certain communities serve as the home office for buyers, but not for harvesters (they go to -100 percent with a 100 percent allocation to harvesters). Most towns with residents that in aggregate are expected to receive in excess of about one half million dollars' worth of QS (based on ex-vessel value of one year's QP) receive more QS as the amount allocated to processors go down (8 of 13 towns). In the north (Washington and Oregon), the aggregate holdings of the residents of six of eight of these towns increase, but in the south (California), the aggregate holdings of the residents of only two of five of these towns increase. In terms of where initial QS holders reside, increasing the allocation to harvesters appears to increase the dispersion of QS among the towns with major QS holdings (those for which associated QP would be worth in excess of one-half million dollars in ex-vessel value). Those towns with less quota than that, and which lose QS as amounts to harvesters increase, represent only 2 percent of the total QS holdings (assuming a 75 percent allocation to harvesters).

Table A-33. Distribution of nonwhiting QS allocations and estimated value of associated QP, by QS owners' residence and/or head office (note the allocation formulas provided as examples here do not include a processor recent participation screen, the recent participation screen would substantially reduce the number of communities listed).

- Options 6a and 7 (FPA) for Whiting

Options 6a and 7 (the FPA) would allocation 20 percent of the whiting QS to processors but none of the QS for bycatch species associated with whiting. While the allocation of QS without bycatch species would create some initial disadvantages, the impact of this option is primarily one of wealth distribution. After the program is implemented, QS will be traded, and processors or harvesters will be free to acquire more QS or divest themselves of their initial allocation. Processors wanting the QS for bycatch species will be able to acquire it through QS trading. Any business that does not receive an initial allocation will be in a situation similar to any other entity that enters the fishery later; they can access more QS by purchasing them.

The effect of this option will likely depend on whether the bycatch species is constraining and whether there is a single shoreside sector or separate shoreside whiting sector.

If bycatch species QP are constraining, then a major portion of the resource rents that would otherwise be associated with the whiting QS would be expected to flow to the bycatch species. Assume the processors stayed at their initial allocation level and held no more than 20 percent of the whiting QS and none of the bycatch species QS. If the bycatch rates were such that taking 80 percent of the whiting QS used up all of the available bycatch species QP, then the remaining whiting QP held by processors would have little, if any, value.[34] The market place would not distinguish between whiting QS issued to processors and whiting QS issued to harvesters, so there would not be a direct impact on the value of the processor-held whiting QS. There are, however, a number of ways the situation could play itself out in the market. One possibility that illustrates the situation is that whiting QS might tend to be traded in bundles with bycatch species. Under such circumstances, processors might find that they would not be able to sell their 20 percent of the whiting QS for an amount that was proportional to 20 percent of the value of the whiting fishery unless they first acquired and bundled it with bycatch species QS. If the bycatch species do not tend to be constraining, then the value of the whiting QS issued processors would likely be close to proportional to the value of the whiting that the QS represents.

The bycatch species are more likely to be constraining if there are two shoreside sectors. Under the single sector approach (the FPA,) the QS needed to cover bycatch for a whiting trip would be the same as that needed to cover catch of the same species taken on a nonwhiting trip. With a larger pool available, the QS for species taken as bycatch in the whiting fishery would be less likely to be limiting than if there is are separate shoreside sectors. However, bycatch could still be substantially constraining for certain overfished species.

With the two-year moratorium on QS trading included under the FPA (Section A-2.2.3.c), processors wishing to balance their whiting QS with bycatch species QS or divest themselves of whiting QS will not be able to do so until the moratorium is over. This enforced imbalance in the species mix held by processors may create increased uncertainty and greater transaction costs during the moratorium.

- Allocation of QS or QP for the Adaptive Management Program

The allocation for the AMP is specified as an allocation of QS with an option for the Council to pass the associated QP through to holders of non-AMP QS in proportion to their holdings of that QS (if the QP is not needed for the AMP program). The other option considered was to allocation 100 percent of QS to permit holders (and possibly processors), but to hold back a portion of the QP each year for adaptive management, on an as needed basis. Holding back QS rather than QP will make it more difficult to

[34] To avoid this situation, processors might try to negotiate preseason agreements with vessels to harvest all of the processor-held QP first or in proportion to the amount of whiting delivered under vessel-held QP.

adjust the base amount of quota held back for the AMP. For example, if the Council decides explicitly to end the AMP, an adjustment would be needed to the holdings of QS by all other entities. Similarly, an expansion of the quota for AMPs would require reduction of QS holdings by all other entities. If instead the AMP program had been funded with quota simply by withholding QP, long-term adjustments to the QS dedicated to AMP program would be less burdensome. The decision would be made to reallocate the AMP QP to QS holders.[35]

[35] During the development of this program, for simplicity and clarity in the analysis, it has been assumed the total amount of QS will sum to 100 percent. In implementing the program, NMFS could choose to abandon that approach and let the total amount of QS range. This approach would change the amount of QP issued each year for any particular amount of QS. Allowing the amount of QS to float (not sum to 100 percent) might be particularly useful during the early phases of the program when appeals are being resolved. However, if such an approach is taken, adjustments to the AMP QS will be needed as additional QS is issued or revoked. The adjustments to the amount of AMP QS would be needed to ensure that the amount stays at 10 percent of the total.

A-2.1.1.b Permits

❖ *Provisions and Options*

Landing[36] history will accrue to the permit under which the landing was made. The owner of a groundfish LEP at the time of initial allocation will receive the QS issued based on the permit. (See section A-2.1.4 on permit combinations and other exceptional situations.)

❖ *Rationale and Options Considered, But Not Included*

Allocating to entities other than the current groundfish permit owner is considered under Section A-2.1.1.a. The provision of this section (A-2.1.1.b) specifies that the landings history over the entire life of the permit will accrue to the permit, including history prior to the time it was held by the current owner, and it explicitly states that the current owner will receive the allocation. An alternative approach, assigning permit history to the owner of the permit at the time the landing was made, would be akin to assigning the landings to a specific person. As mentioned in the previous section, assignment of landing history to a person has been avoided in the Council's groundfish LE system to facilitate entry and exit during deliberations on the program and to consider current participation and dependence in the fishery rather than historic activity. Another approach might be only to count the history of the permit while it is owned by the person who holds it at the time of implementation. While this would consider take current participation, it would not account for the investment and dependence on the fishery that is represented by the current owner's investment in the acquisition of the permit.

❖ *Interlinked Elements*

Assignment of the entire landing history of the permit to the permit's current owner is a key provision of this program. Change in this provision would require substantial reevaluation of many other provisions of the program.

❖ *Analysis*

Assignment of all of a permit's landing history to the current owner results in less disruption of capital investment and dependence than if, for example, the only landing history that counted was that of the current owner during the time he/she owned the permit. Allocation based only on recent history would put new entrants at a disadvantage and substantially redistribute current fishing activities affecting vessels, processors, workers, and communities. Thus this provision addresses both the Council objective of achieving change with minimum disruption (Objective 14 of the groundfish FMP) and section 303A(c)(5)(A) of the MSA, which requires that the Council establish procedures to ensure fair and equitable initial allocations, including consideration of (i) current and historical harvests, and (iii) investments in, and dependence upon, the fishery. Indirectly, the approach provides business stability that supports existing employment and community involvement in the fisheries (items (ii) and (iv) of MSA 303A(c)(5)(A)). Stability for investment also promotes objectives related to net benefits and efficiency.

[36] The term "landing," as defined in the regulations, includes both shoreside and at-sea deliveries.

A-2.1.1.c Processors and Processing Definition

❖ *Provisions and Options*

A special definition of "processor" and "processing" will be used for initial QS allocation. A main intent of the definition is to specify that, if QS is issued for processing, only the first processor of the fish receives an initial allocation of QS. See footnote for definition. *However, due to limitations on available documentation, fish "receivers" may be used as a proxy for "processors," as per the following section.*

Definition from footnote:

"**Processors"**

At-sea processors are those vessels that operate as motherships in the at-sea whiting fishery and those permitted vessels operating as catcher-processors in the at-sea whiting fishery.

A shoreside processor is an operation, working on U.S. soil, that takes delivery of trawl-caught groundfish that has not been "processed at-sea" and that has not been "processed shoreside"; and that thereafter engages that particular fish in "shoreside processing." Entities that received fish that have not undergone "at-sea processing" or "shoreside processing" (as defined in this paragraph) and sell that fish directly to consumers shall not be considered a "processor" for purposes of QS allocations.

"Shoreside Processing" is defined as either of the following:

1. Any activity that takes place shoreside; and that involves:
   - cutting groundfish into smaller portions; OR
   - freezing, cooking, smoking, drying groundfish; OR
   - packaging that groundfish for resale into 100 pound units or smaller for sale or distribution into a wholesale or retail market.

   OR
2. The purchase and redistribution into a wholesale or retail market of live groundfish from a harvesting vessel.

❖ *Rationale and Options Considered, But Not Included*

This section defines the types of activities that will be considered processing and part of the criteria used to identify entities that are eligible for a portion of the initial allocation of QS going to processors (Section A-2.1.1.d). A special definition of processor and processing will be used for initial QS allocation. For the purpose of applying the initial allocation formula for processing, only the first processing counts as processing. If processors are affected by the rationalization of the fleet it is likely that those effects fall on only the first processor of the groundfish, the processing entity most likely to have excess capital after fleet rationalization. This definition is designed, in part, to focus the initial allocation on first processors. Differences in impacts between buyers and processors will be discussed in the following section.

Under the groundfish FMP, the definition of "processor" is as follows:

> The "processor" is a "person, vessel, or facility that engages in processing, or receives live groundfish directly from a fishing vessel for retail sale without further processing.

The special definition used for initial allocation of shoreside sector QS eliminates the following processors from consideration:

- Those who do not take delivery (e.g., a harvesting company that does some processing but is not listed as the fish receiver on the fish ticket)
- Those who have only received groundfish caught with gears other than trawl or have not received any groundfish

- Those who have only received groundfish that has already undergone some processing
- Those who have only received and sold raw unprocessed groundfish

However, the definition of processing is broadened in some areas and more restricted in others. This definition has important implications for who qualifies as a processor.

Under the groundfish FMP, the definition of "processing" is as follows

> "Processing" means the preparation or packaging of groundfish to render it suitable for human consumption, retail sale, industrial uses, or long-term storage, including, but not limited to, cooking, canning, smoking, salting, drying, filleting, freezing, or rendering into meal or oil, but does not mean heading or gutting unless additional preparation is done.

The FMP definition excludes heading and gutting alone, while the special definition used for initial allocation criteria includes heading and gutting (cutting groundfish into smaller portions). The FMP definition is open-ended in that the possible methods of handling the fish are not limited to those on the list. The key part of the FMP definition is that the fish are prepared or packaged for human consumption, retail sale (which might include uses other than eating, e.g., fertilizer), industrial use, or long-term storage (which could go to any other use, e.g., meal for feedlots). Thus the restrictive parts of the FMP definition that are not included in this definition appear to be the words "preparation or packaging," and the exclusion of heading and gutting alone.

The special definition is not open-ended. It does not mention canning, salting, or rendering into meal or oil; therefore, these might be excluded, unless they fall under the category of "packaging that groundfish for resale into 100-pound units or smaller for sale or distribution into a wholesale or retail market." Canning may well come under this definition, as might the production of meal or oil, depending on how it is packaged. The "100-pound units or smaller" implies that any resale of raw fish, regardless of what is done to it, qualifies as processing so long as the unit of sale is less than 100 pounds. This brings into question what might be considered the "unit of sale." For example, if there is a business that buys groundfish and does nothing to it other than transport it and sell it to a processor, and the invoice lists out a number of species, some of which are in quantities of less than 100 pounds, would those transferred in quantities of 100-pound units or smaller count toward history for the selling or buying entity? This question would be most important for Options 2 and 3 of A-2.1.1.d.

❖ *Interlinked Elements*

The definition of processing and processor has important implications in determining who qualifies as a processor for the initial allocation and who processed the fish coming in on a particular delivery. The definitions come into play for initial allocation in Section A-2.1.1.d, where they are used to determine whether an entity is a shoreside processor (Option 2) and whether the history of a particular landing should be attributed to a particular shoreside processor (Option 3). Under Option 1, the entity registered as the receiver of the fish is used as a proxy for shoreside processing and receives credit for all deliveries shown on its tickets; therefore, the special definitions of processor do not come into play if this option is selected. These definitions and the choices made in Section A-2.1.1.d will in turn affect the types and difficulty of issues that may have to be dealt with in the appeals process (Section A-2.1.5).

If an allocation is not given to processors (Section A-2.1.1.a), then the provisions of Sections A-2.1.1.c and A-2.1.1.d will not be needed.

❖ *Analysis*

The primary objectives affected by this definition relate to questions of fairness and equity and administrative costs.

With respect to fairness and equity, there may be an issue of comparable treatment. Conditions under which a processor may qualify for QS based on harvesting history are determined by whether or not the processor has a permit with landing history; the criteria are the same for processors, for entities that only harvest, or any other entity that owns a LEP. However, the conditions under which a harvester may qualify for an allocation based on processing history are contingent not just on the nature of the activity on its face but also on the nature of the economic transactions which have led to that activity (i.e., whether it purchased the fish). Some of the criteria for processing specify that the product must be for resale (implying an initial purchase, third item in the first criteria for shoreside processing), or that the product must have been purchased and redistributed (second criteria for shoreside processing). Other criteria are not phrased to require an initial purchase. Harvesters in the shoreside nonwhiting fishery that are also listed as fish receivers receive credit as processors if their processing was done shoreside and it includes the cutting of groundfish into smaller portions or the freezing, cooking, smoking, and drying groundfish. These criteria apply equally to an entity that only processes or one that also harvests regardless of the nature of the economic transaction that led to that activity. For those criteria phrased to require purchase, if the permit owner is acting as its own processor, i.e., shows up as the purchaser on the fish ticket and subsequently caries out the activities specified in these criteria, it appears that it might not qualify for processing history. Traditional processors receiving fish from their own vessels might also be affected by this wording. We do not have information to tell us the degree to which trawl harvesters that acted as fish receivers may have repackaged fish or sold live fish, therefore, we cannot estimate the magnitude of this issue. The exact impact will depend on how this provision is implemented in regulation by NMFS, and the process of drafting the regulations will provide an opportunity for clarification of intent with respect to these provisions.

The possible need for some additional guidance with respect to the intent of the provision that defines processing as the resale of groundfish in "100 pound units or smaller" is identified in the section on rationale. If disputes arise between the first buyer and second buyer about who was actually the first processor of a particular landing, an argument with respect to some of the landing history may hinge on whether the fish was in units that are smaller than 100 pounds. To the degree that there is uncertainty about this or other criteria, administrative decisions will be more difficult, there may be more appeals, and more call for Council involvement in the appeals process. All of these would elevate the administrative costs of the program.

A-2.1.1.d Attributing and Accruing Processing History

❖ *Provisions and Options*

Use at-sea fishery observer data and weekly processing reports to document history for allocations to **at-sea processors**. [37]

For an allocation to **catcher-processors**, see A-2.1.1-b.

For an allocation to **mothership processors,** history accrues to the vessel on which the at-sea processing occurs.

MS Option 1: The owner of the vessel at the time of the initial allocation will receive the initial allocation.
MS Option 2: If a bareboat charter exists, the bareboat charterer will receive the initial allocation.

For an allocation for **shoreside processors:**

Option 1: attribute history to the receiver reported on the landing receipt (i.e. the entity responsible for filling out the state fish ticket). *The fish receiver would serve as a proxy for processor because of limited availability of official documentation on actual processing history.*

Option 2: attribute history to the receiver reported on the landing receipt, if that entity meets the definition of a processor with respect to trawl-caught groundfish. *The option is similar to Option 1 except that the fish receiver would have to demonstrate at least some processing of trawl-caught groundfish.*

►**Option 3:** same as Option 1, except history may be reassigned to an entity not on the landings receipt, if parties agree or through *an agency* appeals process. *The intent of this option is to provide an opportunity for landing history to be assigned to the entity that actually processed the fish.*

For shoreside processors, allocations go to the processing business. For all three of the options for accruing history, successor-in-interest will be recognized. NMFS will develop criteria for use in determining the successor in interest with respect to the entities listed on the landings receipts or otherwise covered in one of these options.[38]

❖ *Rationale and Options Considered, But Not Included*

The focus of this section is on identification of the entities to which processing activities will be attributed and identifying rules for the accrual of that history. For the allocation to harvesters, landing history is attributed to the permit, and it accrues to the permit and whoever owns the permit at time of initial allocation.

For catcher-processors, the entities identified as catcher-processors are well defined based on their ownership of LEPs and no issues have been raised indicating that there is any difference between those who own those permits and vessels and those who operate them. Because this fleet operates under the

[37] Note: The Council's preliminary preferred alternative does not include IFQs for the at-sea sectors (catcher-processors and motherships). Options related to those sectors will only be relevant if the Council changes the management approach as part of final action.

[38] Transfer of physical assets alone should not be considered a basis for successor in interest. Business relationships such as transfer of the company name and customer base might be reasonable evidence of successor in interest.

trawl license limitation program, the same rules used for the catcher vessel history are used for the catcher-processors.

To apply a QS initial allocation formula to processors other than catcher-processors, the allocation formula is applied to the processing business rather than any particular physical asset. For the mothership sector, the mothership vessel is the primary unit for which data are available. Therefore, in the mothership allocation, we first determine the vessel history and then attribute that history to a processing business. For mothership processors, there is at least one vessel for which there is a difference between the business that runs the processing operation and the one that owns the vessel. On that basis, two options have been identified. These options capture the range between allocating all of the QS to the vessel owner and allocating all of it to the vessel charterer.

If the Council makes an allocation to shoreside processors, the stated intent is that the allocation go to the entities that first process the fishery. In some cases, the first buyer may not be the first processor. It has been the Council view that it is the first processors that have the greatest amount of capital assets that may be affected by the IFQ program. The focus on processors rather than first buyers may also be supported by MSA section 303A(c)(5)(A) which identifies the need to consider processing labor in the development of the initial allocation but makes no mention of fish buyers. However, the Council's ability to carry out the intent to allocate to first processors is affected by the quality of the data available. Government databases that track landings to entities at the needed species and species group level (the fish tickets database) provide information only for the first receivers (buyer-only or buyer-processor) and not for subsequent purchasers. While an allocation to the first processors might possibly be carried out using information not in government databases, it may substantially increase administrative burden and cost. The difficulty of developing standardized criteria for evidence of processing (particularly at the species level), the costs of data collection, and the likely need for extensive dispute resolution led the Council to develop a set of options that, to varying degrees, approximates the ideal result.

The first option allocates only to those entities that are on the fish ticket, no attempt is made to differentiate between those buyers that transfer the fish to first processors and those buyers that process themselves. This option relies solely on information in the fish ticket database. It is generally believed that the large majority of the trawl groundfish landings are delivered to buyers that process their own fish.

The second option allocates to the same set of entities but requires that they demonstrate engagement in at least some processing of trawl-caught groundfish. Once that threshold is met, all LE trawl landings received by that entity would qualify. This may screen out those entities that never acted as a processor, but would not attempt to differentiate between the fish those entities received and processed and the fish those entities received and transferred on to another for first processing. It would require some additional administrative costs but a relatively small amount in comparison to the task of determining of processing history for every landing. If the second had been selected, the Council may have added a timeframe. As currently worded, an entity that does not presently qualify could qualify by arranging to process some trawl-caught groundfish between now and when the applications for an initial allocation are due.

The third option provides an opportunity to base the entire allocation to processors on the history of the entity that first carries out that processing. The default position would be the same as Option 1, that the history goes to the buying entity. However, that landing history could be reassigned to a second receiver of the fish either if both companies came forward and agreed to the reassignment, or if an appeal were granted resolving a dispute between two claimants. If it is correct that the large majority of the catch is in fact processed by the first receiver, the number of potential disputes may be small relative to the total number of landings in the landing history database.

The Council selection Option 3 for its FPA. While there was concern about the lack of documentation available to implement Option 3 and the potential appeals that could result, it was noted

Another issue that had to be decided for shoreside processors is which entity associated with any shoreside activity should be considered the business entitled to the allocation. For the license limitation program, it was decided that the initial permit allocation would follow the hull and go to the current owner of the fishing vessel because the vessel was the primary asset needed to operate a fishing business and the value of that asset would be affected by the initial allocation. Allocating to the owner of the vessel at the time of initial allocation allowed for entry and exit during the deliberations. In that program, a provision was also made to allow for the substitution of one vessel for another due to certain hardship conditions.

For the at-sea processing allocation, following the vessel works as the primary basis for the allocation though there is some question about it with respect to the motherships, as discussed above. For shoreside processors, the physical assets associated with the shoreside business are varied and it is difficult to identify one asset that might be said to define a processing operation. For example, a processor could own its land and all its buildings and equipment or it may lease some or all of its primary assets. If an allocation were based on the current ownership of a key physical asset, fisheries managers might have to choose between owners of a number of primary assets (land, building, processing equipment). Furthermore, over time, some of these assets may have been moved between fishery and nonfishery-related activities. On this basis, the Council decided that with respect to processing history the allocation should go to the processing business itself (the entity running the processing operation) and, hence, not necessarily to the owner of the physical assets used in processing. However, this raises questions about the means by which historic and recent participation are considered. For harvesters, by following the vessels (the Amendment 6 license limitation program) or the permit (the IFQ program allocation to harvesters), changes during the Council deliberations process and historic dependence and involvement are accommodated. If current and historic participation for processors are to be tracked in a manner similar to what is done for harvesters, then some means is needed for the determining the successor in interest for shoreside processing operations. Consistent with the determination of which business entity associated with a processing operation should receive the initial allocation (i.e., the operator of the processing business, rather than the owner of the processing capital), the Council determined that transfer of physical assets alone should not be considered a basis for determining successor in interest. The Council identified that the transfer of business relationships, such as transfer of the company name and customer base, might be the most important evidence of successor in interest. Further development of the provisions will be left to NMFS, both for the criteria to identify successor in interest and the application of those criteria.

Consideration was given to an option that would give processing history to the first entity to receive the groundfish, but only for that groundfish which was processed. This option would have entailed most of the administrative costs of Option 3, but not have provided an opportunity for the first processor to qualify for history associated with fish acquired from a fish buyer. This option lies within the range between Options 1 and 3.

An option proposed by the TIQC, tying the transfer of processing history to the transfer of a facility, was rejected from further analysis. Initially, GAC members noted that the TIQC approach to accrual might be supported based on the numerous changes in ownership that have occurred in recent years within the processing industry. The underlying concepts are that if one company acquires another, it acquires both its assets and liabilities, and, with respect to the leasing provision, it the leaseholder really operates the processing business. This option would attribute the history to the current owner rather than past owners, reducing the dislocation that would occur through the allocation of IFQ to business entities no longer associated with the facility. However, during later deliberations it was decided that customer lists and the business name are more closely associated with the processing company and,

therefore, should be a primary consideration if a determination is required with respect to successor in interest to a shoreside processing operation.

❖ *Interlinked Elements*

Shoreside processing Option 1 would generate fewer reasons for appeal relative to Options 2 and 3. This may influence whether the Council believes there is a need for its involvement in the appeals process (Section A-2.1.5).

The recent participation requirements for shoreside processors (Section A-2.1.2.c) will determine the degree to which there is a significant difference between the allocation results and potential number of appeals for Options 1 and 2, but not with respect to Option 3.

❖ *Analysis*

Objectives related to fairness and equity will likely be affected as well as maximizing net benefits. The effect on net benefits will be primarily through the effect of this choice on the costs of program administration.

- Mothership Entity Options

The issue of whether to give an initial allocation to the owners of motherships or the charterer (where there is a charter) comes up in both the IFQ program and the co-op program. The implications of this decision for the IFQ program are quite different than for the co-op program. For the co-op program, the entity who receives the mothership permit will control whether the vessel is able to participate in the fishery. For the IFQ program, the mothership would not need QS to operate. If the charterer is given the initial allocation of QS, it will be in a stronger position to negotiate prices with the vessel owner. If the mothership owner is given the initial allocation, it can negotiate for some additional compensation from the charterer in return for the QS, or can sell the QS or QP elsewhere, in which case, the charterer can acquire that QS on the market if needed.

An allocation of QS is a distribution of new wealth, and one rationale for its allocation may be to offset losses that might be anticipated to result from the IFQ program. Since program performance will not be affected by the choice of whether to allocate to the vessel owner or charterer, the issue is primarily one of fairness and equity. To the degree that the mothership processors have been engaged in a race-for-fish and, therefore, there have been more participants than necessary, the value of the vessel owner's assets may decline with implementation of an IFQ program. An allocation of QS might then offset some of that reduced asset value. On the other hand, the market value of the charterer's business may change, depending on the effect of the IFQ program on projected profits for the mothership operation and whether the assets of the company include QS. The mothership charterer's profits may increase if it is able to reduce costs in a rationalized fishery, but may decrease if it has to pay higher ex-vessel prices. The net effect is uncertain, but a reduction or increase in the charterer's profits will also change what is available to pay the vessel owner. However, assuming there is a surplus of mothership vessels, the charterer may be less likely to use additional profits to increase what it actually pays for the charter.

- Shoreside Processing Entity Options

The allocation to the first entities that process is premised on the idea that these shoreside entities have more capital at risk than those who just operate buying stations. Implementation of the IFQ program may put returns to capital at risk, primarily to the degree that there is processor overcapitalization. If there is not processor overcapitalization, then processors are expected to earn normal returns on the

investments (technically termed "zero economic profit") under an IFQ program, regardless of whether they receive an initial allocation of QS (see Appendix E). One of the primary arguments given for allocating to processors is the need to maintain a balance of negotiating power between processors and harvesters. While the Council's desire to allocate QS to the first processor may not be fully realized through an allocation to buyers (Option 1), it is presumably the buyers who are in negotiation with the harvesters rather than the processors acquiring fish from the buyers. On that basis, the allocation to buyers (Option 1), while rough in its attempt to compensate those who may experience the most loss in capital value, may be more precise with respect to allocation objectives related to the effective balance of market power between harvesters and those to whom they sell. Option 1 is also the option with the lowest administrative cost because the allocation would be based entirely on information already in a government database.

In some transactions, a processor that normally buys and processes may serve as a buyer for some other business that first processes the fish (i.e., processing businesses are known to buy and process some fish while other fish they buy and pass on to another company). Option 2 would screen out all of those entities that only act as buyers and never process (those entities that only fall in Category 2 of Table A-33). There would be some additional administrative costs associated with determining whether a threshold processing criteria is met and that cost would likely be higher to the degree that there are uncertainties about the measures of those criteria (see Section A-2.1.1.c). This evaluation would be required for every applicant, though the determination would likely be relatively simple for many. As a result of applying this screen, a greater portion of the processor allocation of harvesting QS would go to those entities in Category 1 (there would be some deliveries for which no entity receives processing credit: those delivered to entities that have never processed groundfish). We do not have information available to tell us in advance the amount of QS that would be redistributed as a result of applying the screening criteria, nor do we know the number of entities that might apply. We do know that if the recent participation criteria (Section A-2.1.2.c) of the Council's PPA are applied, out of 208 buying companies with some buying history from 1994 to 2003, only about 42 would be eligible for an initial allocation of QS. It is likely that most of these did some processing of LE trawl groundfish and would have substantial evidence of that; therefore, the number of cases that might require more difficult individual evaluation would be small. If, instead of the preliminary preferred recent participation alternative (6 mt of LE trawl-caught groundfish in each of three years from 1998 to 2003), only one delivery is required, then there would be 124 potential qualifiers. This may result in a greater administrative burden.

Table A-34. Description of categories of buying and processing activities and, for each option for attributing history, whether the fish handled in those activities would be included or excluded in the allocation formula calculations.

Category of Activity	Description of Activity and Risk	Use of the History In the Allocation Formula		
		Option 1	Option 2	Option 3
1. Buy and Process	All purchases from harvesters that an entity bought and processed (activity which may be associated with the need to negotiate prices with harvesters and having the most capital at risk)	Included	Included	Included
2. Buy Only	All purchases from harvesters that an entity bought whether or not they processed (activity which may be associated with the need to negotiate prices with harvesters but may or may not have the most capital at risk)	Included	Included only if at some time the receiving entity processed some trawl caught groundfish	Excluded
3. Process Only (1st Processing)	All purchases from fish buyers made by those who only processed (activity which may be associated with entities not involved with negotiating price with harvesters but having only capital at risk)	Excluded	Excluded	Included

Under Option 3, every landing would be initially assumed to have been delivered to a processor, but every landing would also be open to question. Option 3 provides the opportunity to limit the allocation so that it only goes to those that fall under either category 1 or 3, identified in Table A-33. It most closely matches the stated intent of an allocation to processors and would match it exactly if every landing that falls in the third category is identified and any disputes resolved. For the large majority of the landings, it is likely that there would be no difference between the first receiver and the processor; however, because of the many landings occurring from 1994 to 2003, there is a potential for landings to be split in the processing plant, with some of the fish being processed by the buyer and others being passed on to another entity for first processing. For this analysis, it is not possible to know the number of landings that were not processed by the buyer, and, even if we have this information, it would not be possible to know the number for which a dispute might arise. Unlike for Option 2, the recent participation requirement will have little effect on the potential administrative costs. As with Option 2, clarity of the definition of processing activity will help reduce administrative costs.

The provisions related to successor in interest affects objectives related to fairness, equity, and net benefits. These provisions were developed with the intent of allocating to the entity that is currently active in the processing sector and most closely associated with the historic buying and/or processing activity. To the degree that the history reflects ongoing dependence and business activity, this approach is expected to minimize the number of transactions needed to get the QS into the hands of those who can use it. Processors can use the QS/QP on their own vessels or as leverage in negotiations with vessels delivering to them. Disputes, fairness, and equity concerns are most likely to arise in situations where some assets of one processing entity have been transferred to another, but both remain active in the industry. For example, a portion of the customer base was transferred, or one trademark or name under which a business operates was conferred but not another. Resolution of these issues in a fair and equitable manner that also minimizes disruption will depend in part on criteria that are being left to NMFS to develop.

A-2.1.2 Recent Participation

The recent participation requirement is evaluated in the following sections. Refer to Section A-2.1.3.a, "Allocation Periods" for additional discussion of the rationale for the periods used for the recent participation requirements.

A-2.1.2.a Permits (including catcher-processor permits)

❖ Provisions and Options

Recent participation is not required in order for a permit to qualify for an initial allocation of QS.

❖ Rationale and Options Considered, But Not Included

By allocating to permits, the Council ensures that the allocation will go to those that currently own assets in the fishery (the permit). A recent participation requirement would screen out permits that have been latent in recent years. A number of recent participation options were considered. Most looked at using 1998-2003 as the recent participation qualifying period, but no specifics were determined before this option was rejected. After reviewing the preliminary data, it was determined that the harvest history of the vessels that would be screened out by a recent participation requirement was not significant enough to warrant the costs of developing and implementing the provision and the resistance likely to be encountered by those screened out.

When the recent participation requirement was being considered, an option was proposed under which the requirement could be met for all catcher vessel sectors with participation in any one sector. Thus a permit that participated in the nonwhiting fishery in the early 1990s but only the mothership fishery during the recent participation period would be eligible for an allocation related to its nonwhiting history by virtue of its recent participation in the mothership sector.

❖ Interlinked Elements

The main provisions with which a recent participation requirement would interact are the initial allocation formulas of Section A-2.1.3.

❖ Analysis

The choice to have or not have a recent participation requirement primarily affects objectives related to fairness and equity and program costs. While a recent participation requirement might be considered reasonable and responsive to the MSA direction to consider current and historic participation and to consider investment and dependence, the likely impacts on the initial QS allocation appeared to be minimal with respect to their impact on the landing history based portion of the allocation. However, the impacts of a recent participation requirement may be somewhat more substantial if a portion of the QS is equally divided (Section A-2.1.3.a).

The following sections identify the effects of potential recent participation criteria for each catcher vessel sector. Table A-34 provides an overview of the cross participation among sectors by permits from 1994 through 2003.

Table A-35. Count of permits participating in each catcher vessel sector, by sector combinations for 1994 to 2003 participation.

	Number of Permits by Sector		
	Mothership	**Shoreside Whiting**	**Shoreside Nonwhiting**
Mothership Sector History Only	2	-	-
Mothership Sector and Shoreside Whiting (no shoreside nonwhiting participation)	3	3	-
Mothership and Shoreside Nonwhiting (no shoreside whiting)	2	-	2
Participation in All Three Sectors	25	25	25
Shoreside Whiting Only Catcher Vessels	-	-	0
Shoreside Whiting and Nonwhiting Catcher Vessels (no mothership whiting)	-	31	31
Nonwhiting Only Catcher Vessels	-	-	105
Sector Totals	32	59	163
None (no qualifying whiting or nonwhiting history)	1		
Total Catcher Vessels Permits (All Sectors)	**169***		

* As of the summer of 2008, there are 168 permits: Two permits were combined together.

- Shoreside Nonwhiting Catcher Vessels

Depending on the recent participation requirement, between 12 percent and 48 percent of the permits would be excluded from the shoreside nonwhiting by a requirement that a permit participate for a certain number of years in a recent period in order to qualify for an initial allocation (Table A-35 and Table A-36). A moderately stringent recent participation requirement (requiring participation in three out of six years from 1998 through 2003) would exclude permits with only 8 percent of the landings (Table A-37). Levels of minimum participation more likely to be selected would exclude even fewer landings from the initial allocation. A level which would exclude less than 25 permits would raise the allocation of everyone remaining by about no more than 5 percent, assuming the allocation is based entirely on landings history (i.e., if there is no equal allocation component).

If recent participation is combined with the equal allocation of buyback permit-related QS history (Section A-2.1.3.a), recent participation might have somewhat more of an impact. First we will look at the effect of the recent participation requirement on the 56 percent of the QS allocated based on permit landings history and then on the 44 percent that would be allocated equally. To illustrate, a requirement of a minimum of two years with shoreside nonwhiting landings from 1998 through 2003 will be considered in the context of an 80 percent allocation to permits. This recent participation requirement screens out 26 permits. As a result, the amount of QS an average permit receives based on its landing history would increase by about 2.9 percent and the average amount a permit receives based on equal allocation would increase by 8.4 percent (Table A-38). On average, the total allocation to each permit would increase by 11.3 percent (the actual amount of the increase for a particular permit varies by species and permit specific history). If a vessel could qualify with recent participation through catcher vessel landings in any sector, only 10 vessels would be screened out, and the amount of increase associated with equal allocation would decline from 8.4 percent to 2.8 percent (Table A-38). The effect on the history-based portion of the allocation would be four-tenths of one percent (Table A-39) and if only 56 percent of the allocation is based on history, then the recent participation requirement for the nonwhiting QS would increase the history-based allocation for all permits by about two-tenths of a percent, on average. So the combined effect of a recent participation requirement (two years of

participation from 1998 to 2003) that could be met with landings in any catcher vessel sector would be about a 3.0 percent increase for remaining participants, on average.

Table A-36. Number of permits not meeting recent participation requirements for a variety minimum participation periods and numbers of years of participation required during the participation period (buyback permits not included).

Shoreside Nonwhiting Minimum Participation Requirement						
Recent Participation Period	Number of Years For Which Deliveries Could be Required to Meet Recent Participation Requirement					
	1 year	2 years	3 years	4 years	5 years	6 years

● Shoreside Whiting Catcher Permits

As with the shoreside nonwhiting permits, the impact from screening shoreside whiting with a recent participation requirement would do little to shift the landing history-based portion of the allocation. For the permits with some shoreside whiting landings (59), the proportion affected by recent participation requirements would be somewhat higher than for the nonwhiting vessels, 31 percent (18 permits) for a requirement of two years in 1998 to 2003 (Table A-40 and Table A-41), as compared to 15 percent (25 permits) for the same requirement for nonwhiting. As compared to the nonwhiting vessels, the amount of landing history affected by recent participation would be somewhat higher: 6 percent of the landings for a requirement of two years in 1998 to 2003 (Table A-42), as compared to 5 percent for a similar requirement the nonwhiting fleet. If the shoreside whiting and nonwhiting requirements are combined into a single recent participation requirement, as was proposed early on, the impacts would be even less (8 percent of the shoreside whiting permits and 2 percent of the shoreside whiting landings would be affected by a requirement of two years in 1998 to 2003; Table A-43). The amount of whiting affected by the equal allocation portion of the formula is very small (about 7 percent of all of the shoreside whiting QS would be equally allocated, as compared to 44 percent of the nonwhiting QS). Therefore, the effect of the recent participation requirement decision has a minimal effect on each individual permit's total allocation with respect to the equally shared portion of the shoreside whiting allocation.

Table A-41. Number of permits with some shoreside whiting landings during 1994 to 2003 that did not have shoreside whiting landings during the 1998 to 2003 qualifying period in the indicated number of years (buyback permits not included).

	Percent of 1994-2003 Landings					
Shoreside Whiting	0%	2%	2%	15%	19%	29%

Note: In March 2010, an error was discovered in one of the vessel identifier files that led to the misassignment of catch for six permits. For three of these permits, less than 1 percent of the catch history was affected; for one permit, 4 percent was affected. For the remaining two permits, 100 percent of the catch history was assigned to the wrong permit (i.e., the catch history was swapped between these two permits), and the distribution of harvest among years was off. The error does not have any effect on Table through Table .

- Mothership Whiting Catcher Vessels

A recent participation screen of two years from 1998 to 2003 would screen out fewer permits (8) and a somewhat smaller proportion of the mothership catcher vessel fleet (25 percent), as compared to the 18 permits (31 percent) that would be affected by a similar requirement for the shoreside whiting fishery

(Table A-42 and Table A-45). The amount of landing history screened out would be comparable to the nonwhiting fishery (6 percent, Table A-48). If the recent participation requirement could be met through any catcher vessel sector, the impacts would be even less with only six-tenths of a percent of the mothership whiting landings affected, Table A-39. Only 1 vessel delivering to the mothership sector would be screened out. The amount of mothership whiting affected by the equal allocation portion of the formula is very small (about 3 percent of all of the mothership whiting QS would be equally allocated, as compared to 44 percent of the nonwhiting QS). Therefore, the effect of the recent participation requirement decision will have minimal effect on each individual permits total allocation with respect to the equally shared portion.

Table A-45. Number of permits with some mothership whiting landings during 1994 to 2003 that did not have mothership whiting landings during the 1998 to 2003 qualifying period in the indicated number of years (buyback permits not included).

1998-2003	2%	6%	11%	19%	43%	51%

- Catcher-Processor Vessels

A recent participation criterion for catcher-processors would not be applicable to the preferred alternative because the final Council recommendation did not include IFQs for this sector (see Appendix B).

Beginning in 1998, the catcher-processors operated under a voluntary co-op. Under the co-op structure, costs were reduced as fewer vessels participated (Table A-47), but revenues were shared among permit holders. Because of this voluntary agreement under which some vessels sat out of the fishery, it would be unfair at this point to impose a recent participation requirement. The voluntary co-op has been beneficial for the fishery and the economy. Imposition of a recent participation requirement would discourage the future formation of such voluntary co-ops if similar opportunities were to arrive in other sectors or fisheries.

A-2.1.2.b Processors (Mothership) (N/A)

❖ *Provisions and Options*

This provision is not applicable to the preferred alternative because the final Council recommendation did not include IFQs for motherships (see Appendix B). The section header is maintained to provide continuity of numbering and cross referencing in various documents generated during this process.

Recent participation is required to qualify for QS:
1,000 mt or more of groundfish in each of any two years from 1997-2003.

❖ *Rationale and Options Considered, But Not Included*

Recent participation was considered for mothership processors for the same reasons identified for catcher vessels. IFQs for the mothership sector was not part of the final preferred alternative; therefore, the Council made no determination as to whether or not recent participation would be part of the program if IFQs were adopted for the mothership sector and an allocation give to processors. During deliberations on a recent participation criterion for this sector, in addition to the 1997 to 2003 option included for analysis, 1998 to 2003 and 1998 to 2004 were also considered. A period ending in 2004 was rejected because it went beyond the November 6, 2003, control date. A starting date of 1997 was used because it was the first year in which there was a three-way allocation between the whiting sectors.

❖ *Interlinked Elements*

Initial allocation is the main provision with which recent participation would interact. For recent participation requirements set at what would likely be considered reasonable levels, the effects of having or not having the requirement would be minimal.

❖ *Analysis*

The choice to have or not have a recent participation requirement primarily affects objectives related to fairness and equity and program costs. While recent participation might be considered reasonable and responsive to the MSA direction to consider both current and historic participation and investment and dependence, reasonable levels for such requirements would have little effect.

The recent participation period option selected for analysis of IFQs for the mothership sector coincided with the allocation period (Section A-2.1.4.c). This would make the recent participation criterion more of a minimum threshold than a screen that increases the emphasis on more recent years of the allocation period. Most mothership companies have consistent participation in the fishery (Table A-48). Four have not participated since 1995, and they would not receive an initial allocation for an allocation period that runs from 1997 to 2003. One company only entered the fishery after the allocation period. There is only one company that was absent for a number of years during the allocation period and might, therefore, be affected by requirement for a certain number of years of activity. To screen out any companies, the minimum participation requirement would have to require more than four years of activity; to screen out more than one company, the amount of landings required in each of those years would have to exceed 7,000 mt. The mothership recent participation option (1,000 mt in 2 years from 1997 to 2003) would not screen out any companies that would be eligible for an initial allocation. The option, therefore, would impose some minor administrative costs with respect to promulgation of the regulations with no effect on the allocation.

A-2.1.2.c Processors (Shoreside)

❖ *Provisions and Options*

No allocation was made to processors for nonwhiting trips; therefore, Nonwhiting Options 1 and 2 are not applicable to the Council's final preferred alternative.

Nonwhiting Option 1: 1 nonwhiting groundfish trip delivery from 1998-2003.
Nonwhiting Option 2: 6 mt or more of deliveries from nonwhiting groundfish trips in each of any three years from 1998-2003.

Recent participation is required to qualify for an initial allocation of QS:
Whiting Option 1:1 whiting trip delivery from 1998 to 2003.
Whiting Option 2: 1 mt or more of deliveries from whiting trips in each of any two years from 1998-2003.
►**Whiting Option 3:** 1 mt or more of deliveries from whiting trips in each of any two years from 1998-2004.

❖ *Rationale and Options Considered, But Not Included*

There is more transient participation in the shoreside processing sector than among trawl permits. The shoreside receipt of a trawl delivery from a vessel requires substantially less long-term commitment to the groundfish trawl fishery. Because of these issues related to dependency and involvement, the Council is considered a recent participation requirement for the shoreside processing sector. Initial information indicated that a recent participation requirement might substantially reduce the number of applicants, reducing administrative costs with a relatively minor effect on the allocation to those remaining eligible.

❖ *Interlinked Elements*

This provision most strongly interacts with the initial allocation formula, affecting the distribution of the initial allocation of QS. The fewer the buyers receiving allocations, the more QS exists for those receiving an initial allocation. If there were no QS control-limit grandfather clause and no opportunity to divest, the distribution of the initial allocation among processors would be strongly affected by the accumulation limit, causing a significant portion of the allocation to be redistributed away from those that would otherwise receive shares in excess of the accumulation limit. With the imposition of a recent participation requirement, the number of entities sharing the redistribution declines substantially, increasing the amount of the redistribution received by any one entity. However, while the Council's FPA does not include a grandfather clause, it does include a divestiture provision. Divestiture allows entities to receive an initial allocation in excess of QS control limits and provides them a period to divest themselves of excess shares.

❖ *Analysis*

As with harvesters and at-sea processors, the choice to have or not have a recent participation requirement primarily affects objectives related to fairness and equity and program costs.

A recent participation requirement will screen out some buyers and their associated history. The percent of landing history screened out affects the amount by which all other allocations would increase. For example, screening out 4 percent of the landing history would increase the allocation of all those

remaining by about 4 percent (given that there is not an equal allocation component to the processor allocation formula). The value of QS for which those who are screened out by a recent participation criterion might otherwise qualify could be comparable to the application fees (or substantially offset by the application fees). Under such circumstances, the loss from being screened out might be relatively minor. For example, if, for shoreside nonwhiting processors, a recent participation requirement were adopted of at least 1 mt in one year from 1998 to 2003, 124 firms with 3.7 percent of the 1994 to 2003 landing history would be screened out of the initial allocation (top row middle column of Table A-49). Assuming a total nonwhiting ex-vessel revenue of $24 million, a processor share of 20 percent and that 124 firms were screened out, the average ex-vessel revenue associated with the QP that might be issued annually to the firms eliminated by the recent participation requirement would average about $1,700. If the total Federal cost of the initial issuance of the QS is $500,000, and it is anticipated that about 300 entities will apply (the 121 entities owning permits and the 208 entities with some processing history), the application fees would be about $1,700. If the QS were to trade at a value equal to the annual ex-vessel revenue associated with the QP, then, on average, those screened out would not experience a substantial economic loss compared to their net gain from applying for and receiving QS (i.e., on average their application fee would have been close to value of the QS they received). However, QSs often trade at multiples of the expected ex-vessel revenue and lease QP price, such that the hypothesized application cost would only partially offset the loss a firm would experience from being screened out of the initial allocation.[39] Nevertheless, for those screened out by a recent participation requirement, it would be likely that a substantial portion of the lost opportunity to qualify for QS would be offset by their avoidance of the application fees. Section A-2.3.3 includes estimates of the expected program costs that can be compared to the values hypothesized here.

Using the hypothetical assumption that the processing cost associated with each application is $1,500, a recent participation requirement that screens out 124 companies would save the economy $211,000 and reallocate about 4 percent of the QS among the remaining 84 processors (an amount with an annual ex-vessel revenue equivalent of about $200,000).

The following sections contain information for each shoreside sector on the effect of the recent participation requirements on the number of buyers that would be potentially eligible for an initial allocation and the amount of landing history that would be screened out by application of the criteria.

- Nonwhiting

For the nonwhiting buyers, we consider the Council's two recent requirement participation options and an option included for analytical purposes (at least 1 mt of landings in at least one year from 1998 to 2003). As shown in Table A-49, 124 companies received at least one delivery of nonwhiting groundfish and 84 did not from 1998 to 2003 (Option 1). The deliveries to companies with some 1998 to 2003 participation represents 96.2 percent of the 1994 to 2003 deliveries. Requiring participation of 1 mt in a year would result in 84 qualifying companies and 124 excluded (middle column in Table A-49); however, the change in the 1994 to 2003 share of harvest by those meeting the standard is nearly imperceptible (96.2 percent compared to 96.1 percent). This small change reflects that many companies received very small amounts of groundfish, often in just one year during the 1994 to 2003 allocation period.

[39] QS often trade at a price that is between 3 and 10 times the QP lease price (Asche 2001). The QP lease price will be less than the annual ex-vessel revenue generated by the QP because the lease price will reflect profits related to the resource, after deducting for harvest costs. In 2004, total costs equaled revenue, including 5 percent return on capital (Lian, et. al, 2008). Under IFQs, a cost savings is expected of 50 percent to 60 percent. If QP prices are based on average vessel profits, they might be one half of ex-vessel revenue such that QS for $1,500 worth of fish might be expected to trade for about $3,750 (assuming a 5:1 QP:QP ratio).

Table A-50. Number of shoreside nonwhiting buying firms by maximum number of years of participation from 1998 through 2003 at indicated annual participation levels and those firms' share of the total 1994 to 2003 history (gray cells indicate firms do not meet the criteria of recent participation options).

Maximum Number of Years of 1998-2003 Participation	Annual Participation Level					
	1 delivery (>0 MT) (Option 1 requires 1 year >0 MT)		At Least 1 MT (Analytical Option requires 1 year >0 MT)		At Least 6 MT (Option 2 requires 3 years >6 MT each)	
	Number of Firms	Share of '94-'03	Number of Firms	Share of '94-'03	Number of Firms	Share of '94-'03
No Participation Greater than the Indicated Amount	70	3.7%	110	3.7%	125	4.0%
1	41	4.8%	26	4.9%	25	4.9%
2	31	2.3%	16	2.3%	12	3.7%
3	17	6.8%	15	8.3%	12	6.8%
4	6	3.6%	5	3.6%	5	4.2%
5	8	3.6%	7	2.0%	2	1.4%
6	21	75.1%	15	75.0%	13	75.0%
Total Meeting Standard (total of unshaded cells)	124	96.20%	84	96.10%	32	87.40%

The third column in Table A-49 is most restrictive, requiring an annual minimum participation of at least 6 mt to be counted as a participant in a particular year. Recent participation Option 2 requires such participation in each of three years during 1998 to 2003. As shown above in Table A-49, although fewer companies qualify (just 32 participated in three or more years with at least 6 mt), these companies received 87.4 percent of the groundfish during the 1994 to 2003 allocation period.

Geographic impacts by state are summarized in Table A-50. The number of companies that would not qualify under a given recent participation criteria is displayed above the dotted line (criteria not met), and those that would qualify are displayed below the dotted line (criteria met). Most of the companies receiving nonwhiting are located in California and the impact on California is proportionally greater than for the other states.

Table A-51. Number of shoreside nonwhiting buyers operating within each state and active during the indicated periods (1998 to 2003 and 1994 to 2003) and either meeting or not meeting the indicated criteria.

Recent Participation Options	Number of Firms					
	California		Oregon		Washington	
	1994-2003	1998- 2003	1994-2003	1998- 2003	1994- 2003	1998- 2003
Criteria from Council Option 1 (>0 MT in any year)						
Criteria Not Met	0	48	0	10	0	8
Criteria Met	134	86	38	28	28	20
Criteria from Analytical Option (>1 MT in 1 yr)						
Criteria Not Met	54	77	12	19	3	11
Criteria Met	80	57	26	19	25	17
Criteria from Council Option 2 (>6 MT in each of at least 3 years)						
Criteria Not Met	107	114	22	28	14	19
Criteria Met	27	20	16	10	14	9

The differences in the level of impacts between states are less dramatic when the proportional changes are considered rather than the totals. This is illustrated in Table A-51, which summarizes the effects on number of entities and quantity and raw product cost of the three options. The three options are compared for illustration purposes to the totals of quantity and raw product cost for all companies receiving nonwhiting within the allocation period. For the Option 1 requirement, there is less difference in the proportion of the impacts between Oregon and Washington than there is between either of those states and California. As the recent participation requirement is increased, the proportion of the number of entities affected within the state increases more for California and Oregon than it does for Washington, but the amount of landing history affected for Washington increases more than for California or Oregon,

Table A-52. Number of buyers and deliveries screened out by recent participation requirement options, by state.

Recent Participation Requirement	California		Oregon		Washington	
	Number of Companies Not Meeting the Indicated Recent Participation Requirement, Their 1994-2003 Purchases (weight and ex-vessel value), and Each Expressed as Percent of the State Total					
Option 1 Any Activity (>0 MT)	48 companies 37% of Total		10 companies 26% of Total		8 companies 29% of Total

	133,998.6 mt	$144.78 (mil)	170,424.8 mt	$178.31 (mil)	61,366.1 mt	$49.44 (mil)

- Whiting

For the nonwhiting buyers, the Council initially considered two recent participation options and added a third option when it took final action. The first two options the Council considered focused on a 1998 to 2003 recent participation period. The third option extended the recent participation period and the allocation period to 2004. We will analyze the Council's first two options and then provide a separate discussion of the impact of the Council's final recommendation. As shown in Table A-52, 17 companies received at least one delivery of whiting and 9 did not, from 1998 to 2003 (Option 1). The deliveries to companies with some 1998 to 2003 participation represent 94.3 percent of the 1994 to 2003 deliveries. Requiring participation of 1 mt in any two years would result in 9 qualifying companies and 17 excluded; however, the change in the 1994 to 2003 share of harvest by those meeting the standard is imperceptible.

Table A-53. Number of shoreside whiting buying firms by maximum number of years of participation from 1998 through 2003 at the indicated annual participation levels and those firms' share of the total 1994 to 2003 history (gray cells indicate firms that do not meet the criteria of recent participation options).

Maximum Number of Years of 1998-2003 Participation	Annual Participation Levels			
	1 delivery (>0 mt) (Option 1 requires 1 year >0 MT)		At Least 1 mt (Option 2 requires 2 year >1 MT)	
	Number of Firms	Share of '94-'03	Number of Firms	Share of '94-'03
No Participation Greater than the Indicated Amount	4	5.7%	6	5.7%
1	8	0.0%	6	0.0%
2	0	0.0%	0	0.0%
3	1	3.5%	1	3.5%
4	2	3.8%	2	3.8%
5	1	4.5%	1	4.5%
6	5	82.5%	5	82.5%
Total Meeting the Criteria (total of unshaded cells)	17	94.3%	9	94.3%

Note: The values in the zero row indicate the number of entities active only before or after 1998 to 2003.

The geographic distribution of companies that received whiting are shown in Table A-53 and Table A-54 (for a requirement of at least one landing in a year) and Table A-55 and Table A-56 (for a requirement of at least 1 mt in each of two years). On a state-by-state basis, the share of landings eliminated through the recent participation criteria is much greater for California than Oregon or Washington (in part, because the amount of total landings in California is so much smaller).

Table A-54. Number of shoreside whiting buyers in each state active during the indicated periods (1994 to 2003 and 1998 to 2003) and having a maximum of the indicated number of years of participation during that period (note: Option 1 requires at least 1 year >0).

Maximum Number of Years of Participation	Number of Firms with 1 Delivery For the Indicated Number of Years					
	California		Oregon		Washington	
	1994-2003	1998- 2003	1994-2003	1998- 2003	1994- 2003	1998- 2003

When the Council took final action, it shortened the front end of the allocation period, changing it from 1994 to 1998 and extended the allocation and recent participation periods, changing them from 2003 to 2004. The extension of the recent participation and allocation periods did not allow any more buyers to qualify for an initial allocation. One new buyer first became active in 2004 (a buyer in California). Because the recent participation requirement requires two years of participation, that buyer will not be eligible for an initial allocation. Additionally, there were no buyers with only one year of participation from 1998 through 2003 who picked up a second year of activity with the extension of the recent participation period to 2004. Thus, the effect of extending the recent participation an additional year and modifying the allocation period will be to redistribute QS among those who were already qualified to receive an initial allocation.

A-2.1.3 Allocation Formula

A-2.1.3.a Permits with Catcher Vessel History

❖ *Provisions and Options*

QS will be issued for all fish management units within the scope of the program (see Section A-1.2) based on equal division and permit history, as follows:[40]

Equal Division:

Option 1: All QS allocated based on permit history (see following formulas).

- **Option 2**: An equal division of the buy-back permits' pool of QS among all qualifying permits plus allocation of the remaining QS based on each permit's history (see following formulas). (The QS pool associated with the buyback permits will be the buyback permit history as a percent of the total fleet history for the allocation period. The calculation will be based on total absolute pounds with no other adjustments and no dropped years.)

Permit History: The remaining QS will be allocated based on each permit's history (see following formulas).

For **nonwhiting** trips, permit history used for QS allocation will be calculated:

For nonoverfished species: using an allocation period of 1994-2003. Within that period use relative history and drop the three worst years.[41]

For overfished species taken incidentally:[42]

Overfished Species Option 1: as it is calculated for nonoverfished species.

- **Overfished Species Option 2:** use target species QS as a proxy based on the following approach: Apply fleet average bycatch rates to each permit's depth and latitude distributions and target species QS allocations. Fleet average

[40] Due to the divestiture provision of Section A-2.3.2.e, it is relatively unlikely that accumulation limits will constrain the amount of QS an entity receives in the initial allocation. However, if an entity qualifies for QS in excess of accumulation limits, and is does not qualify to receive that QS under the divestiture provision, the initial allocation will be constrained by first applying the aggregate limits and then, if necessary, the individual species limits. In using this approach, the entity's QS allocation should not be scaled back more than necessary to stay within limits and any QS not allocated will be reallocated to other QS recipients.

[41] State landings receipts (fish tickets) will be used to assess landings history for shoreside deliveries, and observer data will be used for deliveries to motherships. State landings receipts (fish tickets) will be used to assess landings history for shoreside deliveries. In some cases, fish ticket records do not identify species to the same level of detail used for the IFQ management units (e.g., reports "unspecified rockfish"). Under such circumstances, standard species composition routines usually used at the port level have been applied to vessel level data to estimate the species composition of such landings. In some instances, even after applying species composition information, there may be some fish ticket records that have a groundfish species categorization that does not match with one of the IFQ management units. Under such circumstances, when the initial allocations are made information other than that on the landings records and in logbooks might be used to assign the landing to its most probable species category.

[42] The intent is to provide an allocation method for QS for overfished species that addresses the vessel's need to have the QS to cover incidental catch in fisheries that target healthy stocks. The method would attempt to allocate the species to those who will be receiving QS for related target species. By allocating overfished species QS to those most in need of it, such an allocation would be expected to reduce disruption and transition costs. Currently, the list of overfished species that fall into this category is as follows: bocaccio, canary rockfish, cowcod, darkblotched rockfish, Pacific Ocean perch, widow rockfish, and yelloweye rockfish. This list may change by the time the program is ready to be implemented. If a major target species became overfished, it would not be intended that such a species would be allocated this alternative method (for example species such as Dover sole, sablefish, or Pacific whiting).

bycatch rates for latitudinal areas[43] divided shoreward and seaward of the RCA will be developed from West Coast Observer Program data for 2003-06. For the purposes of the allocation, a permit's QS for each target species will be distributed shoreward and seaward of the RCA and latitudinally based on the permit's logbook information for 2003-06. If a permit does not have any logbooks for 2003-06, fleetwide averages will be used.[44]

For **whiting** trips, permit history used for QS allocation will be calculated as follows:

For whiting, use an allocation period of 1994-2003. Within that period, use relative history and drop the two worst years. If a permit participated in both the shoreside and mothership whiting sectors, the same two years must be dropped for calculation of the permit's QS for each sector.[45]

For bycatch species (if IFQ is used for bycatch species):

Bycatch Option 1: use history for that species, as it is calculated for whiting

► **Bycatch Option 2:** use the whiting history as a proxy (i.e., allocation will be pro rata based on the whiting allocation).

Area Assignments: Landings history will be assigned to catch areas based on port of landing.[46]

Relative history (percent). For each sector, the permit history for each year is measured as a percent of the sector's total for the year.

In some situations the initial allocations may be constrained by accumulation limits. See Section A-2.2.3.e for a discussion of the limits and divestiture requirements.

Organization of the Analysis

The analysis will evaluate each of the elements of the allocation formula for permits, then the allocation formula as a whole in the following sections:

- Equal Allocation
- Allocation Period for History Based Allocation
- Drop Years Provision
- Incidental Catch Species Allocation
- Area Assignments
- Relative History
- Allocation Formula Results

The allocation formula results will be strongly influenced by the grandfather clause option selected in Section A-2.2.3.e. Not having a grandfather clause or divestiture would result in the reallocation of QS away from those who would have otherwise qualified for the shares, expanding the shares of all other recipients in proportion to their allocations. The Council's FPA adds a divestiture provision to the grandfather clause, substantially reducing, if not eliminating, any reallocation that might occur as a result of the application of accumulation limits (QS control limits).

[43] The four areas are as follows: (1) north of 47°40 N Lat; (2) between 47°40 N Lat and 43°55 N Lat; (3) between 43°55 N Lat and 40°10 N Lat; and (4) south of 40°10 N Lat.

[44] In order to determine an amount of aggregate target species to which bycatch rates will be applied, each vessel's QS will be multiplied by the trawl allocation at the time of implementation.

[45] State landings receipts (fish tickets) will be used to assess landings history for shoreside deliveries and observer data will be used for deliveries to motherships.

[46] Catch area data on fish tickets are not considered appropriate for this purpose. It is often filled out by fish receivers that assume the vessel has been fishing in nearby ocean areas. Therefore, it will be assumed that all catch comes from ocean areas near the port of landing.

The allocation of catcher vessel QS is intended for permits that are used for catcher vessels (permits other than those associated with catcher-processors). The first decision point in the allocation formula is whether a portion of the QS will be equally divided among permits. The portion that is not allocated equally will be allocated based on permit history. All other options for the initial allocation formula relate to the method used to allocate the portion of the QS that will be allocated based on history.

Early in the program, the quality of the vessel landings data set (fish tickets) was evaluated, and the amount of fish landed in species groups was compared to the current allocation categories. Landings are sometimes reported in nominal categories and species composition proportions developed from port sampler data are applied to those categories to estimate the actual catch composition. Estimation of catch composition in this manner provides statistically valid results for the fleet as a whole, but may not reflect the actual catch composition of a particular vessel on a particular day (for a particular landing). Despite this, it was decided that the species composition proportions applied to individual landings would be used for the initial allocation because it would yield a QS allocation that more closely parallels the actual catch composition than an approach that used landings information aggregated at a higher level to allocate individual QS for each species category.

Even after the application of the species composition information for some years and species, there were substantial amounts of unspecified rockfish that remained unclassified. Because there are sorting requirements for rockfish species for which there are specific management targets (OYs) it is assumed that the unclassified rockfish belong in the remaining rockfish category. "Shelf Rockfish" is the most likely single category to which the unspecified rockfish would likely belong; therefore, all unspecified rockfish were assigned to this category for purpose of analysis. During the initial allocation process there may be other evidence available, such as logbook information and the other species taken on the trip, which could indicate that a particular delivery would best be assigned to an alternative remaining rockfish category (either nearshore or slope rockfish). For 1994 to 2003, rockfish that was unspecified after application of species composition data composed 10 percent of all remaining rockfish in the north and 1 percent of all remaining rockfish in the south. However, for particular states and years, the proportion remaining in the unspecified is substantially greater (Table A-59).

Table A-58. Unspecified rockfish as percent of all remaining rockfish by year and state.

		1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	1994-2003
Unspecified rockfish north as a percent of minor rockfish north												
CA		1%	1%	2%	2%	0%	4%	1%	3%	0%	0%	2%
OR		3%	11%	11%	17%	29%	24%	0%	0%	0%	0%	12%
WA		2%	6%	20%	12%	11%	14%	1%	0%	0%	0%	10%
Total		2%	8%	11%	14%	21%	18%	0%	0%	0%	0%	10%
Unspecified rockfish south as a percent of minor rockfish south												
CA		0%	1%	0%	1%	3%	1%	0%	0%	0%	0%	1%
OR		0%	-	-	100%	43%	100%	0%	0%	-	0%	40%
Total		0%	1%	0%	1%	4%	1%	0%	0%	0%	0%	1%

While on a percentage basis, the amount of rockfish involved may be relatively small, the potential number of fish tickets with some unspecified rockfish remaining after application of species composition information may be substantial (Table A-57).

Table A-59. Number of fish tickets with unspecified rockfish by year and state (1994-1999).

	1994	1995	1996	1997	1998	1999	Grand Total
California	1,873	981	1,085	821	998	696	6,454
Oregon	1,081	1,332	1,913	2,073	1,658	1,459	9,516
Washington	1,259	2,011	1,845	1,551	1,045	1,147	8,858
Total	4,213	4,324	4,843	4,445	3,701	3,302	24,828

Equal Allocation

- Rationale and Options Considered, But Not Included

Equal allocation among all catcher vessel permits is intended to address equity concerns. During deliberations on allocation, it is often argued that past harvest does not create a prior right to future harvest; those with the history have "already been paid for those fish" and, therefore, their history should not entitle them to a greater allocation. Lotteries and equal allocation are two ways in which this concern can be addressed (NRC, 1999). Lotteries might be used if the amount to be equally allocated among all qualified recipients would be too little.

Under the equal allocation provision, all catcher vessel permits would receive an equal share of the allocation attributable to the buyback permit-related history, including history related to participation in the nonwhiting, shoreside whiting, and mothership whiting sectors. Development of the IFQ program started just as the LEP buyback program was being completed. The removal of permits representing approximately 44 percent of the landing history was used to provide a pool of QS that could be allocated equally without substantially reducing the amounts that a permit would receive if there had not been a buyback program, and QS had been allocated through a formula based completely on permit landing history.

The QS in the buyback permit pool will be tied to the sector that generated the landing history. For example, shoreside-landing history will generate QS tied to the shoreside sector. A catcher vessel permit that delivers to motherships will receive some shoreside nonwhiting QS from the buyback permit pool but those QS can only be used to cover catch delivered shoreside. The vessel receiving that shoreside QS might either decide to sell the QS or start making some shoreside deliveries, but it could not use the shoreside QS to cover deliveries to motherships.

The equal allocation element of the allocation formula has particular importance with respect to the allocation of overfished species because it is expected that some overfished species will substantially constrain the harvest of target species. Equal allocation with respect to overfished species is considered below in the section on overfished species allocation.

The Council's final preferred alternative would use co-ops to rationalize the mothership whiting fishery; however, because mothership catcher vessels are subject to the buyback program fees they would still receive a share of the equal allocation distribution of QS. Only two permits that participate in the mothership whiting fishery have not participated in the shoreside trawl fishery (Table A-34). While the shoreside sector will not gain the benefit of an equal share of the mothership sector allocation, the share of mothership history that would be equally allocated is relatively small, 2.3 percent of the mothership sector whiting compared to an average of about 44 percent for shoreside nonwhiting species.

- Interlinked Elements

Number of Trawl Sectors (Section A-1.3). Under the final preferred alternative, there is a single shoreside sector. Vessels making whiting deliveries will be able to cover nonwhiting bycatch using nonwhiting QS received as part of their initial QS allocation under the equal sharing provision.

Transfer Moratorium (Section A-2.2.3.c). Equal allocation redistributes QS to smaller harvesters in quantities in excess of what they have taken historically. If smaller harvesters wish to divest themselves of that QS, rather than using it themselves, the two-year moratorium on the transfer of QS will prevent them from making a permanent transfer, however, during that period they will be able to transfer their QP.

Accumulation Limit Grandfather Clause (Section A-2.2.3.e). If Council had selected an accumulation limit (QS control limit) and grandfather clause without a divestiture provision, incorporation of an equal allocation provision would change the impacts of the accumulation limit grandfather clause. Under such circumstances, those permit holders with the most history would be grandfathered in at lower levels with an equal allocation provision as compared to without an equal allocation provision. If there were no equal allocation and a grandfather clause, those receiving QS in excess of limits would be able to harvest at levels closer to their historic shares.

Overfished Species. In terms of impacts of the allocation formula, there is a strong interaction between the choice of allocation approaches for overfished species (an approach based on bycatch rates applied to targets species or one based on direct catch history) and the decision on whether to apply equal allocation to overfished species. Because of this interaction, equal allocation of overfished species is covered in the section below on the allocation approach used for overfished species.

- Analysis

The following are the categories of goals and objectives most affected by the equal allocation decision.

	Related Category of Goals and Objectives

Communities								X			

♦ *Fairness, Equity and Disruption*

One of the rationales for the initial allocation relates to the compensation of the holders of physical assets for the loss in value of assets they have purchased. LEPs are one asset the value of which will be substantially diminished after implementation of an IFQ Program. Under status quo, permits of similar size are of similar value (assuming there is no speculation on permit value based on the associated landings history and the anticipation of an IFQ program). Comparable value of permits tends to support emphasis on equal distribution of QS among permits, since holders of permits of similar size would be similarly affected. On the other hand, long-term landing history relates to a harvester's overall investment and dependence on the fishery, a factor identified by Congress as important in considering the fairness and equity of the initial distribution (MSA 303A(c)(5)(A)(ii)). Allocation to those most invested and dependent on the fishery tends to reduce disruption. These factors support a landings emphasis on history-based allocation.

Part of the original rationale for the equal allocation of the buyback portion of the landing history was that since those permits were removed from the fishery no one would miss the QS that might be associated with that landing history; therefore, it could be equally distributed among all participants with little expected objection. However, the removal of those permits allowed fishing opportunities to improve starting in 2004. Harvesters have now had a number of years to adapt to their new harvest levels and will have had a number of additional fishing years before the program is implemented. This makes it more likely that an initial allocation that includes an equal allocation component will disrupt recent practices in the fishery and be perceived as less equitable.[47] At the same time during that period, harvesters were on notice that landings occurring after the control date would not count toward the initial allocation.

Table A-59 shows the share of 1994 to 2003 landing history by permits that were bought back in December 2003. The table shows that 91 buyback permits participating in the nonwhiting sector landed 43.62 percent of total groundfish round-weight during 1994 to 2003. This total includes more than half of certain groundfish species, such as arrowtooth flounder, spiny dogfish, and chilipepper. By contrast, the 20 buyback permits participating in the shoreside whiting fishery landed only about 7 percent of total groundfish in that sector, and the three at-sea catcher vessel buyback permits accounted for only about 2 percent of total groundfish delivered in that sector. Table A-60 shows aggregate landing history (mt) during 1994 to 2003 of OY species recorded by all non-CP LE trawl permits (i.e., permits that were bought back in December 2003, plus remaining permits). Table A-60 provides amounts that would be distributed equally per permit, assuming 169 permits.[48]

The initial allocation of QS will provide some compensation to owners of permits, the value of which is expected to decline substantially if an IFQ program is put in place. As was mentioned, under status quo permit values vary based on length. A 70-foot permit may have been worth about $200,000 in 2004 (Table A-19). Just over half the permits are 70 feet or less in length and, therefore, of equal or lesser value. Assessing the value of the QS that will be issued for permits is difficult because of uncertainties about trading prices for QS. There will be some relationship to the ex-vessel value, after subtracting harvesting costs and taking into account the multiyear stream of revenue that a QS holder might expect. While not a very precise or unbiased estimate of QS value, the ex-vessel value that might be associated with the amount of QS to be allocated equally provides a sense for the order of magnitude of the compensation that the equal allocation might provide to permit holders. An average ex-vessel value per

[47] This assumes that the vessels with permits that have the greatest amount of 1994 to 2003 history are the vessels most likely to have expanded their harvest with the increased opportunity occurring after implementation of the buyback program.

[48] As of the summer of 2009, the number of catcher vessel permits has declined to 167.

permit of $63,000 may be attributable to the equal shared portion of the nonwhiting QS allocation (Table A-61). Another approach to provide an order of magnitude estimate is to look at the estimated total value of nonwhiting QS that would be issued ($68 million to $180 million, Table A-20) and assume that the quantity of the QS allocated equally is proportional to the value of the QS allocated equally.[49] On this basis, the total value of the amount allocated equally would run between about $28 million and $79 million. Divided equally among 169 permits, this comes to between around $160,000 to $470,000 per permit (excluding whiting). These revenue and QS estimates should be reduced by 10 percent to account for the amount of nonwhiting QS that will be allocated for use in the AMP. There will be some marginal additional amount of value from equal allocation attributable to the equally shared whiting; however, this amount is likely to be relatively small (about $4,600 per permit before reducing by 20 percent to account for the amount to be allocated to processors).

A closely related issue is excessive shares. Accumulation limits are intended to prevent individuals from acquiring excessive shares; however, a grandfather clause was considered that would allow those with history qualifying them for initial allocations in excess of accumulation limits to receive allocations greater than the accumulation limit (QS control limit) and to retain that allocation indefinitely (divestiture not required). For those entities, a grandfather clause would provide a long-term advantage over those who receive an initial allocation below the limits. This advantage is viewed by some as an inequity. When combined with a grandfather clause, an equal allocation component would reduce the level at which entities were grandfathered in, thus reducing that long-term advantage. The Council's final preferred alternative allows entities to receive a full initial allocation (unrestricted by accumulation limits), but requires them to divest of their allocation within the first four years. This reduces the duration of the advantage of the allocation in excess of control limits and diminishes the importance of equal sharing in reducing the size of that advantage.

[49] Since the 44 percent that will be allocated equally is an average across a number of species and the value varies across species, the value of the equally allocated QS may be more or less than 44 percent of the value of all QS allocated. Using 44 percent of the value of the QS provides only a rough estimate for the value of the amount to be equally allocated.

Table A-60. 1994 to 2003 Aggregate Landing history Shares (percent) for *Buyback Permits*.

Species Group	Shoreside Nonwhiting	Shoreside Whiting	At-Sea (Mothership) Whiting CVs	Total nonCP Groundfish CVs

* Estimates do not include a reduction of 10% for nonwhiting species allocated to the AMP and do not include a reduction of 20% for whiting allocated to processors; at-sea whiting catcher vessel QS would not be available for equal allocation since this sector will be managed with co-ops.

♦ *Net Benefits and Sector Health*

Equal allocation may result in some misalignment between recent harvest patterns and the initial allocation, requiring the redistribution of either capital assets or the QS following the initial allocation. The need for the redistribution would depend on the desire and ability of those receiving QS in excess of their typical usage to use the QS themselves on their existing vessels (assuming the vessels have adequate capacity) and efficiency of their harvest operations relative to other harvesters that will be looking to acquire additional QS to increase production. Equal allocation may result in more transfers after initial implementation, increasing both private transaction costs and administrative costs. Additionally, if there is a correlation between historic size of harvest operations and efficiency (with smaller operations being less efficient) then QS will be initially allocated to less efficient operations. Transaction costs will always present a hurdle slowing the transfer of QS to more efficient operators. Thus, benefits early in the program will be somewhat greater whenever the initial allocation can be made to those who will use the QS most efficiently.

Often when there is an initial allocation of IFQ, few harvesters receive shares in amounts that are sufficient for them to pursue what they may view as their normal landings levels for recent years, [50] particularly the average and larger harvesters. One of the reasons for this is that allocations are often made based on averages. Under status quo, every year some vessels experience lower than their normal harvests or are absent from the fishery for the year. This creates greater opportunity for the remaining vessels but makes it impossible to allocate all vessels an amount of QS that might reflect their operating level for what they view as normal years. This dynamic leads to lower average allocations for the largest producers, however, the same kind of dynamic also diminishes the amounts the smaller producers receive relative to their landing history. After the initial allocation, there will be an opportunity for a harvester to purchase quota and restore its opportunity to harvest at its normal level. However, in bidding for the purchase of quota, even if a particular smaller operator has efficiency that is comparable to a larger operator, if smaller operators are less well capitalized, they may have a lesser ability to compete to purchase the additional QS needed to restore their operations to normal harvest levels. Under such circumstance, equal allocation may help preserve the economic health of smaller operators while larger operators are able to weather the additional capital demands on their own. On the other hand, if there is no difference between smaller and larger operators in their ability to access capital, or if for some reason larger operators tend to have more debt (or less equity) when the program goes into place, the equal allocation component could diminish overall sector health.

Figure A-27 illustrates expected shares of nonwhiting harvest allocated to each permit (vertical axis) as compared to the 2004 to 2006 average share of nonwhiting harvest for each permit (horizontal axis) assuming 100 percent of the allocation goes to harvesters. The top graph shows this comparison using a QS allocation formula based entirely on landing history, and the bottom graph shows the comparison using a QS allocation formula that includes equal sharing of the landing history related to buyback permits. Permits along the diagonal line would be expected to receive an allocation comparable to their 2004-2006 catch. The graphs show that with an allocation formula based only on landing history 93 permits would receive more than their 2004 to 2006 average, but with a formula that includes an equal allocation

[50] For example, if, over a four-year period, every vessel in a fleet had a pattern in which it harvested 100 mt for three of those years and 60 mt in another (with that pattern rotating randomly through the fleet) then when a harvest history based allocation is made, each vessel would only receive 90 mt, not enough to sustain its "normal" harvest level. Additionally, other factors in allocation formulas tend to reduce the peak amounts of harvest, for example being able to drop worst years. Using the previous numeric example, if every vessel drops its 60 mt year and takes credit for the three 100 mt years, the result is the same, 90 mt, because everyone's harvest history would increase by the same amount (i.e., their share of harvest history would be constant).

component 103 permits would receive more than their 2004 to 2006 average. Under either allocation formula, nearly all permits with more than about 1.0 percent of the 2004-2006 harvest receive less QS than their recent history. However, without equal allocation there were a number of permits with more than about 1.0 percent of the 2004-2006 harvest that received amounts of QS much closer to their 2004-2006 history. With equal allocation, the minimum share would be about 0.2 percent and all the permits with less than about 0.4 percent of the 2004-2006 harvest receive more QS than their recent history. With an allocation formula based on landing history the maximum share of total annual ex-vessel revenue for QS attributed to any permit would be about 2.5 percent while with an equal allocation the maximum share would be about 1.6 percent.

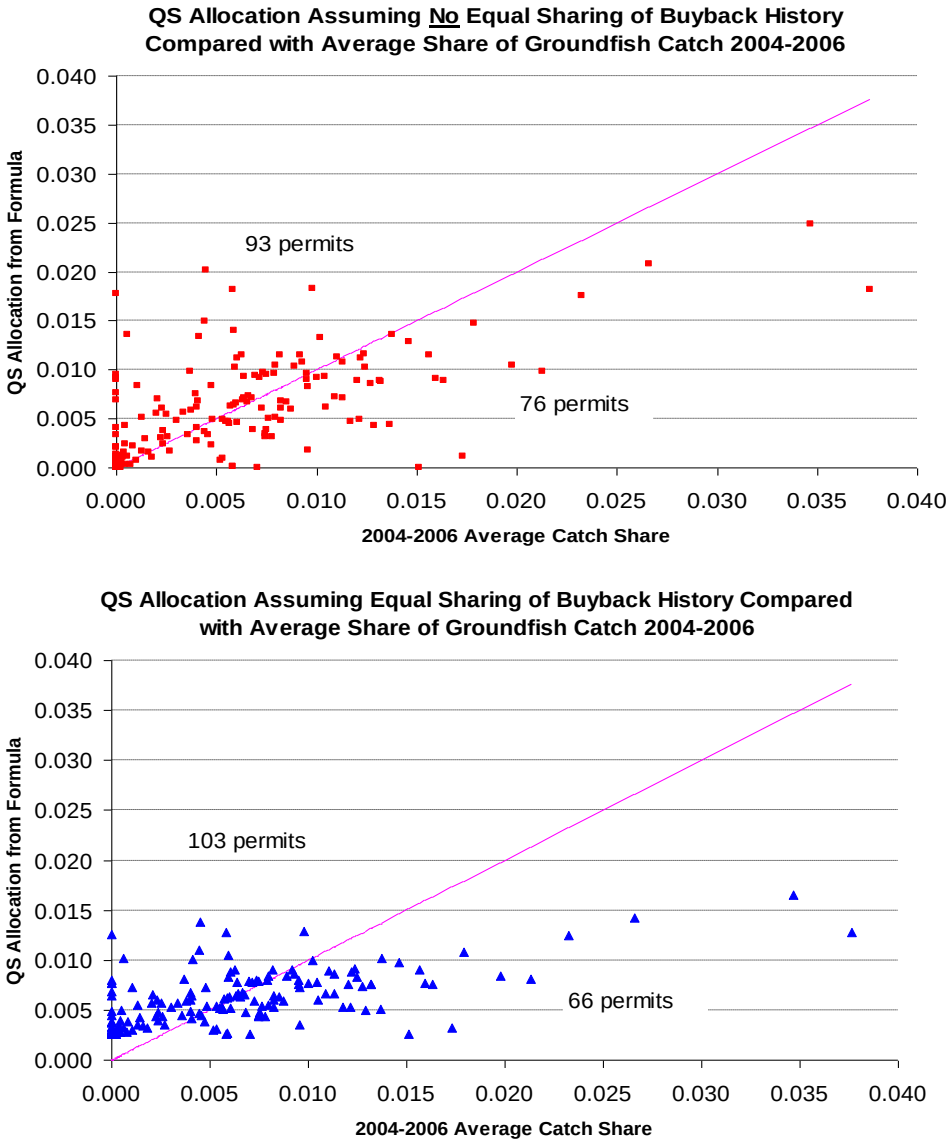

Figure A-27. Effects of equal sharing on the nonwhiting QS allocation given to permits depending on whether or not there is an equal allocation component and relative to the 2004-2006 catch share for each permit (assumes a grandfather clause and 100 percent allocation to permits).

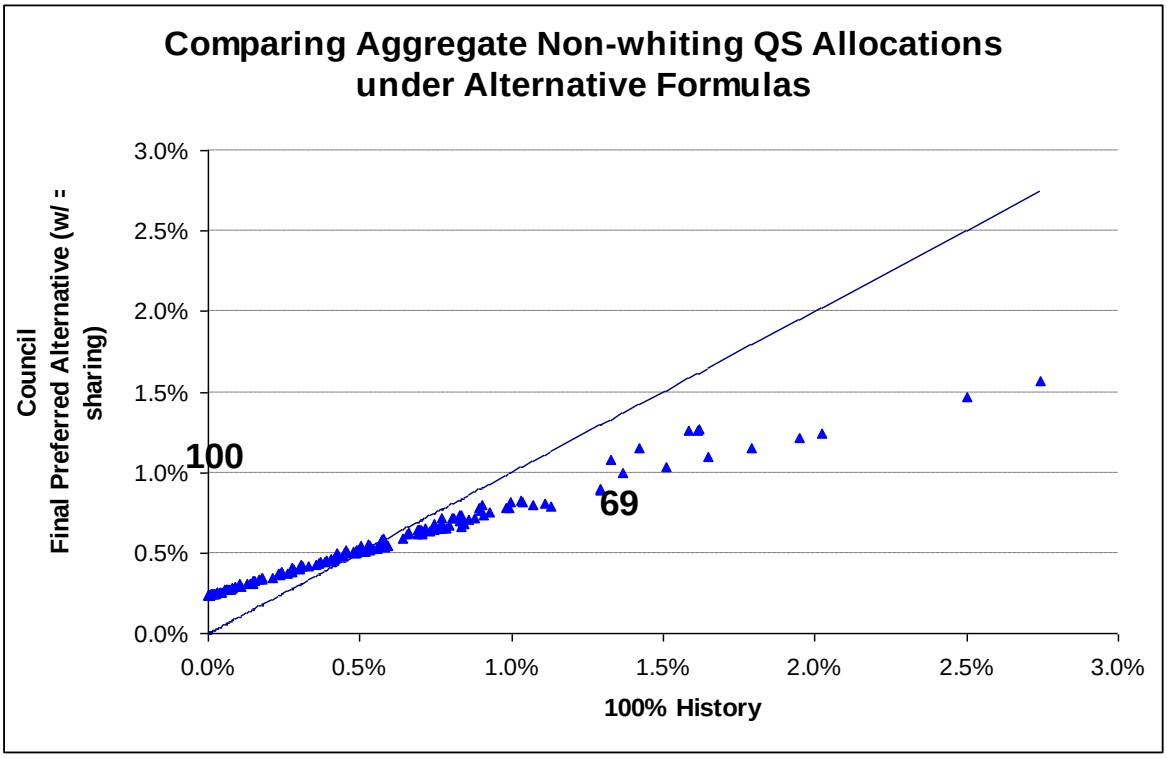

Figure A-28. Comparison of the QS allocation to permits using a formula based 100 percent on landing history to the QS allocation to the same permits using a formula that includes an equal sharing element.

♦ *Communities*

Assuming that past patterns are maintained after the initial allocation, equal allocation would cause a geographic redistribution among communities, primarily benefiting Newport, Brookings, Eureka, and Princeton/Half Moon Bay, as compared to an allocation based entirely on landing history (Section 4.14.5.4).

Allocation Periods

- Rationale and Options Considered But Not Included

The Council's final preferred alternative specifies 1994 to 2003 as the period for allocating QS based on landings history for processors (1994 to 2004 for shoreside whiting processors). This allocation period for permits runs from the inception of the license limitation program (1994) through the year of the Council's control date (2003). The 10-year span for the IFQ allocation is similar in length to the fixed gear sablefish tier program that used 1984 to1994, an 11-year period. When adopting its final preferred alternative for shoreside whiting processors, based on a compromise arrived at during industry negotiations, the Council extended the allocation period to 2004.

The allocation period that would most likely minimize dislocation and the attendant costs would be the few years just prior to the initial allocation. That period is not used, in part, because of issues related to the need to establish credible control dates to effectively manage the fishery while deliberations on new LE programs are underway.

A number of different periods were considered for different parts of the trawl rationalization program and different sectors (Table A-62). At its November 2007 meeting, the Council narrowed the options and standardized the periods to end in 2003. However, as noted above, the Council extended the period used for the shoreside whiting processors to 2004. The periods are detailed in Table A-63. For many sectors, there is a qualifying period to determine eligibility and a period on which the amount of the allocation is based. The primary purpose of this section is to focus on the periods used for the trawl IFQ program, however, the section also covers the rationale for each year considered as a start date or end date for all of the periods considered for both IFQ and co-op management.

Table A-63. Rationale for periods considered for various qualifying and allocation period provisions during development of the IFQ and co-op alternatives.

Time Period	Sector and Provisions (permit qualification/recent participation and allocation)	Summary of Rationale
1994-1999	IFQ – QS allocation, all sectors.	Emphasizes status of fishery prior to constraints to protect overfished species.
1994-2003	IFQ - QS allocation, all sectors. Co-op – Shoreside and mothership CV permits and allocations.	From the beginning of L (1994) to the control date (2003).
1994-2004	IFQ – Shoreside processor QS allocations. Co-op – Shoreside CV permits and allocations. Mothership CV allocations.	From the beginning of LE (1994) to a year that includes more recent participation, as compared to a period ending in 2003. For shoreside processors 2004 was included as a compromise that developed during negotiations leading to an industry consensus.
1997-2003	IFQ – Mothership processor recent participation and QS allocation. Co-op – Shoreside and mothership CV permits and allocations. Mothership processor permits. Catcher-processor endorsements.	A block of years that starts with the period in which there was a 3-way split of the whiting allocation and ends with the control date.
1997-2004	Co-op – C/P endorsement.	A block of years that starts with the period in which there was a 3-way split of the whiting allocation and adds a year beyond the control date to include more recent participation.
1998-2003	IFQ – Recent participation, all sectors. Co-op – Shoreside CV permits and allocations. Mothership CV allocations.	A block of years that reflects the fishery before and the disaster declaration in 2000, and acknowledges the control date (2003).
1998-2004	IFQ – Mothership recent participation qualification. Shoreside processor recent participation and allocation. Co-op – Shoreside and mothership CV permits and allocations. And Mothership processor permits. Shoreside processor permits.	A block of years that reflects the fishery before and after the disaster declaration in 2000, and adds a year beyond the control date (to include more recent participation). For shoreside processors 2004 was included as a compromise that developed during negotiations leading to an industry consensus.
1999-2004	IFQ – Recent participation, all sectors.	A block of years that includes one year just before the disaster declaration and an end date that includes more recent participation (increases emphasis on post disaster conditions relative to periods with earlier start dates)
2000-2003	IFQ – Recent participation, all sectors. QS allocation, all sectors.	A block of years starting with the year of the groundfish disaster declaration and covering four years (a period length similar to LEP allocation period).
2001-2003	IFQ – Allocation period, all sectors. Co-op – Shoreside CV permit.	A block of years that most closely reflects the current conditions for the fishery and at the same time acknowledges the control date (2003).

CV = Catcher Vessel.

Table A-64. Periods used in various qualifying and allocation provisions that remain as options in the trawl rationalization program alternatives.

Sector	Qualifying for Participation		Allocation	
	IFQ Recent Participation	Co-op Alt Endorsement/ Permit	IFQ Allocation	Co-op Landing history
Catcher Vessel Permit Owners				
o Nonwhiting Shoreside Catcher Vessels	None	N/A	'94-'03 (drop 3 worst years)	N/A
o Whiting Shoreside Catcher Vessels	None	'97-'03 (>500 mt)	'94-'03 (drop 2 worst years)	97-'03 (drop worst year)
o Whiting Mothership Catcher Vessels	None	Options: 1) 94-'03 (>500 mt) (FPA) 2) 97-'03 (>500 mt)	'94-'03 (drop 2 worst years)	Options: 1) 97-'03 (drop worst year) 2) 94-'03 (FPA) (drop 2 worst years)
Catcher-Processor Permit Owners	None	97-'03 (at least 1 delivery)	'94-'03 (drop no years)	N/A
Mothership	'97-'03 (>1,000 mt in 2 yrs)	97-'03 (more than 1,000 mt in each of 2 years)	97-'03 (drop no years)	N/A
Shoreside Processing Companies	Qualifying Period Options: 1) '98-'03 2) '98-'04 (FPA) Options for shoreside nonwhiting: 1) 1 delivery option, and 2) 6 mt in each of 3 years, Options for shoreside whiting 1) 1 delivery of any size 2) 1 mt of whiting in any 2 of years (FPA).	98-'03 (more than 1,000 mt in each of 2 years)	Allocation Period Options: 1) '94-'03 2) '98-'04 (FPA) (drop 2 worst years)	N/A

N/A = Not applicable
FPA = Council final preferred alternative.

1994. The earliest year for the allocation period options was set at 1994 because this was the first year of the license limitation program, which substantially changed participation in the fishery and altered delivery patterns. If the program is to allocate based on permit history, there would be no permit history before 1994 unless it is determined that permit history includes vessel history prior to that time. However, given the complexities of the qualification requirements for the original license limitation program, history prior to 1994 may be difficult to track and treat in an equitable fashion.[51] An initial year of 1994 implies a long allocation period. An allocation period from 1994 to 2003, 10 years, would not be unprecedented. The fixed-gear sablefish tier program used 1984 to 1994 as the allocation period, an 11-year period. An initial allocation covering this long period may give more weight to those who have long-term investment and participation in the fishery (and their successors in interest) as compared to those who may have made their investment in more recent years.

1997. The first year in which there was a fixed allocation among the three whiting sectors was 1997. The co-op portion of the rationalization program initially used 1997 to 2004 as the qualifying allocation period for catcher-processors, but using a start date of 1999. For the nonwhiting vessels, the choice of

[51] For example, LE permits were issued to vessels that replaced qualifying vessels prior to the start of the license limitation program. Additionally, for vessels under construction or conversion LE permits were granted on a par with vessels that qualified based on 1984 to 1988 landings history. The use of vessel landings history prior to 1994 may be viewed as inequitable for those that qualified for permits in 1994 based on having a vessel construction or conversion, as compared to those that qualified for permits based on 1984 to 1988 landings history, the former having had no opportunity to establish landings history prior to the completion of work on their vessels.

1997 as the start of an allocation period would decrease the emphasis on conditions prior to the declaration of a groundfish disaster in 2000, as compared to an allocation period that started in 1994. A start date of 1997 and an end date of 2003 would include three years prior to declaration of disaster conditions in the groundfish fishery and four years after that declaration.

1998. This year is used to start an allocation period that would run from 1998 to 2003 or 2004. In considering 1998 as the start for an allocation period, the Council would have to determine whether six or seven years is a period of sufficient length to allow vessels to demonstrate their level of activity and landings mix without needing to include special hardship provisions. Excluding 1994 to 1997 puts more emphasis on more recent participation patterns. A six-year period starting in 1998 would include landings history two years prior to the 2000 disaster declaration and four years from 2000 and after. Using 1998 as a start date for the allocation period covers a greater variety of fishing strategy opportunities than a period that starts in 1999, but not as much as one going back to 1997 or earlier.

1999. While a disaster was not declared until 2000, the first reductions in response to the discovery that some groundfish species were overfished began in 1999. An allocation period starting in 1999 would include the period after the disaster declaration as well as the one-year prelude to those more severe restrictions.

2000. In response to the discovery that a number of groundfish species were overfished, a disaster was declared for the 2000 fishery, and a number of severely constraining management measures were imposed. Using 2000 as the start of an allocation period would base the allocation entirely on fishermen's opportunities and choices under conditions present after the disaster declaration. Regulations prior to 2000 allowed extensive use of large footropes on trawl gear. In 2000, restrictions on the use of large footropes were used to shift trawl effort away from reef and rocky bottom substrates. Additionally, large closures on the shelf (rockfish conservation area closures) were imposed at that time. This substantially changed fishing opportunities and the mix of species landed. The year 2000 was used to start a four-year allocation period option that was considered (2000-2003). Four years is the period used to qualify vessels for the license limitation program. The use of the shorter qualifying period puts more emphasis on more recent conditions in the fishery but also increases the need to take into account short-term hardships.

2003. In order to prevent speculative effort and the consequent exacerbated management problems, a control date of November 6, 2003 was announced. This announcement put fishery participants on notice that fishing after 2003 would not be counted toward qualifying for IFQ. Since there was little fishing opportunity in the last two months of 2003, all of 2003 is being included in the allocation period.

2004. Using 2004 instead of 2003 as the final year for the qualification period would allow entities with more recent participation and less longevity in the fishery to have one additional qualifying year. It would include in the allocation period one year of fishing after the buyback program implementation, a year in which all remaining vessels had greater fishing opportunity. It would also violate the Council's 2003 control date and may adversely affect the Council's future ability to credibly use control dates to prevent vessels from racing for participation status.

● Interlinked Elements

This element does not directly interact with provisions other than the allocation formula (it is not dependent on nor is it depended on by provisions outside of the allocation formula). While it may somewhat modify the impacts of other provisions, the indirect interactions are not believed to be strong enough to make a substantial change to the analytical results for other provisions.

- Analysis

The following are the categories of goals and objectives affected by the decision on the time periods to use for qualification and allocation.

Section	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Fairness, Equity, and Disruption			X	X	X		X	X			
Net Benefits and Sector Health		X	X			X			X		

♦ *Fairness, Equity, and Disruption*

This section will focus on the relevance of history during the allocation period to the current needs of participants in the fishery and customary standards for establishing resource allocations. To the degree that the QS allocation deviates from the current needs of participants, there is likely to be more disruption, which may also affect the distribution of job opportunities on vessels and possibly the distribution of activity among communities. Greater disruption decreases the likelihood that the allocation will be considered fair and equitable. At the same time, longtime participants in the fishery may view it as appropriately fair and equitable that they should receive recognition for the seniority of their participation and thus claim the privilege to use the resource. Seniority of use is often a factor considered in deliberation over who should have claim to future use of a resource (e.g., issues of "beneficial use" and "first-in-time" related to how surface and ground water use rights are assigned) (NRC 1999).[52] Additionally, the MSA requires consideration of both current and historic harvests in determining the initial allocation of QS (MSA 303A(c)(5)(A)(i) and (iv).

Longer allocation periods take more account of seniority and reduce the need for consideration of hardship provisions. At the same time, use of a longer allocation period implies reliance on long-term averages. If there has been a trend in the change from the start to the end of the allocation period, then the average will not reflect recent conditions in the fishery as well as would a shorter period of more recent years. Additionally, in a changing fishery, the amount of change that the initial allocation will induce will increase as the time between the allocation period and the actual allocation increases. Certain features of the IFQ program will mitigate some of these concerns. They include dropping worst years to address hardship (Section A-2.1.3.a, "Drop Years Provision"), using relative history to address changing fishery conditions across time (Section A-2.1.3.a, Relative History"), and the attribution of

[52] The allocation period may also affect communities if there have been geographic shifts in harvests while the distribution of vessels and permits have remained in the fishery. To the degree that permits have not moved out of an area, an allocation that includes older years may at least temporarily reverse a previous geographic trend that has shifted harvest from north to south (see Section A-1.2).

landing history to a permit to facilitate entry and exit and reduce the disruption that might otherwise occur through the initial allocation (Section A-2.1.1.b).

Longer allocation periods help to address hardships. Temporary circumstances may interfere with a particular vessel's operations such that its harvests over a certain period do not reflect its level of investment and dependence on the fishery. There are number of ways to deal with such hardship circumstances. One is to provide hardship exceptions and an appeals process, another is to allow vessels to drop their worst years, and a third is to provide a longer period of time over which level of involvement and dependence is determined. The Council's PPA relies on a combination of the latter two mechanisms (the opportunity to drop worst performance years and a long period across which to demonstrate performance).

In the context of a longer allocation period, relative history helps adjust for the variation in fishing opportunity among years. When a longer allocation period is used, it is more likely that it will encompass changes in the fishery such that conditions at the end of the period may vary substantially from those at the start as well as from the average over the period. The use of "relative history" is intended to adjust for changes in the fleet harvest opportunity by measuring each year's landing history for a permit as a percent or share of the total for the fleet rather than in pounds caught (also termed "catch over catch"). This compensates for changing opportunity across time but does not address changes in participants.

The long allocation period and associating the allocation with the permit provides for "seniority" of use, while at the same time new entrants receive an allocation that helps protect their more recent investment. By attributing and accruing landing history to a permit, those who have made investments to enter the fishery more recently do not necessarily lose out to those who made their investments earlier in time. This also allows longtime participants to receive more value for the business that they have built, if they choose to leave the fishery before a privilege system such as IFQs has been developed.

A shorter allocation period would provide less credit for seniority in use while still allocating to those who have invested more recently, according to their level of participation. A shorter period would potentially raise more issues of hardship by making it more difficult to allow an entity to drop enough years to cover hardship issues. Some may experience no hardships during the allocation period while others may have circumstances that affect production for a number of years. Allowing permits to drop any more than their one worst year from a four year allocation period would substantially dampen the amount of QS received by those with a consistent participation history (evening out the allocation). On the other hand dropping the worst 2 or 3 years from an 11-year allocation period can be done with much less impact on the allocation to those with consistent participation.

One of the major factors that will result in differences between the pattern of initial QS allocation and the patterns of fishery harvest in more recent years will be the effects of the buyback program. The buyback program occurred just after the 2003 control date. It substantially expanded fishing opportunity for all vessels, as reflected by higher trip limits, and initially resulted in a change in the proportional distribution of permits along the coast. The most effective way to address these changes would be to include years after 2003 in the allocation period. However, doing so would reward those who disregarded the control date announcement, create perceptions of inequity, and encourage fishermen to ignore such dates in the future, negatively affecting the Council's ability to credibly use control dates.

To indicate the degree to which certain conditions in the fishery have changed of the course of an allocation period beginning in 1994 we will look at three pieces of quantitative information. The first is the length of time a vessel has been associated with its current permit, the second is the length of time

the permit has been under the same ownership, and the third is the expected distribution of QS among communities in comparison to the recent distribution of harvest.

The longer the permit and vessel have been together, the more likely it is that the initial allocation of QS will reflect the needs of the current operation. If many permits and vessels have been together a relatively short period, it is more likely that a shorter allocation period would better reflect the level of involvement and dependence on the fishery. Fifty-seven percent of all permits are with the vessel for which they were originally issued (in 1994).

The longer the permit and owner have been together, the more likely it is that a longer allocation period will reflect a seniority or first-in-time allocation approach. At least 35 percent of the permits have not changed ownership since the implementation of the license limitation program.[53]

The expected initial redistribution among communities resulting from the initial allocation, as compared to the 2004 to 2006 harvest patterns are shown in Table A-71 on page A-209. For this table it is assumed that all individuals receiving QS will distribute their activity proportionally to their 2004 to 2006 averages. Additional shifts that may occur as a result of the move to the new IFQ program are not estimated due to the lack of needed data for geographically differentiated harvest cost and revenue models. There has been a northward shift in the groundfish harvest in more recent years (see Section A-1.2 discussion of area management). A more recent allocation might result in an initial geographic allocation more reflective of the current fishery. For example, a 2000 to 2003 allocation period would encompass years during which the fishery has been severely constrained to rebuild overfished species. The fishing opportunities during this period are probably more similar to the opportunities present in the 1990s and, therefore, might be more reflective of the current distribution of harvest. Since an allocation formula was not developed based on a shorter more recent period, we do not have any quantitative results to show whether a more recent but pre-2003 period might come closer to the 2004 to 2006 geographic distribution.

♦ *Net Benefits and Sector Health*

Where there is not a good match between the initial QS allocation and the distribution of capital and labor, dislocation and transaction costs could be incurred as a result of the need for realignment, adversely affecting net benefits and sector health. Under a situation in which ownership and harvest patterns are relatively stable, an allocation based on a long period that ends a number of years before the initial allocation would likely generate a good match between investment in the fishery and result in relatively low dislocation and transactions costs. In general, under a situation with changing conditions, an allocation period of shorter but adequate length[54] puts more emphasis on recent years and may result in a better match between the initial allocation and harvest distribution under current conditions. However, when the changing conditions involve a contraction of fishing opportunity (as for the groundfish trawl fishery), the distribution of capital in the fishery may be reflected more by the longer term fishing patterns than the pattern observed in the most recent years.

[53] The 35 percent estimate is based on an examination of name and address changes. It is possible that even more permits have remained under the same ownership if changes in name and address occurred without there being a true ownership change.

[54] Adequacy of the length used for a history-based allocation is dependent on the length of time needed to demonstrate the fishing levels and patterns on which a business relies relative to other participants.

Drop Years Provision

- Rationale and Options Considered But Not Included

Temporary circumstances outside of the control of the harvester may interfere with a particular vessel's operations, raising fairness and equity questions with respect to history-based allocation formulas and often leading to calls for special consideration of hardships and the need for an appeals process. Allowing permits to drop their worst years is intended as an alternative means of addressing hardship that will reduce program costs. At the same time, the general effect will be that those with a consistent history will lose QS to those who had at least some years of harvest significantly lower than other years. The use of a long allocation period complements the drop year provision in terms of reducing the need for hardship considerations and an appeals process.

- Interlinked Elements

This element reduces the need for hardship provisions and Council involvement in an appeals process (see Section A-2.1.5).

- Analysis

If a drop year provision can be substituted for hardship consideration and an appeals process, administrative costs will be reduced. While possibly an adequate substitute for a hardship consideration, it is imperfect in certain ways. First, the number of years dropped may not be adequate for some special circumstances (i.e., a longer-term hardship situation or a few shorter-term hardships during the 11 year allocation period). Second, dropping years may benefit some who have no claim to a hardship provision, to the detriment of those with larger more consistent landings history. Thus while creating a lower administrative cost method for providing fairness and equity to those who have experienced a hardship, the drop year provision may detract some from perceptions of fairness and equity for the more consistent harvesters. As an example of the effects on those who gain and lose from a drop year provision, the aggregate effect for Dover sole, thornyhead and sablefish shows that if landing history is measured in relative pounds (as it would be under the Council's final preferred alternative), the number of gainers from a drop year provision is between 118 and 132, while the number of losers is between 39 and 53, depending on the number of years a permit is allowed to drop (Table A-64). As the number of drop years increases from one to three, the number of gainers diminishes somewhat, from 132 to 118 permits, but the average amount gained by each permit increases over threefold from $732 to $2,565 (annual ex-vessel revenue assuming 2005 ex-vessel prices and levels of harvest). Results are shown for a number of other species, all of which show similar trends. At the top of the table, a comparison is provided for the effect of combining the drop year provision with absolute pounds instead of relative history (the choice between absolute and relative history is discussed in a following section). The effect is to slightly diminish both the number of gainers and the amount of their gain. While not displayed in this table, the difference in impacts between drop years using relative history and using absolute pounds was consistent across species. Table A-64 also shows the number of permits for which a particular year was the lowest. Years after the fishery disaster was declared (2000) have the most permits showing those as their lowest years. The first two years of the program also tended to have higher counts for low years with the middle years, 1996 to 1999, tending to show up less often as low years for permits. When absolute pounds are counted rather than relative history, the fishery disaster years show up even more frequently as the lowest years.

* Permits with more than one zero year are counted multiple times in the lowest row. When this occurs they do not show up in the 3rd lowest or 2nd lowest rows (depending on whether they had two or three zero years).

Allocation of Incidentally Caught Overfished Species

- Rationale and Options Considered, But Not Included

♦ *Equal Allocation and Methods of Allocating Based on Harvest History for Overfished Species*

As with other species, incidentally caught overfished species would be allocated either entirely based on history (A-2.1.3.a, Option 1) or based on an equal sharing of the portion of the QS associated with the buyback permits and the remainder based on a formula relying on some variation on permit specific harvest history (A-2.1.3.a, Option 2). With respect to the portion of the overfished species QS allocated based on a method related to harvest history for nonwhiting trips, the formula may either directly assess overfished species harvest history using the 1994 to 2003 allocation period (Overfished Species Option 1), or it may take harvest history into account indirectly by assessing a permit's target species QS allocations and applying its recent harvest pattern (as measured by logbooks) and fleet average bycatch rates from the West Coast Groundfish Observer Program (Overfished Species Option 2). For whiting trips, a similar set of options is provided for allocation of the portion of the bycatch species QS that is to be allocated using a method related to harvest history: assessing history using 1994 to 2003 harvest information (Bycatch Option 1); or allocating overfished species in proportion to the whiting QS allocation (Bycatch Option 2).

In the Council's PPA (from June 2008), QS associated with the permit history of buyback permits (including QS for overfished species) was to be allocated equally among all nonbuyback permits (A-2.1.3.a Option 2). The equal allocation component of the PPA ensured that every permit would have some overfished species QS to go along with its target species QS. The remainder of the QS for overfished species was to be allocated on a basis that was expected to closely reflect a permit's need for overfished species bycatch (Overfished Species Option 2 and whiting trip Bycatch Option 2). However, when the Council took final action, it eliminated the equal allocation of the overfished species (with the exception of canary rockfish) QS associated with the buyback permits so that overfished species would be allocated entirely based on the portions of the allocation formula which the Council believed would most reflect the permit's need for overfished species QS to accommodated its target species. Thus, the Council's final preferred alternative for noncanary overfished species QS allocated for nonwhiting trips is to allocate it entirely based on the application of bycatch rate and logbook information to target species QS allocations (A-2.1.3.a Option 1 combined with Overfished Species Option 2). For whiting, all noncanary overfished species QS would be allocated in proportion to the whiting allocation (A-2.1.3.a Option 1 combined with Bycatch Species Option 2).[55] [56] For canary, the Council found that absent an equal allocation element there would be a geographically disproportionate impact on permits in areas such as Fort Bragg, California. On this basis, the Council at its November 2009 meeting revised its final preferred alternative from November 2008, deciding that the initial allocation of canary rockfish QS should be based on the PPA (i.e., the final preferred alternative for canary rockfish should include the equal allocation of QS associated with buyback permits).

[55] The Council's final preferred alternative is to manage the shoreside nonwhiting and whiting sectors as a single combined shoreside sector. Therefore, after determining the amount of overfished species QS to be allocated to a permit based on its past nonwhiting and whiting trips, the QS types would be merged so that only one type of QS would be issued, shoreside QS.

[56] All non-overfished bycatch species would be allocated equally based on the buyback permit history with the remainder being allocated to each permit holder in proportion to its whiting allocation.

The other main, overfished species, allocation option considered was to base the allocation directly on landings history (Overfished Species Option 1 and Bycatch Species Option 1). This approach would allocate overfished species to those who in the 1990s targeted the species that have since become overfished or who caught overfished species incidentally after they were declared overfished, rather than to those who need overfished species QS to prosecute current target fisheries. This approach was rejected on the basis of the desire not to reward bycatch during the rebuilding period and in order to provide QS to those who would need it to cover incidental catch taken with their target species QS allocation.

Numerous other methods were considered that are not reflected in the current options. One of these was the use of a constant fixed ratio applied to target species QS to determine the amount of bycatch species QS that would be issued for each permit. This approach, while better at meeting current needs than an allocation based on harvest history, would not be as precise in meeting current need (as measured by amounts of target species QS a permit receives) as an approach which uses each individual permit's logbooks and allocation of target species QS (the final preferred alternative). However, constant fixed overfished species to target species QS ratios based on fleet averages will be used for those permits that do not have logbook records for 2003 to 2006.

♦ *Specification of the Bycatch Method for Allocating Overfished Species*

Initially, the Council approved consideration of an option for allocating overfished stocks based on a bycatch rate that would be applied equally to all permits (a constant fixed ratio). The initial bycatch rate option would have used logbook data for the fleet as a whole, aggregated on a species-by-species basis. In other words, if 90 percent of the trawl caught Pacific cod occurred north of Cape Mendocino, and shoreward of the trawl RCA, each permit with Pacific cod catch history would be estimated to take 90 percent of its Pacific cod from that same area. However, it is unlikely that any single permit's distribution of fishing activity would be reflected by the fleet average; and the bycatch rate of overfished stocks can vary widely from one area to another. Therefore, a more detailed method was developed to estimate where permits might be fished under rationalization and assess the associated bycatch rates. Under the final preferred alternative, the bycatch rate method for allocating overfished species uses four latitudinal strata, two depth strata, and a permit's fishery patterns evaluated over the strata using 2003 to 2006 logbooks.

A complete description of the bycatch method for allocating overfished species is provided in Appendix C. This section of Appendix A documents some of the choices made by the Council in developing that method and related impacts.

LATITUDINAL STRATIFICATION

For the bycatch rate approach, the main design element that required additional Council deliberation was the question of the latitudinal strata to use for application of this approach. The bycatch rate approach can be applied on a coast wide basis or refined by stratifying into areas, which might result in allocations that better match the needs of permits that would most likely be fishing in a particular area. Available data indicate that bycatch rates can differ substantially by latitudinal area and by seaward or shoreward of the RCA. During its deliberations, the Council considered three latitudinal stratifications to apply the bycatch rate methodology Table A-65.

Table A-66. Latitudinal strata considered for the allocation of overfished species.

Number of Strata	Latitudinal Area Stratifications (North Lat)
2 Areas	North of 40°10' South of 40° 10'
4 Areas (preferred)	North of 47° 40' Between 47° 40' and 43° 55' Between 43° 55' and 40° 10' South of 40° 10'
5 Areas	North of 47° 40' Between 47° 40' and 43° 55' Between 43° 55 and 40° 10' Between 38° 0'and 40° 10' South of 38° 0'

The number of and dividing lines used for the stratifications were limited because the bycatch rates developed for the strata are based on samples and for smaller areas insufficient sample sizes exist to estimate a bycatch rate. The bycatch rates for eight latitudinal subareas that were used to compose the approaches for these area stratifications are provided in Figure A-29 though Figure A-35. For the above options, the entire area south of 38 ° north latitude is combined because several sub-areas do not appear to have sufficient observations for calculating an independent bycatch rate. The bycatch rates used for the Council's final preferred alternative are provided in Table A-66.

At its June 2008 meeting, the Council's PPA used the two-area approach for allocating overfished species for nonwhiting trips based on bycatch rates. When it took action after the public comment period on the preliminary DEIS (in November 2008), the Council indicated it would prefer to use an approach based on finer levels of stratification (either four or five strata). The Council reviewed these two finer area stratifications in March of 2009 and chose the four-area stratification over the five-area stratification. The Council selected the four-area stratification over the five-area stratification because observer program bycatch rates indicated that if the area south of 40° 10' north latitude were subdivided some permits would receive substantially reduced QS for some overfished species. Even with a four-area approach, at a later point in the process the Council found that there were some permits would receive very minimal amounts of QS for overfished species, for canary rockfish in particular. At that time (November 2009), the Council addressed this problem by deciding to equally allocation among all permits the QS associated with the permits that were bought back in the 2003 buyback program.

LOGBOOK PERIOD

The bycatch rate approach to the allocation of overfished species relies on each permit's logbooks to determine the depth and latitudinal strata associated with the permit. The proportion of catch associated with each strata is used to distribute a permit's initial allocation of target species QS by strata. The bycatch rates are then applied to the permit's initial target species allocation associated within each strata. There were two periods considered for evaluation of a permit's logbook records: 1994 to 2003 and 2003 to 2006.

At its meeting, the GAC recommended that for the overfished species bycatch allocation formula the distribution of catch for each individual permit be determined based on 2003 to 2006 logbooks, as the best estimate for where the permit was most likely to fish after rationalization. The TIQC disagreed with this recommendation. Initially the TIQC believed that fleet average logbook data would be more

appropriate than individual permit logbook history during 2003 to 2006 because in more recent years vessels were forced to choose between fishing shoreward or seaward of the trawl RCA in the north. Since the catch history formula is based on the years 1994 to 2003, permits will receive QS for species that are found both shoreward and seaward of the RCA. Therefore, the TIQC initially favored the application of fleet average logbook data to each permit's QS allocation, so that each permit would be assigned both shoreward and seaward catch history. However, after further deliberations, the TIQC recommended the use of 1994 to 2003 logbooks as superior to the use of either fleet averages or the 2004 to 2006 permit specific logbooks. The TIQC viewed 1994 to 2003 permit specific logbooks as a better choice because it accounted for variation in the geographic distribution of each permit's harvest strategy and would better match with both the target species QS allocations (which were allocated based on 1994-2003 history) and the strategies that would have to be pursued to take those target species allocations. However, the GAC recommended that each permit's 2004 to 2006 logbooks be used. The Council concurred with the GAC and recommended use of 2004 to 2006 logbooks. It may be better to use a period when the RCAs were in place to estimate a permit's most likely pattern of activity, since the RCAs will remain in place after the trawl rationalization system is put into place. The RCAs were not in place for most of the 1994 to 2003 period but were in place for 2003 to 2006. Thus, use of 2004 to 2006 logbooks may better mirror the opportunities present with the RCA closures and other efforts to avoid overfished species.

● Interlinked Elements

An approach that allocates incidentally caught overfished species by transforming target species QS allocations using bycatch rates eliminates some of the problems that would result from application of the relative weights approach to measuring landing history. For example, using a relative weights approach a pound of canary caught in 2003 gives the same credit toward QP as would 100 pounds caught in 1998 (rewarding the retention of overfished species during rebuilding).

The equal allocation element of the allocation formula interacts with the allocation approach used for overfished species, significantly affecting the resulting allocation impacts.

● Analysis

The following are the categories of goals and objectives affected by the decision on how to allocate incidentally caught species.

♦ *Overview*

Empirical evidence from other quota programs throughout the world has shown that initial allocations of IFQ that differ substantially from current or recent fishing practices result in some negative consequences during the initial years of the program (dislocation of fishermen and high discard rates) (Branch, *et al.* 2006). Over time, these consequences would be reduced through QS trading and adjustments by capital and labor, but a more refined initial allocation, one that better matches expected needs, may still be able to avoid such negative consequence, reducing costs associated with the transactions necessary to realign the QS allocation and fishery participation patterns. Additionally, while the market is likely to end up making necessary adjustments to the ownership of quota, overfished species quota is likely to be extremely costly because it will constrain access to target species. An allocation that provides target species QS without the overfished species QS needed to cover bycatch may be economically disruptive to those already in the fishery that receive an initial allocation and must then choose between making the expenditures to acquire additional overfished species QS/QP or selling off their target species QS/QP and perhaps leaving the fishery.

For the foreseeable future, overfished species will be a constraint to the access of target species. In addition to potential efficiency benefits and reduction of disruption, an initial allocation of overfished species QS that is well matched to allocations of target species QS may be viewed as being more equitable.

The general categories of impacts described here are associated with each of the specific choices described in the following sections. For the purpose of the first section of this portion of the analysis, the focus is on comparing an allocation based on landings history to one based on bycatch rates, logbooks, and target species allocations. In order to isolate and highlight this difference, figures are provided that compare a scenario under which all overfished species QS is allocated based on landings history to one in which all overfished species QS is allocated based on the bycatch rate approach (there is no equal allocation component for either the target species or the bycatch species). After reviewing these results, we will look at the effect of the decisions on the strata to be used for the bycatch rate approach, the choice of time periods over which to assess individual permit logbooks, and the equal allocation element of the overfished species allocation formula (the Council's PPA) in comparison to the same formula without the equal allocation element (the Council's final preferred alternative).

♦ *Direct Harvest History vs. Bycatch Rate Approach*

In general, if allocations of overfished species are made based on landings history, the distribution of overfished species quota would be more heavily weighted toward a fewer permits. This is because recent incidental landings are proportionally more evenly distributed among permits than landings occurring when the now overfished species could be targeted. The permits that would receive the most are those were that had previously targeted overfished species when they were abundant and under more recent regulations catch of overfished species in the shoreside nonwhiting fishery has been largely discarded rather than landed. In Figure A-36 through Figure A-42, it can be seen that for all species more permits will receive a greater allocation under the bycatch rate approach than under a history approach for allocating QS. These data are summarized in Table A-67. By definition, the allocations using the bycatch rate approach would be in closer proportion to the target species QS than with a direct history approach. With the exception of canary rockfish, the amount of QS going to the recipient who would receive the most of a particular overfished species QS is greater with the landing history approach than with the bycatch rate approach. Additionally, with the exception of bocaccio, there are more recipients receiving in excess of 2 percent (20 percent for cowcod) for the direct history approach than with the bycatch approach (Table A-67). For cowcod the extreme is greatest. One permit would receive all of the cowcod using a landing history approach (assuming there is a grandfather clause).

Table A-68. Number of permits receiving more under the indicated method as compared to the alternative method (data summarized from Figure A-36 through Figure A-42).

	Allocation Method	
	Bycatch Rate Approach	**History Approach**
	Bocaccio	
Permits Favored by the Approach	51	45
Permits with More Than 2%	12	11
	Canary	
Permits Favored by the Approach	92	77
Permits with More Than 2%	7	8
	Cowcod	
Permits Favored by the Approach	72	1
Permits with More Than **20**%	0	1
	Darkblotched	
Permits Favored by the Approach	116	53
Permits with More Than 2%	0	10
	Pacific Ocean Perch	
Permits Favored by the Approach	120	44
Permits with More Than 2%	4	16
	Widow Rockfish	
Permits Favored by the Approach	112	57
Permits with More Than 2%	2	13
	Yelloweye Rockfish	
Permits Favored by the Approach	100	68
Permits with More Than 2%	6	11

Note: the allocation amounts shown in Figure A-36 through Figure A-42 and Table A-67 are based on an assumption that 100 percent of the initial QS allocation would go to permits. In the Council's final preferred alternative only 90 percent of the QS is allocated to permits, reducing all of the allocations under either approach by 10 percent. The general conclusions about the relative impacts of these two approaches to overfished species allocations would not be affected by an across the board reduction of 10 percent.

Figure A-41. Allocation of widow rockfish QS for the nonwhiting fishery to entities based on landing history as compared to allocation based on individual permit logbook information on area strata and fleet average bycatch rates applied to target species QS (equal sharing is not included in either approach).

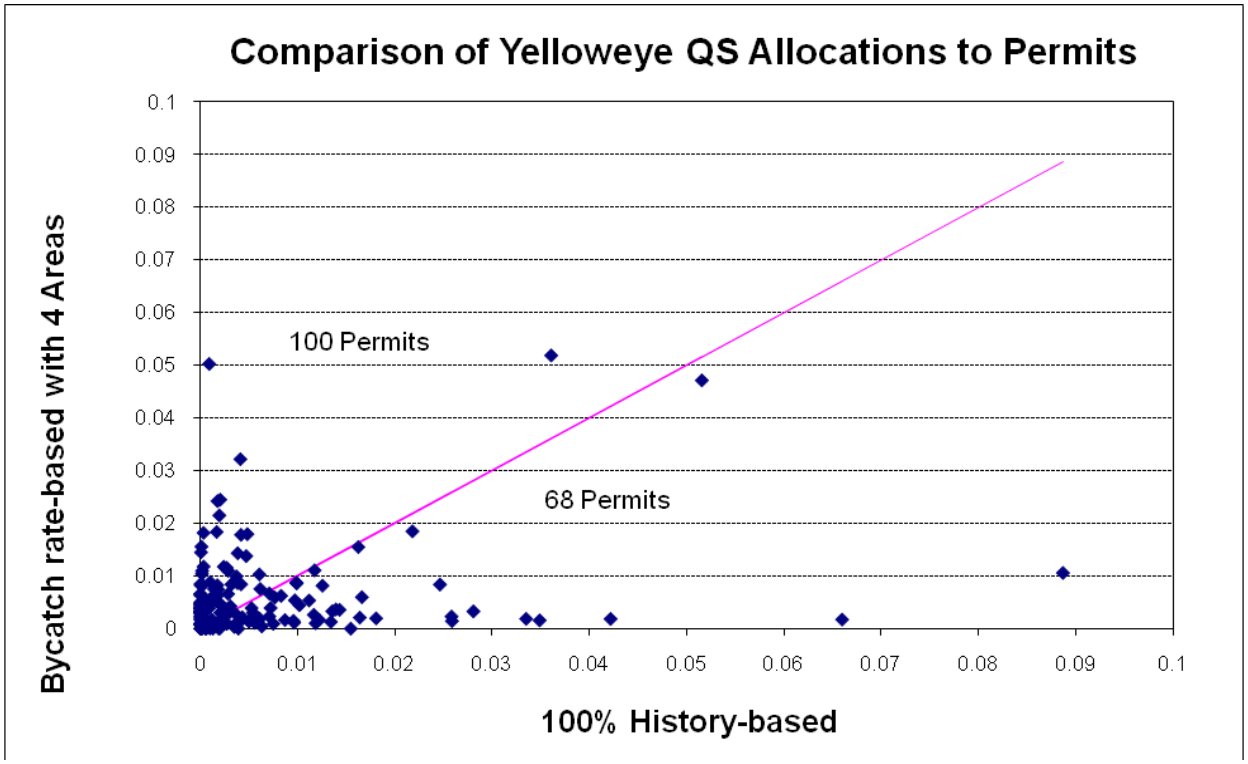

Figure A-42. Allocation of yelloweye rockfsh QS for the nonwhiting fishery to entities based on landing history as compared to allocation based on individual permit logbook information on area strata and fleet average bycatch rates applied to target species QS (equal sharing is not included in either approach).

Using the bycatch rate approach, there are 24 permits that do not have logbooks for 2004 to 2006 but would receive 10 percent of the nonwhiting QS. For these permits, logbook information would not be available to determine the appropriate bycatch rates to apply to their target species QS. Fleet average effort distributions would be used in the overfished species allocation formulas for those permits. Additional information on these permits is provided when the preliminary preferred and final preferred alternatives are compared, below.

Program costs will be increased by the need to determine the allocation for each permit based on that permit's 2004 to 2006 logbooks. Not all logbook data can be matched to fish ticket data and vice versa. The use of both of these data sets in the allocation formula could increase the likelihood of appeals. However, many of the details in the logbook data will not affect the results of the allocation formula. The overfished species allocation formula that relies on logbooks (see Appendix C for a more extensive description) uses the proportion of each permit's target species catch by depth and area strata. The allocation is affected by the ratios of the permit's effort in each of these areas, aggregated across all the target species harvested; therefore, the amount of any particular target species is less important than the proportion of the catch taken in each latitudinal and depth area strata. Use of a fleet wide average for all permits, instead of permit specific logbooks, would lower administrative costs. Administrative costs would also likely be higher if 1994 to 2003 logbooks were used, simply because the data are older and covers more years, increasing the amount of data processing needed, the potential data quality issues, and the potential number of appeals.

♦ *Latitudinal Strata for the Bycatch Rate Approach*

The Council considered assessing permit specific logbooks over two, four, and five latitudinal strata (Table A-65). Using a finer area approach (four or five areas) will tailor the overfished species allocations more specifically to a particular area. A finer area approach might result in less disruption for permits that continue to be used in a manner that is reflected by the period used for assessment of the permit's logbooks but might result in more disruption for permits that have been moved to different areas of the coast since the time period for which the logbooks were assessed. Figure A-43 through Figure A-49 illustrate the effect of the difference between the two-area and four-area approaches. In general, for most species more permits would receive a higher initial allocation using only two areas as compared to four areas, with those receiving the highest allocations generally receiving greater amounts of QS with the four-area approach than they would with the two-area approach. The exceptions are bocaccio and cowcod. For these species, more permits receive greater allocations with the four-area approach than with the two-area approach; and the result for those permits receiving larger amounts is relatively neutral with respect to the difference between the two-area and four-area approaches. However, there is one permit that would receive in the neighborhood of 10 percent of the bocaccio and cowcod under the two-area approach and that would receive substantially less under the four-area approach. For canary and darkblotched rockfish, the results are generally similar whether the two-area or four-area approaches are used (most permits are relatively close to the diagonal line that indicates the points at which there is no difference between the two alternatives). For Pacific Ocean perch and widow rockfish, there are groups of permits that receive substantially less under the four-area approach (less than one quarter of a percent under the four-area approach) which would receive substantially more under the two-area approach. However, even for these species, the pattern is maintained under which those receiving the highest amounts of QS do better under the four-area approach. This pattern, of those receiving the greatest allocations doing the best under the four-area approach, reflects the manner in which the allocations using four-area strata are more tailored to permit needs based on specific areas of activity rather than broader averages that come using the two-area approach.

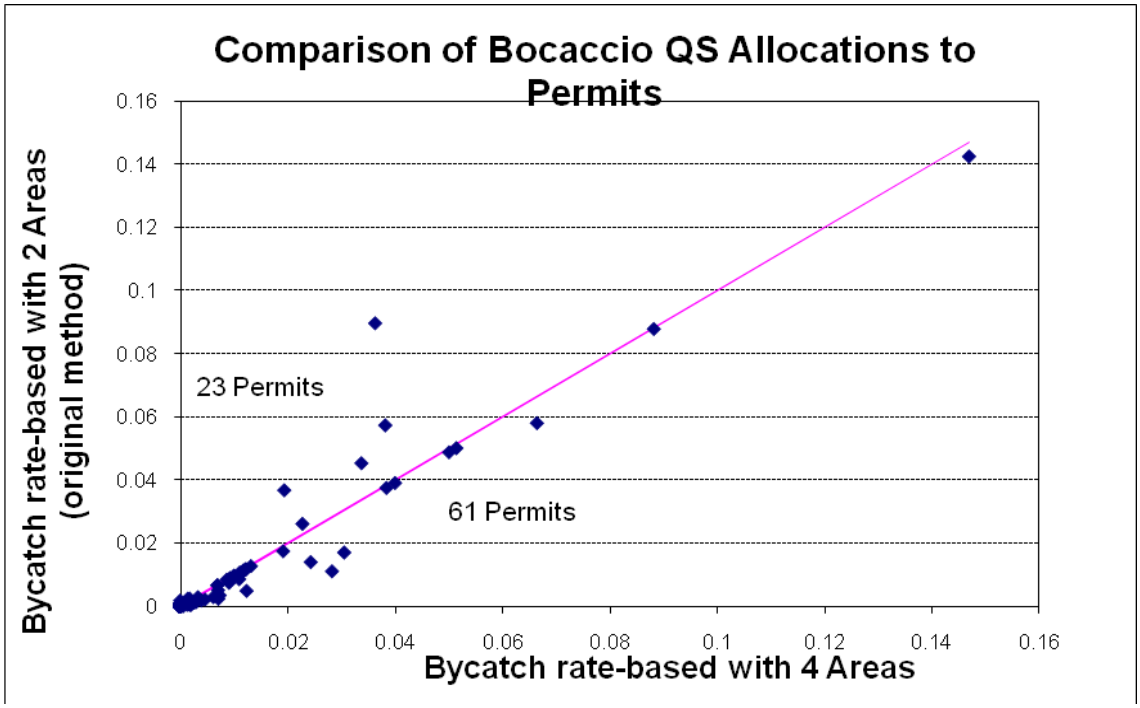

Figure A-43. Bocaccio allocations to permits under the two-area approach (north and south of 40°10'N Lat) and four-area approach (final preferred alternative) (includes allocations for nonwhiting trips only).

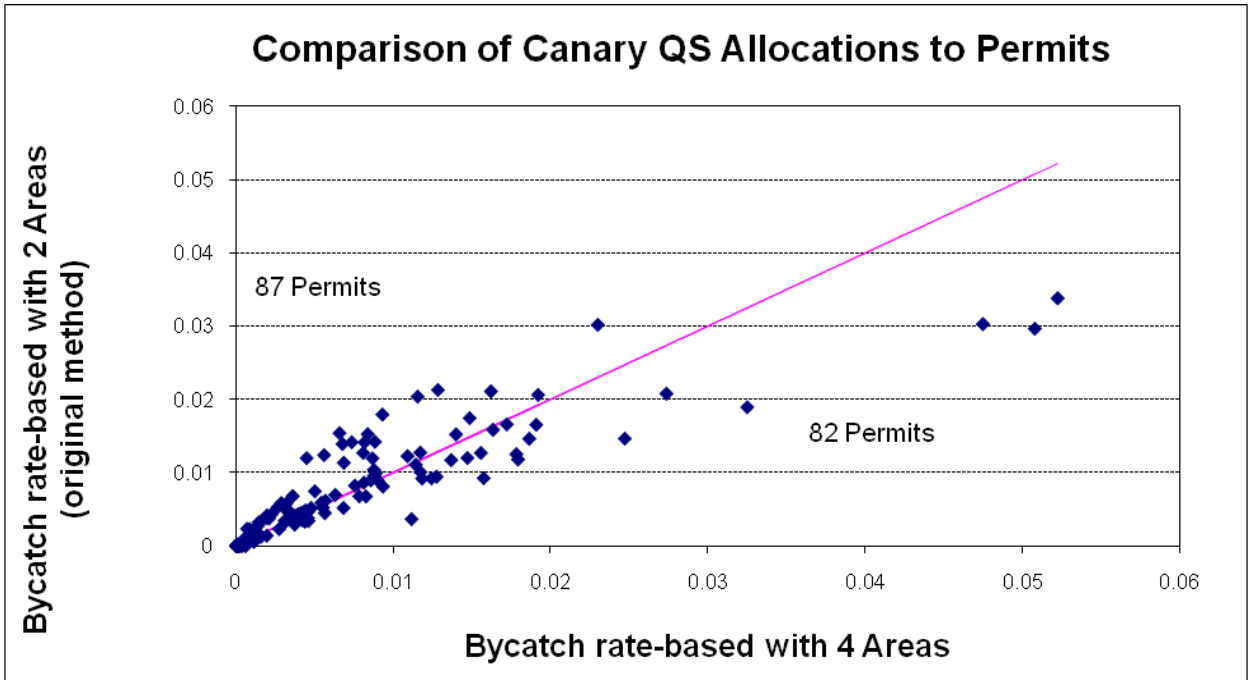

Figure A-44. Canary allocations to permits under the two-area approach (north and south of 40°10'N Lat) and four-area approach (final preferred alternative, but does not use the equal allocation element which is part of the Council's final preferred alternative for canary) (includes allocations for nonwhiting trips only).

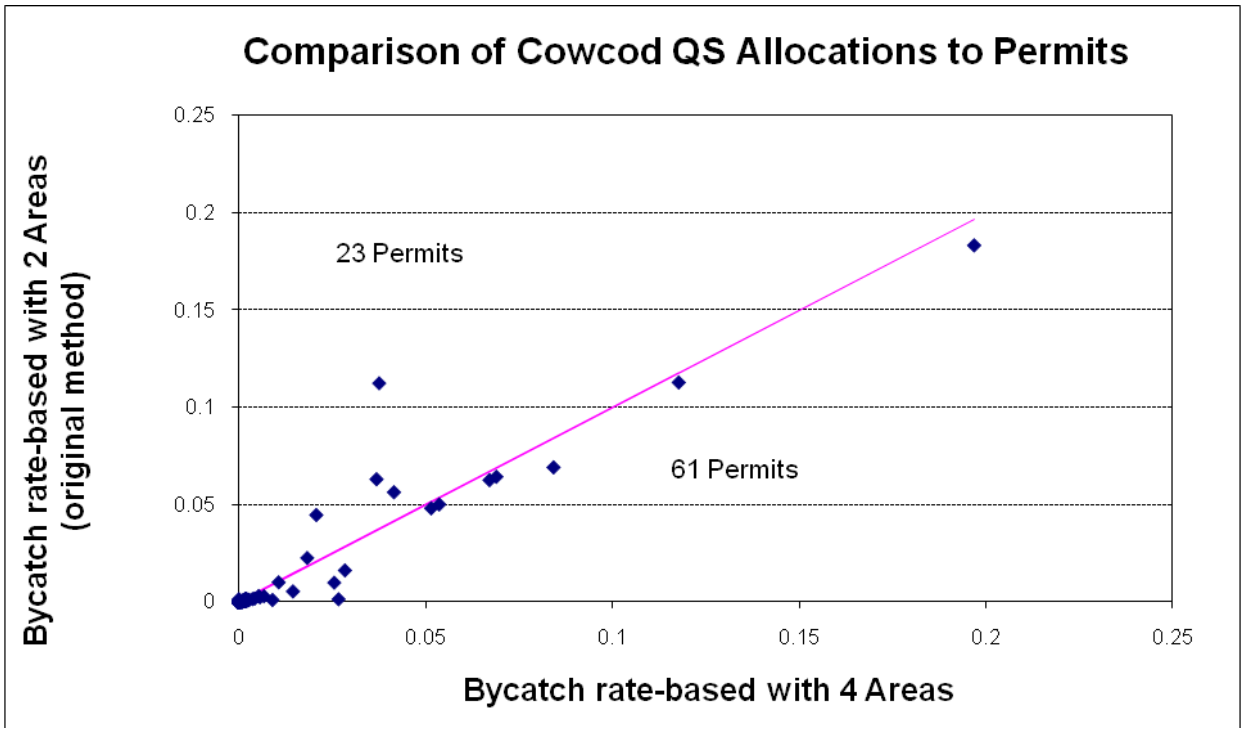

Figure A-45. Cowcod allocations to permits under the two-area approach (north and south of 40°10'N Lat) and four-area approach (final preferred alternative) (includes allocations for nonwhiting trips only).

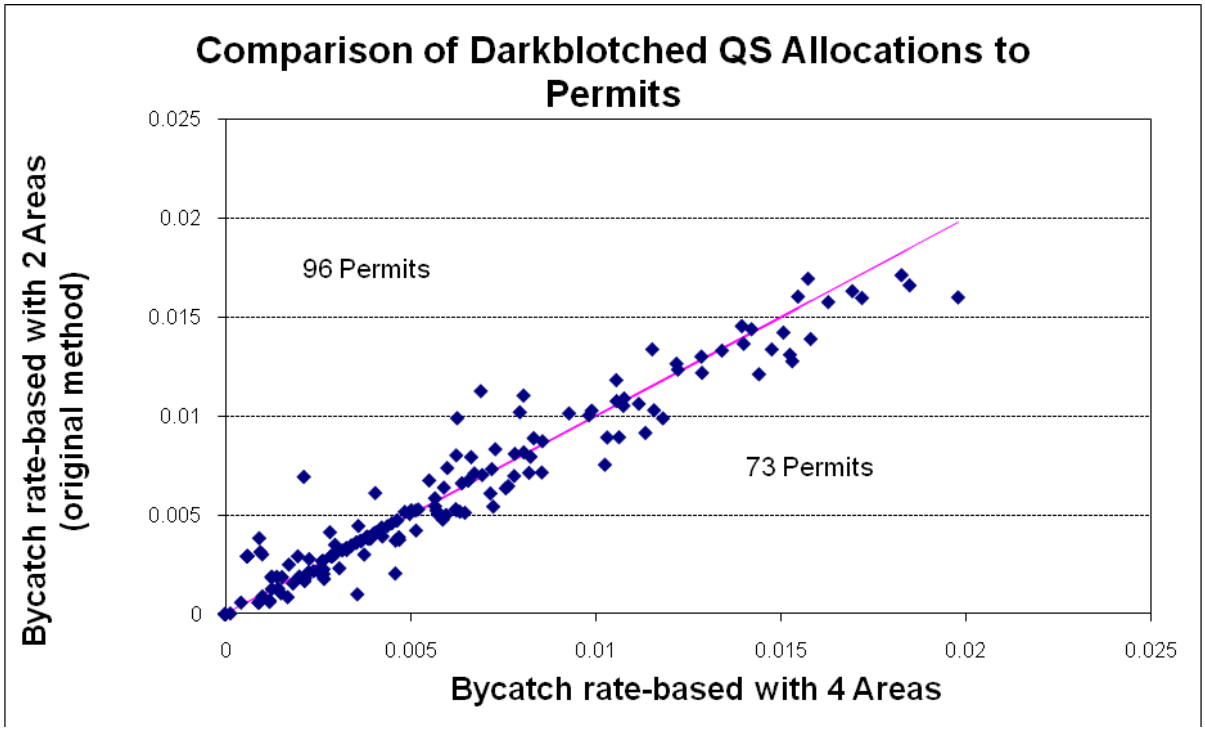

Figure A-46. Darkblotched allocations to permits under the two-area approach (north and south of 40°10'N Lat) and four-area approach (final preferred alternative) (includes allocations for nonwhiting trips only).

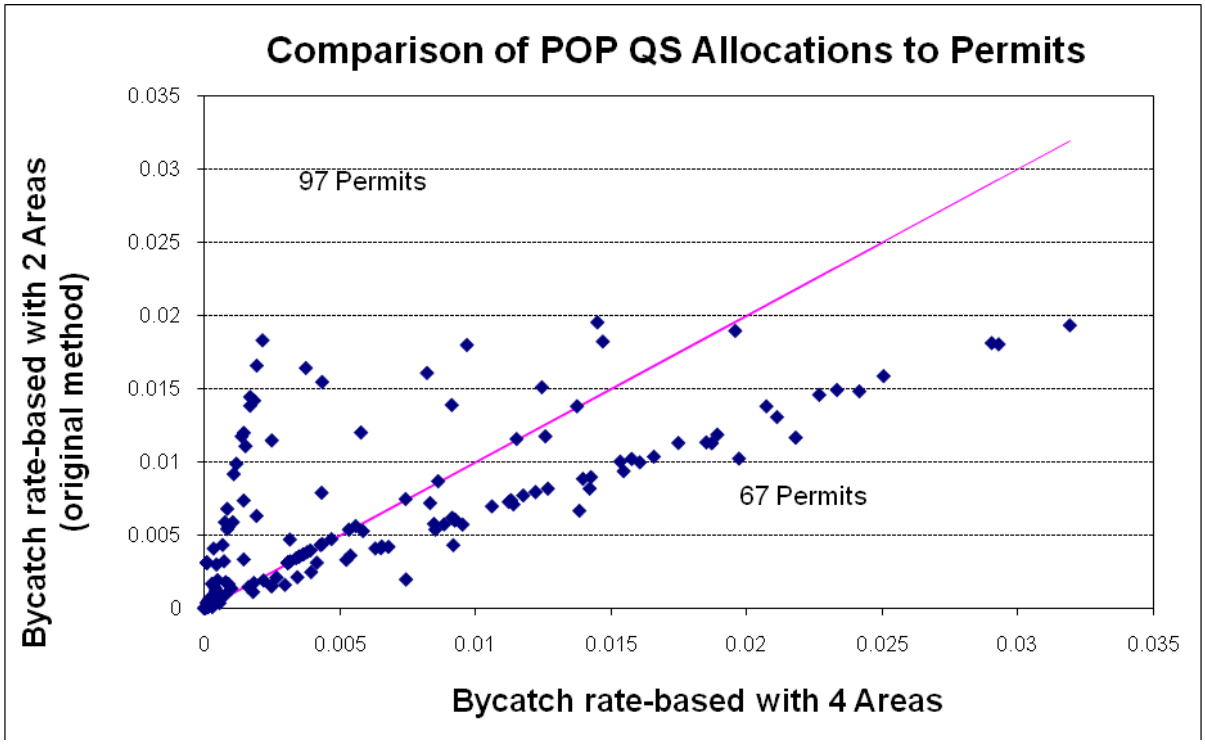

Figure A-47. Pacific Ocean perch allocations to permits under the two-area approach (north and south of 40°10'N Lat) and four-area approach (final preferred alternative) (includes allocations for nonwhiting trips only).

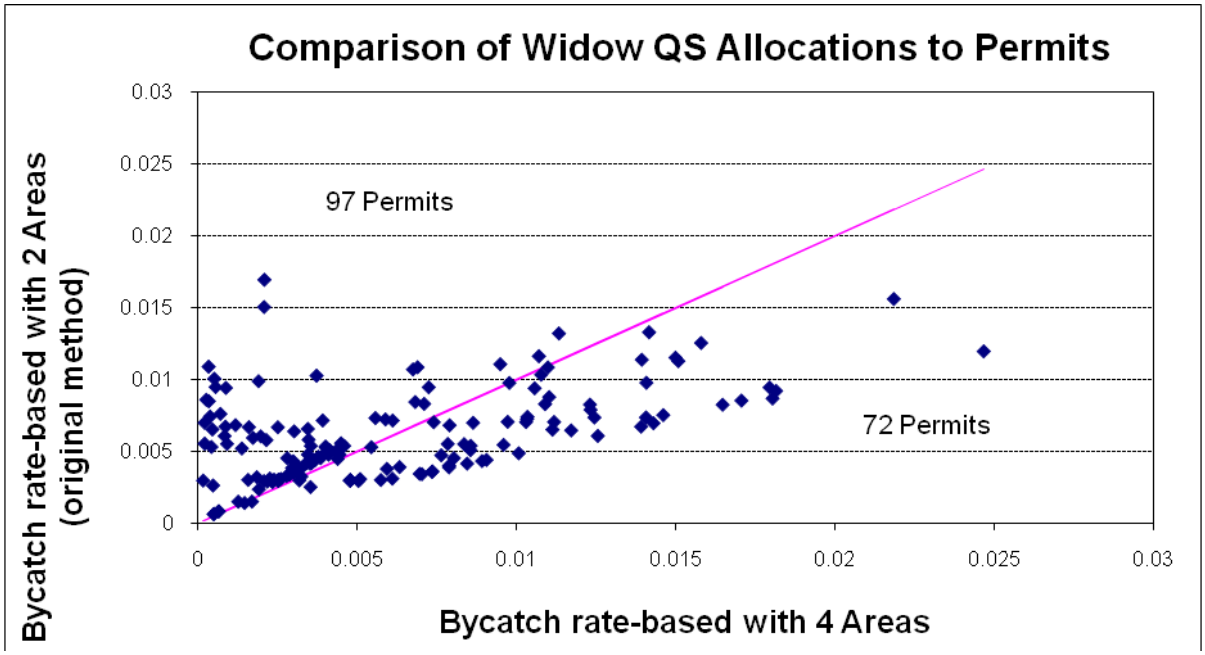

Figure A-48. Widow allocations to permits under the two-area approach (north and south of 40°10'N Lat) and four-area approach (final preferred alternative) (includes allocations for nonwhiting trips only).

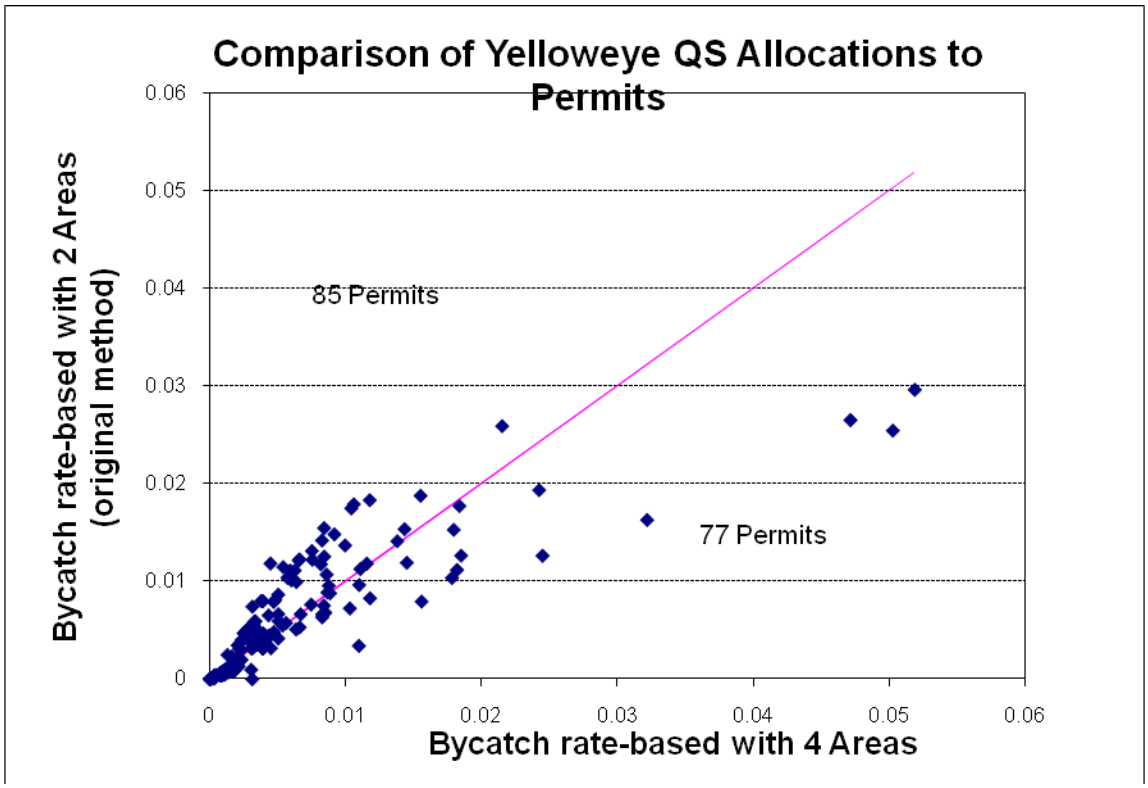

Figure A-49. Yelloweye allocations to permits under the two-area approach (north and south of 40°10'N Lat) and four-area approach (final preferred alternative) (includes allocations for nonwhiting trips only).

Figure A-50 though Figure A-56 illustrate the effect of the difference between the four area and five area approaches. From these figures, it is evident that the initial allocation of bocaccio, darkblotched, and widow are the species most highly affected by differences in the initial allocation formula. These results are different only for those entities with some 2003 to 2006 logbook history south of 40° 10' north latitude. The effect of applying the finest scale bycatch rate area, the five-area approach that splits the area south of 40° 10' north latitude into two regions, is that those entities with history in areas where darkblotched, bocaccio, and widow are most abundant would tend to receive relatively greater amounts of QS for those species. Inversely, the effect of applying the four-area approach is to more evenly spread out the initial allocations of darkblotched, widow, and bocaccio to entities with history south of 40° 10' north latitude.

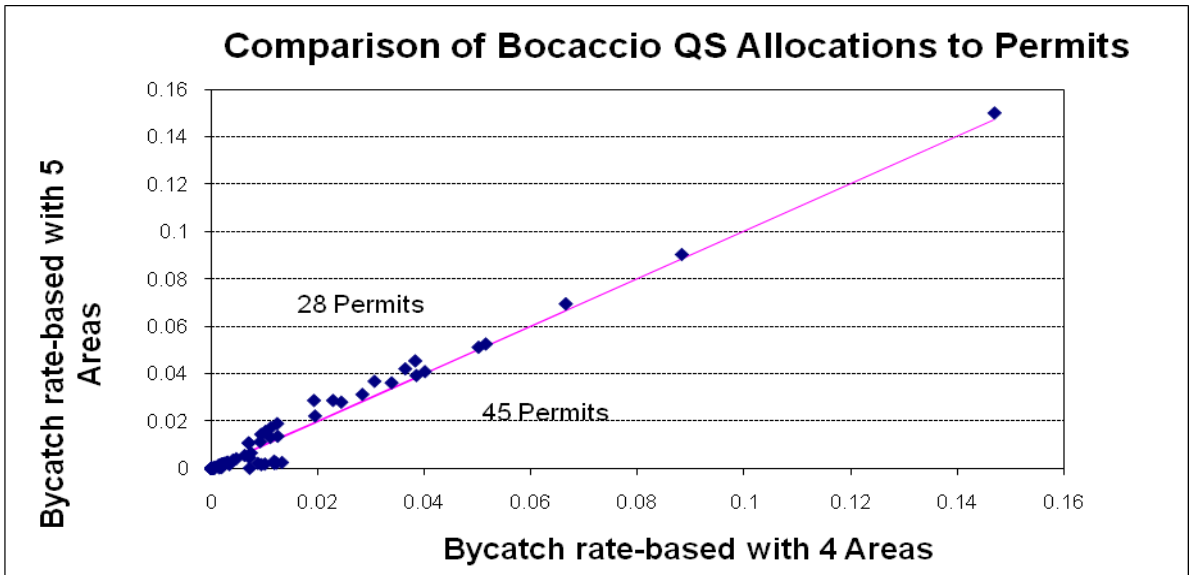

Figure A-50. Bocaccio allocations to permits under the four-area approach (moderately fine area) and five-area approach (finest area) (includes allocations only for nonwhiting trips).

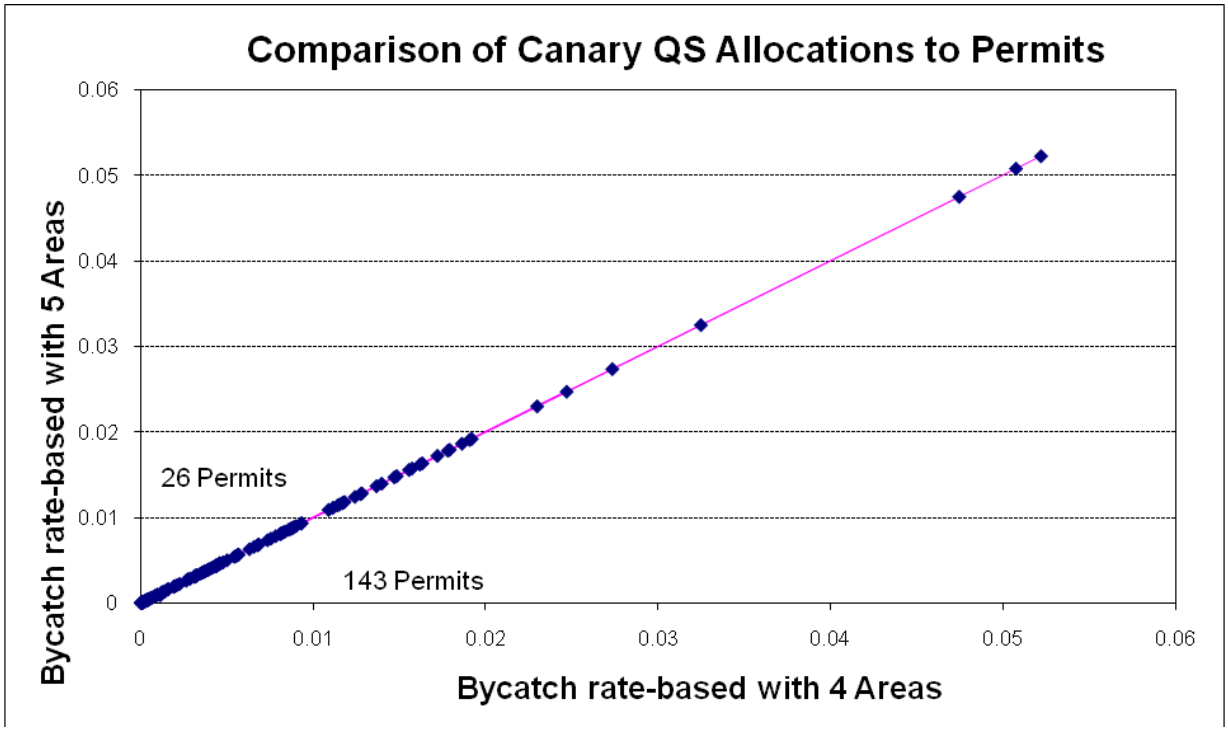

Figure A-51. Canary allocations to permits under the four-area approach (moderately fine area) and five-area approach (finest area) (includes allocations only for nonwhiting trips and does not use the equal allocation element which is part of the Council's final preferred alternative for canary).

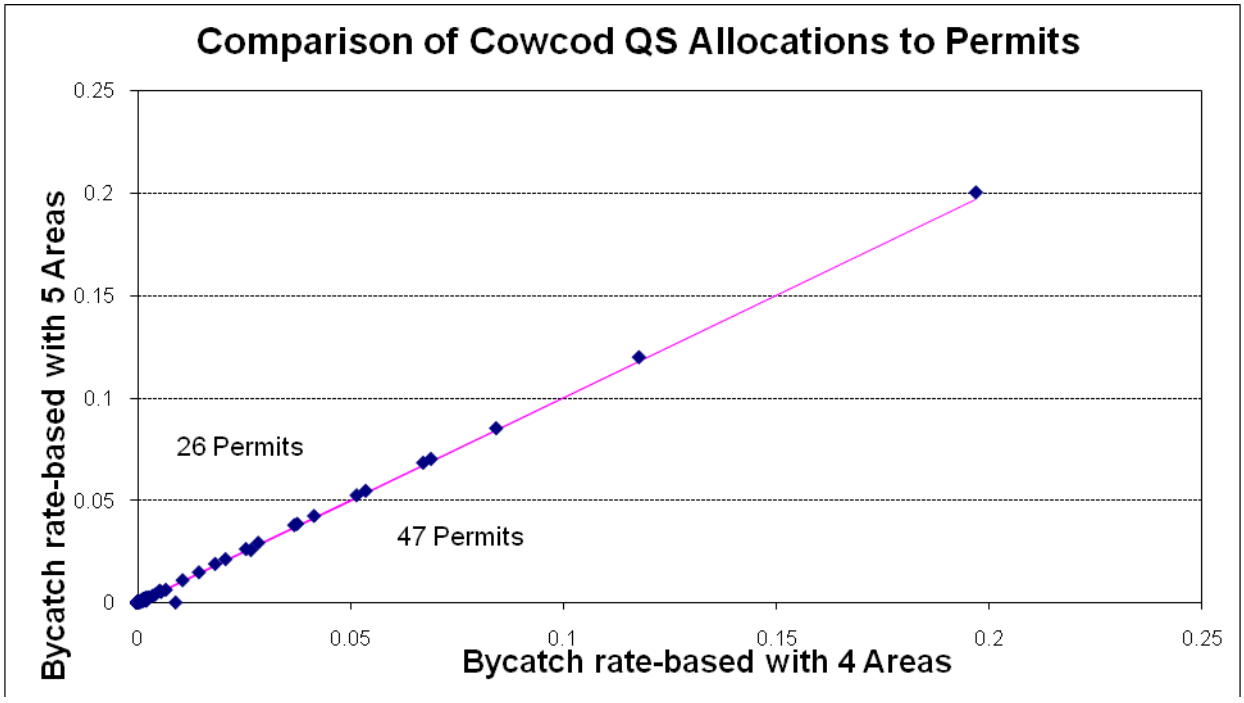

Figure A-52. Cowcod allocations to permits under the fou- area approach (moderately fine area) and five-area approach (finest area) (includes allocations only for nonwhiting trips).

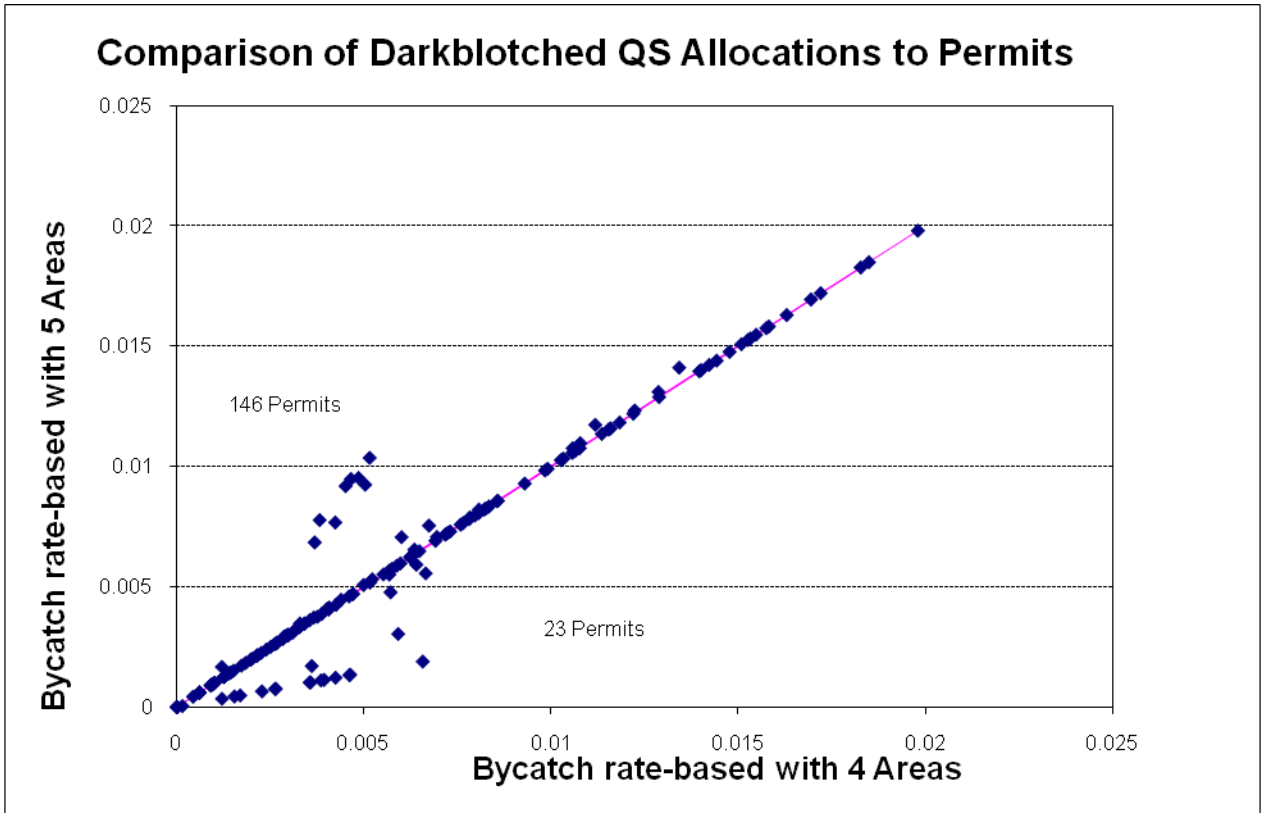

Figure A-53. Darkblotched allocations to permits under the four-area approach (moderately fine area) and five-area approach (finest area) (includes allocations only for nonwhiting trips).

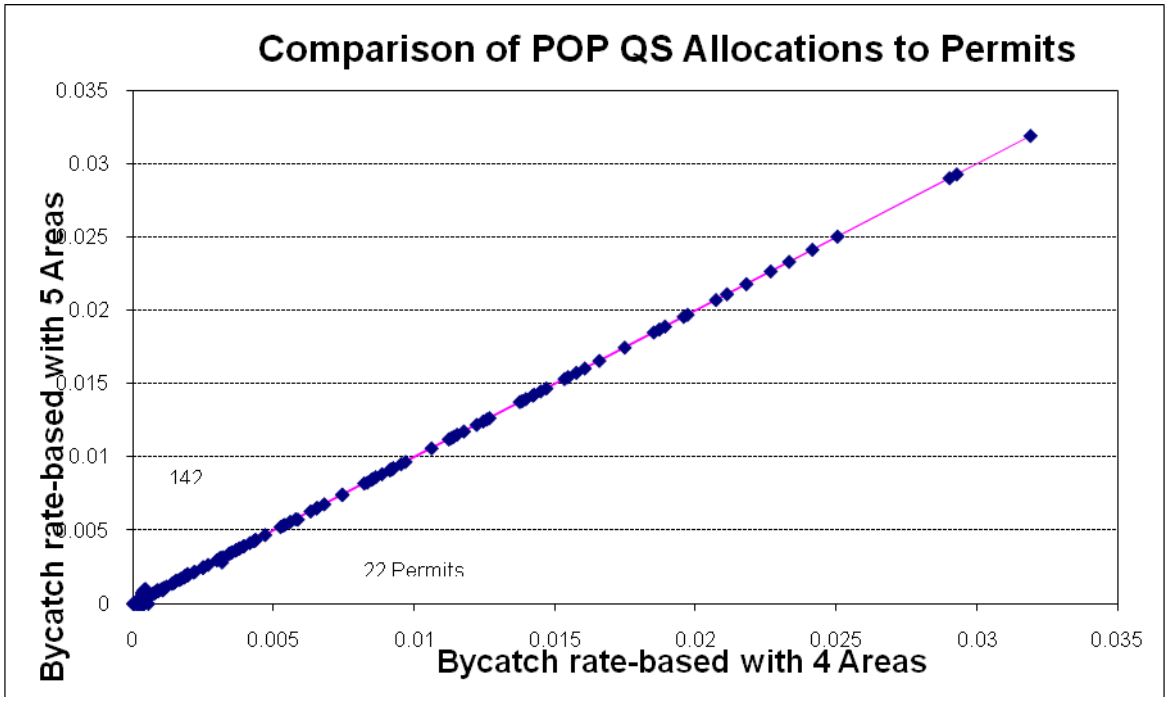

Figure A-54. Pacific Ocean perch allocations to permits under the four-area approach (moderately fine area) and five-area approach (finest area) (includes allocations only for nonwhiting trips).

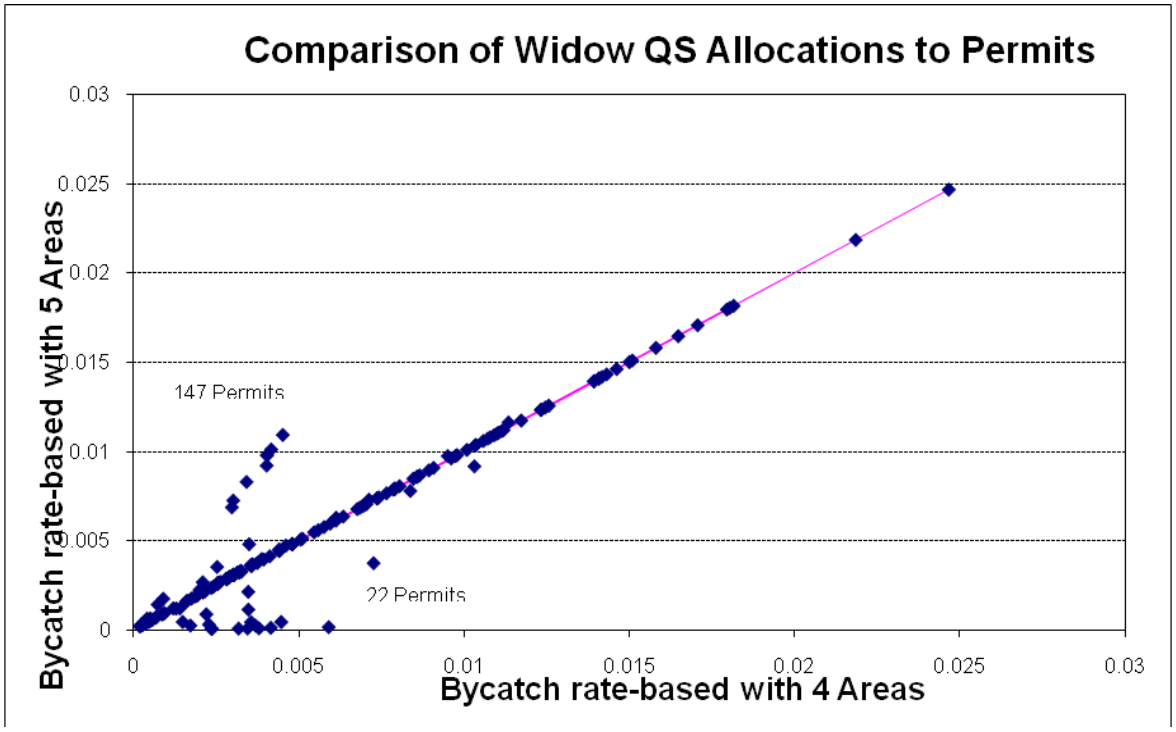

Figure A-55. Widow allocations to permits under the four area approach (moderately fine area) and five-area approach (finest area) (includes allocations only for nonwhiting trips).

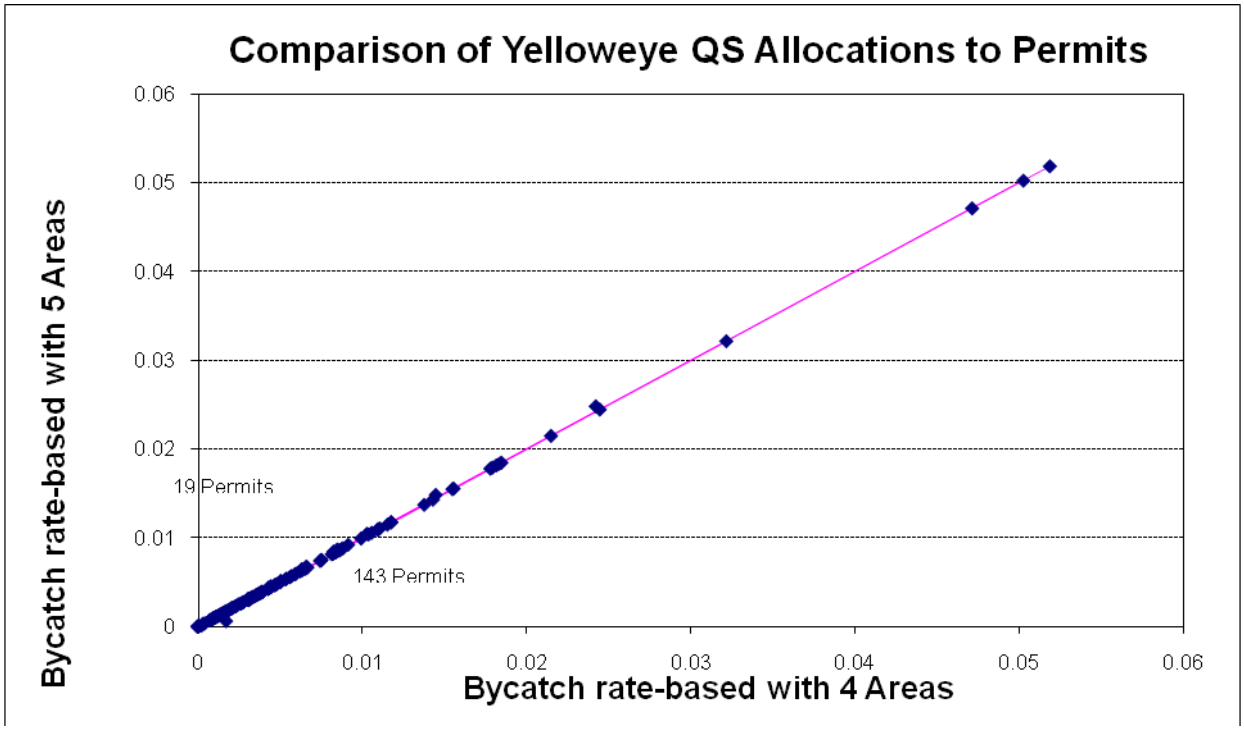

Figure A-56. Yelloweye allocations to permits under the four-area approach (moderately fine area) and five-area approach (finest area) (includes allocations only for nonwhiting trips).

♦ *Logbook Period for the Bycatch Rate Approach*

The choice of logbook periods has distributional implications for individual permits and geographically. For example, use of more recent logbook periods substantially increases the amount of bocaccio and cowcod going to permits associated with ports from San Francisco south (Figure A-57 and Figure A-58). Part of the reason for this is that some permits that were used to fish off California in the 1990s have moved and now fish in more northern ports. Thus, an allocation using 1994 to 2003 logbooks may not reflect current need for bycatch, not only because of the changes in fishing patterns within an area caused by changes in stock availability and area closures put in place to protect overfished species, but also because permits have been transferred to entirely different regions of the coast.

One concern about the use of more recent logbooks for the Council's final preferred alternative was been the impact on the canary QS allocations for permits in the Fort Bragg area. These Fort Bragg permits would receive very small amounts of canary QS (amounts that translate to only a few QP based on 2010 expected allocations). While, on a percentage basis, use of 1994 to 2004 logbooks would substantially increase the allocations to Fort Bragg permits because their allocations are so small to start with, and the observed bycatch rates are so low for the Fort Bragg area, the difference in allocation that results from using 1994 to 2003 logbooks, as opposed to using 2003 to 2006 logbooks, is not perceptible in Figure A-57 and Figure A-58. The Council revised its final preferred alternative to include an equal allocation element in order to provide some canary to permits that were receive close to none.

.

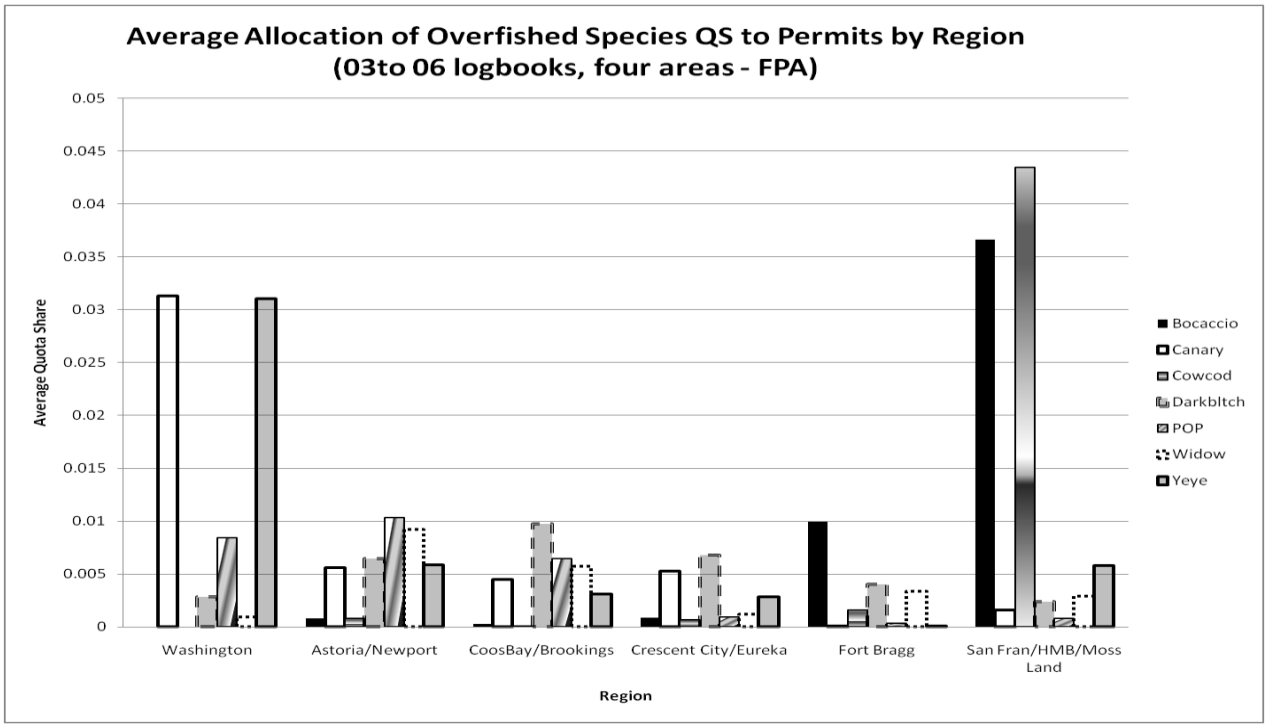

Figure A-57. Amount of QS allocated by region when the 2003-2006 permit logbooks are used to allocation overfished species QS (data in this graph reflect the Council's final preferred alternative, with the exception of canary [which does not include the equal allocation element of the Council's final preferred alternative]).

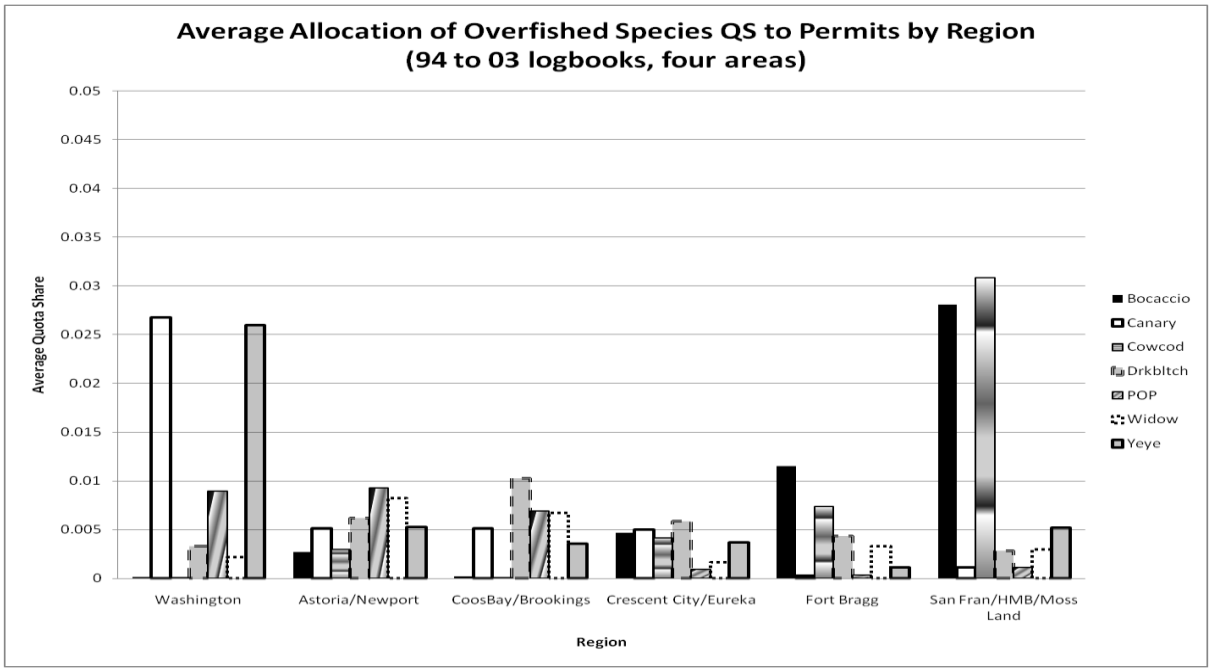

Figure A-58. Amount of QS allocated by region when the 1994 to 2003 permit logbooks are used to allocate overfished species QS (data in this graph reflect the Council's final preferred alternative, except that 1994 to 2003 logbooks are used instead of 2003 to 2006 logbooks and for canary the equal allocation element of the Council's final preferred alternative is not used).

♦ *Impacts of Equal Allocation Choice on the Bycatch Rate Approach*

We will now turn to a comparison of the PPA and the final preferred alternative with respect to the bycatch method for allocating overfished species and its interplay with the equal allocation component of the allocation formula. As discussed above, for overfished species, the equal allocation component of the allocation formula was included in the PPA but not in the final preferred alternative, except with respect to canary. Initially (November 2008), the Council specified there would be no equal allocation component for any overfished species, including canary. However, in November 2009, after reviewing the regionalized effects of the allocation formula and the minimal allocations of canary QS provided to vessels operating in ports such as Fort Bragg California, the Council decided to revise its final preferred alternative and include an equal allocation element for canary rockfish. On the following pages, we provide three sets of graphs for each overfished species (Figure A-59 through Figure A-80). The first graph in each set provides information for the Council's final preferred alternative (except for canary). For canary, the November 2008 final preferred alternative is displayed in the first graph of the group. That alternative was later revised. In the first graph in each group, permits are first assigned to an area based on the port in which they made the most landings from 2004 through 2006. Within each area, the permits are displayed in order from those with the least nonwhiting groundfisH QP allocation to those with the most.[57] For each permit, points are provided indicating the amount of its nonwhiting target QP allocation and the amount of its QP allocation for an overfished species. The set of nonwhiting target species displayed in the graph is the same as the set used in the overfished species allocation formula (the same as the set used by the WCGOP to calculate bycatch rates). Since the permit order within a graph does not change, the amount of nonwhiting QP and overfished species QP going to a particular permit will show up as points above/below one another. The units in which the QP are displayed are noted in the legend and vary among the graphs (e.g., metric tons, pounds, tens of pounds, hundreds of

[57] QS was converted to QP using the 2010 OYs and the Council's Amendment 21 allocation decisions.

pounds). Some permits will receive an initial allocation of overfished species in proportion to their allocation of whiting. In order to isolate the permits with some whiting history from the permits with no whiting history, the overfished species QP for permits with no whiting history are indicated using a triangle and the overfished species QP for permits with some whiting history are represented using a solid circle. Additionally, there are some permits with no 2003 to 2006 history. These permits have no recent logbooks and so they are allocated QP based on distribution of effort among areas for the fleet as a whole. The overfished species QP for these permits are identified with an open circle. The ports for these vessels were assigned using whiting delivery history or permit owner residence. The second graph in each set provides the same information using the PPA (i.e., the overfished species allocation formula does not include an equal allocation component). For the canary, group the second graph in the group is both the PPA and the revised (November 2009) final preferred alternative. To isolate the effect of the equal allocation of overfished species, the amount of the target species allocation to permit holders was kept constant between these two figures (i.e., 90 percent of the allocation for target species was allocated to permit holders[58]), and the bycatch rate method was held constant.[59] The final graph in each set shows for each permit the amount of overfished species allocated to the permit under the final preferred alternative as compared to the PPA. The permits are placed in order based on the results for the final preferred alternative, such that the estimates for each permit are above/below one another.

To illustrate how to read the graphs, we will look at the results for Pacific ocean perch (POP). In Figure A-72, it can be seen that for the area north of Westport and from the Columbia River to Newport there are a few permits that will receive almost no POP under the final preferred alternative, some of which have some relatively large nonwhiting quota allocations. The number of permits not receiving POP increases to the south, where POP encounter rates are lower. The nonwhiting QP amounts are displayed in metric tons, and the POP amounts are displayed in tens of pounds. The maximum amount of POP QP any single permit would get is just over 10,000 pounds (1,000 x 10 pound units), by a permit with at least some whiting history. The second and third highest amounts would be slightly less than 9,000 pounds each for two permits that do not have any whiting history. Under the PPA, the maximum amount of QP any single permit would receive is between 6,000 and 7,000 pounds and no permit would receive less than about 800 pounds (Figure A-73). Under the final preferred alternative, most of those permits in the south (south of Fort Bragg) which receive significant amounts of QP are those which had no logbooks from 2003 through 2006 and so are provided POP based on fleet averages. Approximately 110 permits would receive more POP under the PPA, with the remainder receiving more POP under the final preferred alternative (Figure A-74).

For canary, the maximum QP allocation to a single permit under the November 2008 final preferred alternative is just over 1,600 pounds and the minimums are very close to zero (Figure A-63). Under the PPA, which is also the November 2009 revised final preferred alternative, the maximum initial allocation to a single permit is just under 1,000 pounds and the minimums are just under 100 pounds (Figure A-64).

[58] The target species allocation formula was the same in the preliminary preferred and final preferred alternative. The only difference was that in the preliminary preferred alternative 80 percent of the QS for all species went to the permits and in the final preferred alternative 90 percent of the QS for all species went to the permits. Two isolate the effect of the equal allocation element, 90 percent allocation to permits was used for both figures.

[59] In the spring of 2009, the Council revised the bycatch rate method, specifying that four latitudinal subareas be used instead of two. For purposes of isolating the most important difference between the preliminary and final preferred alternative (the presence and absence of the equal sharing part of the allocation formula), the four-latitudinal-area bycatch method has been used in both the preliminary and final preferred alternatives for the overfished species allocations.

Under the final preferred alternative for darkblotched, five permits would receive only about 10 pounds of darkblotched rockfish Figure A-69. All of these are located from Fort Bragg south, and one of the permits has more nonwhiting groundfish than any other permit in the area.

In general, one of the patterns that shows up in the figures is that permits receiving larger amounts of QS for overfished species tend to be better off without equal allocation than with equal allocations. Two exceptions stand out: canary rockfish (Figure A-65) and widow rockfish (Figure A-77). For these two species, some of the permits receiving larger allocations receive even more with an equal allocation element. The permits in these situations appear to be permits with significant whiting history but lesser amounts of nonwhiting fishery relative to the rest of the nonwhiting fleet. Therefore, their allocation of overfished species QS for their nonwhiting trips increases with the equal allocation of QS related to buyback permit history. The amounts of overfished species associated with whiting trips that would be equally allocated is quite small because only 7 percent of the shoreside whiting was taken by permits that were bought back and the amount of nonwhiting species allocated to the shoreside whiting fishery is small for most species.

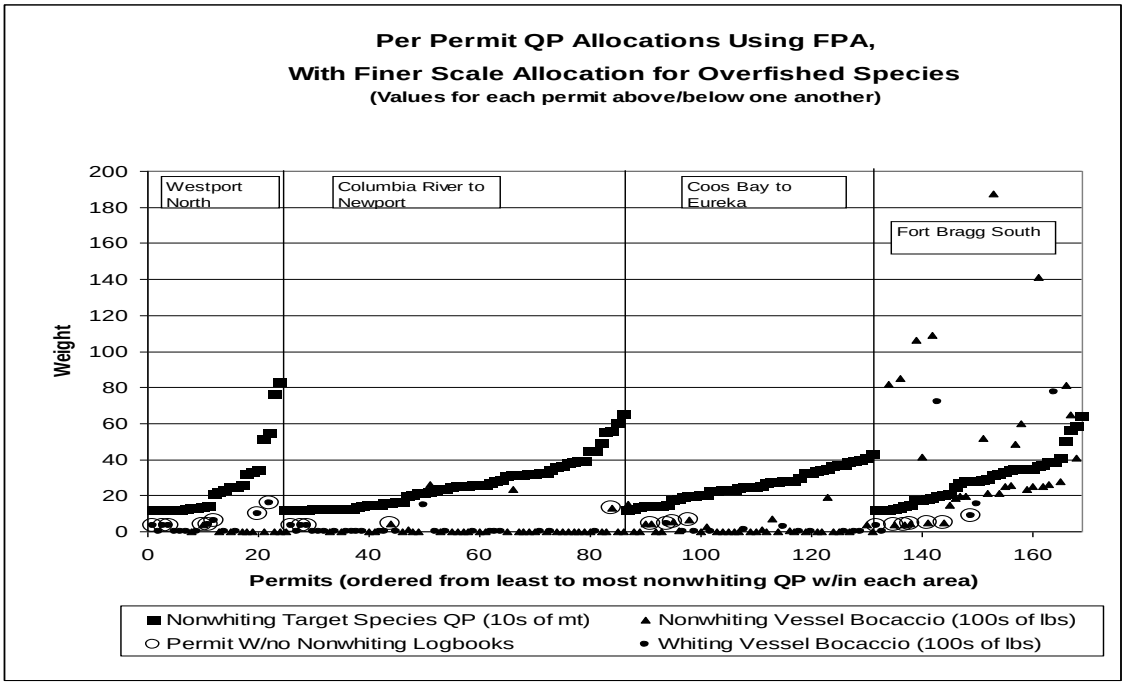

Figure A-59. Per permit allocations of nonwhiting target species and bocaccio QP using 2010 allocations under the Council's final preferred alternative (any permit with some shoreside whiting trips was classified as a whiting permit, permit locations assigned based on primary port from 2004 to 2006).

Notes: Assumes half the OY projected to go unused in 2010 is allocated to the trawl fishery.
Last permit in series has a value of 31,100 pounds for bocaccio (off the graph).

Area Assignments

- Rationale and Options Considered But Not Included

The assignment of catch area for landings recorded on fish tickets affects the allocation of QS for management units that have geographic subdivisions. Under the final preferred alternative, catch area would be assumed to be the same as the area of landing. This approach is used because, in the past, the catch area has often not been filed out, or when it is filled out, is not believed to have been filled out reliably. The catch area is filled out by the buyer rather than vessel and it is believed that they often assume that the catch area is the same as the area off the port. Catch area data quality will be a concern on tickets going back as far as 1994, the start of the allocation period.

- Interlinked Elements

The area assignment decisions would be most important if all management units have geographic subdivisions. Providing geographic subdivisions for all species was an option in Section A-1.2 that was

not selected as part of the Council's FPA. The FPA provides geographic subdivisions of the IFQ management units only for those species with an existing geographic subdivision in the ABC/OY.

- Analysis

There is unevenness in the data quality for area of catch information across geographic areas, across time, and between buyers. On one hand, landing area provides a reasonable approximation to catch area, resolves missing data aresues, and ensures that everyone is treated the same in the assignment of their landing history to an area. On the other hand, if some vessels have travelled outside of their local area to fish, by not using the area of catch information available, a greater mismatch between the permit's initial allocation and its actual fishing pattern is created than necessary. Use of ports as a proxy for catch areas could also be a complicating factor if logbook data are used to allocate overfished species and the area information from the logbooks does not match the catch area assumed based on the port of landing.

The degree to which the quality of the area of catch data are of concern depends on the species for which there are geographic subdivisions and the degree to which permits cross between areas. The final preferred alternative would create north and south QS for those species for which a north-south subdivision already exists in the ABC/OY table. Table A-68 provides the species that are either subdivided geographically, or managed as parts of different management units depending on the geographic region (e.g., bocaccio is managed separately in the south but managed as part of minor shelf rockfish in the north).

Table A-69. Species for which the OY varies by geographic area.

Species	Geographic Division/Differences in OY
Species with Geographic Subdivisions of OY	
Sablefish	OY split north and south of 36° N
Shortspine Thornyhead	OY split north and south of 34°27' N
Longspine Thornyhead (longspine south is not an IFQ species)	OY split north and south of 34°27' N
Black Rockfish (not an IFQ species)	OY split between WA and OR-CA
Minor Rockfish	.
Nearshore (not an IFQ species group)	OY split north and south of 40°10' N
Shelf	OY split north and south of 40°10' N
Slope	OY split north and south of 40°10' N
Species Managed W/Different Species Groupings North and South	
Bocaccio	Separate OY south of 40°10' N. Part of Minor Shelf Rockfish in the north.
Chilipepper	Separate OY south of 40°10' N. Part of Minor Shelf Rockfish in the north.
Cowcod	Separate OY south of 40°10' N. Part of Minor Shelf Rockfish in the north.
Splitnose	Separate OY south of 40°10' N. Part of Minor Slope Rockfish in the north.
Yellowtail	Separate OY north of 40°10' N. Part of Minor Shelf Rockfish in the south.
Pacific Ocean Perch	Separate OY north of 40°10' N. Part of Minor Slope Rockfish in the south.
Cabezon (not an IFQ species)	Separate OY in California. Part of Other Fish in Oregon and Washington.

Logbook data show that while vessels tend to center their activity around their port of landing they will sometimes travel moderate distances to fishing grounds. Appendix C provides maps showing the distances that vessels tend to travel from their ports of landing. For example, vessels out of Astoria will sometimes fish as far north as Neah Bay. Based on the Appendix C maps and with respect to a latitudinal division at 40°10' north latitude, catch area assignments based on port of landing would not appear to create a substantial deviation from catch area assignments based on ports. There is very little overlap of fishing grounds for vessels coming out of ports to the north and south of 40°10' north latitude. The greatest areas of overlap are between vessels based out of Astoria and Washington catch areas and at the Oregon-California border. For these areas, there are no geographic subdivisions for any

species managed under the scope of the IFQ program). Further south, assigning catch area based on landing port may create some problems for permits of vessels that fished out of Moss Landing (36° 49' north latitude) or Morro Bay 35° 20' north latitude but took their catch south of 36° north latitude (sablefish) or 34° 27' north latitude (thornyheads). If an assignment is made based on port area, catch that actually occurred to south of these lines would be counted to the north.

For those species for which the approach to area of catch will make a difference for some permits, we have displayed the results from the initial allocation using ports to determine area of catch and using area as reported on fish tickets to determine area of catch (Figure A-103 through Figure A-112). For shortspine thornyheads south, the coding used in the catch area field does not allow us to determine whether catch occurred north or south of the dividing line. For this species, port is used to identify area of catch in both methods. For overfished species with area divisions (bocaccio, cowcod, and POP) the allocations are driven by amounts of target species QS and effort distribution, as recorded in logbooks, not the assignment of catch areas as recorded on fish tickets. Only a few of the numerous target species have an area component, and the effect on those species is minor. Therefore, the impact of this decision on the distribution of overfished species QS is nearly imperceptible. For all other species in Table A-68, the approach used makes a relatively minor difference in the permit allocations for most species, the exception being for sablefish south of 34°27 north. However, a single entity owns permits with 60 percent of the relative pounds catch history in the sablefish south area, and another entity accounts for an additional third. Therefore, at the entity level, the difference between these two approaches is relatively minor for all affected species categories. Most of the analysis in the EIS uses the area identifier rather than the port identifier to evaluate catch history. However, based on the results provided here the difference between the two approaches would be of little consequence for policy level decisions.

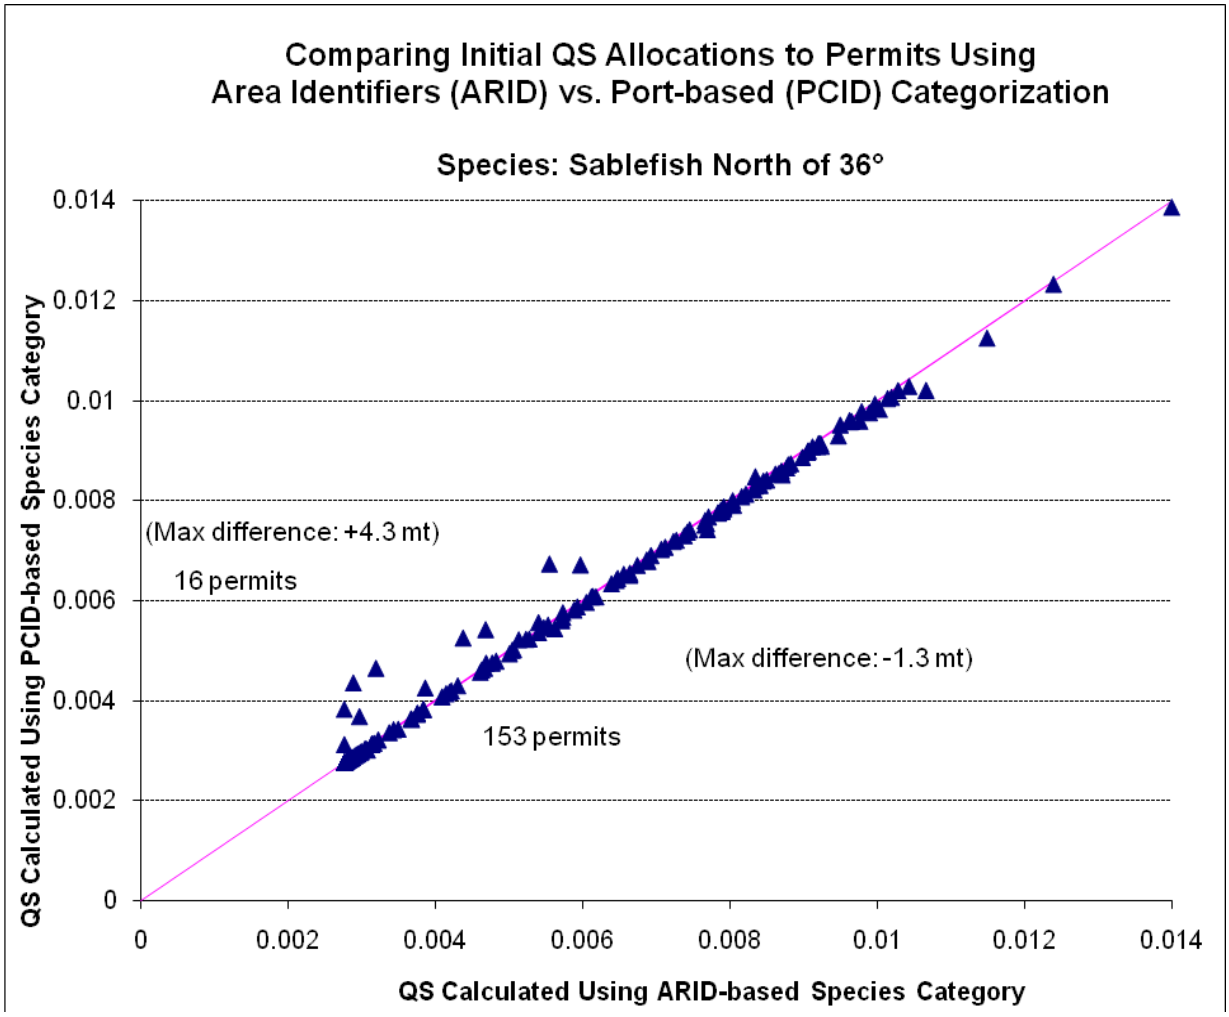

Figure A-81. Comparison of initial allocations of sablefish north QS using port (PCID) to determine area as compared to using area of catch as coded on fish tickets (ARID) to determine area.

Relative History

- Rationale and Options Considered But Not Included

Relative history is used instead of absolute pounds as a way of taking into account changes in fishing opportunity between years. Using relative history, each permit's history for each year is measured as a share of the fleet total for that year rather than in pounds (absolute history). Under the relative pound approach, harvesters that landed fewer pounds during a year because of low fishing opportunities but still performed as a "highliner" relative to other harvesters in the year will receive the same credit as a harvester that put in relatively similar "highliner" effort when total available harvests were greater. Because of the declining trend in harvest, use of relative history increases the emphasis on history occurring in the later part of the allocation period, (i.e., increases the emphasis on more recent participation).

- Interlinked Elements

The weighting formula results in some very high weighting for some years for rarely caught species (e.g., kelp greenling and overfished species). Additional attention may be needed for the weightings of some of these species depending on whether or not they are included within the scope of the program (Section A-1.1) or an alternative allocation approach is used (application of bycatch rates to target species QS to allocate overfished species). The Council's final FPA excludes some of the rarely caught species that are not overfished and uses a bycatch rate approach for overfished species. Since the bycatch rate approach is used for overfished species, these species will not be affected by the use of the relative history measurement of landings history.

- Analysis

The following are the categories of goals and objectives affected by the decision on whether to use relative history (shares of annual catch) or pounds.

	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
		X	X		X	X	X	X			

The relative history approach to allocation bases each permit's QS on its landings history for each year of the allocation period, measured as a proportion relative to the catch of the fleet. The permit's QS is then determined by summing the annual ratios of a permit's catch of a given species in a given year and dividing by the sum of the ratios for all vessels across all years. The effect of this calculation is to weight each year's catch by the ratios displayed in Table A-69. For example, a pound of sablefish caught in 1996 would give a permit about half as much credit toward an allocation as a pound caught in 2003.[60] The ratios between years for some overfished species are very high, more than a hundred to one (2003:1994), however, under the final preferred alternative allocation for these species will be based on bycatch rates applied to target species QS rather than actual landing history for the overfished species. Similarly, there are some very large ratios for species like kelp greenling. Some of these species have not been included in the alternative scope for the program (see Section A-1.1). For selected species, Table A-70 provides the relative weight for a pound of catch each year, examples of three actual catch histories and the differences in allocation that result depending on whether a relative or absolute approach is used. Also shown for each species (grey box) is the difference in weighting between the year given the greatest weight and that given the least weight. For example, for nearshore rockfish a pound caught in 2003 would be the equivalent of 50 pounds caught in 1998.

On one hand, relative history may be considered more fair and equitable because it weighs each vessel's performance each year based on how it did in its competition with the rest of the fleet given the opportunities present that year (its relative effort level). On the other hand, some may view it as most equitable to distribute QS to benefit those with the greatest investment in the fishery; and the amount and distribution of private and community capital involved in the fishery may be more related to total harvests than the proportion of harvest each year. It should also be noted that under a relative weighting scheme, as compared to a straight summing of pounds, catch histories that diverge from the pattern exhibited by the entire fleet tend to be rewarded when determining an initial allocation.

The relative history measure puts a heavier emphasis on more recent landing history because landings have generally declined during the 1994 to 2003 allocation period. This may be consistent with MSA language that encourages consideration of current harvests when making an initial allocation.

[60] While 2003 is the base year used in Table A-69, the choice of which year in the period to use as the base year does not make a difference with respect to illustrating the implicit relative weights).

Increasing the emphasis on more recent years through the mechanism of relative weighting could better reflect the distribution of capital and labor in the fishery. The MSA also encourages consideration of historic harvest, which may also relate to the current distribution of capital in a fishery depending on the particular circumstances of the fishery.

Alignment of the initial allocation to existing patterns of investment and participation in the fishery reduces disruption to labor, capital, the fishing sector, and communities. Reduced disruption implies greater net benefits because there will be less need for transactions to bring the distribution of capital and labor and the distribution of QS into line with one another. There are two issues to be considered, the amount and distribution of investments and whether they are currently used. The amount and distribution of private and community capital involved in the fishery may be more related to total harvests than the proportion of harvest each year. When there is a contraction in production, fixed capital assets that cannot be easily moved to other uses may persist. There has been a recent contraction in the groundfish fishery. Depending on how long the capital persists in a particular use after the investment is made, harvests during more distant years of higher production may have a greater correlation with the current distribution of capital in the fishery than more recent years in which harvest has been lower. During an expansion, recent year history might reflect current distribution but during a contraction recent history is more likely to indicate where existing capital is still in use (and the current distribution of human capital) but less likely to indicate the distribution of all relevant capital. During a contraction, the capital that remains active may be that which is most efficient or otherwise most beneficial to keep in production and, therefore, that which is likely to persist as the fishery is rationalized. Under such circumstances, even if existing capital is distributed in a manner that correlates more with older history, using a QS allocation formula with greater emphasis on recent history may allocate QS to those entities with the assets still in use, e.g., the assets most likely to persist during the initial implementation and rationalization period. Such an allocation might be expected to result in less disruption. As discussed above, because of the recent contraction in the fishery, the relative history approach increases emphasis on recent history, as compared to a straight summing of a permit's total history across all years.

Allocation Formula Results

In Section A-2.1.1, figures are provided illustrating a number of comparisons of the Council's final and PPA to a variety of allocation formulas and to the distribution of landings among permits in 2004 to 2006 (Figure A-8 through Figure A-21). This information is provided for both processors and harvesters. In the section on Control Percentage Limits on page A-362, information is provided on the number of entities the initial allocation formulas would place over the limits and on initial allocations in comparison to recent and historic vessel activities. Table A-71 shows the effects of the expected geographic distribution of QS in comparison to the distribution of 2004 through 2006 landings, as measured by home office location. Estimates of the initial allocations for QS for all species for each permit have been placed on the Council letter for public reference (with masked permit identifiers) (http://www.pcouncil.org/groundfish/gffmp/gfa20/gfa20progtrack.html#qs).

Table A-72. Distribution of nonwhiting ex-vessel value from 2004 to 2006 compared to distribution of QP value, based on zip codes reported for the businesses that would receive the QS allocations assuming an 80/20 permit/processor split, equal allocation of buyback landing history, and a grandfather clause for initial allocations over the control limits ($ thousands).

A-2.1.3.b Permits with Catcher-processor History

❖ *Provisions and Options*

This provision is not applicable to the preferred alternative because the final Council recommendation did not include IFQs for catcher-processors (see Appendix B). The section header is maintained to provide continuity of numbering and cross referencing in various documents generated during this process.

Allocate whiting QS based on permit history[61] for 1994-2003 (do not drop worst years) and using relative history as defined for catcher vessel permits.

For bycatch species (if IFQ is used for bycatch species):

Bycatch Option 1: use history for that species, as it is calculated for whiting

►**Bycatch Option 2:** use the whiting history as a proxy (i.e., allocation will be pro rata based on the whiting allocation).[62]

❖ *Rationale and Options Considered But Not Included*

The allocation methods proposed for catcher-processors differ from those for catcher vessels in that they do not include an equal allocation component or a drop-year provision. The rationales for aspects that are in common with the catcher vessel sector (use of permit history, the 1994 to 2003 allocation period, and use of relative history) are provided in the section on allocation to catcher vessel permits (Section A-2.1.3.a). The drop-year provision was not included because of the absence of a perceived need for consideration of possible hardship circumstances with respect to any of the initial recipients and because of the co-op arrangements under which the fleet has been managed. The equal allocation component was not included mainly because there was not a convenient source for the equal allocation QS. For the catcher vessels, that source was the buyback permits. No catcher-processor permits were bought back; therefore, there was not a similar pool of harvest history from which to draw on for the catcher-processor sector. However, the Council's FPA for catcher processors (a system that helps preserve the voluntary co-op) would default to an IFQ program if the current voluntary co-op system ended. Under such circumstances, IFQ would be allocated equally to all catcher-processor permits.

Since permits with catcher-processor history do not participate in the catcher vessel sector(s), they would not receive QS allocations for any catch history associated with permits that have been combined into catcher-processor permits. In contrast, catcher vessels and permits for catcher vessels move between the shore-based and at-sea whiting fisheries, so such permits are allowed to qualify for initial allocations for both sectors.

❖ *Interlinked Elements*

For catcher vessels and shoreside processors, one of the main elements linked to the initial QS allocation is the accumulation limit and grandfather clause (specifically the QS control limit, Section A-2.2.3.e). The allocations to catcher-processors would not approach the accumulation limit levels that were proposed for whiting; therefore, there would not be an interaction with the accumulation limit provisions.

---

[61] Permit history from observer data.

[62] The Council's preliminary preferred alternative included the allocation of bycatch species in the mothership and catcher processor sectors pro rata based on the whiting allocation. These options could come into play if the Council does not go with its preliminary preferred alternative to adopt the co-op alternatives for these two sectors.

❖ Analysis

The allocation of QS to catcher processors would run from 3 percent to 23 percent with 6 of the 10 permits receiving between 7 and 13 percent of the QS allocation. For five of the permits, the allocation would be within 1 percent of their recent 2004 to 2006 average harvest. For the one permit that would receive the most QS, the amount of the allocation would be just over half of its recent year average. For those permits for there would be a substantial decrease, there could be some potential disruption, unless the voluntary co-op is able to continue to operate as a co-op under the IFQ program. Continuation of the co-op could be a challenge because the incentive to co-operate to avoid a race for fish would be gone. Additionally, those receiving the most QS might benefit most from operating on their own and hoping to acquire additional shares at a good price from those less able to operate efficiently. However there may be some cost-saving and co-operation opportunities that might preserve the voluntary co-op program, even under an IFQ system (for example, sharing observer costs).

Table A-73. Allocation to catcher processor permits using 1997 to 2003 landing history (relative history) and no-drop years.

	Catcher Processor Permits									
	CP-1	**CP-2**	**CP-3**	**CP-4**	**CP-5**	**CP-6**	**CP-7**	**CP-8**	**CP-9**	**CP-10**
Quota Share	13%	11%	11%	5%	23%	10%	7%	11%	5%	3%
Hvst Share 2004-2006	12%	11%	4%	10%	40%	9%	7%	2%	4%	0%

A-2.1.3.c Processors (Mothership)

❖ *Provisions and Options*

This provision is not applicable to the preferred alternative because the final Council recommendation did not include IFQs for motherships (see Appendix B). The section header is maintained to provide continuity of numbering and cross referencing in various documents generated during this process.

Allocate whiting QS based on a vessel's processing history for 1997-2003 (do not drop worst years) and using relative history as defined for catcher vessel permits.

For bycatch species (if IFQ is used for bycatch species):

Bycatch Option 1: use history for that species, as it is calculated for whiting

►**Bycatch Option 2:** use the whiting history as a proxy (i.e., allocation will be pro rata based on the whiting allocation). [63]

❖ *Rationale and Options Considered But Not Included*

The allocation methods proposed for motherships differ from that for catcher vessel and catcher-processor permits in the period used for the allocation. Additionally, the mothership formula differs from that for catcher vessel permits and is similar to that for catcher-processors permits in that it does not include an equal allocation component or a drop year provision. The rationales for aspects that are in common with the catcher vessel sector are provided in that section (Section A-2.1.3.a). The rationale for starting in 1997 rather than 1994 is that the allocation among the three whiting sectors did not start until 1997. The drop year provision was not included because of the perception that there was no need for consideration of possible hardship circumstances with respect to any of the four initial recipients. The equal allocation component was not included mainly because there was not a convenient source for the equal allocation QS. For the catcher vessels, that source was the permits bought back in 2003.

❖ *Interlinked Elements*

For catcher vessels and shoreside processors, one of the main elements linked to the initial QS allocation is the accumulation limit and grandfather clause (specifically the QS control limit, Section A-2.2.3.e). The allocations to motherships would not approach the accumulation limit levels that were proposed for whiting; therefore, there would not be an interaction with the accumulation limit provisions.

❖ *Analysis*

For harvesters, the degree to which the initial allocation of QS deviates from the recent landings levels is an indicator of the potential disruption that may occur as a result of the initial allocation. For processors, this is less of an indicator of disruption since processors do not need the QS to purchase groundfish. However, the receipt of QS will affect the profit per pound of fish landed, either through the leverage it provides for processor negotiation with harvesters, or through the additional revenue from the resource rents collected by the QS holder. The degree to which one processor receives more of an allocation relative to its 2004 to 2006 delivery history than another may indicate relative differences

[63] The Council's preliminary preferred alternative included the allocation of bycatch species in the mothership and catcher processor sectors pro rata based on the whiting allocation. These options could come into play if the Council does not go with its preliminary preferred alternative to adopt the co-op alternatives for these two sectors.

in the advantage processors may have compared to one another with respect the collection of rents per unit of product delivered and their relative bargaining advantages.

The allocation of QS to mothership companies would be relatively evenly distributed, running between 4 percent and 6 percent (Table A-73). MS Companies 03 and 06 were active in the early 1990s but do not have any activity during the allocation period. They are effectively screened out by the chosen allocation period; however, they participated in only one or two years, and their participation was at a level substantially lower than for all other motherships during those years and since. Therefore, had the allocation period gone back to 1994, the allocation that would have been received by those entities would have been relatively small. One new mothership entered the fishery after the allocation period and took a very small percentage of the total harvest in one year (MS Company 04). That mothership was included as a participant under the Amendment 15 action that limited participation for motherships. Amendment 15 provided notice that the trawl rationalization program would supersede the limitations on participation provided in Amendment 15.

With respect to the absence of a drop year provision in the allocation formula for motherships, the allocation to one out of the four companies receiving an allocation would have benefited by the inclusion of a drop year provision (i.e., the company was absent from the fishery two years).

Table A-74. Allocation to mothership companies using 1997 to 2003 processing history weighted (relative history) and no drop years.

	Mothership Companies						
	MS Comp 01	**MS Comp 02**	**MS Comp 03**	**MS Comp 04**	**MS Comp 05**	**MS Comp 06**	**MS Comp 07**
Share of QS Allocation to Processors	19%	30%	-	-	21%	-	31%

Share of 2004-2006 Average Whiting	32%	29%	-	1%	10%	-	28%
MT (2004-2006 average)	1,626	2,560	-	-	1,757	-	2,610
Average 2004-2006 Harvest	13,526	12,589	-	450	4,258	-	11,939

A-2.1.3.d Processors (Shoreside)

❖ *Provisions and Options*

► The Council's preferred alternative includes only an allocation for whiting taken on whiting trips.

For nonwhiting trips:

- Allocate QS for all species *other than* incidentally-caught overfished species based on the entity's history for the allocation period of 1994-2003 (drop two worst years) and use relative history.
- Allocate QS for incidentally-caught overfished species by considering the same **overfished species** allocation options identified for permits in Section A-2.1.3.a. (*Note: the preliminary preferred option under A-2.1.3.a is* ***Overfished Species Option 2***.)

For whiting trips:

Whiting Option 1: Allocate whiting QS based on the entity's history for the allocation period of 1994-2003 (drop two worst years) and use relative history.

► **Whiting Option 2:** Same as Option 1 but use 1998-2004 as the allocation period.

- If bycatch species are allocated to shoreside processors (not part of the FPA), allocate all species other than whiting by considering the same **bycatch species** allocation options identified for permits in Section A-2.1.3.a (*the preliminary preferred option under A-2.1.3.a is* ***Bycatch Option 2*****)**. *Note: Under A-2.1.1.a, Options 6a and 6b, the Council will decide the allocation of species other than whiting to processors.*

Initial allocations may be constrained by accumulation limits. See Section A-2.2.3.e for a discussion of the limits and divestiture requirements.

❖ *Rationale and Options Considered But Not Included*

The allocation methods proposed for shoreside processors (first receivers) are similar to those that would be used for the catcher vessel permits delivering shoreside. The allocation criteria include use of relative history, the dropping of two worst of landings history, and an allocation period option that runs from 1998 to 2003. The criteria for shoreside processors vary from the catcher vessel options mainly in the shorter allocation period (starting in 1998 instead of 1994), a recent participation requirement (see Section A.2.1.2.c), and an equal allocation element not being included. Additionally, in its FPA the Council recommended that the allocation period and recent participation period for whiting processors be extended to 2004 (no allocation is provided for nonwhiting processors). The rationales for the use of relative history and the dropping of worst years are similar to what is identified for the catcher vessel permits in Section A-2.1.3.a. Equal allocation was not used for processors because of the relatively small amount of QS going to processors and the absence of a pool of "unclaimed" QS from which to draw. For the permit allocation, 91 permits were bought back in 2003, and the harvest history associated with those permits was used to designate a pool of QS that would be allocated equally among all remaining permit holders. The allocation period for processors was part of an industry compromise that brought permit owners and processors together in agreement that 20 percent of the initial allocation of QS should go to processors. The first year in which there was a three-way split of the whiting allocation (shoreside, mothership, and catcher-processor) was 1997. The use of 1998 as the start of the allocation period increases slightly the emphasis on more recent years. The allocation period for processors was extended to 2004 because keeping the date at 2003 was viewed to disadvantage a processor that was present as a participant during the window period but had increased its share of the processing substantially since the close of the original allocation period (2003).

For shoreside processors the method of allocating bycatch species would be applied somewhat differently than for permits, since processors do not have logbooks. The approach would be to apply the average logbook distributions used for the permits delivering to a particular processor, weighted by the amount of catch the processor receives from each of the permits. However, under the Council FPA, this method will not be used because processors are only allocated whiting and are not allocated QS for groundfish bycatch in the whiting fishery.

❖ Interlinked Elements

For catcher vessels and shoreside processors, one of the main elements linked to the initial QS allocation is the accumulation limit and grandfather clause (specifically the QS control limit, Section A-2.2.3.e). While this may have been an issue for shoreside processors if they had received nonwhiting QS (as proposed under the PPA), under the final preferred alternative, shoreside processors would only receive QS for whiting. The allocations to shoreside whiting processors would not approach the accumulation limit levels that were proposed for whiting; therefore, there would not be an interaction with the accumulation limit provisions.

❖ Analysis

While some of the effects of the 20 percent allocation of QS to processers are discussed here, the primary focus of this analysis is not on whether and how much to allocate to processors (see Section A-2.1.1.a), but rather on the initial QS allocation formula and its impacts among the qualified processors (Section A-2.1.2.c for determination of qualified processors based on recent participation).

For harvesters, the degree to which the initial allocation of QS deviates from the recent landings levels is an indicator of the potential disruption that may occur as a result of the initial allocation. Figure A-7 shows the amount of initial nonwhiting QS that would be allocated to processors compared to their recent levels of purchases under the Council's final preferred alternative. Figure A-16 provides similar information for whiting QS compared to whiting purchases. For processors, differences between initial allocation and recent activity are less of an indicator of direct disruption since processors do not need the QS to purchase groundfish. However, the receipt of QS will affect the profit per pound of fish landed, either through the leverage it provides for processor negotiation with harvesters, or through the additional revenue from the resource rents collected by the QS holder. The degree to which one processor receives more of an allocation relative to its 2004 to 2006 delivery history than another may indicate relative differences in the advantage processors may have compared to one another with respect the collection of rents per unit of product delivered and their relative bargaining advantages. If the Council had recommended no allocation to processors, it appears that five processors have permits that would have entitle them to between 0.5 percent and 5 percent of the initial nonwhiting QS allocation (Figure A-113), and one processor has permits that would entitle it to just under 4 percent of the initial whiting QS allocation (upper right-hand graph in Figure A-17). The 20 percent allocation of whiting QS to processors recommended in the Council's final preferred alternative would provide seven processors with amounts of whiting QS in excess of 0.1 percent of the total QS (Figure A-16).

For whiting, the Council chose to use a 1994 to 2004 allocation period over a 1994 to 2003 allocation period. Figure A-115 shows very small differences in the amounts of whiting QS processors receive based on their processing history with an initial allocation period of 1994 to 2003 as compared to one of 1994 to 2004 (points for all processors are on or very close to the 45 degree line that indicates no difference between the to allocation periods).

Another indicator of disruption resulting from the initial allocation formula is the number of entities that have entered the fishery since the allocation period and their levels of participation. While the Council did not recommend an allocation of nonwhiting QS to processors, the Council's PPA provided a 20 percent allocation of nonwhiting QS to processors. Table A-74 and Table A-75 show that 18 new nonwhiting buyers that have entered the fishery since 2003 and that these buyers have purchased less than 1 percent of the total nonwhiting landings in terms of weight and value. The Council's final preferred alternative would provide a 20 percent allocation of whiting QS to processors. With respect to whiting, five new buyers have entered the fishery since 2004 (the end of the whiting QS allocation period for processors), but these buyers have purchased nearly 3 percent of the shoreside whiting landings and about 9 percent of the landings in California (which are much smaller than for Oregon and Washington, Table A-76). With the possible exception of California, it does not appear that there are many post-2004 entrants with significant amounts of landings that will not receive an initial allocation of whiting QS under the IFQ program. It should be noted that there was one new whiting processor entrant in 2004 that does not qualify for a QS allocation because it does not meet the recent participation requirement (which requires delivery receipts in two years). This new entrant was active in California where there was only one other competing purchaser that will qualify for whiting QS. In 2004 and 2006, the deliveries it received were of an amount for it to be classified as a significant competitor within the context of the scale of the California segment of the whiting fishery (about 30 percent of the states' total whiting deliveries).

Table A-75. Comparison of shoreside nonwhiting receivers, 200 to -2006: all receivers versus new entrants with zero history during 1994 to 2003 (mt).

	All Receivers (MT)	New Entrants (Number)	New Entrants (MT)	Share of Total
California	16,383.08	10	46.96	0.29%
Oregon	32,100.75	6	1.49	0.00%
Washington	7,936.47	2	42.58	0.54%
Grand Total	56,420.31	18	91.03	0.16%

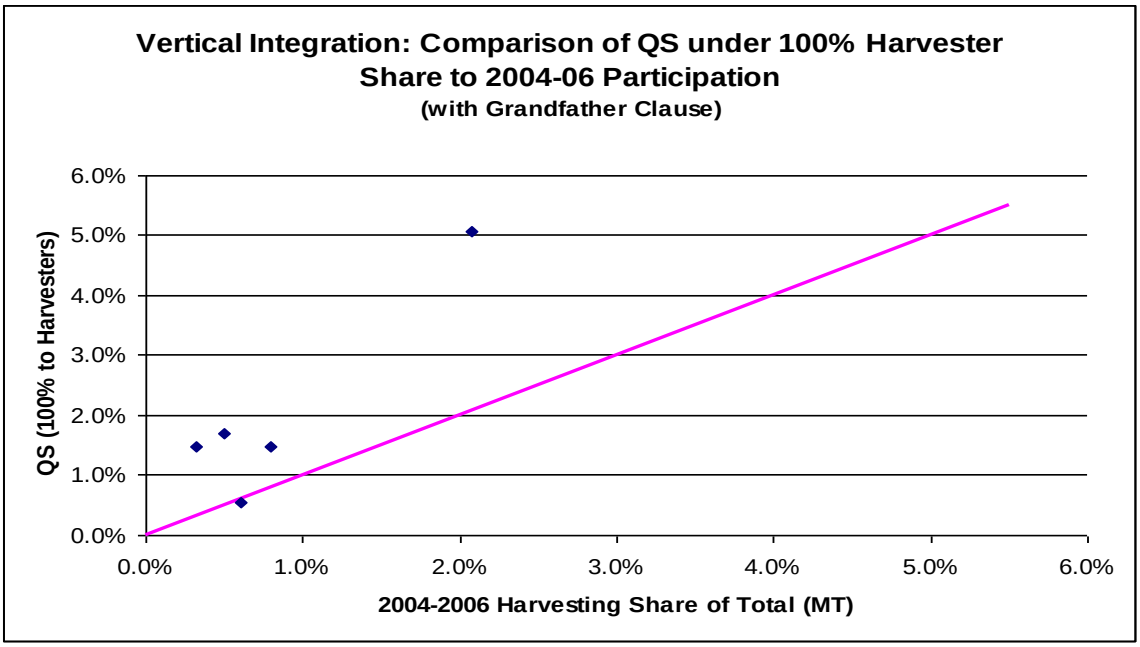
Table A-76. Comparison of shoreside nonwhiting receivers, 2004 to 2006: all receivers versus new entrants with zero history during 1994 to 2003 (revenue).

	All Receivers (MT)	New Entrants (Number)	New Entrants (MT)	Share of Total
California	$20,690,595	10	$85,890	0.42%
Oregon	$39,741,747	6	$3,870	0.01%
Washington	$8,118,285	2	$50,612	0.62%
Grand Total	$68,550,627	18	$140,372	0.20%

Table A-77. Comparison of shoreside whiting receivers, 2005 to 2006: all receivers versus new entrants with zero history during 1994 to 2004 (mt).

	All Receivers (MT)	New Entrants (Number)	New Entrants (MT)	Share of Total
California	9,302.69	3	861.24	9.26%
Oregon	122,778.52	2	4,124.02	3.36%
Washington	62,742.81	0	0	0.00%
Grand Total	194,824.02	4*	4,985.26	2.56%

* One new entrant operates in both California and Oregon.



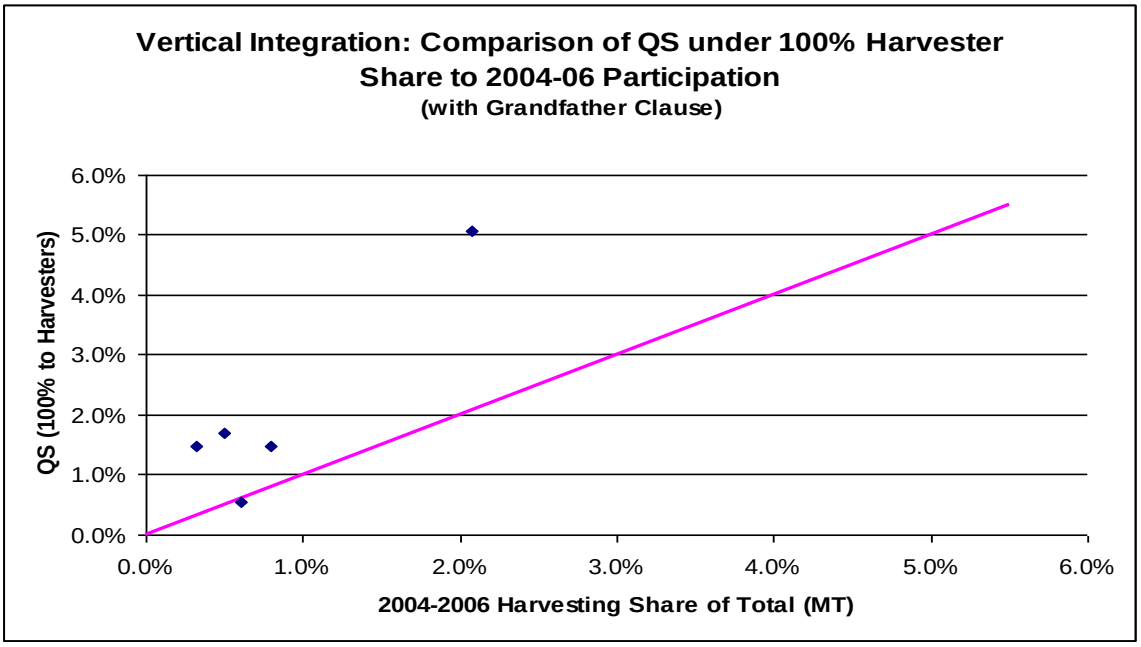


Figure A-91. Vertical integration and nonwhiting QS allocations to processors compared to 2004-2006 history (% of total mt) assuming 100% harvester allocation of QS (no equal allocation element).

c

Figure A-92. Vertical integration and nonwhiting QS allocations to processors (harvesting share) compared to 2004 to 2006 harvesting history (% of total mt) assuming 80/20 permit/processor split of QS and an equal allocation element for permits.

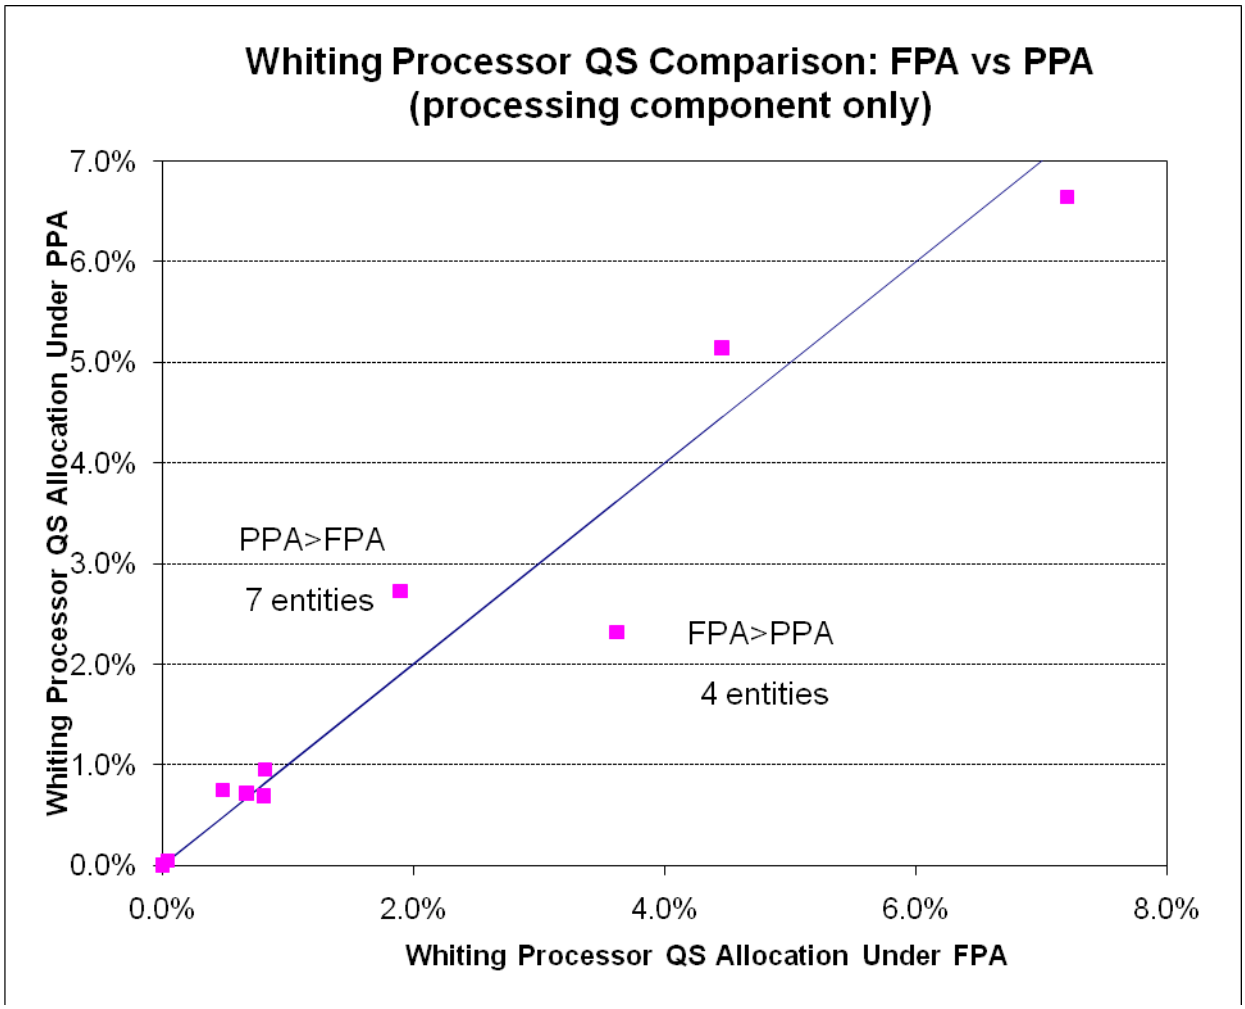

Figure A-93. The allocation from processing history going to each buyer based on the FPA (which uses a 1998 to 2004 allocation period) and the PPA (which uses a 1994 to 2003 allocation period, the only difference between the two alternatives with respect to the whiting QS allocation to processors).

A-2.1.4 History for Combined Permits and Other Exceptional Situations

❖ Provisions and Options

Permit history for combined permits will include the history for all the permits that have been combined. For history occurring when two or more trawl permits were stacked, split the history evenly between the stacked permits. History for illegal landings will not count toward an allocation of QS. Landings made under nonwhiting EFPs that are in excess of the cumulative limits in place for the non-EFP fishery will not count toward an allocation of QS. Compensation fish[64] will not count toward an allocation of QS.

❖ Rationale and Options Considered, But Not Included

Combined Permits – When permits are combined to generate a single permit with a larger size endorsement, and later there is an allocation scheme based on permit history, the question arises as to how to assess the catch history of combined permits. In the past, the catch history of a combined permit has been assessed as the sum of the histories of the combined permits (as it was for the fixed gear sablefish endorsements). The rationale for combining the catch histories is that the resulting permit is for a larger vessel, which may require more fish, and that the person who has combined the permits has likely paid the market value (the value of the harvesting opportunity) represented by the permits being combined. If permit history were not combined, the owner of a permit that has been combined would have to select one of the combined permits to use for catch history, and the fleet as a whole might benefit from any catch history not counted, depending on the allocation scheme being used. Since permits for catcher-processors do not participate in the catcher vessel sector(s), they would not receive catcher vessel history associated with the permits combined into permits large enough for catcher-processors. Hence, they would not be eligible for an initial allocation of QS for the catcher vessel sector(s). In contrast, catcher vessels and permits for catcher vessels move between the shore-based and at-sea whiting fisheries, so such permits are allowed to qualify for initial allocations for both sectors, based on the history of the permits.

Permit Stacking – During the initial allocation period, there was more than one permit registered to a single vessel at the same time, even though such "permit stacking" provided the vessel with no additional harvest opportunities. Nevertheless, while permit stacking was rare, it did occur, and some means is needed to allocate the landing history for the stacking period. A few different approaches were considered, including the following:

1. Associating the landings with the first permit that was on the vessel until such time as the first permit is removed (i.e., there appears to be a transitory period from one permit to another during which there were two permits on the vessel)
2. Associating the landings with the second permit if the first permit was subsequently transferred off the vessel (same transitory situation as described in the first approach)
3. Associating the landings with the first permit if it continues to stay with the vessel after the second permit is removed (i.e., a permit is moved on and off the vessel while the original permit remains)

[64] According to Federal regulations, "*Compensation fishing* means fishing conducted for the purpose of recovering costs associated with resource surveys and scientific studies that support the conservation of species in a fishery, or to provide incentive for participation in such studies. Compensation fishing may include fishing prior to, during, or following such surveys or studies. Compensation fishing shall be conducted under an EFP if the activity would otherwise be prohibited by regulation." [draft FR notice on proposed rule for EFP regs. One published, can cite.]

Unfortunately, it is difficult to know the reasons and circumstances under which two permits were associated with a trawl vessel at the same time. Therefore, an equitable approach appears to be to split the history between the two permits.

Illegal Landings – Rewarding illegal landings with allocation of IFQ is inequitable, on its face.

Landings Under EFPs in Excess of Cumulative Limits and Compensation Fish – In both of these situations, the rest of the fleet did not have the same opportunity to make landings as the EFP and compensation fish vessels. It is proposed that the landings made because of those special opportunities not count toward IFQ as a matter of equity.

❖ *Interlinked Elements*

The decision on how to count landings under these special circumstances will affect the quantities allocated to individuals. Changes in these provisions would not likely necessitate the need for changes in other parts of the program and vice versa.

❖ *Analysis*

Combined Permits – Over the course of the license limitation program, 25 permits were combined (17 of which had some landings history) into 17 permits used for catcher vessels (transactions involving 42 permits), plus 99 permits (37 of which had some landings history) were combined into 10 permits used for catcher-processors (transactions involving a total of 48 permits). Permit combination was taken into account in the initial allocation analysis.

Permit Stacking – There were 13 permit stacking events. An event is defined here as permit stacking occurring sometime during a single year. Two permits stacked on the same vessel across two years would count as two events. There is only one occurrence of the same permits being stacked on the same vessel for more than one year. Of these events, most were of less than one month long (Table A-77). Eleven of the events are depicted in Figure A-116. Of all the events, four involved more than 100,000 pounds of history (the three depicted in Figure A-116 and the one not included in the figure for confidentiality reasons). If permits were stacked and then combined (as occurred in one instance), all of the permit history during the stacked period goes with the permit that resulted from the combination.

Table A-78. Number and duration of stacking events.

Number of Months	Number of Events
1	7
2	1
>5	5

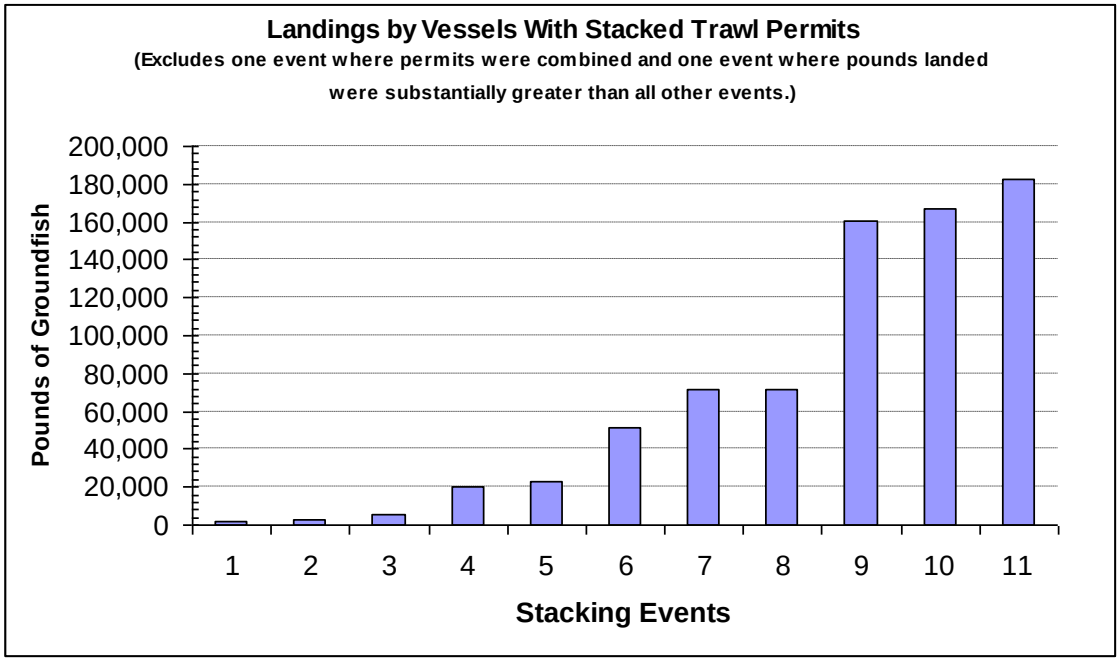

Figure A-94. The amount of allocation period landings that occurred during periods of trawl permit stacking for each of 11 stacking events.

Illegal Landings – Not counting illegal landings is an equity concern about which there is little disagreement. No additional analysis is available. We do not have information about the number or amount of landings that might fall in this category over the allocation period.

Landings under EFPs in Excess of Cumulative Limits and Compensation Fish – The issue argued here is one of equity. Those who say that credit should not be given for EFP landings, including compensation fish, argue that these vessels had opportunities that were not available to other vessels and should not receive additional compensation in the form of an initial allocation of QS. Others argue that had the vessels not been taking part on these special activities, they would have put more effort into other fisheries or groundfish targeting strategies. If they had put their effort into other available groundfish strategies, they would have more landings history, regulations would have been more constraining, and the landings opportunity for other vessels would have been diminished.

A-2.1.5 Initial Issuance Appeals

❖ Provisions and Options

There will be no Council appeals process on the initial issuance of IFQ. NMFS will develop a proposal for an internal appeals process and bring it to the Council for consideration. Only revisions to fish tickets accepted will be those approved by the state. Any proposed revisions to fish tickets should undergo review by state enforcement personnel prior to finalization of the revisions.

❖ Rationale and Options Considered But Not Included

While an administrative appeals process will be provided by NMFS, as required by law and section 303A(c)(1)(I), the Council has not identified any areas of potential that would warrant Council advice. The license limitation program included numerous such grounds for appeal related to hardship and other circumstances and specified that there be an appeals board and Council involvement in the appeals process. Most of these related to initial allocation. The fixed gear sablefish IFQ program (permit stacking) did not include explicit consideration of hardship provisions; most decisions were based on relatively easily determinable facts. This IFQ program does not include hardship provisions. The need for such provisions is avoided, in part, with allocation rules that allow a vessel to drop its two worst years for the initial allocation formula and the long periods covered by such a formula.

One of the judgment calls that may come up on appeal pertains to the attribution of shoreside processing history under Option 3 of Section A-2.1.1.d and the determination of successor in interest where one processing company is acquired by another. The issue to be decided will be determining who processed the fish from a particular landing for those situations in which there is a dispute between the parties.

Another area in which some discretion will be exercised is the classification of fish ticket records for which species remains unspecified, even after the application of species composition information (unspecified flatfish and unspecified rockfish). Unspecified flatfish can be reasonably assigned to the "Other Flatfish" category. Unspecified rockfish are most likely remaining shelf rockfish, but might also be remaining nearshore rockfish (outside the scope of the IFQ program) or remaining slope rockfish. A more accurate determination may be made by considering other species listed on the fish ticket, as well as any logbook data that can be correlated with a particular trip. Judgments made in the application of these ancillary data to determine the correct attribution for unspecified rockfish may be a source of appeal. Data on the extent of this issue are provided in Section A-2.1.3.

The precautionary note regarding changing fish tickets is included in response to rumors that state agency personnel were changing fish tickets at fishermen's requests during the license limitation program implementation without realizing the implications with respect to the license limitation permit issuance process.

❖ Interlinked Elements

The lack of special hardship provisions and a clear allocation formula (A-2.1.3) that take into account hardships by allowing applicants to drop worst years reduce the need for an appeals process involving the Council. If those provisions are changed, the Council might want to revisit the appeals process provision.

Clarity in the definition of processors and processing (Section A-2.1.1.c) will reduce controversy over administrative decisions and possibly the perception of need for Council involvement in appeals.

Allocation of QS based on species and species group information recorded on individual landings records may generate appeals, particularly where some landings remain unidentified due to incompleteness in the species composition information. The other landings-history-based approach available seemed to be to allocate based on aggregates (e.g., allocate all nonwhiting QS based on total landings of nonwhiting groundfish).

After initial allocation, an area of the program in which considerable judgment may be required is the determination of whether control exists to apply control limits. These determinations will likely be based on fact-finding and legal criteria for which the Council and its advisors may not have special expertise. This section, and requirements for appeal listed under the LAP provision of the MSA, address only the need for appeals with respect to initial allocation (MSA 303A(c)(1)(I)).

❖ *Analysis*

The primary objectives affected by the decision on whether or not to involve the Council in the appeals process are those related to equity and program costs.

Exclusion of the Council from any appeals process will not deprive program participants of the opportunity for appeal, but will only exclude the Council from being an advisor in that process. This will reduce program costs. The main reason for involving the Council in the license limitation program process was that there were numerous hardship provisions requiring judgment calls for which industry and Council body expertise were of value in fact finding and evaluation. As an example, a member of the Council appeals panel was able to identify that an aluminum pole that was purported to have been purchased for a gear conversion was of no value as fishing gear, but rather was the kind of pole that would be used for a street light. The panel also assisted fishermen. Since the members of the panel were well educated in the various provisions of the program, they were able to help fishermen identify the relevant facts and better articulate their case. In many cases, this led to the issuance of permits that were initially denied. The Council appeals body, by providing fishermen an opportunity to be heard and assisted, or told "no" by other fishermen, provided a greater sense of equity for the license limitation program.

For the IFQ program, the rules for which judgment calls will be required are substantially less complex than with the license limitation program, so there may be less need for a Council-based appeals process to ensure a sense that the rules have been applied equitably. With respect to processors, determination of who in the marketing chain was the first processor of a particular landing may come up for appeal (under the Council's preferred option of A-2.1.1.d), as well as a determination of the legitimate successor in interest to the history of a particular processing company (where there have been ownership changes). While there may be some complexity around determination of who processed the fish or an evaluation of successor in interest, the rules that are being applied are relatively simple compared to the license limitation program. Under the license limitation program, there were numerous ways program rules might be applied to qualify a particular vessel owner. A vessel owner could qualify directly for an "A" endorsement via a provisional endorsement through criteria related to vessel building or gear conversion, or through a number of different hardship provisions. The situational facts of a particular vessel owner had to be considered with respect to each of the alternative qualification and hardship criteria.

Another main area for appeal may be the categorization of landings records by species for those situations in which the categorization is incomplete, even after application of the species composition information. This will primarily be an issue for unspecified rockfish. Again, while making an appropriate categorization may require the consideration of some complex logbook and fish ticket information, it is simple relative to the IFQ program because there is only a single program rule that is being applied, i.e., the allocation of QS using a formula based on harvest history.

A-2.1.6 Direct Reallocation and Future Allocations after Initial Issuance

❖ Provisions and Options

Reallocation With Change in Overfished Status. When an overfished species is rebuilt or a species becomes overfished there may be a change in the QS allocation within a sector (allocation between sectors is addressed in the ISA process). When a stock becomes rebuilt, the reallocation will be to facilitate the re-establishment of historic target fishing opportunities. When a stock becomes overfished, QS may be reallocated to maintain target fisheries to the degree possible. That change may be based on a person's holding of QS for target species associated with the rebuilt species or other approaches deemed appropriate by the Council.

Reallocation With Changes in Area Management (Changes in management lines are expected to be rare, however, when the occur the following provides for the reallocation of QS in a manner that will give individual QS holders with the same amounts of total QP before and after the line changes.)

Area Subdivision: If at any time after the initial allocation an IFQ management unit is geographically subdivided, those holding QS for the unit being subdivided will receive equal amounts of shares for each of the newly created IFQ management units.

Area Recombination: When two areas are combined, the QS held by individuals in each area will be adjusted proportionally such that (1) the total QS for the area sums to 100 percent, and (2) a person holding QS in the newly created area will receive the same amount of total QP as they would if the areas had not been combined.

Area Line Movement: When a management boundary line is moved, the QS held by individuals in each area will be adjusted proportionally such that they each maintain their same share of the trawl allocation on a coast wide basis (the fishing area may expand or decrease, but the individual's QP for both areas combined wouldn't change because of the change in areas). In order to achieve this end, the holders of QS in the area being reduced will receive QS for the area being expanded, such that the total QP they would be issued will not be reduced as a result of the area reduction.[65] Those holding QS in the area being expanded will have their QS reduced such that the QP they receive in the year of the line movement will not increase as a result of the expansion (nor will it be reduced).

Reallocation With Subdivision of a Species Group: If at any time after the initial allocation an IFQ management unit for a species group is subdivided, those holding QS for the unit being subdivided will receive equal amounts of shares for each of the newly created IFQ management units. For example, if a person holds 1 percent of a species group before the subdivision, that person will hold 1 percent of the QS for each of the groups resulting from the subdivision.

Future Allocation of Groundfish Outside the Scope of the IFQ Program: For the "Other Fish," category of groundfish, if at some time in the future the Council adds it to the IFQ system, the initial allocation would be determined using the same history criteria as was used for other IFQ species (i.e., 1994 to 2003 history), unless otherwise specified by a future Council action.

[65] Unless there is a change in the total OY or other factors affecting trawl allocation for the areas involved, in which case, their change in quota pounds would be proportional to the change in the trawl allocation.

❖ Rationale and Options Considered But Not Included

Overview

The main reason for these provisions is to plan for future changes in the management units that may be needed for conservation of the resource. Reallocation may be appropriate under the following circumstances:

- If there is a broad swing in the amount of a stock that is available for harvest (as may occur when a stock is rebuilt or becomes over fished)
- When a latitudinal management line is added to subdivide a stock, subtracted to combine separate stocks into a larger geographic unit, or changed to better reflect the stock's population biology
- When species that have been grouped together for management are separated out

Additionally, at some future time, there may be a need to allocate QS for species that are currently outside the scope of the IFQ program.

Consideration of provisions to address situations that may be encountered in the future is in line with National Standard 8, which required the Council to provide for variations and contingencies in the fishery resources.

Reallocation with Change in Overfished Status

Situation. As a species moves out of (or into) overfished status, the opportunities for targeting the species may change significantly. A number of overfished species are not currently targeted, but are caught incidentally in other trawl target strategies. When an overfished species is rebuilt, there will often be a sudden and substantial increase in the OY. As these opportunities change, it may be appropriate to consider reallocation of QS within a trawl sector to accommodate directed fishing on the rebuilt species. If it could be developed, a predetermined approach for such reallocation would provide desired regulatory consistency and predictability for industry and government.

Need. One of the primary concerns behind the reallocation of QS when a species is rebuilt relates to equity. Those who in the 1990s relied on certain species that became overfished (and who took their harvest in line with what were believed to be sustainable levels at the time) have had their fishing opportunities (and their share of the catch) reduced to allow for the continuation of other targeting strategies. Those participating in these other strategies needed only relatively small amounts of the overfished species to cover their bycatch. Under the Council's PPA, the initial allocation of QS for these overfished species will be based on the fleet bycatch rates in the current target fisheries. Those who had their fisheries cut back because their target species had become overfished believe that they have sacrificed for the rebuilding and should, therefore, receive a greater share of the harvest once the stock is rebuilt. Further, because they were targeting on the stocks that are being rebuilt, they do not have as much history for some of the other stocks for which QS will be issued. If no adjustment to the allocation is made when a stock is rebuilt, those who hold the stock primarily to cover bycatch will be the ones receiving QP in sufficient quantities to redevelop a targeted fishery on the rebuilt stocks.

Challenge. The main challenge in a post-implementation reallocation of QS for an overfished species will be the trading of the QS that occurs before the species is rebuilt. Initial issuance of overfished species QS will be to permits. Through the rationalization process and new entry and exit, there is likely to be substantial reshuffling of the QS. If the intent is to reallocate the QS to those who

prosecuted the directed fisheries in the mid-1990s, there will need to be a historic link between those harvesters and the ones who are present when the stock becomes rebuilt. The main vehicles available are harvester identity, the vessel, and the permit. Harvester identity (an individual or business entity's history) has not been used an allocation basis in part because the information would be difficult to acquire, and it does not take into account exits and new entries that occur prior to achievement of rebuilt status. The vessel and permit are the other two vehicles available, and the permit is the primary one on which the Council has relied for the QS allocation decisions. Again, by the time of rebuilding, there may be little relationship between the harvesters that own the permits and the types of fisheries in which the permit is employed at the time of rebuilding, and the target fisheries in which the permit participated in the mid-1990s, making it difficult to make a future reallocation to achieve the desired equity outcome.

Considered, but Rejected.

Allowing reallocation through market mechanisms. Under this approach, there would be no direct reallocation. The concern motivating consideration of direct reallocation would not be addressed.

Auction. Under this approach, there would be a direct reallocation through an auction (e.g., upon rebuilding, adjust everyone's QS holdings downward and auction off the remainder). This would prevent those who were given an allocation of overfished species QS to cover their bycatch needs from benefiting from the rebuilding that was facilitated through the reduction of targeting on the overfished species but would not direct the benefits to those who participated in the target fisheries (or to the current holders of their permits).

Issuance of Shadow QS. In anticipation of the difficulties that would be entailed in reallocating QS at a future time based on history, straw man provisions for reallocation upon rebuilding were presented to the GAC at its September 2007 meeting. These provisions were based on the concept of issuing shadow QS for overfished species based on the 1994 to 2003 history of the initial QS recipients. Shadow QS would be held, but would be dormant (no QP would be issued for shadow QS) until the species is rebuilt. At the same time, at the start of the program, incidental catch QS would be issued for the same species based on bycatch rates and the amount of target species QS an entity receives, as is specified in the Council's final preferred alternative. The incidental species QS would become inactive or would expire when the species is rebuilt, and the shadow QS become inactive. A similar straw man proposal was provided for situations in which a currently healthy stock is declared overfished. Under such circumstances, the existing QS would become inactive (shadow QS), and new incidental species QS would be issued to those needing them to cover incidental catch in fisheries targeted on other species. This approach would add some cost and complexity to the start of the program, including the need to track the transfers of shadow QS.

Final Preferred Provision. The approach of the final preferred alternative is to develop the rules for reallocation when a species is rebuilt or becomes overfished at the time they are needed. Provisions for reallocation with change in overfished status have not been developed because of the high degree of circumstance-specific information that will be important in determining an appropriate reallocation. Therefore, at this time, notice is provided that the Council intends to make a reallocation upon rebuilding but the specific means for reallocation have not been identified.

Reallocation with Changes in Area Management and Subdivision of a Species Group

The provisions for reallocation with changes in latitudinal management areas and subdivisions of species groups were initially developed simply as a test to determine the feasibility and impacts of adjusting the management units once the IFQ program is in place. They have been included as program provisions to avoid the need for separate action later and so that all participants are on notice as to the potential changes that may occur to the QS they hold and the management units for which the QS is designated. These changes may affect QS value; therefore, it is helpful to provide advance information about how adjustments will be carried out if they become necessary.

The basic philosophy behind the geographic and species subdivision provisions is that the change should be carried out in such a manner that no one who holds QS will receive fewer pounds after a change than they would have before the change. The provisions may, however, result in the redesignation of an individual's QS such that they end up with some QS for an area in which they do not fish or for species that are of less interest to them.

Future Allocation of Species Currently Outside the Program Scope

There is concern that fishermen may target species not covered by the IFQ program with the intent of establishing history for an allocation of QS for those species if, at a future time, they are brought under the scope of the program. In this regard, the Council was particularly concerned about the "Other Fish" category of groundfish. Of those species outside the scope of the program, this is the only category for which there are some larger amounts of trawl vessel catch. Additionally, some of these species are longer lived and may be more sensitive to fishing pressure. To reduce the incentive for vessels to target the "Other Fish" category, the Council has indicated that it will continue to rely on 1994 to 2003 permit history, unless it makes some other decision in the future. Also suggested for Council consideration were options that would specify future allocation on some basis other than the 1994 to 2003 permit history, but not on permit history occurring after program implementation (e.g., equal allocation or allocation based on an entity's holdings of other types of QS). By choosing the 1994 to 2003 allocation period, the Council signaled that the permits themselves might have some future value with respect to the harvest history that they represent.

❖ *Interlinked Elements*

Of these provisions, the future allocation of species outside the scope of the program is the only one that is specifically linked to other provisions. The need for this provision is created by the Council decision to exclude some species from the IFQ program and, in particular, a species group for which trawl vessels have some more substantial landings.

❖ *Analysis*

Reallocation with Change in Overfished Status

The primary objectives affected with respect to reallocation upon rebuilding relate to equity, net benefits (market certainty, transaction costs), disruption, administrative costs, and complexity. The provisions for reallocation upon rebuilding identify an equity concern but do not identify the means by which that concern will be addressed at some future time. Notice is given that a reallocation may occur. This advance notice will contribute to the perception of equity when the adjustment is made, but, without knowing the mechanism by which it will be carried out, there will be considerable market uncertainty.

Making no reallocation would reduce uncertainty in the market and potential future disruptions, but not address the equity concern. Reallocating through an auction would address the equity concern of those who would view recipients of QS to cover their bycatch needs as receiving an unearned benefit when they are then able to target the rebuilt species. However, an auction would not provide compensation to those who argue that they sacrificed their fisheries to facilitate the rebuilding. The shadow QS approach would address equity concerns and provide market certainty, but would result in trading of shares that have no immediate purpose with respect to management of the fishery, thereby causing an increase in management costs. The approach also increases costs by adding to program complexity.

With respect to reallocation when a species becomes overfished, there is some guidance provided for how the reallocation would be carried out (i.e., as needed to facilitate target fisheries). The concern with respect to conditions that occur when a stock becomes overfished is that targeting healthy stocks be facilitated (addressing objectives related to net benefits, efficiency, sector health, labor, communities, and the general public), and that individuals not take unfair advantage of those who may desperately need QS to cover their incidental take in other fisheries targeted on other groundfish stocks (addressing equity related objectives). The guidance that is provided for action when a stock becomes overfished implies that there may be a reduction in QS for the newly overfished species for those holding QS for that species who do not also hold QS for a target species with which the overfished species is taken incidentally. Those whose QS is revoked will likely request, as an equity issue, that such QS be reinstated when the stock is rebuilt (essentially the same argument that is made now by those who previously lost directed fishing opportunities for overfished species). A concern has also been voiced that if those who target the overfished species are allowed to keep their QS, they might take their small amounts of QS as target rather than providing it for the incidental catch needs of others. While it might occur, such an action (using the overfished species QS as a target) would likely result in a lower profit than if they had sold it to those who need it to cover their incidental catch.

Reallocation with Changes in Area Management and Subdivision of a Species Group

The primary purpose of these provisions is to allow the achievement of conservation objectives while minimizing any adverse effects on net benefits, disruption, equity, sector health, or communities. The primary reason for changing the area or species composition of the management units would be to enhance achievement of conservation objectives. The specification of the exact means by which these benefits would be achieved reduces uncertainty and allows the market to function more efficiently and for businesses to plan for changes. The provisions have been specified in a way that ensures that an entity holding QS will experience the minimum possible change in total fishing opportunities.[66/67] It may, however, result in some temporary dislocation as QS holders could end up with QS for management units outside of their normal fishing area or species that they do not normally catch. Under such circumstances some QS trading may be required which will result in some increase in transaction and administrative costs. Nevertheless, the approach specified here will likely result in the least disruption and most equity possible, while still achieving the conservation objectives. Alternative approaches would require either a data-intense exercise to develop formulas for requalification and reissuance of QS based on recent practices, or relatively arbitrary increases or decreases of entities' QS holdings, which would entail equity issues.

---

[66] Line Movement Example: first assume that 50 percent of the trawl allocation for a species is for north of the 40°10' line and 50 percent is for south (i.e., the coast wide trawl allocation is evenly distributed between these two areas). Now assume that a decision is made to move the management line to 38° and that as a result of this movement 70 percent of the QP for the species would be for north of 38° and 30 percent would be for south of 38°. The QS holdings would be adjusted as follows:

> Those persons holding QS for the southern area would continue to hold QS for the new southern area (their QS that previously represented 50 percent of the coast wide OY would be scaled back such that it represents only 30 percent of the coast wide OY).
>
> In addition, those persons would be allocated QS for the new northern area representing 20 percent of the coast wide trawl allocation (they would receive 28.6 percent of the QS for the new northern area (20 percent/70 percent=28.6 percent)). Thus, those holding QS for the south would still hold 50 percent of the coast wide QS (all of the southern 30 percent and 20 percent represented in northern QS). The allocation of northern QS would be made in proportion to their holdings of southern area QS. Those with QS for the expanded northern area would each have their QS reduced by 28.6 percent such that their total QP would remain unchanged.
>
> On an individual basis, if a person holds 1.5 percent of the coast wide trawl allocation through a 3 percent holding of the southern QS, when the adjustment in the latitude line is made, they continue to hold 3 percent of the southern area QS, but it represents only 0.9 percent of the coast wide trawl allocation (3 percent times 30 percent). So they would receive an amount of the northern QS that is equivalent to 0.6 percent of the coast wide allocation. This would bring them back to a total of 1.5 percent of the coast wide allocation. The amount of northern area QS necessary to achieve this would be a little less than 0.9 percent of northern QS (0.9 percent times 70 percent equals about 0.6 percent).

[67] Recombination Example: 50 mt (5 percent) of the trawl allocation is for the Conception area, and 950 mt (95 percent) of the trawl allocation is for latitudinal line 40°10' to the Conception area. An individual who holds 50 percent of the allocation in the Conception area would get 25 mt. Should these areas be combined, that person would receive 2.5 percent of the new 1,000 mt south of 40°10' trawl allocation (50 percent multiplied by 5 percent, i.e., the individual's allocation for the conception area multiplied by the Conception area portion of the new south of 40°10' area)). Similarly, the QS allocation for an individual to the north would be the percent of QS times 95 percent.

Future Allocation of Species Currently Outside the Program Scope

The primary objectives affected with respect to future allocation of a species outside the scope of the program relate to conservations concerns, equity, disruption, net benefits, and administrative costs. The provision adopted by the Council indicates that 1994 to 2003 landings history will be used if, some time in the future, a new species or species group is brought within the scope of the program. The problems entailed by such a provision are similar to those identified for using permit history to reallocate a stock when it becomes rebuilt. Once the QS are issued, QS and permits start changing hands, and there is entry and exit, the relationship between the entities owning the permits, their current activities, and the 1994 to 2003 permit histories will diminish. If, at that time, a stock must be brought into the IFQ program, there is a good likelihood that the permits to which the allocation is given may not be held by those currently targeting the new QS stocks. This could lead to some disruption and dislocation. However, the Council's action also states that some other basis for allocation might be considered. The Council's intent is to avoid creating an incentive for increased targeting on species outside the IFQ program, and the "Other Fish" category of groundfish, in particular. Based on that intent, the industry should expect that if the Council does select some basis other than 1994 to 2003 permit landing history for a future allocation, it is unlikely to select a criterion involving more recent harvest history. Development of an alternative method for allocation would entail some administrative costs. Additionally, the uncertainty about how the allocation would be carried out may dampen significant investment in the harvest or development of markets for species outside the scope of the IFQ program. Under such conditions of uncertainty, it is likely that businesses would plan to recoup any investments they make over a short period on the chance that they may not receive the QS if the species is pulled into the IFQ program. Given the belief that some of the species in these groups may be highly sensitive to exploitation, actions that dampen development of new targeting on those species may be appropriate until stock assessments are available, particularly for dogfish.

A-2.2 Permit/Holding Requirements and Acquisition

A-2.2.1 Permit/IFQ Holding Requirement

❖ *Provisions and Options*

1. Only vessels with limited entry trawl permits are allowed to fish in the trawl IFQ fishery.
2. For a vessel to use QP, the QP must be in the vessel's QP account.
3. All catch a vessel takes on a trip must be covered witH QP within 30 days of the time that data or documentation from the trip shows there is an overage[68] unless the overage is within the limits of the carryover provision (Section A-2.2.2.b), in which case the vessel has 30 days or a reasonable time (to be determined) after the QP are issued for the following year, whichever is greater. [69]
4. For any vessel with an overage (catch not covered by QP), fishing that is within the scope of the IFQ program will be prohibited until the overage is covered, regardless of the amount of the overage. Vessels which have not adequately covered their overage within the time limits specified in paragraph 3, must still cover the overage before resuming fishing, using QP from the following year(s), if necessary. If a vessel covers it overage, but coverage occurs outside the specified time limit (paragraph 3), the vessel may still be cited for a program violation.

   Exception Prohibition Suboption (not selected in preferred alternative): There may be exceptions and additions to the activities which will be prohibited when a vessel has an overage. A vessel with a deficit in its quota pound account would not be prohibited from participating in any of the following fisheries, even if they fall within the scope of the program: salmon troll; HMS troll/surface hook-and-line; Dungeness crab; all other HMS gears, except small mesh gillnet; and CPS purse seine. Additionally, vessels with a QP deficit would be prohibited from participating in state trawl fisheries such as pink shrimp, California halibut, ridgeback prawn, sea cucumber, and small mesh gillnet.
5. For vessels with an overage, the LEP may not be sold or transferred until the deficit is cleared.
6. **"Alternative Compliance Options (all options were rejected in preferred alternative):"**
   Option 1: After two years in deficit, a vessel may resume fishing.
   Option 2: A sliding scale exception would allow a vessel that does not cover its deficit to resume fishing after a period of time. The period of time the vessel would be prohibited from participating in certain fisheries would vary depending on the degree of the uncovered overage. The scale that would be used is still to be developed. [70]
   Option 3: No exceptions to Element 4 of this provision.

❖ *Rationale and Options Considered But Not Included*

The MSA requires that any LAPP do the following:

> (I) Include an effective system for enforcement, monitoring, and management of the program, including the use of observers or electronic monitoring systems.... [MSA 303A(c)(1)(I)]

While the enforcement and monitoring system elements are covered in Section A-2.3, the permit and IFQ holding requirements will have a substantial bearing on the organization and costs of such a system. Therefore, much of the rationale provided here relates to the provision of an effective enforcement and monitoring system.

---

[68] Underscored text is a modification made at the April 2010 Council meeting.

[69] QP from a subsequent year may not be accessed until sucH QP have been issued by NMFS.

[70] Example: a minimum of 4 months (120 days) for 100 lbs plus an additional month for every additional 50 pounds of overage (1 mt overage = 44 months)

Element 1 – Trawl Limited Entry Permit Required to Participate

Requiring a LEP for participation is expected to control costs by limiting the number of platforms that must be monitored.

Element 1 option considered, but not included for detailed analysis:

Allowing vessels without trawl permits to participate in the fishery

This option was rejected from consideration because it could dramatically increase the number of vessels in the fishery that would have to be monitored and the number of accounts that would have to be managed. Additionally, there would not be a fixed set of participants in the program, making it more difficult for enforcement to monitor the system. These factors would substantially add to program costs and, absent sufficient additional funding, increase the likelihood that enforcement effort would be diluted.

Element 2 – Vessels Required to Acquire QP

Requiring that QP be placed in a vessel account in order to be used to cover catch is expected to control costs and assist in determining who is responsible for compliance, by linking each landing to one and only one account and responsible party. The holder of that account would be responsible for ensuring that a landing is covered witH QP.

Element 2 option considered, but not included for detailed analysis:

Allowing QP that are not in the vessel's QP account to be used for a vessel's catch

Under this rejected option, for example, a vessel might be able to cover catch witH QP held in a crewmember's account. This option was rejected because it would add to the complexity of the data entry and tracking tasks. Rather than just counting all catch of the vessel against a particular QP account, catch might need to be subdivided and counted against a variety of accounts. Under Element 2, as recommended by the Council, in order to maintain control over the QS/QP, crewmembers would hold QS/QP outside the vessel account until the QP is needed by the vessel and would, at that point, transfer the QP to the vessel (or some other point agreed upon by the vessel and crewmember).

Element 3 – Time Allowed to Cover a Landing (and Minimum Holding Requirement)

The extremes of this provision run from requiring that a vessel have QP to cover its anticipated catch (or hold some minimum amount of QP) prior to departure to allowing a vessel a period after its landing to acquire the QP it needs, specifically 30 days after data are reported that indicate an overage has occurred. The Council's PPA provided a vessel up to 30 days after a landing to cover its catch and was intended to provide the vessel with substantial flexibility (addressing objectives related to efficiency and sector health), as may be needed in a multispecies fishery in which the availability of QP for some species may be relatively limited. Key to the effectiveness of this provision was that the vessel would be prohibited from participating in certain fisheries if it has a negative balance in its QP account (see Element 4). The Council modified the approach at its April 2010 meeting by providing a vessel with 30 days after the time the first data are reported indicating that a catch overage has occurred. The Council felt this approach would be more equitable, flexible, and enforceable since a vessel would not necessarily be demonstrably in violation of the program until data are available indicating that an overage had occurred.

Element 3 options considered, but not included for detailed analysis:

Requiring a vessel to cover its landing witH QP (the following are suboptions)
within 24 hours of the landing
at the time of landing
when it brings the fish on board

Requiring a vessel to have some minimum amount of QP (particularly overfished species) if it is fishing in certain depth strata or hotspots;[71] *including a suboption that would allow the vessel to fulfill that option by participating in a risk sharing pool.*[72]

Requiring a vessel to have some minimum amount of QP before it leaves on a trip.

The first of these options was rejected because of the consequences of the time pressure that it would place on the vessel, potentially encouraging attempts to under-report or put pressure on observers, or forcing the vessel to pay unnecessarily high prices for the QP. The two minimum holding requirement options were rejected because of the difficulty of appropriately specifying the mix of species for which a vessel would be required to hold QP and the need for there to be maximum availability of overfished species, for which the amount of QP available may be quite limited. With respect to this last point, the concern was that QP could end up being unnecessarily tied up by vessels needing it to meet a minimum holding requirement and, therefore, be unavailable to vessels that had encountered the species and needed the QP to cover their catch. Finally, given the strong monitoring and enforcement system, it will be very difficult for a vessel to escape having to cover landings witH QP. Therefore, a minimum holding requirement did not seem necessary.

Element 4 – Fishing Restriction While In Deficit

Element 4 prohibits a vessel from engaging in certain fishing activities if it has a deficit in its account (even if that deficit is within the carryover provision, A-2.2.2-c). Two approaches were considered for designating the time at which a deficit occurred. Under the Council's PPA, the deficit would have been deemed to occur as soon as fish were caught in excess of the vessel's QP balance. The vessel would have been responsible for tracking and accurately estimating its own catch. Under the second approach, a deficit is deemed to occur as soon as the first official data are reported indicating that a deficit has occurred. The second approach starts the fishing prohibition at the same that the Element 3, 30-day clock starts.

Under the first approach (fishing must stop as soon as catch in excess of QP holdings is taken), it would be entirely the vessel's responsibility to avoid fishing with a deficit. A vessel would <u>not</u> be required to refrain from additional fishing while it waited for an official determination of its QP account balance.

---

[71] The GMT recommended consideration of a mechanism that would establish a minimum holding requirement to access a certain area. These areas would be defined based on the presence of overfished species and the probability that a trawler would catch them during a fishing trip. This would require that trawlers declare their intent to fish either in the area that requires a minimum holding requirement or outside that area. For example, if trawlers intend to fish in depths shallower than 200 fathoms, a minimum holding requirement for canary and yelloweye rockfish could be required. Vessels could fish deeper without meeting the minimum holding requirement for canary and yelloweye, but would have to meet those minimum holding requirement provisions if they desire to fish shallower than 200 fathoms.

[72] The GMT also recommended consideration of a minimum holding requirement provision that would allow vessels to enter into voluntary pooling agreements in order to reach that minimum holding requirement. This would require that trawlers forming voluntary risk pools register with NMFS. By registering as a member of the risk pool that had an adequate amount of overfished species (an amount that would have to be determined and based in part on the number of participants in the pool), the vessel would be considered in compliance with the minimum holding requirement.

Allowing a vessel to take responsibility for ensuring it is not fishing in deficit reduces the pressure to implement a data system with extremely rapid account resolution turnaround times. This would allow the development of a lower cost data system while at the same time ensuring full monitoring and detection of violations (through 100 percent observer coverage). Under the second approach (a vessel must stop fishing as soon as data are available indicating its catch may have exceeded its account holdings), either a vessel might be required not to resume fishing until data from a trip had been processed, or a vessel might be allowed to start another trip right away but be required to stop as soon as data in the system indicate that it may be in deficit.

One decision required with respect to this element of the program was the scope of the fisheries the vessel would not be able to participate in if it has a deficit. The primary legal concern in specifying the restriction is that any limitations placed on the vessel be necessarily reasonable for effective program design and not an action which would be considered punitive and, therefore, require due process (e.g., an opportunity for a hearing and appeal). A central element to the effective functioning of the program is that a vessel covers its landing witH QP. Therefore, prohibiting a vessel that has not met that condition from participating in the program is a necessary and reasonable result required for an effective program. In contrast, prohibiting participation in fisheries for whicH QP is not required may more likely be considered punitive. On this basis, it is likely that the Council will have to modify the fisheries in which vessels in deficit are allowed to continue to participate so that participation is prohibited and exceptions made only for those fisheries outside the scope of the program. Alternatively, if there are fisheries that are outside the scope of the program specified in A-1.1, but from which the Council believes vessels with a deficit should be excluded, the Council could explore modification of the program scope to incorporate those fisheries.

When the Council took final action in November 2008, there were some fisheries for which a decision was needed as to whether to consider them as part of or outside of the trawl groundfish IFQ program. In particular, the situation of the California halibut fishery had not been clear. Participants in this fishery are considered to be participating in the groundfish trawl fishery if they have a LEP and retain groundfish. Excluding those who do not retain groundfish from the bimonthly cumulative limit rules of the trawl groundfish fishery was feasible when the regulations primarily pertained to landings rather than total catch. The IFQ program requires that all groundfish trawl permitted vessels acquire QP to cover their catch taken with directed commercial groundfish gear. Thus there is no opportunity to avoid the harvest control regulations by discarding groundfish. On this basis, the Council included as part of the PPA an option that would consider the California halibut fishing by LE trawl vessels within the scope of the program (i.e., prohibit California halibut fishing by trawl LE permitted vessels that have a deficit in the QP account). The Council also included in this option all other state water trawl fisheries such as pink shrimp, ridgeback prawn, and sea cucumber trawl, as well as small mesh gillnet. When it took final action under Section A-1.1, the Council clarified that inclusion of California halibut did not cover California halibut gear with a mesh size of greater than 7.5 inches used in state waters.

Element 4 options considered but not included for detailed analysis:

Prohibiting all fishing by a vessel with a deficit in its QP account

This option was rejected because it was viewed to be punitive and, therefore, did not include adequate provisions for due process.

Element 5 – Transfer of Permits Prohibited While In Deficit.

Element 5 is intended to support accountability by ensuring that an individual not be able to dispose of its LEP if it is not in compliance with the program. This provision implies that the processing of any

applications for transfers would have to be delayed until a sufficient time has passed since the vessel's last landing to allow for full resolution of the vessels QP account balance.

Element 5 options considered but not included for detailed analysis:

Prohibiting the sale or transfer of the QS and/or QP in the vessel account

Prohibition of the sale of the QS or QP was rejected because the QS is not assigned to a vessel, and the vessel may have to sell its surplus QP in order to acquire the funds needed to buy the QP to cover the species for which it has a deficit. Additionally, if the vessel is unable to cover its deficit during a particular year, prohibiting the vessel from transferring its surplus QP would be to the detriment of processors, communities, and the general public.

Element 6 – Alternative Compliance Options

Element 6 was intended to provide some alternative avenues for compliance with the program to ensure that the program does not become overly restrictive. Vessels may face a fishery situation in which overfished species are sometimes encountered at very high incidental catch rates on a very random and infrequent basis ("disaster tows") and that the amount of QP available to the fishery may be very limited. Under such circumstances, there is a concern that it may take several years for a vessel to acquire the QP needed to cover an overage. If a vessel is in deficit, even after if it is cited for going beyond the maximum length of time allowed for resolving the deficit (see Element 2), it still must cover the deficit before it resumes participation in the program. Some perceive this as potentially victimizing the fisherman; therefore, these alternative compliance options were developed. Element 6 was not included as part of the final preferred alternative because there was concern it might invite abuse. Fishermen might assess the length of time they would be required to be off the water and time overages to coincide with planned major repairs or transitions to other fisheries.

Element 6 options considered but not included for detailed analysis:

Vessel can continue fishing by voluntarily surrendering QS of other species.

Vessel can continue fishing by voluntarily posting a bond.

Vessel can continue fishing by voluntarily making a payment based on the amount of target species typically associated with the amount of overage species taken (using incidental catch rates) (variation on the deemed value system in New Zealand).

Vessel can continue fishing by voluntarily paying an amount based on the fish on board (similar to the deemed value system in New Zealand).

The payment and surrender options were rejected because they appeared to be punitive (required an action at the vessel's expense that would not be required in the normal course of meeting the objectives of the program). The option of a bond was rejected because it was not apparent that under the MSA the Federal government would have the authority to impose such a requirement.

Related to this element was an option the Council considered for auctioning off QP for overfished species. This option will be discussed at the end of the analysis of Element 6.

❖ *Interlinked Elements*

Element 1 –Trawl Limited Entry Permit Required to Participate

The number of nontrawl vessels able to harvest trawl QS will be constrained by the number of trawl permits not needed after the trawl fleet has consolidated. Thus, if this provision is changed to allow participation in the IFQ program without a trawl permit, there may be a substantial change in the

impacts of the gear switching opportunity provided by the scope of the program (Section A-1.1). This provision parallels the scope of the IFQ program, which covers harvest by LE trawl vessels (as defined by their possession of a limited entry trawl permit).

Element 2 – Vessels Required to Acquire QP

By requiring all QP be deposited to a vessel account in order to be used, this element interacted with the control accumulation limit. Vessel limits were set above the control limits and accumulation limits were originally specified to apply to both the QS and QP. Since a vessel's account would generally be considered under the control of the vessel owner/operator this created a discontinuity, it would be impossible for a vessel to reach the vessel limit without violating the control limit. Therefore, the vessel limits in Section A-2.2.3-e were respecified so that control limits applied only to QS and vessel limits only to QP.

Element 3 – Time Allowed to Cover a Landing (and Minimum Holding Requirement)

The 30-day period a vessel is allowed to cover its landings increases the possibility that the fleet could exceed its annual allocation (but not the multiyear average). The carryover provision provides some mitigation for this risk in that it reduces the incentive for vessels to use all of their QP. This has two closely related effects. First, it increases the probability that some vessel owners will have unused QP at the end of the year, decreasing the probability of an overage on the fleet allocation. Second, those QP may then be available, at the right price, for those with an overage to acquire during the 30-day settle up period. However, the carry-over provision itself creates some possibilities for annual overages. These possibilities are discussed in the section on that provision.

Element 4 – Fishing Restriction While In Deficit

If vessels with a QP deficit can only be restricted from participating in those fisheries that fall within the scope of the program, then there is an interaction between the scope of the program (Section A-1.1) and scope of the prohibition that can be implemented under this element.

The need for a catch and QP tracking system with rapid turn-around times is reduced if vessels are allowed to start on another trip immediately after completion of offloading. This can be achieved either by holding the vessel responsible for fishing while in deficit (even if the deficit has not yet shown up in its account) or by applying the restriction only when the deficit is recorded in the data system (making it legal for the vessel to fish until the deficit shows up in its account).

Element 5 – Transfer of Permits Prohibited While In Deficit.

There are no other provisions in the program that are strongly interlinked with this element.

Element 6 – Alternative Compliance Option

Element 6 does not interact with other provisions of the program, except indirectly through its impacts on other elements of this section. Element 6 may have implications for the effectiveness of those other elements, particularly with respect to meeting conservation objectives over the long term and the strength of the incentives vessels have to ensure that they are able to acquire the QP they need to cover their landings.

❖ Analysis

Element 1 – Trawl Limited Entry Permit Required to Participate

Requiring that a LE trawl permit be held in order for a vessel to participate in the IFQ program has implications for objectives related to conservation; net benefits, program costs, and complexity; and fairness and equity.

By limiting the number of vessels involved in the fishery, this requirement may limit the amount of gear switching that may occur and, therefore, have conservation implications, particularly with respect to habitat impacts. The impacts of gear switching are covered in Section A-1.1 and Section A-7.

If a greater number of vessels were allowed to participate in the fishery, program costs and complexity would increase, and net benefits might decrease, unless all program costs are borne by industry. An unlimited number of vessels would increase the number of accounts to track and could increase the diversity of alternative strategies in which the trawl IFQ is used. This could require the specification of more regulations for how opportunities for the use of trawl IFQs would be mixed with the opportunities provided under the general regulations for nontrawl gears. Most likely it would require a declaration procedure, and vessels would either have to be fishing under the trawl IFQ regulations or the regulations for the gear they use. Vessels fishing under the trawl regulations would have to be in full compliance with those regulations, including requirements to carry observers. The high costs of complying with the program alone might keep the number of participants low, even without the number of vessels being limited by the permit requirement. The number of vessels that participate in the fishery would not be a concern if all costs were privatized and born by the users in proportion to their responsibility for those costs. Under such circumstances, a larger fleet would occur only if that were the most efficient result. The market would allocate the QS out to the most efficient number of participants with the best mix of activities (from an efficiency perspective). However, it is unlikely that all costs will be fully born by the users. On the basis of the anticipated compliance and administrative costs, it is expected that restricting the number of vessels to the number of trawl permits will result in a program with lower total governmental costs.

The LE trawl permit requirement is also viewed to preserve equity with respect to one fleet's ability to access the allocation of another. On one hand, members of the trawl fleet felt that it would be unfair for others to have access to their allocation while they would not be able to access/purchase allocation given to other sectors. On the other hand, if an individual member of the trawl fleet gives its QS to a member of a different fleet, other members of the trawl fleet are not directly harmed so long as all QS holders participate and are responsive to the market for QS/QP (e.g., do not hold on to QS for strategic reasons unrelated to its most efficient use). Even with the LEP requirement, gear switching is allowed, and some nontrawl vessels will likely be able to participate in the trawl sector IFQ program by acquiring permits not needed by the consolidated trawl fleet. However, the ability of other fleets to participate will be limited by the number of surplus permits available after rationalization.

Element 2 – Vessels Required to Acquire QP

Requiring that QP be placed in a vessel account prior to use affects objectives related to conservation, net benefits, program costs, and fairness and equity.

If the QP did not have to be transferred to a vessel account in order to be used, then the data tracking system would have to be set up to allow each landing to be subdivided and counted against a variety of different QP accounts, increasing the costs of the program. Requiring that the QP be transferred to a vessel account breaks the link between the QS holder and the QP (except with respect to vessel owners

owning QS). That link could be preserved but it would require that data be kept to link eacH QP with the QS account from which it was originally issued. The effect on the complexity and cost of the data tracking system would be similar that of not requiring the QP be transferred to the vessel account in order to be used. Therefore, after QP is transferred to a vessel account the QS owners contributing that QP will lose control over it, except as they may be able to otherwise provide through private contract.

Because the QS holder is not held accountable for how the QP is fished and whether an overage is incurred, there is no incentive for the QS holder to ensure that it sells QP to a responsible vessel. A vessel could knowingly harvest an amount of fish that far exceeds the QP it holds in its account, then that vessel could be taken out of the trawl fishery and never cover the overage witH QP. The QS holder that transferred its QP to that vessel would be not be held responsible. Holding the QS liable for overages could increase self-policing within the fishery, but might also raise questions about fairness and equity with respect to the QS holder's responsibility for the vessel's actions.

Setting up a program in which QS holders that do not own vessels are not able to directly use their QP may be viewed as inequitable by some. However, as long as the providers of the QP have been fully compensated for the QP, there appears to be little reason that they should maintain some claim to those QP. If a QS holder, a crewmember for example, wants to retain control of the QP it receives until they are needed by the vessel, Element 3 facilitates that. By providing 30 days for the vessel to cover its landing, the vessel could contract with the crewmember for the QP to be provided as needed after a landing is made, and the crewmember would maintain control over the QP.

Element 3 – Time Allowed to Cover a Landing (and Minimum Holding Requirement)

The provision allowing 30 days to cover a landing has a bearing on objectives related to conservation, net benefits, program costs, sector health, and program performance. The B.C. groundfish trawl fishery allows 30 days; in New Zealand, 15 days are provided; and in Nova Scotia, 45 days are provided (Sanchirico, et al. 2005). The Icelandic system provides three days from the time vessels are notified they have an overage. After three days, the vessel's permit is suspended. Under the Council PPA, the vessel would have been given 30 days to cover its overage from the date of landing, regardless of when data were available indicating an overage had occurred. Additionally, the vessel would have been held responsible for ensuring that it never fished with an overage (see Element 4). Under Element 4, if it were detected that a vessel had fished with a deficit at any time, the vessel would have been subject to a notice of violation. Thus, in a sense it was more restrictive than the Icelandic system, which provides a three-day grace period. However, it was also more liberal in that the vessel could have carried a deficit for up to 30 days without being in violation of the program, so long as during that period it did not take part in any fishing that falls under the scope of the program. Under the Council's final preferred alternative, the vessel would be given 30 days from the time catch data show it may have an overage.

Ability to monitor and enforce this provision will be a major determinant of its impacts. Therefore, we will first discuss the relationship between this provision and monitoring and enforcement with respect to program performance and then look at different requirements and their impacts on other objectives.

- *Monitoring and Enforcement*

The IFQ program will require 100 percent at-sea monitoring (Section A-2.3.1). Complete monitoring is required because the QP is required to cover catch, including discards. QP for some species is likely to be quite expensive (overfished species), while the per-pound value of those species is relatively low;

thus, there will be significant incentive for vessels to discard overfished species if there is not full at-sea monitoring.

A program that requires QP be held at some time prior to offloading would allow a greater opportunity for enforcement activity during fishing or offloading activities. Enforcement officers in the field (USCG at-sea, or state or NMFS agents on the dock) could determine whether the vessel has sufficient QP to cover the fish on board at the time of interception. When violators can be detected and cited in the field, or shortly after a landing, enforcement actions can be taken more efficiently (e.g., the collection of needed evidence), and deterrence is created as information about citations made reaches the fleet rapidly. Thus, providing a 30-day period to acquire QP will make follow-up investigations more difficult, and information about later investigations may be slow to reach the fleet, reducing the deterrence effect of those enforcement actions. However, given the tight monitoring system, field enforcement will not likely increase the frequency with which violations are detected.

With a coverage requirement that provides little or no time after a landing for vessels to acquire the needed QP, if the consequences of the overage are economically significant (as might be the case for an overfished species) the vessel will have incentive to seek to under-report catch. For example, they might have more incentive to interfere with the observers' activities (e.g., discarding fish before the observer has a chance to identify and weigh them), put excessive pressure on observers by questioning the observers' measurements, or by other means. Allowing for delayed resolution of accounts (e.g., 30 days) will somewhat reduce incentives to underreport by providing vessels a longer opportunity to find QP at the lowest available price.

A program that requires some amount of QP be held prior to departing from port would add another rule that would have to be monitored and enforced. Specifying the mix of species that a vessel must have would be difficult, and requiring that vessels hold some minimum amount could reduce QP availability for those who need it. The reduction in QP availability could be a particular problem for overfished species. Under such a rule, it is likely that the species for whicH QP must be held would depend on where the vessel is intending to fish. This would be enforced either during at-sea boardings, or during after-the-fact matching of the vessel's fishing locations to the balances in its account before it departed. Such a requirement would add to program administration and enforcement costs. With strong monitoring of catch, it is not clear that a minimum holding requirement would add anything to encourage compliance and facilitate enforcement.

♦ *Conservation*

The conservation concern is whether this provision will increase the likelihood that the fleet might exceed its allocation of a particular stock and as a consequence all sectors taken together exceed the overall OY. Assuming that vessels fish without all the QP they need for a particular trip, providing a 30-day period to balance the QP account will create a lag time between when the last of the trawl allocation for the year is taken and when the last of the QP disappears from the market. The Council's FPA, which starts the 30-day clock from the point at which data on the overage is reported, rather than the time of landing, potentially creates a somewhat longer lag between catch and the time the QP to cover that catch is removed from the market. The additional lag will be the time it takes for data from a trip to be recorded in the data system. However, the prohibition on fishing for vessels with a deficit, and the high cost of QP when they are in short supply provide substantial disincentives for risky behavior, such as delaying until the last moment the acquisition of needed QP. Additionally, not allowing a vessel with a deficit to fish under the program ensures that over the longer term of a few years the fleet will not, on average, exceed its allocation (this could have changed if Option 1 or 2 of Element 6 had been adopted). The overage and underage aspects of the carryover provision will increase the probability that

the fleet as a whole does not go over its allocation in a particular year since vessels will not face losing QP (up to 10 percent) if they do not fish to the maximum in the current year. The Canadian system allows 30 days to cover an overage and has a carryover provision. There, trawl sector total allowable catches (TACs) are only occasionally taken and rarely exceeded. If that experience holds true for this program, there would appear to be little risk that OY would be exceeded due to vessels catching fish for which they do not have QP and then not being able to acquire the needed QP after landing. However, based on observations of the Canadian experience, the greatest risk in this regard will be for constraining species. If, on an annual basis, the trawl fishery approaches harvest levels that exceed their allocation, the Council will have to ensure that the provisions of the MSA are met with respect to annual catch limits. To do this, the Council may take action in advance or inseason. For example, buffers might be established in advance of the season (see discussion of this issue in the section on carry-overs (Section A-2.2.2-b)). During the season, if fleet catch for a particular species starts approaching the total trawl allocation, and significant amounts of target species QP for the year remain, there may be restrictions on fishing areas, e.g., expansion of the RCAs (Section A-1.3).

With respect to the minimum holding requirement that was considered, in particular for overfished species, the conservation benefits appear to be minimal given strong monitoring provisions and the difficulty in constructing such a requirement for a multispecies fishery. While potentially helpful in ensuring that a vessel could cover its landing of an overfished species, it would not be possible to set such a requirement at a level that would ensure a vessel could cover an unexpectedly high catch rate ("disaster tow"). The requirement could be set well below disaster tow levels, but this could make QP difficult to acquire for vessels that actually need it to cover a disaster tow. Additionally, maintaining the required amounts of minimum holdings would become even more difficult as the season progressed, and vessels used up the QP. If the minimum holding requirement were based on fishing areas or hot spots, it would encourage fishermen to stay out of those areas if they were unable to acquire the needed QP, as might particularly be the case toward the end of the season. However, with the scarcity of overfished species QP such areas could well become de facto closed areas. Given that major overages could result in restrictions on the fleet as a whole, and even lead to a derby atmosphere in the IFQ program, conservation concerns might better be addressed by closing the high bycatch rate areas rather than leave them available for fishermen willing and able to take the risk.

♦ *Economic Effects*

Providing a significant period of time after a landing to cover the catch might result in the following:

- Decrease the average price paid for the QP
- Provide greater business flexibility and increase the availability of QP on the market
- Improve the market function

The less time a vessel has between when it knows the exact composition of its trip and when it has to have the QP to cover that catch, the less time a vessel will have to search for QP at the cheapest price. Vessels in that situation are more likely to pay a higher "spot price" for the QP they need. To avoid paying those higher prices, a vessel is more likely to hold a larger QP inventory on the chance it might need it. This would reduce the amount of QP available on the market and result in even higher spot prices. Conversely, providing a longer time to acquire QP will allow vessels more time to search for the lowest available price and reduce their need to carry an inventory of QP. This would likely improve market function, particularly if markets for some species are relatively thin (meaning the amount of QP available for trade at any time is relatively limited).

In the extreme, a minimum holding requirement would require that a vessel have certain QP in its account before departing on a trip or entering into certain fishing areas (hot spots or depth zones). The

species for which a vessel would be required to hold QP would likely be those for which there are the fewest QP available and the greatest conservation concern (overfished species). As discussed in the section on conservation, requiring vessels to hold those QP on the chance they are needed would reduce their availability to those who have already encountered those species and need them to cover their catch. This would increase the QP price for the already expensive overfished species and may hamper the fleet's ability to take target species. If this provision were structured such that a vessel could meet this minimum holding requirement by entering into a risk pool with other vessels, the minimum holding requirement would likely drive more vessels into such pools. Given that these pools would be voluntary associations, those who had a reputation for encountering high amounts of bycatch or otherwise were not welcome in an association would likely face higher risks and higher costs. Thus, a minimum holding requirement might force those individuals out of the fishery more rapidly.

Element 4 – Fishing Restriction While In Deficit

Prohibiting a vessel from fishing while in deficit may have an impact on objectives related to conservation, net benefits, efficiency, program performance, and equity.

The prohibition on fishing while in deficit is expected to provide an incentive to vessels to cover their QP in a timely manner, including minimizing their risk of being caught in a situation in which they are unable to acquire QP. This strong incentive is expected to mitigate the potential negative effect of the 30-day time lag provided in Element 3 and thereby expected to promote conservation objectives.

Under the PPA, Element 3 would have allowed a vessel to go on another trip immediately upon completion of a landing, without waiting for an official resolution of its QP account balance. However, if, after the account balance had been resolved, it turned out that the vessel had gone fishing with a deficit, the vessel would have been subject to a notice of violation. The two concerns in this regard were the potential for an accounting error on the vessel's part, or an intentional flagrant violation by a vessel that had determined that it no longer wished to continue to participate in the fishery. Under the latter circumstance, a vessel might knowingly make as many trips as possible before the overage balance is detected. However, such activities would still be illegal and subject to prosecution. Because of the vessel monitoring system (VMS) system requirements and the requirements to carry an observer, it is virtually certain that once the vessel's negative balance became known, illegal fishing occurring during the period of that negative balance would be flagged, and a notice of violation would be issued, similar to the situation vessels are in under the current two-month cumulative trip landing limit system. Therefore it was expected that the restriction on fishing while in deficit could be effectively enforced even with the 30-day accounting lag of Element 3 and the allowance for vessels to continue fishing prior to an official determination of their account balance. Under the final preferred alternative, the Council modified the 30-day clock for covering an overage such that it commences once data are available showing that the overage exists. Application of this rationale to the "no fishing while in deficit" provision leads to the implication that a vessel should not be considered in deficit until the information is in the data system showing that a deficit may exist. This then opens a greater opportunity for vessels that suspect they are in deficit to make a last minute dash to catch additional fish before the deficit shows up in the data system, since such fishing would not be a violation of the program. In terms of an impact on conservation, with the tight monitoring and requirement that all overages be covered, there is little chance that a long-term conservation problem could be created by vessels that remain in the fleet, since these vessels would eventually cover their deficits witH QP. The greatest problem would be for vessels planning to leave the fishery; however, the incentive to engage in such last-minute fishing dashes would be minimized to the degree that harsher penalties might be expected for such irresponsible behavior. In addition to potential conservation concerns, last-minute dashes could also create an equity concern to the degree to which the additional fish taken would lead to the need to impose inseason constraints on the rest of the fleet (e.g., depth restrictions to reduce bycatch). The opportunity for last-

minute dashes will depend on the speed with which data on a particular trip are entered into the tracking system and whether vessels are allowed to go on a subsequent trip before all the data from their current trip are entered into the system.

Under the PPA, efficiency and net benefits were expected to be promoted by allowing vessels to estimate QP balances on their own and continue fishing directly after completion of an offload. Such flexibility was expected to reduce vessel operating costs and allow for the development of a catch-QP tracking system that is less costly and has a somewhat slower turnaround, but still performs well enough to meet industry needs. Under the final preferred alternative, the impacts of the no fishing provision will depend on whether vessels are allowed to go out on a subsequent trip prior to the resolution of the balance in their QP account and/or the speed with which data are put into the system. If, immediately after completion of a trip, vessels are allowed to go out on another trip, there will still be substantial flexibility for vessels to reduce operating costs, but irresponsible operators may generate adverse conservation and equity benefits, as described above. On the other hand, if a vessel cannot go out on another trip until data from its last trip are entered into the system, then flexibility would be reduced, and there would likely be pressure for a data system with faster turnaround times, a system that is likely to be more expensive.

Element 5 – Transfer of Permits Prohibited While In Deficit

This provision provides a disincentive for activities that might otherwise compromise conservation objectives. The purpose of prohibiting a vessel with a deficit from transferring its permit is to provide further incentives for a vessel to avoid the deficit and reduced opportunity to abuse the system. In particular, it puts additional assets at risk for a vessel that might decide to flaunt the system and maximize its catch before overages are detected. Thus it increases the vessel's risk exposure if it were to decide to engage in an illegal action. To administratively complement this requirement, no permit transfers would be allowed between the time of a vessel's landing and the time its QP account has been debited for that landing. Because permit values are expected to decline substantially with the imposition of an IFQ program, the disincentive provided by the potential loss of ability to transfer a permit will be lower than might be expected based on current permit values.

The impounding of QS and QP transfers while a vessel is in deficit was also considered. QS is not associated with a vessel, so there is no opportunity to freeze QS account transfers while account balances are being resolved, and the vessel may need its QP to generate revenue to acquire the QP it needs to cover the species for which it has a deficit. Freezing QP would also penalize other vessels by eliminating that QP from availability on the market, potentially increasing market prices.

Element 6 – Alternative Compliance Options

This provision is intended to address objectives related to fairness and equity, efficiency and net benefits, and sector health, but may also affect conservation objectives.

- Conservation

With respect to the conservation objectives, a potential negative impact of this provision is that a vessel, knowing there is a limit to the time it is off the water, might take advantage of this provision by intentionally fishing into a deficit and planning to rely on other fishing activities until such time as the Element 6 exception allows it to resume fishing (e.g., a vessel might fish its QP account into a large deficit, go to Alaska for two years, then return or sell off its permits after the fishing restriction has expired). When a vessel resumes fishing without having ever covered its deficit, then the conservation

objectives will not have been met unless there has been a buffer or some other measure that has kept total harvest within the OY.

The sliding scale option (Option 2) would provide a variable way for determining the amount of time that a vessel would be off the water and may provide some additional equity by being more responsive to particular circumstances, but would not avoid the possibility that fishermen will determine in advance the amount of time they would be off the water and accept that as part of the cost of their overage.

- Fairness, Efficiency, and Sector Health

The fairness and sector health concern is related to the relatively random nature of the encounters with overfished species. Under status quo management, the effect of harvest in excess of what is expected falls to the individual, but also across the entire fleet in the form of inseason reductions in cumulative limits. Additionally, the duration of the direct impact of the unexpected high harvests on vessels and the fleet is limited in that the cumulative limits start over every two months, and the fishery starts over each year with a new OY and fleet allocation. Under the IFQ program, the effect of random occurrences of high bycatch "disaster" tows may fall on a few vessels at a time, and, absent the exceptions provided in this element, the burden of making up for the random occurrences is not relieved at the end of a year. If the occurrence of high bycatch tows is truly random, there could be fairness concerns, as well as concerns about sector health and efficiency of the fishery. A few vessels could end up bearing the burden for a situation that is faced by the fleet as a whole. Further, if a certain number of vessels are sitting out every year waiting to accumulate enougH QP for a particular species in order to re-enter, a larger fleet may result (as an example, if the optimal fleet size is 70, and 7 vessels on average sit out every year, something close to 10 percent more capital might be dedicated to the fishery than is optimal).

Some vessels encountering overfished species may have substantial difficulty acquiring QP to cover their unexpected high bycatch rate because of the expected high cost of the QP. Given the uncertainty surrounding potential catch of overfished species, vessels with unused overfished species QP may withhold those QP from the market to ensure that they can cover their own needs. Vessels holding QP as insurance against a low probability event may create even more of a market shortage and higher prices.

Available information shows that there are more trawl tows that result in zero encounters of relatively rare overfished species (such as yelloweye, Figure A-117) than there are tows where there are substantial quantities. The encounters of overfished species may not affect most of the fleet since more vessels are avoiding them than not, but the implication to the individual who has an encounter may be quite large given the individual accountability of the trawl rationalization program.

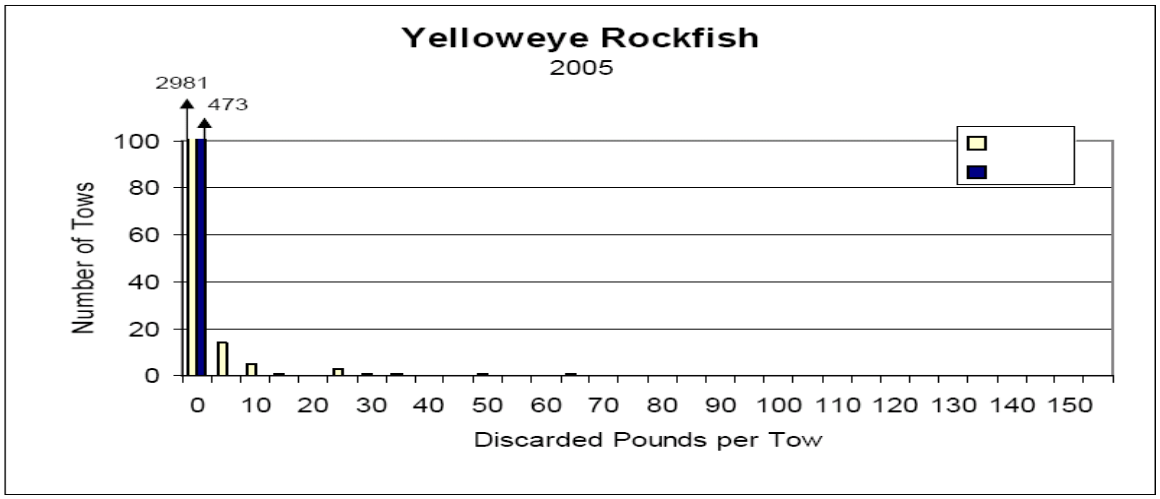

Figure A-95. Observed Discard of Yelloweye Rockfish in the Nonwhiting Trawl Fishery (note: at least one tow occurred in 2004 with > 100 pounds).

To outline the magnitude of the problem, the following scenario was developed. This scenario assumes that the nonwhiting trawl sector will be allocated 0.5 metric tons of yelloweye rockfish and that the number of participants in that fishery consolidates to 60 vessels. This means that there would be approximately three yelloweye rockfish available to each vessel. If each of those vessels intends to hedge against uncertainty by holding on to only one fish, the effect is that approximately 40 percent of the sector allocation is not available for purchase on the market. This reduces the chance that vessels with deficits can cover their catch by purchasing QP, and it increases the cost of purchasing QP because the supply on the market is lower.

	Available Quantity of Yelloweye under Initial Allocation	**Quantity Available on the Market if Hedging Occurs**
Pounds available to the sector	1,102	682
Pounds per vessel	18	11
No. of Fish per Vessel	3	2

The potential for unexpected overages will likely be exacerbated by the rebuilding paradox. The rebuilding paradox has to do with the lag time between when fish become more available to the fishery (more abundant in the catch) and when the increased abundance is detected and OYs appropriately increased. It results in greater than expected harvests. Under an IFQ program, it would mean less QP would be available than might be appropriate given the true stock abundances and encounter rates.

The primary equity and conservation concerns of this provision apply to overfished species that are taken incidentally along with target species. The provision, as currently worded, covers all species. It, therefore, may provide more of an exception than is necessary to address the identified objectives related to fairness and sector health.

To address this concern with respect to overfished species, the Council also considered but rejected the release of overfished species through an IFQ auction. Concern was expressed about the administrative cost and complexity, whether it would ultimately relieve price concerns about overfished species QP, and how vessels would be able to access QP as needed (before auctions occurred).

A-2.2.2 IFQ Annual Issuance

A-2.2.2.a Annual QP Issuance

❖ Provisions and Options

QP will be issued annually to QS holders based on the amount of QS held.[73]
As specified above, QS holders will have to transfer their QP to a vessel account in order for those QP to be used.

❖ Rationale and Policy Issues

Annual issuance of QP is in line with the annual setting of the OYs. Providing the IFQ as shares (QS) rather than absolute poundage provides flexibility so that reallocation is not needed as the OYs or trawl allocations change.

❖ Interlinked Elements

Numerous features of the program rely on this structure of the IFQ privilege (the issuance of QS witH QP issued annually to QS holders). Any change in this basic provision would require substantial reconsideration of numerous provisions and the redevelopment of the IFQ alternative.

❖ Analysis

Issuing IFQ as shares that then entitle the holder to annual harvest privileges (QP) is a means by which the Council "take[s] into account and allow[s] for variations among, and contingencies in, fisheries, fishery resources, and catches," as required by National Standard 6 of the MSA. Alternatives might be to issue IFQ anew each year (eliminating the benefits from long-term planning, increasing program complexity, reducing the opportunity to rationalize the fishery, and substantially increasing program costs) or issue IFQ that is valid across a number of years (increasing program costs and creating equity and reverse allocation issues[74]).

[73] Including QS that an entity received in excess of accumulation limits in place at the time of initial allocation (see Section A-2.2.3.e).

[74] Reverse allocation would be required if some QP have to be recalled because of declines in the amounts of fish available to trawlers for harvest.

A-2.2.2.b Carryover (Surplus or Deficit)

❖ *Provisions and Options*

To the extent allowed by the conservation requirements of the MSA, a carryover allowance will allow **surplus** QP in a vessel's QP account to be carried over from one year to the next or allow a **deficit** in a vessel's QP account for one year to be carried over and covered witH QP from a subsequent year. QP may not be carried over for more than one year.

A vessel with a QP **surplus** at the end of the current year will be able to use that QP in the immediately following year, up to the limit of the carryover allowance (see below). However, if there is a decline in the OY, the amount of QP carried over as a surplus will be reduced in proportion to the reduction in the OY.

A vessel with a QP **deficit** in the current year will be able to cover that deficit witH QP from the following year without incurring a violation if

(1) the amount of QP it needs from the following year is within the carryover allowance (see below), and

(2) the QP are acquired within the time limits specified in A-2.2.1.[75]

Carryover Allowance: There is a limit of up to 10 percent carryover for each species. This applies to both non overfished species and overfished species. The percentage is calculated based on the total pounds (used and unused) in a vessel's QP account for the current year. The percentage used for the carryover provision may be changed during the biennial specifications process. *Note: This provision relates only to carry-over of what is in the vessel's account.*

❖ *Rationale and Options Considered but not Analyzed Further*

In order to understand how the carryover provision would work, it helps to revisit how the distribution and use of QP will work. Before the start of the fishing season and after the OY has been established, the trawl sectors will be allotted apportionments of the OY for each quota-managed species. The trawl sector portion of the OY will be distributed to QS holders. Each QS will be equivalent to a certain poundage for that year for each quota species (poundage will change from year to year if the trawl allocations or OY changes). The QP must then be transferred from the QS holder to a vessel. The QP is then associated with a vessel: the vessel is responsible for any QP overage or underage incurred, because it is at the vessel level where the catch accounting will occur. Any overage or underage is not linked back to the QS, and the QS holder the next year will be allocated 100 percent of the QP associated with the QS. In other words, a QP overage will not be deducted from the original QS holder's future QP. The responsibility for the overage stops with the vessel. The 10 percent allowable carryover for a vessel would be calculated based on all the QP the vessel held (used or unused) in its account for the entire season. "Used" QP is QP a vessel has used to cover catch (it does not include QP that was transferred into and then out of the vessel account).

The term "carryover" in this analysis refers to the vessel's QP that is either in surplus or deficit from one year to the next (it does not apply to QP remaining in the QS holder's account). A carryover provision would allow a vessel to keep a percentage of unfished QP (a surplus of quota pounds) for use the following year. If 90 percent of a vessel's QP is harvested in the first year, then that remaining

[75] Carryover of deficits provides some flexibility to use pounds from a year to cover a deficit from a previous year. Without a carryover provision, a vessel would still have to use pounds in a subsequent year to cover an overage but would incur a violation.

10 percent could be harvested in the second year in addition to whatever QP the vessel acquired in the second year (e.g., acquired from QP issued to QS held by the vessel owner). Conversely, the carryover provision would allow up to 10 percent over-harvest in one year to be covered by QP the vessel acquires in the following year (by QP from the vessel owner's QS or QP acquired from other QS owners). The carryover allowance for a vessel would be 10 percent of the used QP in its account at the end of the 30-day period that it has to cover any overage. Since a vessel must stop fishing as soon as a deficit is recorded, the amount in it account at the end of the 30-day period would be similar to the amount that will be in its account at the end of the year, unless it has been able to resume fishing by covering the overage. If the harvest in a year was equal to 110 percent of the QP in the vessel account, that 10 percent QP overage would be deducted from the following year's QP acquired by that vessel. QP surpluses could not be carried over for more than one year. If a vessel catches more than 10 percent in excess of its QP holding, it would still be required to cover its catch witH QP from a subsequent year, but it would also be subject to penalties for violating provisions of the program.

The Council could have chosen to allow carryover of surplus QP, but not deficit, or provide an asymmetrical carryover provision. An asymmetrical carryover provision is one where the carryover percentages would be different from each other. For example, Iceland allows a 20 percent carryover of a surplus and 5 percent "carry back" of QP to cover an overage (Sanchirico, *et al.* 2005). Additionally, carryover allowances need not be set at a constant level indefinitely. The Council specified the carryover provision to allow for changes to be made as part of the biennial specifications process. These changes might be made based on stock conditions and previous years' experiences.

The Council considered the carryover provision as a means of 1) decreasing the incentive to take the maximum harvest within a year by fishing as close as possible to individual annual limits and, in a multi-species fishery, provide more flexibility for fishermen to fully take the allowable catch on average across years, 2) decreasing the incentive to attempt to underreport when an individual does not have enougH QPs to cover catch, and 3) reducing the need to penalize fishermen for overages (if that overage is within the 10 percent carryover allowance). Additionally, the carryover provision imbues the asset (QPs) with usefulness over a longer timeframe than a single season.

This type of flexibility would be particularly useful in multispecies fisheries. In a multi-species fishery, it is highly likely that not all species will be fully exploited because the catch ratio of species to other species is imperfect.

Applying the QP carryover provision to QP in the vessel account and not at the level of the individual QS holders is expected to result in lower administrative costs than if QS holders were allowed to carry over unused QP. Applying a carryover provision to the QP issued to a particular QS holder would be quite expensive if unused QP had to be tracked back to the QS holder's account. Under such circumstances, instead of tracking just the QP balances in a vessel account, NMFS would also have to track from which accounts the QP was transferred. Further, when catch is taken, in addition to designating species, the vessel would have to designate how to distribute the catch against the QP in its account that comes from various QS holders. This tracking would add a layer of complexity to the tracking and monitoring component of the trawl rationalization program and would increase administrative costs. For this reason, the carryover provision would apply only to QPs held in a vessel account, and the vessel owner, not the original QS owner, would be responsible for any overage/underage occurring on that vessel.

The following options for the carryover allowance were considered but rejected:

- For all species (of which the carryover could be different percentages for overfished than for non-overfished species): 5 percent or 30 percent
- For overfished species only: no carryover

- For QPs that were never transferred to a vessel account: carryover would apply.

The range above and below 10 percent was rejected because of too little benefit (5 percent) or too much risk of overharvesting the fleet's annual limits (30 percent). The option of not having a carryover for overfished species was rejected because it is the overfished species for which the greatest flexibility may be needed. Applying the carryover to QP that was never transferred to a vessel account was rejected to encourage the use of the QP by increasing the incentive to transfer the QP to a vessel account. Ultimately, the Council adopted a provision requiring the transfer of all QP to a vessel account, making the possibility of applying a carryover provision to a QS holder account irrelevant.

To help meet conservation objectives, the Council included in its final recommendation a provision that would proportionally reduce the surplus carryover QP in a vessel account when there is a decline in the OY. For example, if an ABC/OY declines by 50 percent, all carryover QP would be reduced by 50 percent. If someone had 100 QP carried over to the coming year, they would instead have 50 pounds to carryover. Additionally, the Council retained flexibility by allowing the carryover provision to be re-examined and changed during the biennial harvest specifications process, as needed. The net impact of the carryover provision on the fleet's catch of its allocation would not be known until vessels have the opportunity to exercise that provision. Presumably, some harvesters will carry over a surplus and others a deficit. If many vessels carry over a large percentage of the QP for a particular species, then the Council may have to examine the collective effect of the carryover on attainment of conservation objectives and make adjustments to the carryover allowance in future years. While the Council believes that the carryover provision is not likely to result in the fleet exceeding its allocation, there is some chance that a fleet overage could still occur. In the face of this uncertainty, and uncertainty about the other mechanisms that may be in place to ensure fleet overages do not result in harvest in excess of conservation thresholds (e.g., buffers), the Council specified that this provision only be implemented by NMFS to the degree that would be permissible under the conservation requirements of the MSA.

❖ *Interlinked Elements*

Permit/IFQ Holding Requirement – The carryover provision will affect the timeframes in which the enforcement provisions are carried out. In the section on QP holding requirements, an exemption is provided such that a vessel may have a deficit in its QP account and not be in violation of the program, so long as the amount of the deficit does not exceed the carryover provision.

Individual Bycatch Quota – The carryover provision would not apply to IBQ species (Pacific halibut).

❖ *Analysis*

The carryover provision is anticipated to increase individual flexibility for harvesters/vessels and improve sector health. Therefore, the carryover provision affects the achievement of objectives related to MSA National Standard 5 (consider efficiency), Groundfish FMP Goal 2 (maximize the value of the groundfish resource as a whole), and Objective 2 of Amendment 20 (provide for an efficient groundfish fishery).

Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
	X				X					

This section will focus primarily on the impacts to individual harvesters, links to enforcement issues, collective impacts at a sector level, and market and conservation implications. The carryover provision is related to the sector health goals and objectives. Those effects will be reviewed here in the context of impacts on harvesters (vessels) and sectors.

- Impacts on Individual Harvesters (Vessels) and Enforcement

  - *Carryover of a deficit*

At the start of a season, QPs of varying amounts for various species would be registered to a particular vessel. Once that vessel harvests more pounds of a certain species than the poundage held in the account, the vessel is anticipated to buy QPs from another vessel or QP holder to cover the catch. While midseason quota purchases/transfers can facilitate coverage of catch, as the season progresses there would be fewer QP available for transfer. Near the end of the fishing season, there may be little or no quota available for purchase or lease to cover overages for certain species.

The carryover provision would allow a vessel to avoid a penalty for overages of up to 10 percent of the total QP a vessel holds for a particular species. A vessel could cover a deficit with future QPs until the following year's QPs are calculated, issued to a QS holder, acquired by the vessel, and placed in a vessel account.

Counting the catch against the following year's QP provides flexibility while still holding the vessel accountable for exceeding its QP holdings. The carryover allowance reduces the incentive for vessels to attempt unmonitored discarding (NRC 1999), and is, therefore, a useful provision for both management and enforcement. Despite the carryover allowance, a vessel is still not allowed to continue to fish under the IFQ program if it has a deficit in its account (Section A-2.2.1).

Some vessels may choose to view the quota poundage in their accounts plus the 10 percent overage allowance (carryover of a deficit) as their target harvest amount. However, this would require fishing close to the point where penalties would be incurred for overages and would risk going beyond the 10 percent carryover. Hitting the 10 percent overage exactly would be made particularly difficult by the requirement that a vessel must stop fishing as soon as it has a deficit for any of the species covered by the IFQ program. If a vessel would want to fish into its allowance for a deficit carryover, it would have to fish as close as it could to the amount of QP it holds and then target an amount for its next tow that would take it over its QP holdings but not risk going over those holdings by more than 10 percent

(unless it was relatively certain it could go to the market to acquire additional QP to cover an overage of more than 10 percent). For those wishing to avoid penalties, the carryover provision provides the vessel with a cushion – to attempt to fully harvest each year's QPs without incurring penalties from small overages or business losses from leaving fish "on the table."

With no carryover provision, vessels could attempt to utilize QP fully by transferring QP among themselves. Full utilization of their QP portfolio would likely be achieved through a combination of their own harvest and the sale of QP to vessels needing it to fill out a trip. However, unless the QP market is highly liquid, and the transfer costs are low, it is likely that not all QP for all species will be harvested. Given limited QP liquidity and transfer costs, the carryover provision provides the harvester with some additional flexibility to more fully utilize their QP allocation without transferring QP to others. This provision is most likely to come into play at the end of the fishing season when there may not be enough quota to cover the catch of the various mixes of species either in an individual's account or on the quota market. The advantage that vessels would gain from being able to hold QP over from one year to the next creates a disadvantage to vessels looking to acquire QP to cover their catch. Absent the carryover provision, it would be more likely that vessels with surplus QP would release those QP onto the market. With a carryover provision, they are more likely to hold onto surplus QP for use in the following year.

Any overage one year reduces the QP available to the vessel in the following year. Thus, the advantage a vessel might gain if it fished at the 110 percent level the first year would be at the cost of lost flexibility in all future years until such time as the vessel had an underage. Table A-78 shows an example for a series of years of harvest for a vessel that acquires 100 pounds of QP each year and makes use of the overage provision. In the first year of the series (2011), a 10 percent overage is shown, and the vessel harvests 110 pounds. In the following year (2012), it acquired 100 pounds, but 10 pounds must go to pay back the 2011 debt, so it can only harvest 90 pounds, unless it acquires more than 100 pounds in 2012 or chooses to incur another overage. In this example, the vessel does not incur another overage in 2012. However, in 2013, it repeats the 2012 season with a 10-pound overage, taking a total of 110 pounds, and in 2014 it pays back the 2013 overage, but also incurs a 10 percent overage for the second year in a row. In 2014, the vessel's harvest is limited to 99 pounds. The vessel can continue to acquire 100 pounds a year and catch close to 100 pounds a year indefinitely (as illustrated for 2014 through 2016) making use of the carryover provision, but it will not be able harvest more than about 100 pounds until such time as it has a year in which it harvests substantially less than the 100 pounds it acquires each year (or until it acquires more than 100 pounds in order to pay back its deficit).

Table A-79. Example—carryover of QP overage.

	2011	2012	2013	2014	2014	2015
QP Acquired by the Vessel During the Year	100 lbs.	100 lbs	100 lbs.	100 lbs	100 lbs	100 lbs
QP Available for Use in the Year	100 lbs	90 lbs (100 – 10)	100 lbs	90 lbs (100 – 10)	91 lbs (100 –9)	90.9 lbs (100 –9.1)
Overage	10%	0%	10%	10%	10%	10%
QP debits for year (catch for the year)	110 lbs.	90 lbs.	110 lbs.	99 lbs.	100.1 lbs.	99.99 lbs.

♦ *Carryover of a Surplus*

Vessels with unused QPs from one year would be able to use those QPs, up to 10 percent of that vessel's total QPs, in the following year. The 10 percent unused QP is applied to the vessel account and

would not go to the QS holder. If the OY for a species should be reduced (due to a point of concern or other inseason stock issue), the individual carryover percentage would also be reduced by the same proportion to help achieve the conservation of that species while still providing flexibility to the harvester. This reduction would equally affect all vessels that carried over a surplus of QP. Vessels will know before the end of one year if there will be a reduction in the following year. Anticipation of a reduction in OY could create an incentive for vessels to use up QP before the end of the year rather than carrying over a surplus and having that surplus reduced as a result of the OY reduction.

Because this is a multispecies fishery, it is likely that for any single vessel several species would be under-harvested in any particular year, and, as a result, there would be carryover of a QP surplus. Allowing a vessel to carry over a portion of its unused QPs from one year to the next would decrease the incentive for the vessel to attempt to take its full QP holdings and hence decrease the risk of exceeding those QP holdings. By increasing the probability that a vessel will have surplus QP in its account and the likely size of those surpluses, the provision allowing carryover of a surplus may help balance out the carryover of deficits such that the fleet as a whole does not exceed its annual allocation and that groundfish conservation objectives are met.

The carryover provision would not allow pounds to be carried over for more than one year. Underages could not be allowed to accumulate across many years, such that potential harvest might far exceed the target in some future year. Like Table , Table provides an example for a vessel that acquires 100 pounds of QP every year; however, in this case, the vessel is mainly making use of the provision that allows it to carry over an underage. In the first year (2011), the vessel takes only 90 pounds and, therefore, has 10 pounds left over. In the second year, it also makes use of the carryover provision, acquires 100 pounds, taking 10 pounds of QP from the previous year, and leaving 10 pounds unused. Its total harvest in the second year is 100 pounds. Because overages cannot be carried over for more than one year, it cannot accumulate more than 110 QP in its account (unless it increases its annual acquisitions to more than 100 pounds). In this example, the vessel uses its entire QP balance in 2014, runs a surplus in 2015, then uses its surplus in 2016 and runs a deficit, using QP from 2017.

Table A-80. Example—carryover of unused QP.

	2011	**2012**	**2013**	**2014**	**2015**	**2016**
QP Acquired by the Vessel During the Year	100 lbs.	100 lbs	100 lbs.	100 lbs	100 lbs	100 lbs
QP Available for Use in the Year	100 lbs	110 lbs (100 + 10)	110 lbs (100 + 10)	110 lbs (100 + 10)	100 lbs	110 lbs (100 + 10)
Unused QP	10% of 2011 QP acquisitions	10% of 2012 QP acquisitions	10% of 2013 QP acquisitions	0%	10% of 2015 QP acquisitions	-10% of 2016 QP acquisitions (fishes on 2017 QP)
QP debits for year (catch for the year)	90 lbs.	100 lbs.	100 lbs.	110 lbs.	90 lbs.	120 lbs.

QP not associated with a vessel would be zeroed out at the end of the year (e.g., QP held by a crew member, processor or community that have not been transferred to a vessel would not be carried over). In order for a surplus to be eligible to carry over to the following year, the QP would have to be transferred to a vessel's account. As discussed in the section on rationale, this creates an incentive to transfer QP to vessel accounts. Additionally, when the Council took final action, it decided to require that all QP be transferred to a vessel account during the year.

- Impacts on Trawl Sectors

♦ *Effect on Total Harvest*

In any particular year, the trawl sector could collectively harvest either more or less than its sector allocation for a species, if enough vessels use the carryover provision in the same way (i.e., many carry over a surplus or many carry over a deficit). If the collective result is that the sector as a whole carries over a surplus QP, this could result in underharvest of the ABC/OY in one year, and a carryover of a surplus can become an amount in excess of the sector allocation in the following year, if the fleet takes its full allocation plus the carryover. This possibility will have to be integrated with the future FMP amendment for establishing annual catch limits (see below – Effect on Flexibility). However, it may also develop as a onetime deferral of harvest, as has occurred to a certain degree for some species in the B.C. trawl fishery. In the B.C. trawl fishery, harvesters consistently carry over QPs for many species from one year to the next. Often, it is as much as 30 percent. This means that for those species about 70 percent of the current year's groundfish is harvested (rather than the full allocation), and 30 percent of the previous year's allocation (the surplus carried over) is also harvested. If the same behavior occurs in the west coast trawl fishery, as much as 10 percent of some species may go unharvested in the first year only; in each subsequent year, that 10 percent would be harvested in the next year along with 90 percent of the current year's QSs. In other words, 100 percent of the ABC/OY trawl allocation would be taken in year 2 and beyond, although the allocation would come out of two different years.

♦ *Effect on Flexibility*

MSA specifies an annual catch limit that cannot be exceeded in any given year without invoking the "overfishing" label. However, the groundfish FMP has not yet been amended to comply with the annual catch limit requirements. Conceivably, the FMP amendment to address ACL could contain buffers or multi-year nuances that would allow the carry-over provision to function on a year-to-year basis while not violating annual limits. Any carryover amount would either have to be under the annual catch limit to keep the fishery in compliance with the MSA, or the FMP amended to show how the carryover of any underage or overage meets the conservation and rebuilding targets without causing overfishing. Those species that currently have an OY set equal to the ABC and that are predominantly caught in the trawl fishery might be especially problematic and include the following:

Species with OY set to ABC
Yellowtail rockfish
Shortbelly rockfish
Black rockfish (WA and OR/CA)
English sole
Arrowtooth flounder

For overfished species, OYs are set below ABCs and harvest in excess of the OY might be allowed in a single year but not on average, so long as the rebuilding plans are revised to take into account the potential overage and ensure that rebuilding targets are not compromised.

A carryover provision might help address the problem created by the rebuilding paradox, depending on how quickly science and management are able to catch up with conditions on the grounds. Under the rebuilding paradox, the lag between when a stock makes rebuilding progress and the adjustment of management restrictions to reflect the increased biomass creates a situation in which fishermen encounter a rebuilding stock at higher rates before management measures can be relaxed based on the stock's improved health. Under such circumstances, the need for QP to cover overfished stocks that are

caught incidentally will increase prior to the time catch limits are increased to accommodate increased retention. This mismatch between management measures and conditions on the grounds would create a shortage of QP. Some of that shortage might be covered by fishing on a subsequent year's QP, however, unless OYs are increased in the following year, the deficit fishing in a current year will reduce supply in a subsequent. This fluctuation in supply will impact markets, as described in the following section.

- Impacts on Market Conditions

Carryover provisions affect the markets through two related mechanisms: the nature of the QP as a commodity and the amount of QP supply available in a year.

In terms of the nature of the QP commodity, without a carryover, the value of the QP goes to zero at the end of the year. Thus, at the end of the year, there would be no incentive to hold on to unused QP, and all QP would likely be released into the market. With a carryover, up to 10 percent of the QP will have some value for use in the following year. In particular, for overfished species that may be high-priced and relatively unavailable, even if the end of year prices are very high, vessels may hold on to overfished species QP as insurance against the consequences of a disaster tow in the following year (see the analysis on Element 6 in Section A-2.2.1, for additional discussion of this issue). Thus, with a carryover, those witH QP that could be sold would have more to lose buy selling the QP than if the QP expired at the end of the year; with a carryover, the sale of QP will entail the loss of opportunity for its future use, while, without a carryover, sale of unneeded QP would not entail any lost opportunity with respect to its use in the following year. Whether the price is higher or lower as a result of this change in the nature of the commodity will depend on the balance between the effect of the carryover on nature of the commodity and its effect on the total supply of QP at particular points in time.

The other main market implication of a carryover provision is its effect on variability in the short-term supply or short-term price fluctuations. As an example, the opportunity to cover QP overages witH QP from a following year increases the total QP available in the first year, but any increase in the amount consumed in one year will result in a decreased availability the following year (across all years there is not a net increase in the total supply). Thus, with a carryover, there may be a wider swing in the total amount of QP that may be available to the market in any particular year.

- Impacts on Conservation of the Resource

Without a carryover provision, any fish that are unharvested one year would remain to contribute to biomass, but the underage would be accounted for in stock assessments, and some subsequent increase in allowable catches would be expected.

Carryover provisions might also have some biological risks and potential benefits. One benefit is that vessels may be more likely to choose to avoid harvesting 10 percent of certain species, thereby giving themselves a buffer in the following year against accidental or unanticipated catch. Under such circumstances, some of the fish are left in the water a year longer, allowing them to continue to contribute to biomass. Without a carryover provision, vessels would be trying to fish as close as they could to their maximum allowable harvests without incurring a violation. On the other hand, if fish are removed earlier through fishing on QP from a subsequent year, there may be an increment of adverse impact on biomass. However, either way, because carryovers are limited to one year, and a surplus or overage one year simply either increases or decreases what can be harvested in the subsequent year, and because of the generally long-lived nature of the groundfish species, relative to achievement of target harvests under status quo management, the impacts of a carryover provision on stock conditions are not

expected to be significant. On average, the annual targets for removals and harvest thresholds such as ABCs will not be exceeded; at worst, there is a onetime advance or delay in 10 percent of the harvest. For overfished species, meeting the annual targets on average and the onetime advance or delay may be permissible if the policies are taken into account in the rebuilding plans.

This concept of hitting the target harvest amounts "on average" is complementary to the OY concept. The OY is a target to be achieved over the long term. One exception is for rebuilding species where the OY is a hard cap that should not be exceeded in a given year, unless accounted for in the rebuilding plan. If the carryover provision is applied to rebuilding species QP, as indicated, rebuilding plans may have to be amended. For healthier groundfish stocks (where OY is set below ABC), there may be more management flexibility to allow OY overages so long as the OY is achieved on average. Whether the carryover provision is appropriate for a particular stock will depend on whether the OY is set below the ABC and, for overfished species, on whether the carryover provision is accounted for in the rebuilding plan. Currently, there are only three nonoverfished species that are covered by the final scope of the IFQ program and for which the OY is set equal to the ABC: yellowtail rockfish, English sole, and arrowtooth flounder (for all other species, the OY is set below the ABC, creating an opportunity to use the carryover provision without violating MSA standards).

Managing the trawl fishery by achieving the OY "on average" could also be facilitated by creating a buffer for the trawl sector, a general buffer to cover overage by any sector (including trawl), or a two-year or a multi-year OY/ABC. These considerations must comply with the MSA and will be explored further during the development and analysis of Amendment 23 - Annual Catch Limits (ACL) for the groundfish fishery. At one extreme, to achieve the needed buffer, the OY could be set far enough below the ABC to accommodate the possibility of all vessels harvesting in a single year the 10 percent carryover from the prior year, plus all the QP for the current year, plus the 10 percent overage to be deducted from the following year. That would be one extreme. The other extreme would be that all vessels under-harvested all species each year by 10 percent and never sought to harvest the surplus of QP in the following year, creating a 10 percent surplus in the first year, but taking the target amount of harvest in each subsequent year (90 percent plus 10 percent carryover from the previous year). It is likely that neither extreme will be the actual situation, although all possibilities will be analyzed in the ACL FMP amendment. In addition, stock life history characteristics[76] should be considered, as well as a strategy for incorporating new stock assessment information in the middle of a management period. While an OY could be set for a multi-year period, QPs would be issued annually. The GMT suggested that the carryover QP could be reduced by the same percentage that the OY is reduced to address the concern that the carryover has the potential to be detrimental to stock management if there is a substantial reduction in OY from one year to the next. In the B.C. program, managers reserve the right to retract or alter the carryover QP if necessary for conservation purposes. The Council included in the final preferred alternative the ability to reduce the individual carryover of surplus QP by the same percentage as the OY is reduced for that species, as well as adjusting the carryover through the biennial harvest specifications process.

● Other IFQ Programs with a Carryover Provision

Several domestic and foreign IFQ programs utilize a carryover tool to provide increased flexibility to individual harvesters and allow for various fishing strategies. Typically, QPs carry over for only one

[76] Faster growing stocks with shorter mean generation times and fewer age classes should probably be managed with shorter OY periods. The most constraining rockfish stocks on the west coast (i.e., cowcod, canary, and yelloweye rockfish) have many age classes in their populations and might be better managed with longer OY periods. Factors such as mean generation time and recruitment variability may be important considerations in selecting a risk-averse multiyear OY period.

year due to administrative/tracking burdens and biological risks of extending carried over QP for several years.

Some carryover provisions are symmetrical where the percentage that can be carried over or carried back is the same. For example, the Southeast Australia trawl fishery has a symmetrical carryover provision, which started at 10 percent and later increased to 20 percent.

Iceland has an asymmetrical provision where a 20 percent underage can be carried over, but only a 5 percent overage carried forward. In the Icelandic management program, about 60 percent of harvesters carry over a surplus while only about 10 percent carry over a deficit (Sanchirico, *et al.* 2005). A general pattern in QS management programs is that the carryover provision for a surplus is used to a greater degree and to a larger volume than the carryover provision for a deficit.

Nova Scotia had a graduated carryover schedule that depended on the total overage amount. As the total overage amount grew, the greater the number of next year's QP it would take to cover one pound of overage. For example, if the overage was in excess of 20 tons, three QP from the next season would be carried back to cover one QP of overage. However, due to a court case that deemed those graduated ratios as overly punitive, the Nova Scotia program has since reverted to a one-to-one ratio.

New Zealand no longer has a 10 percent carry-back provision, and now overages must either be covered by purchasing QP within the same fishing season/year, or by making a payment based on the deemed value of the overage.

The North Pacific region of the U.S. has a number of IFQ, cooperative, and rationalization programs, but only one has a carryover provision. The halibut and sablefish IFQ program, the first to be developed in the North Pacific, has a 10 percent carryover provision for both surplus and deficit quota. All subsequent rationalization programs in Alaska, including pollock cooperatives, Community Development Quota, crab rationalization, rockfish pilot program, and the head and gut trawl catcher/processor LAPP, do not have carryover provisions. Applying the carryover/under to halibut/sablefish QS has proven difficult to implement. In the halibut/sablefish regulations, the carryover provision is required to follow the QS. Because QS and QP can change hands many times throughout the year, it is not simple to follow the QS, determine how they are fished, and then deduct or add on carryover pounds to the following year's QS. Furthermore, the carryover/under calculation is not done until the TAC is established by IPHC in late January, which delays the ability of fishermen to sell QS because they are not able to tell the buyer exactly how many surplus or deficit QPs are tied to the QS until close to the start of the season. The administrative burden of the carryover provision in halibut/sablefish is high, due to the structure of the carryover provision and the timing of the catch reporting and annual quota issuance. This IFQ program is specifically designed to avoid the need to track QP back to QS holders, and, for that reason, the carryover provisions only apply to QP in a vessel account.

The groundfish trawl fishery in British Columbia has similar species and gear types to the U.S. west coast groundfish LE trawl fishery. The British Columbia individual vessel quota (IVQ) program has a symmetrical 30 percent carryover provision for most species. Anecdotal accounts report that most harvesters attempt to carryover the full 30 percent each year for many species. Species with low TACs have low or no overage allowances. If catch exceeds the allowed overage, QP must be obtained to match the catch overage within 30 days or before the next fishing trip. Until the catch overage is covered by the QP in the fishing area where the overage occurred, the fisherman is restricted to mid-water trawl fishing for the remainder of the fishing year.

In the B.C. system, anyone owning a vessel license is allowed to carry over a surplus or deficit up to 30 percent of pounds held.[77] In the instance where catch exceeds the allowed carryover of a deficit, catch can be retained, but the revenue from that catch must be relinquished to the Canadian Groundfish Research and Conservation Society, an organization that conducts research for the benefit of the fishery. The Society is responsible for securing the monies owed. In addition, the pounds of fish caught in excess of the overage allowance are deducted from next year's allocation. The B.C. experience has been that penalties for violations of carry-back provisions have only been assessed twice in the past seven years. The British Columbia Groundfish Trawl Management Plan can be accessed through: http://www-ops2.pac.dfo-mpo.gc.ca/xnet/content/.

The following table indicates that the B.C. fleet under-harvested targets far more often than they exceeded targets. The number of TACs exceeded and the amount by which they were exceeded are significantly lower in the last three years, as compared to the first three years of the program.

Table A-81. British Columbia Groundfish Total Allowable Catch Overages.

Fishing Year	Number of TACs	Number Exceeded	TACs Exceeded - Species (Percent Over)
'97-'98	54	3	Silvergray Rockfish, Area 5C/D (3.34%) Pacific Ocean Perch, Area 5E (1.04%) Roughey Rockfish, Coast wide (10.30%)
'98-'99	52	5	Yellowtail Rockfish, Rest of Coast (0.11%) Silvergray Rockfish, Area 5C/D (2.62%) Pacific Ocean Perch, Area 5E (4.79%) Pacific Hake, Coast wide (7.72%) Pacific Hake, Joint Venture (10.33%)
'99-'00	52	5	Yellowtail Rockfish, Area 3C (5.40%) Yellowtail Rockfish, Rest of Coast (3.61%) Silvergray Rockfish, Area 5E (3.12%) Pacific Ocean Perch, Area 5E (3.65%) Pacific Hake, Joint Venture (4.00%)
'00-'01	53	2	Yellowtail Rockfish, Rest of Coast (4.78%) Pacific Ocean Perch, Area 5E (2.92%)
'01-'02	53	2	Yellowtail Rockfish, Rest of Coast (0.77%) Pacific Ocean Perch, Area 5E (2.92%)
'02-'03	54	1	Yellowtail Rockfish Area 3C (0.87%)
'03-'04	54	3	Silvergray Rockfish, Area 5E (7.80%) Pacific Ocean Perch, Area 5E (2.43%) Sablefish, coast wide (8.32%)
'04-'05	55	2	Silvergray Rockfish, Area 5A/B (1.24%) Pacific Ocean Perch, Area 5E (10.86%)
'05-'06	56	1	Pacific Ocean Perch, Area 5E (4.00%)
'06-'07	58	1	Pacific Ocean Perch, Area 3C (11.13%)

Source: http://www-ops2.pac.dfo-mpo.gc.ca/xnet/content/Groundfish/GFTrawl/GfTrawlInfo.htm

The TACs are adjusted each year based on the previous year's overage or underage. Thus the yellowtail rockfish TAC that was exceeded in the 2002 to 2003 fishing year had been reduced by an amount equal to 2.92 percent of the 2001 to 2002 TAC (if the 2002 to 2003 TAC had not been adjusted downward due to the previous year's overage, the harvest would have been within the unadjusted 2002 to 2003 TAC).

[77] Overages are set lower for some species including hake (15 percent), Pacific cod in certain areas (0 percent), and halibut (15 percent underage, 0 percent overage) to safeguard against an undesirable deviation from the TAC.

Because there is 100 percent observer coverage in the Canadian system, the small percent overage estimates are more likely to reflect actual overages than would be the case if such an estimate were derived for the current U.S. west coast bottom trawl fishery.

Social Benefits versus Net Economic Benefit Trade-Off

This section summarizes the effect of the carryover provision by looking at it from the perspective of the impacts of not having a carryover provision.

Without the carryover provision, the following would occur:

- There would be less flexibility, and it would be more difficult for harvesters to take all of their own QP without risking overages and penalties. Alternatively, they may reap some benefit from most of their QP and avoid the risk if, as they reach their limits, they sell their left over QP rather than trying to harvest it.
- If there are more overages, more penalties would have to be imposed. There would be associated enforcement and administrative costs with these other penalties.
- There would be a downward influence on the end-of-year QP price due to their expiration at the end of the year (no one would hold on to QP in anticipation of being able to use them in the following year).
- Supply of QP in a year would be more consistent because QP could not be moved between years. [With a carryover, more QP made available on the market and used one year would mean less available on the market in the subsequent year. Greater fluctuation in supply would tend to influence more price fluctuation, with prices being lower some years and higher others.]
- Adjustments to OYs, trawl allocations, buffers, and rebuilding plans would not be required to keep the system in compliance with the MSA.
- Any surplus QP from one year would not be taken in the next year and would be left to contribute to ecosystem processes.

A-2.2.2.c Quota Share Use-or-Lose Provisions

❖ *Provisions and Options*

This section was deleted from the final preferred alternative but the numbering is being maintained as a placeholder so as not to change section numbering and corresponding references in the analysis. Since the Council spent a considerable amount of time considering this issue, the rationale for its action and analysis is preserved here.

Before its deletion, the provision was as follows:

None. The need for this provision will be evaluated as part of the program review process, and the provision could be added later, if necessary.

❖ *Rationale and Policy Issues*

A use-or-lose provision would require that QS (converted to QP) be actively fished within some time period or the QS would have to be surrendered (possibly to be reallocated). While there was a strong desire to include methods to ensure that available QP would be used, no use-or-lose provision was included in the IFQ alternative because of effectiveness and tracking and monitoring obstacles. In the PPA, despite there being no use-or-lose provisions, the section was left in as a signal of the Council's strong concern about this issue and intent to evaluate it during the five-year review process. At that time, based on program performance, it would reconsider whether the administrative costs of such a provision would be worth bearing. When it adopted its final preferred alternative, the Council decided not to highlight this issue over others that would be evaluated during the review process. Therefore, it directed that this section be removed.

Concerns motivating consideration of this provision stem from a desire to ensure that one of the primary Council goals for the groundfish fishery is met: full utilization within biological constraints. A use-or-lose provision would prevent the reservation of quota by persons who may not use it for a variety of reasons including withholding QP for key species in order to exert market leverage, or withholding QP to impose more restrictive conservation measures than those determined by the Council and NMFS to be necessary to achieve OY levels. Nonuse of QS/QP may adversely affect objectives for the IFQ program related to net benefits and efficiency, fairness and equity, sector health, labor opportunities, community benefits, impacts on small entities, and new entrants. While the Council has not adopted a use-or-lose provision at this time, it is the Council's intent that the Federal government, acting under the authority of the MSA, not abdicate its role in determining the appropriate level of removals.

A number of use-or-lose provisions were considered for inclusion in the current program, but were rejected because of tracking costs; absent an adequate tracking program, it would be easy to evade the use-or-lose provision. For example:

- Use-or-lose Provision: Require a minimum amount of QS/QP usage to retain ownership (e.g., some minimum poundage landed within x number of years to keep active status), otherwise the QS is revoked and redistributed (e.g., the QS could be divided among the active participants proportionally to their QS holdings, allocated to new entrants, crewmembers, etc.). Time periods considered included use in at least one in three years and in at least three in five years.

In deciding not to pursue development of a use-or-lose provision at this time it was noted that the accumulation limit provision would make it somewhat more difficult for a single entity to acquire and not use significant amounts of QS/QP. However, there was still some concern that multiple entities

might acquire QS/QP and withhold use in concert with one another. It was also noted that once the program is in place it may become more difficult to add a use-or-lose provision.

❖ *Interlinked Elements*

There are certain provisions of the program that make the use-or-lose provision more of a concern than it might otherwise be. One of these is the rule on who is eligible to own, which is specified so as to include many who do not have direct links to the fishery. It had been suggested that this provision might be narrowed to reduce that concern. The TIQC recommended achieving the intent of a use-or-lose provision by adding a new provision to the IFQ alternative that requires that all QSs be assigned to a vessel with a LEP. The rationale was that while it would not require the vessel to fish that quota, the need to obtain cooperation from the vessel owner in order to own and withhold shares could still serve as a partial, though not insurmountable, deterrent. There was also mention of including processors in the group eligible to own QS. However, this recommendation would run counter to a significant feature of the program, the facilitation participation by crew and communities though QS ownership.

Also making the need for a use-or-lose provision a concern is the question of whether the QS control limits will be effectively enforced.

While a use-or-lose provision penalizes non use, a carryover provision for underages (Section A-2.2.2-b) would be designed to accommodate non use. If both use-or-lose and carryover provisions are included in the program, nonuse threshold levels for the use-or-lose provision would have to be set to accommodate carryover provisions. Carryover provisions may be an important part of an effective IFQ program because in a multispecies fishery, catching almost 100 percent of all QP without exceeding some QP holdings would likely be impossible.

To encourage use, the Council added a provision requiring that all QP be transferred to a vessel in the year for which they are issued.

❖ *Analysis*

The use-or-lose provision affects conservation and socio-economic objectives (e.g., efficiency, sector health and communities).

These will be covered in the following sections:

- Likelihood of Nonuse
- Conservation
- General Socioeconomic Objectives
- Program Costs and Effectiveness
- Experiences in Other Programs

● Likelihood of Non Use

The concern that entities might acquire and hold significant amount of QS is partially mitigated by the control accumulation limits, if they can be effectively enforced and depending on how entity and control are defined; for example, whether several entities working separately for the same purpose (perhaps to drive up market prices, limit a competitor's business, or reduce total fishing impacts) would be considered to control the QS in aggregate and, therefore, be in violation of the control limits. With respect to attempts to drive up prices by restricting the market, in a typical production situation, an

entity attempting to manipulate the market would benefit both from reduced production costs and increased price of their output. Unlike the typical production control situations, it costs the QP holders virtually nothing to "produce" their product in a given year (the QP); there are no variable costs of production. Further, the amount QP holders produce is predetermined by their QS holding. With no "cost savings" from withholding production, the price increase they receive for what they sell must be enough to offset the normal market price of the QP withheld. Additionally, even if, despite accumulation limits, someone is able to effectively exert some control over QP market prices, it is likely that, by the end of the year, it will be in that individual's financial interest to release nearly all of its QP rather than earn zero revenue on the portion of its QP inventory that expires at year end. This reduces the likelihood that there will be nonuse motivated by the intent to control market prices will occur. On the other hand, in certain circumstances, it might be possible for an entity like a processor to gain advantage by withholding QS to adversely affect a competitor. For example, if a processor held substantial amounts of QS that it used for vessels from which it received deliveries, and if over a period of time those vessels had been able to avoid a key bycatch species (such as an overfished species), rather than selling the QP to further increase its revenue, that processor might withhold its unneeded QP from the market if it could gain advantage by adversely affecting a competitor's production and profits. Another concern regarding the possibility that significant amounts of QS/QP might be withheld from the fishery is that a number of entities might acquire QS and withhold QP with the intent of reducing fishing related environmental impacts.

- Conservation

Nonuse of QS (i.e., not using the associated QP) would decrease mortality, which could benefit the resource if the Council and NMFS have allowed harvests in excess of that which is advisable. If the harvest levels are appropriately set with respect to conservation objectives, the environmental effect of the reduced protein production would depend on the food sources to which people turn as an alternative to fish protein and the relative impacts of producing that food as compared to the fish protein.

A use-or-lose provision could increase impacts on the stock if it encouraged the vessel to harvest fish and discard them, just to use their QP and avoid QS forfeiture. This might occur if the provisions required harvest of amounts that are more than a commercial vessel would normally take (given species availability and market conditions). If a use-or-lose provision is eventually developed, certain species might be exempted, such as those that are under a rebuilding plan or for which the Council might otherwise specify a special precautionary status.

- General Socioeconomic Objectives

In general, the socioeconomic objectives of the program require that groundfish be harvested at sustainable levels that also meet other conservation objectives, such as rebuilding. Any actions that withhold QP and reduce harvest to below those levels is likely to diminish the achievement of socio-economic objectives. If it turns out that a use-or-lose provision is unnecessary, having deferred its creation will have been socially and economically beneficial in reducing the complexity of the IFQ program and implementation costs. On the other hand, if problems develop, and such a provision is needed, it may be more costly to implement at a later time because it will involve the disruption of existing expectations and practices.

- Program Costs and Effectiveness

The main reason for not developing a use-or-lose provision was the heavy cost that would be entailed in tracking QP usage back to the QS accounts for which they were originally issued and tracking QS

transfers between accounts, combined with the potential for relatively easy circumvention. For a vessel using QP from multiple QS accounts the data system would have to track the QS account from which the QP originated. Moreover, since QS can be traded among accounts from one year to the next, in order to avoid circumvention of the intent of the use-or-lose provision individual amounts of specific QS would have to be tracked. For example, if QS has not been used and will be subject to revocation if not used in the following year, the system would have to be set up to prevent avoidance of the use-or-lose provision through simply moving of the QS into a different account. The needed tracking system would be analogous to tracking the particular dollars used in a purchase back to the assets which originally generated them, only more difficult because of the need to also track the movement of divisible and fungible assets associated with those particular dollars as those assets moved among owners. Even if a full blown tracking system were developed, it could still be subject to circumvention given that QS are fungible, and a person withholding QS that are about to expire due to nonuse could simply sell them into the market and use the funds to purchase recently used QS.

The cost of such a program might be diminished if the number of participants were more limited than what is currently allowed under the eligibility provision. Additionally, costs of QP tracking might be reduced by a somewhat different rendering of the provision, such that, rather than tracking the QP to a QS account, (1) only the QP is tracked, (2) all QP must be transferred from a the QS holder directly to a vessel account before the end of the year, (3) any entity not meeting the lose-or-lose provision requirements would be responsible for submitting the required amount of QS for forfeiture from whatever source it could acquire it. Specifically, for example, any vessel account that does not use at least a certain percent (say 75 percent) of its QP holdings (aggregated across all species) in two successive years must forfeit the QS equivalent to one half of the unused QP for the average mix of species that went unused. This approach would keep the current eligibility rules for owning/holding QS/QP, but would ensure that QP is transferred to a vessel and avoid the need to track the QP back to its source QS. It would not entirely prevent circumvention of the provision, but circumvention would require the cooperation of more than one vessel.

- Experiences in Other Programs

The following describes experiences in two Canadian programs that did not start out with use-or-lose provisions (B.C. has implemented one more recently). One of the reasons this issue has been less of a concern for either the B.C. or Nova Scotia fishery is the qualification requirements that quota purchasers must meet. These requirements (e.g., vessel ownership) make speculative activity or ownership without harvesting more expensive and difficult.

British Columbia - There have not been any use-or-lose provisions or other design elements implemented to discourage underutilization of QP. However, there are design elements that became active in April 2005 to help prevent speculative activity and "armchair fishermen." In April, quota owners were required to harvest 25 percent of groundfish equivalent (GFE) or they would lose that 25 percent minus the rollover allowance. This will increase to 40 percent after three years and last for four years. In addition, the number of permanent reallocations (quota transfers) will be restricted to two over each of those periods of time. Purchase of quota by environmental groups that would not harvest what they owned has never been a big concern.

Nova Scotia - There are no use-or-lose provisions or other design elements implemented to discourage underutilization of QPs. Currently, there are "armchair fishermen." Approximately one-third of the "fleet" (100 out of 350 quota owners) leases out all of their pounds each year to other fishermen.

Note: In order for an entity to hold pounds and not harvest them, the entity would have to either purchase quota or purchase pounds each year. In order to purchase quota or pounds, the entity would have to own a groundfish license for the IVQ fishery. To own a groundfish license, a license holder has to be a full-time fisherman. This is defined as a person with two years of experience fishing for seven months each year. The Nova Scotia fishery representatives contacted believe that the expense to hire a fisherman not to fish would be significant.

A-2.2.2.d Entry Level Opportunities

❖ *Provisions and Options*

Under the MSA, the Council is required to consider entry level fishermen, small vessel owners, and crew members, and in particular the possible allocation of a portion of the annual harvest to individuals falling in those categories. No special provisions have been identified for analysis, given that new entry is addressed indirectly by allowing crew, captains and others to acquire QS in small increments.

❖ *Rationale and Policy Issues*

Section 303A(c)(5)(C) of the MSA requires that in developing a LAPP, the Council do the following:

> Include measures to assist, when necessary and appropriate, entry level and small vessel owner-operators, captains, crew, and fishing communities through set-asides of harvesting allocations, including providing privileges, which may include set-asides or allocations of harvesting privileges, or economic assistance in the purchase of quota [78]

The MSA requires that the Council consider, and, <u>if appropriate</u>, provide additional measures to benefit the named groups. The Council has considered these groups, and certain other elements of the program have been designed with impacts on these groups in mind, including the following:

1. Allocating based on the history of the permit, allowing new entrants to receive a greater initial allocation than they would if the allocation were based just on their personal history in the fishery (Section A-2.1.1).
2. Including an equal allocation component as part of the initial allocation formula for permits, this will benefit historically smaller producers (Section A-2.1.3).
3. Not including a minimum holding requirement provision; this might be more difficult for smaller vessels to comply with than larger vessels (A-2.2.1).
4. Specifying a broad class of eligible owners that includes crews and fishing communities (Section A-2.2.3.a).
5. Specifying that the QS/QP be highly divisible so as to facilitate the acquisition of QS/QP in small increments by crewmembers, those who have just entered the fishery, and operators of small vessels (Section A-2.2.3.d).
6. Including provisions for a set-aside, as needed, to support an AMP that may be used at some future time to address community concerns or create other incentives to benefit the groups listed in 303A(c)(5)(C) or for other purposes (Section A-3)

The TIQC also debated and reported to the Council options for a loan program and a provision that would allocate shares forfeited through a use-or-lose provision to new entrants. The TIQC did not recommend that the Council adopt the loan program because the rationalization program already has high costs, and the program would act as a subsidy that might drive up QS prices. The use-or-lose provision was not included as part of the package because of implementation obstacles. The TIQC also noted that providing a central lien registry would facilitate obtaining financing by increasing security in the collateral, reducing risk and, therefore, lower interest rates. This would benefit new entrants. Such a registry, while required by the MSA, has not been implemented.

[78] An **Assisted Purchase Program** may be developed to aid in financing quota purchase by small vessel fishermen and first-time purchase by entry-level fishermen (MSA – 303A(g)(1)).

❖ Interlinked Elements

The section on rationale contains of list of provisions that were considered adequate to address the concerns about entry level opportunities. If those provisions are modified, consideration should be given as to whether the provisions are still considered to adequately address the congressional direction provided in MSA 303A(c)(5)(C).

❖ Analysis

Much of the focus in developing the program is on the impacts of those who are currently in the industry and who will benefit from receiving an initial allocation of QS. Those individuals will be in an economically stronger situation. The value of the QS they receive will be a stream of resource-related rents (additional profits). Because of the infusion of wealth provided by the QS, they will likely be in an economically better position to bear the brunt of increasing fuel prices, program costs, and, if it should occur, declines in the available harvest. As holders of the QS, they will also accrue the benefits that occur from factors that increase the value in the fishery.

However, over the long term, the constituents of the commercial fishery who come before the Council will be those who at one time or another have been new entrants. New entrants who choose to own QS will have paid an amount for their QS based on the best projections of future profits after taking into account expected fuel prices and other production costs, including observer costs, expected ex-vessel prices for raw fish, expected harvest levels, and, significantly, the cost of the QS. If it turns out that costs are greater than expected or revenue is less than expected, they will not have the same revenue buffer initial QS recipients have. Under such circumstances, a new entrant may experience below-normal levels of profit, possibly even similar to those seen in the status quo fishery. At the same time, if costs are lower or revenues higher, they will experience a higher than expected return that will not be dissipated by increased competition. Thus, the IFQ program provides some expectation of more stable profits even for second-generation participants who choose to own QS. However, second-generation participants need not necessarily take on the risk of QS ownership.

The need to acquire quota will add to costs for second-generation owners, as compared to those who came before. In addition to paying for the physical capital (vessel, etc.) they will have to acquire QP each year and may choose to do so by making a capital investment in QS (by acquiring QS). By owning their own QS, they would control their risk with respect to changing QP prices. However, by holding their own QS, they will bear risk and reward from the changing value of the QS asset (increases, if there is a trend toward higher vessel costs or lower revenue, or decreases if conditions move in the other direction). If there were not an IFQ program, entering the fishery would require less of an investment, but revenues would likely be lower. Assuming that all extra profits (resource rents) under status quo are dissipated, the fishery would have similar downside risks, but less upside potential as compared to a fishery managed with IFQs. Upside potential would be lower under status quo because higher than expected profits would likely be dissipated by increased competition. If harvesters enter the fishery and chooses not to acquire QS, but rather to lease QP, the capital investment will be lower, they will not risk the potential decline in value of the asset they purchase, they will have a more limited benefit from any long-term improvement in economic conditions in the fishery, and, if they are able to be competitive, will fish at a normal profit level througH QP they buy during the season or are provided by processors. [Note: a normal profit implies zero economic profit but sufficient profit to compensate for their investment.]

No specific provision is provided here, but there are a number of provisions in other parts of the program that address the concern of MSA 303A(c)(5)(C). The impact of those provisions on entry level, crew, small entity, and community opportunities are discussed in the sections on those other provisions.

A-2.2.3 IFQ Transfer Rules

A-2.2.3.a Eligible to Own or Hold

❖ *Provisions and Options*

► No person can acquire QSs or QPs other than 1) a United States citizen, 2) a permanent resident alien, or 3) a corporation, partnership, or other entity established under the laws of the United States or any State, that is eligible to own and control a U.S. fishing vessel with a fishery endorsement pursuant to 46 USC 12113 (general fishery endorsement requirements and 75 percent citizenship requirement for entities). However, there is an exception for any entity that owns a mothership that participated in the West Coast groundfish fishery during the allocation period and is eligible to own or control that U.S. fishing vessel with a fishery endorsement pursuant to sections 203(g) and 213(g) of the AFA.

> Previous language: "Those eligible to own QS/QP will be restricted to (i) any person or entity eligible to own and control a US fishing vessel with a fishery endorsement pursuant to 46 USC 12108 (general fishery endorsement requirements) and 12102(c) (75 percent citizenship requirement for entities) and (ii) any person or entity that owns a mothership that participated in the West Coast groundfish fishery during the allocation period and is eligible to own or control that US fishing vessel with a fishery endorsement pursuant to sections 203(g) and 213(g) of the AFA."

❖ *Rationale and Policy Issues*

Section A-2.2.1 dealt with who receives an initial allocation. Here the issue is "Who is allowed to acquire QS/QP in the future?"

The Council's policy intent for the permit system on which the trawl rationalization program is built (the Amendment 6 license limitation program) is to require that an entity must be eligible to own a U.S. documented fishing vessel in order to hold a permit. It is important to note that actual vessel ownership is not required, only eligibility to own a vessel. In developing the ownership eligibility provision for the IFQ program, the Council's intent was similar, i.e., to allow those eligible to own a U.S. documented fishing vessel (i.e., to own a permit under the Amendment 6 program) to own QS. In developing language to implement its intent, the Council checked the MSA provisions on who should be restricted from holding a LAP (QS/QP), and the NMFS LE program website has forms indicating who is eligible to own a LEP in the current permit system. On the basis of the latter information, the Council included legal resident aliens in its specification of those eligible to hold QS/QP. Additionally, the Council provided an exception to provide certain foreign entities with an opportunity to hold QS/QP based on their status under the AFA and participation as a mothership owner in the west coast at-sea whiting sector.

The following are some of the intents for this provision that were identified by the TIQC during the first stages of the provision's development (related categories of objectives are in parenthesis; see Chapter 6 for a full description of the objectives):

- Allowing current participants to continue (minimizing disruption)
- Limiting foreign ownership (national net economic benefits)
- Preventing absentee ownership (sector health, communities)
- Preventing ownership by interests who might leave the QS unused (net benefits, sector health, labor, communities)

- Providing entry level opportunity for crewmembers (labor)
- Providing opportunity for community participation (communities)

The new LAPP program provisions of MSA Section 303A restrict those allowed to own QS/QP to a particular set of individuals:

> IN GENERAL.—Any LAPP ... shall—
> (D) prohibit any person other than a United States citizen, a corporation, partnership or other entity established under the laws of the United States or any State,[79] or a permanent resident alien that meets the eligibility and participation requirements established in the program from acquiring a privilege to harvest fish, **including** any person that acquires a LAP solely for the purpose of perfecting or realizing on a security interest in such privilege." (MSA, 303A(c)(1)(D), emphasis added)

In other words, the Council may allow any of the entities listed in 303A(c)(1)(D) to hold QS/QP, or a subset of those entities, but it may not allow anyone not on the list to hold QS/QP. For example, the Council could make a more restrictive eligibility provision by prohibiting corporate ownership or restricting QS ownership to vessel owners but it could not allow a foreign corporation to hold QS/QP.

According to a preliminary determination by NMFS, in the last phrase of 303A(c)(1)(D), "including" refers to being included among those allowed to acquire privileges (as opposed to being included among those who are prohibited from acquiring QS/QP). This last phrase refers to banks or other lenders that might accept the QS/QP as collateral for a loan. The Council language would allow banks and lenders to hold QS/QP, and to be consistent with 303A(c)(1)(D), these entities would need to be established under the laws of the United States or any state.

Another requirement with respect to who is eligible to own QS/QP specifies that those who substantially participate be authorized to acquire QS/QP. The definition of those who substantially participate is left to the Council.

> (5) ALLOCATION.—In developing a LAPP to harvest fish a Council or the Secretary shall—
> . . . .
> (E) authorize LAPs to harvest fish to be held, acquired, used by or issued under the system to persons who substantially participate in the fishery, including in a specified sector of such fishery, as specified by the Council. (MSA, 303A(c)(5)(E))

The Council eligibility provision is intended to include all of those who are presently substantial participants in harvesting activities, and the Council did not opt to further define "substantially participate." The first criterion of the Council's eligibility provision, (i), is intended to ensure that almost all who currently participate as harvesters would be allowed to continue, minimizing disruption while limiting new foreign entry. The current participants that might not be covered by the first criterion are those foreign entities that have participated in the ownership of motherships in the whiting fishery. The criterion of the second part, (ii), was added with the intention of including those entities that have

[79] The definition of "person" under the MSA means "any individual (whether or not a citizen or national of the United States), any corporation, partnership, association, or other entity (whether or not organized or existing under the laws of any State), and any Federal, State, local, or foreign government or any entity of any such government." (MSA, 3(36)). The persons allowed in section 303A(c)(1)(D) are a subset of this broader definition of person (MSA, 3(36). The broader definition includes persons not organized under the laws of the United States or any state. The persons prohibited from QS/QP ownership in 303A(c)(1)(D) include those not so organized.

participated on the west coast and may not have been covered by the first criterion, i.e., entities that include foreign interests and participated in the at-sea mothership sector would be allowed to hold QS/QP. More specifically, the second criterion includes entities with some foreign control that own a west coast mothership and received an exemption to the requirements of 12102(c) under Section 203(g) or 213(g) of the AFA (see discussion below regarding foreign operators). Since the Council criteria allows QS/QP ownership by those who currently participate as vessel owners, any participant who is eligible to own a U.S. documented fishing vessel, and, via the AFA exception, all owners of vessels active in the at-sea whiting sector, it might, therefore, be considered consistent with MSA 303A(c)(5)(E) to authorize participation by substantial participants. Those who do not own vessels but might be able to acquire QS/QP include, for example, shoreside processors, crewmembers, and communities. Additionally, the Council QS/QP eligibility criteria go further than MSA 303A(c)(5)(E) by allowing QS/QP ownership by, for example, those who may wish to hold IFQ to control the way in which the QS/QP is used (e.g., members of conservation organizations), individual members of the general public, those with security interest in the IFQ (e.g., a lender), and any other person (including business entities such as corporations), so long as those entities are eligible to own a U.S. documented fishing vessel.

While intentionally broad, the scope of the Council's eligibility provision is not intended to extend beyond that of MSA 303(c)(1)(D). The MSA allows foreign controlled entities organized under state or Federal laws to hold QS/QP. In that regard, the Council provision is more restrictive in that it prohibits most foreign holding of QS, as is permissible under the MSA. With respect to the requirement that entities not organized under state or Federal laws be excluded from QS/QP ownership, the Council's criterion requiring eligibility to own a U.S. documented fishing vessel was believed to be implicitly compliant because entities must be organized under state or Federal laws in order to be eligible to own a U.S. documented fishing vessel. However, to be certain that compliance was clear, the Council added to its language an explicit statement that a partnership or corporation must be organized under Federal or state law.

It should be noted that the AFA exception within the Council's eligibility provision is intended to apply to the entities in their entirety and not to the individual ownership interests that make up the entity. In other words, if a foreign entity has partial ownership of a company that controls a U.S. fishing vessel and that company has an exemption under the AFA, it is only the company that would be able to own the QS/QP. The foreign entity's participation in the AFA exempted company would not allow the foreign entity on its own acquire QS/QP.

The Council considered an option that would not allow any foreign controlled entities to control QS/QP (i.e., requiring that all entities be eligible to own U.S. documented fishing vessels). This option was rejected because it could not be determined that it would not eliminate some current participants from QS/QP ownership. The Council also considered restricting ownership to stakeholders, including owners and lessees of LEPs or vessels, skippers/crew, processors, buyers, and communities. This option was rejected (1) because of the increased cost associated with development and monitoring of the qualifying requirements for each of these groups and (2) because simple group eligibility requirements that might be easy and less costly to implement would also be easy to circumvent.

Also considered were more extreme restrictions, e.g., allowing only LEP holders to own IFQ. It was believed that such a restriction would reduce program costs by substantially reducing the number of QS/QP holders, make it more likely that QS/QP owners would be community members (make absentee ownership less likely), and make it more likely that QS/QP would be used. The substantially smaller number of potential owners might also increase the feasibility of tracking QP to the owner of the QS for which the QP was issued, facilitating implementation of a use-or-lose provision (see Section A-2.2.2.c).

At the same time, there are considerable social and equity benefits from an ownership eligibility scope that includes crewmembers, communities, and processors.

❖ *Interlinked Elements*

The main direct interdependency between the provisions for eligibility to own or hold and others is with the initial allocation criteria. Specifically, those eligible to own QS must include those eligible for an initial allocation. Mothership Option 2 of Section A-2.1.1.d would allocation QS to the bareboat charter operators of motherships. The language of the second part (ii) of the eligibility criteria was adjusted to cover both owners and operators of motherships.

❖ *Analysis*

The following are the categories of goals and objectives affected by the decision on eligibility to own and the section in which each are addressed.

Section	Related Category of Goals and Objectives (see Chapter 6 for detailed description)										
	Conservation	**Net Benefits**	**Disruption**	**Excessive Shares**	**Fairness and Equity**	**Harvester and Processor Sector Health**	**Labor**	**Communities**	**Small Entities and New Entrants**	**General Public**	**Program Performance**
Conservation and Social Impacts	X							X			X
Net Benefits and Disruption		X	X								
Sector Health						X					
Labor and New Entrants (Labor)						X			X	X	
Communities								X			
Small Vessels and New Entrants (Harvesters)									X		X
Program Performance											X

- Conservation and Social Impacts

The Council eligibility recommendation allows a very broad class of entities to own QS based on an assumption that this will lead to the highest value use of the resource within conservation limits. The broad class of individuals allowed to own QS includes conservation organizations. Conservation organizations or others who strongly believe that the Federal management system is allowing too much harvest could acquire QS and hold the QP for those shares off the market, leaving some of the available catch unharvested. However, it is also the Council's intent that the Federal government, acting under the authority of the MSA, not abdicate its role in determining the appropriate level of removals for meeting conservation objectives. Private interests withholding QP would frustrate the intent of Federal policy that is to allow for an optimum sustained yield and provide social and economic benefits from the fishery. As a result, impacts on the human environmental would change, increasing or decreasing, depending on the impacts associated with the protein sources consumers turn to as a substitute for west coast groundfish. On the other hand, if the Federal policy has not been set appropriately or is not

sufficiently risk averse, a private entity choosing to hold QP back could improve conservation. While allowing a broad ownership class, the Council has indicated that if the intent of the Federal harvest policies are being frustrated it may create a use-or-lose provision at some future time (Section A-2.2.2.c). Adaptive response of this sort would mitigate possible adverse impacts that could result from nonuse of amounts of the resources that is available within harvest constraints.

The limitation of foreign ownership may have some conservation and social benefits. If multinational corporations are not dependent on a particular coastal community or ecosystem and are able to rotate their resource extraction activities from one locale to another, they may have less concern about the long-term sustainability of fisheries in any one nation and less concern about localized effects of harvest activities. As compared to domestic firms, they may also be somewhat more independent of the influence of local and national politics. The ocean fisheries are managed as a trust for the people of the nation. The interest of the people, as expressed by their state and Federal governments through such laws as the MSA, National Marine Sanctuaries Act, and California's Marine Life Protection Act, goes far beyond the economic benefits that might accrue from sustainable removals of the resource. While the laws of a state and nation constrain behavior for domestic and international firms alike, conduct in line with general social values often goes beyond what is strictly required by the letter of the law. While it is possible that an international firm may act more strongly based on local ethics and values than a domestic firm, a firm run by domestic interests may be more likely to act within the local ethics than an international firm simply because more of the decisions will be determined by individuals from the domestic culture.

- Net Benefits and Disruption

It is believed that the greatest benefits would be achieved by providing QS/QP ownership opportunity to a very broad group. Specifying broad eligibility criteria that encompass those who value the resource to different degrees for different reasons would encourage the distribution of QS/QP in a manner that maximizes net benefits over the long run. Net benefits would be enhanced by an active QS/QP market with participation by all of those who may have some reason to value QS/QP. However, net benefits may be less than might otherwise be achieved if, as a result of the broad eligibility requirements, those who are likely to withhold QS/QP from the fishery gain control of the QS/QP. As described in the section on conservation and social impacts, the Council is aware of this possible outcome and will evaluate nonuse as part of future reviews and revision of the program.

In the rationale above, we described the Council's intent to minimize disruption of current practices by allowing ownership of QS/QP by all who currently participate as harvesters or by using mothership vessels in the at-sea whiting fishery, including those with foreign ownership interests. The language developed to achieve this end focuses on those individuals eligible to own a U.S. documented fishing vessel, including some who achieve that eligibility under exemption provisions of the AFA. The AFA exemptions incorporated into the Council eligibility provisions refer to Section 12113 (Chapter 46 of the U.S. Code). This section requires 75 percent domestic ownership and prohibits the chartering of a vessel by any entity that has some foreign ownership. The exemption of 203(g) appears to apply to both those entities eligible to *own* the vessels under 203(g) and those entities eligible to *operate* the vessels under 203(g). Section 213(g) is a catch all that provides an exemption to the AFA for any other entity that owns a vessel as of July 24, 2001, as necessary to comply with international treaty. As pointed out by the NRC (NRC 1999) (pg. 211) because of foreign ownership interest in the existing fishery, limitations on foreign ownership could be problematic and discriminate against U.S. co-owners and investors. The language of the eligibility provision was intended to be sufficiently broad to cover all participants, including processors, however, any shore based processing company that is more than 25 percent foreign owned or controlled may not be eligible to own QS/QP. We do not know whether

there are any shore based processors that do not meet the eligibility. Also bearing on the issue of foreign ownership are current trends toward the liberalization of direct foreign investment worldwide. Net benefits are generally addressed from a national perspective. On that basis, the limitation on foreign participation will likely ensure that a greater proportion of the fishery benefits accrue to citizens of this nation, as compared to a system that allows more foreign ownership. On the other hand, if foreign participation were allowed as part of general trade liberalization and if trade liberalization has a positive overall effect on total benefits that accrue to U.S. citizens, then allowing foreign ownership as part of that broader policy might generate greater domestic economic benefits.

Three motherships participate in the west coast whiting fishery and come under the exceptions provided under Section 203(g) of the AFA. Of these, at least one was believed to be operated by a company with substantial foreign ownership, although the ownership structure may have changed since the provisions were first developed.

- Sector Health

While the initial allocation would be split between harvesters and processors, over time, the eligibility provisions will allow for all of the QS to migrate to the hands of harvesters or all of it to processors (or to any other group that is able to acquire it through transfers). In the event that an extreme distribution occurs, one sector may be able to exert market power over the other and adversely affect the health of a sector. In contrast, the B.C. IVQ program allows only those who own vessels to hold QS. The Council considered a provision that would have restricted QS/QP ownership to those in the harvesting sector. If only harvesters are allowed to own QS/QP, harvesters (and processors who own vessels) could be at an advantage over other entities. There are provisions in the B.C. program intended to prevent the exclusive harvester ownership of QS from allowing harvesters to take unfair advantage of processors. Specifically the groundfish development quota (GDQ) system was designed to encourage harvesters to remain in their relationships with domestic processors. The program under consideration here, while it would not start out by restricting QS ownership to one side or the other, allows it to develop over time. Because it is not starting out with a one-sided restriction, it is also not starting out with a compensating mechanism for a one-sided distribution. If QS migrates to the hands of one group over time, the AMP would provide an opportunity to compensate for effects on the health of the adversely impacted sector.

The broad ownership eligibility criteria also allow ownership of QS/QP by entities that may acquire it and withhold it from use. This is discussed in the sections on conservation and net benefits. Such withholding of harvest opportunity would adversely affect sector health.

- Labor and New Entrants (Labor)

The eligibility criteria have been specified broadly to allow crewmembers or processing plant employees to own QS. QS/QP eligibility provides laborers a way to incrementally acquire capital assets in the fishery. The ability to acquire some capital and then accumulate wealth both from their wages and from capital ownership may allow them more rapidly to accumulate the assets they need to enter the fishery as business operators. With respect to the opportunity to incrementally become owners of capital, what applies to laborers within the industry also applies to others outside the industry looking to enter. The value of the QS/QP to those who wish to sell it and leave the fishery will be sustained, in part, by those interested in and able to enter the fishery. However, those employees that are not citizens of the U.S., not resident aliens, or not otherwise eligible would not be allowed to own QS/QP.

- Communities

It is believed likely that more benefits will flow to communities if foreign and absentee ownership is limited. Allowing the potential for entities to acquire QS/QP and withhold them from use could adversely impact communities. Of these, the Council's provision only limits foreign ownership. Absentee ownership and QS/QP withholding is not limited at this time.

Making sure that communities themselves are eligible to own QS/QP is one way the Council takes into account the needs of communities. QS/QP eligibility allows communities who so desire to increase security over their economic base, to acquire QS/QP. Under the eligibility provision, a community could, for example, acquire QS/QP and auction the QP off each year to those willing to commit the most matching QP for delivery to that community. With respect to allowing communities an opportunity to participate, the NRC study notes that some communities may be heavily dependent on fishing for social, cultural, and economic values and/or are lacking in alternative economic opportunities; and recommends that Councils be permitted to "authorize communities to purchase, hold, manage and sell IFQs" (NRC 1999) (pg. 206). The GAO notes the following: "The easiest and most direct way to help protect communities under an IFQ program is to allow the communities themselves to hold QS" GAO-04-277. In addition to allowing communities to own or hold QS and QP, CFAs may be developed in conjunction with the trawl rationalization program as a trailing amendment. Presumably, CFAs would be eligible to hold QS/QP for an express purpose benefitting communities, such as community stability, sustainability, and avoidance of economic vulnerability.

- Small Vessels and New Entrants (Vessels)

Again, the broadly specified group of those eligible to acquire QS/QP (combined with the divisibility of the QS/QP into small units, Section A-2.2.3.d) facilitates incremental acquisition and participation by small vessels and new entrants.

- Program Performance

Program cost would be minimized with a very restrictive limit on those eligible to own QS/QP because there would be fewer QS/QP accounts to track. Allowing only those with LEPs to own QS/QP would be one such option. This would limit the number of entities eligible to hold QS/QP to just fewer than 170. The very broad provision that is currently specified would allow for a large number of QS/QP accounts and would require the transfer of QP from QS holders into vessel accounts in order to be used. Depending on the groups to which an allocation will be made, as well as recent participation criteria, there might be 200 processors alone that would qualify for an initial allocation. The greater number of accounts and transactions would add to program costs. An intermediate approach would allow a class of fishery stakeholders to qualify broader than just those who hold LEPs but more limited than under the current provision. However, this intermediate approach could be more costly to implement because of the need to determine and track the criteria for membership in the various classes of stakeholders. While simple low cost criteria might be designed, such criteria are likely to be relatively easy to circumvent, making the program ineffective with respect to limiting the class of those who own QS. For example, if status as a crewmember were required, a simple low cost requirement would be that to own QS/QP, a person would have to hold a crew license.[80] However, most U.S. citizens could get a

[80] Even if a qualifying class is "licensed crewmembers," there is not consistent licensing of crewmembers or other means of crew identification among the states. Therefore, some consistent system would need to be developed to identify members in this class.

crew license without actually working as a crewmember. Therefore, to make this an effective barrier, some other provisions would be needed such as having worked as a crewmember for a certain period. The need to process documentation on crew hours and enforce the provision would add substantially to the program costs. Similar results would be expected for simple versions of processor, buyer, or community participation requirements.

A-2.2.3.b Transfers and Leasing

❖ *Provisions and Options*

QS/QP will be transferable and transfers must be registered with NMFS. NMFS will not differentiate between a transfer for a lease and a permanent transfer.[81]

Each year, all QP must be transferred to a vessel account. A penalty for not meeting this transfer requirement has not been recommended; however, this requirement is intended to encourage its availability for use by the fleet.

QP can only be transferred into vessel accounts. Once in a vessel account QP can be transferred from one vessel account to another.

❖ *Rationale and Policy Issues*

QS/QP transferability is key to the conservation, economic, and social benefits described in Chapter 4. These benefits include the rationalization of the fleet that is expected to increase efficiency and allow the industry to support 100 percent observer coverage (with the attendant conservation benefits), the ability of crewmembers to acquire QS and enter the fishery as owners, and the opportunity for communities to acquire QS and increase their control over their economic base.

- Leasing

Consideration was given to limiting leases of both QS and QP. Each year, QP will be issued to those holding QS and be valid for that year (with some exception for the carry-over provision, Section A-2.2.2.b). The sale of QP might be considered an annual lease of the QS privilege; however, such transactions are not considered a lease for the purpose of this discussion. Here, a lease with respect to QS refers to a temporary but multiyear transfer of the QS from one entity to another. For the period of the lease, the entity with which the QS is registered would receive the annual QP. For QP, a lease would be considered the temporary transfer of QP from one entity to another, within the period over which the QP is valid. Such a temporary transfer would be of limited utility, because, once it is used, the QP cannot be returned to the lessor. A QP lease might be useful if there were some a minimum amount of QP a vessel might have to have before it left port. Under such circumstances, a vessel might lease QP for species it needed, but did not expect to encounter, and then return the unused QS at the end of the trip (presumably paying a premium if they were, in fact, used). While it has been considered, a minimum holding requirement is not part of the Council's PPA.

Leasing might be prohibited in order to reduce opportunities for absentee ownership; however, such prohibitions would be difficult to enforce. Entities might easily establish private arrangements for the transfer of QS and execute those contracts through transfers with NMFS that are registered as permanent. For the same reason, the decision was made not to register lease transfers distinctly from sale transfers because it is not necessary.

Another reason for not tracking leasing is the cost and complexity it might add to the program. There is no specification in the IFQ program that the source of any QS or QP transfers will be tracked over time (i.e., like money, QS and QP will be interchangeable ([fungible]; one will not be distinguished from another, except based on who holds it at the time). This is particularly important with respect to the QP.

[81] QS may be transferred on a temporary basis through private contract (leased), but NMFS will not track lease transfers differently than any other transfer.

QP will be transferred to a single account (see Section A-2.2.1), and, once in the account, QP from various sources will not be differentiated from one another. This is expected to simplify program administration substantially compared to systems in which individuals are allowed to retain control over the QP and fish them from a vessel.

Leases can be established entirely through private contract, and there appears to be little need to incur the added costs that would be entailed in tracking leased quota separate from permanent transfers. However, for the purpose of data collection and interpretation, NMFS may have to request information on whether a QS transfer is a sale or lease and, if a lease, the duration of the transfer. NMFS will be collecting information on payments for QS transfers to evaluate program impacts. Without knowing whether a particular transaction is a lease or sale, it will be difficult to interpret and use the QS price data.

- Mandatory Transfer to Vessel Accounts

The Council was concerned about the potential for absentee ownership and nonuse of QS. A major concern has been that nongovernmental organizations or others might acquire QS and withhold it from the fishery. There is also a history in other systems of some small amounts of quota simply going unused from one year to the next, despite the opportunity cost of nonuse (e.g., Alaska sablefish and halibut IFQ). However, the Council did not want to substantially restrict ownership because of administrative expenses such a restriction would entail, the desire to provide for crewmember and community ownership of QS, and the difficulty of doing so effectively. Additionally, design of an effective use-or-lose provision was problematic (see Appendix A section on use-or-lose provision). As one step in the direction of ensuring that QP would end up in the hands of fishermen who would use it, the Council included in its provisions a mandatory requirement that all QP be transferred to a vessel during the year in which it was issued.

- Allowing QP To Be Transferred Only to Vessel Accounts

The Council developed control limits that apply to QS and vessel limits that apply to QP and set vessel limits above control limits to allow greater vessel efficiency and to provide room on vessels for QP owned by crewmembers, communities, processors, etc. However, in establishing these rules, a situation was created in which there was no restriction on the amount of QP an entity could stockpile during the year. To address this concern, and reinforce its desire to tie QS as tightly as possible to vessels, the Council specified that once issued, transfer of QP would be allowed only to and among vessels.[82]

❖ *Interlinked Elements*

Transferability is a key aspect of many provisions of the IFQ program. Without it, significant program redesign would be required. NMFS will consider all transfers permanent, and individuals will rely on private contracts to execute lease agreements. While this feature may alter the effects of the grandfather clause associated with the accumulation limits (as described in the following analysis), there are no direct interdependencies between the leasing and accumulation limit grandfather clause provisions.

[82] The Council could not tie QS directly to vessels because of its desire to allow for QS ownership by crewmembers, communities, processors, and others while maintaining a cost-effective program. Tying the nonvessel QS/QP to a vessel creates tracking and monitoring challenges that are costly to address. See the section on permit/IFQ holding requirements.

❖ *Analysis*

As noted in the rationale, QS/QP transferability is the key to performance of the program with respect to conservation, economic, and social goals and objectives. The mechanisms by which these objectives are addressed through transferability are described in Chapter 4. Transferability is necessary for the rationalization of the fleet that is expected to increase efficiency and allow the industry to support 100 percent observer coverage (with the attendant conservation benefits), the ability of crewmembers to acquire QS incrementally to enter the fishery as owners, and the opportunity for communities to acquire QS and increase their control over their economic base.

- Leasing

♦ *Net Benefits and Sector Strength*

A leasing prohibition was considered and could be attempted to reduce the likelihood of absentee ownership, increasing the likelihood that QS will be held and controlled by active members of the fishery. However, such a prohibition, if it could be effectively enforced, would reduce the flexibility businesses have in organizing their activities. For example, a harvester either would have to acquire and pay the full value of the QS, or purchase QP on an annual basis. There would be no intermediate positions through which a harvester might acquire QS at a lower cost on a shorter-term basis. Less flexibility implies lost efficiency opportunities and diminished sector strength, compared to what might otherwise be achieved. For these reasons, there is no prohibition on leasing.

♦ *Program Performance*

There is no requirement that lease transactions be registered, as distinct from sales transactions. By not registering lease transfers, there is expected to be some saving of administrative costs. Additionally, if formal leasing were registered, it would extend the life of the accumulation limit grandfather clause. Individuals would be able to benefit from longer-term divestiture of QS via lease mechanisms without reducing the total amount of QS they are able to hold under the accumulation limit grandfather clause (assuming there is such a clause, and the clause is not modified to specify that a lease would be considered the same as a sale). By not prohibiting and not requiring registration of leases, the program is simpler than it would have otherwise been.

- Mandatory Transfer to Vessel Accounts

The provision requiring mandatory transfer to vessel accounts may affect objectives related to conservation net benefits, harvester and processor sector health, labor, communities, small entrants and new entrants, the general public, and program performance. All of the objectives related to economic performance will be discussed together (all objectives the conservation and program performance objectives).

♦ *Conservation*

Conservation may be affected by this provision's impact on total harvest. Ultimately, any impact will depend on how effective the measure is (see program effectiveness). Under status quo, the Council sets target harvest levels and establishes the regulations intended to achieve them. Those targets will then be harvested if the market conditions (e.g., fuel costs, ex-vessel prices) and technical relationships (e.g., the relation between the mix of species in the catch and the species limits) allow. This is because the

harvest opportunities are open to all vessels, and no one permitted vessel may exclude the activities of another permitted vessel. Under an IFQ program, an entity may hold IFQ and exclude others from accessing that harvest. A major concern has been that nongovernmental organizations or others might acquire QS and withhold it from the fishery to implement an alternative conclusion regarding the appropriate balance between harvest and risk to the stock and ecosystem. Reducing harvest to below identified optimum levels could move the ocean stocks and ecosystem more toward an unexploited condition, depending on how reduction in groundfish stock harvest balances with human induced changes in other parts of the ocean ecosystem. This would further the "preservation" aspect of conservation with respect to the ocean environment. The net effect on the global environment depends on how people respond to reduced availability of fish protein. Increased reliance on animal protein sources from feedlots could have an adverse effect, while increased reliance on soybean or other protein sources might have a positive effect, depending on the relative resource and energy consumption of fishing operations as compared to farming and ranching operations. Conservation also has meaning relative to the preservation of renewable resources for the purpose of ongoing current and future use.

♦ *Economic Performance*

As mentioned under the assessment of the conservation impact, the OYs and allocations for the fishery are set based on a best assessment of an appropriate balance between preservation and harvest. Given that the fishery management agencies have appropriately identified an appropriate balance, any reduction in harvest will diminish short- and long-term economic performance of the fishery. A reduction in harvest would adversely impact net benefits, the health of the harvester and processor sector, payments to labor, income for coastal communities, opportunities for new entrants and small entities, and the protein and benefits received by the general public for appropriate use of a public resource. The reduction would benefit the segment of the public that places an existence value on the resource (where that existence is defined not just in terms of its presence or absence, but rather its existence at higher biomass levels that then would be provided through fishery agency management). The required transfer of QP to a vessel is intended to encourage full harvest at sustainable levels, as determined by fishery management agencies.

♦ *Program Performance*

The effectiveness of this provision will depend on its impacts on two types of behavior. One is the withholding of QP to reduce harvest intentionally, and the second is the withholding of harvest due to inattention to what might be considered best business practices, nonvessel owners with QS ignoring the opportunity to sell the QP for revenue.

With respect to the withholding of QP to reduce harvest intentionally, effectiveness of the provision will depend on whether the costs of circumvention are enough to discourage such circumvention. There are a number of ways this provision might be circumvented. They include(1) acquiring a LE trawl permit, placing it on a low-cost vessel, and transferring QP to that vessel account; (2) acquiring a LE trawl permit, enlisting or paying a nongroundfish harvester to allow the permit to be registered to its vessel, and transferring QP to that vessel account; and (3) paying a vessel with a permit to receive, but not use, QP. For any particular vessel, the amount of QP that could be "parked" in a particular vessel account would be limited by vessel accumulation limits. Whether the costs that would be related to these strategies are enough to discourage the activities will depend on the importance that some entities place on nonuse of the QS. It should also be noted that there is no time during the year by which transfers must be completed. Therefore, someone intent on withholding QP could wait until the last day of the year to effect the transfer.

With respect to leaving QP unused and ignoring revenue opportunity, for the Alaska IFQ programs where this behavior is reported, those entities that do not transfer their QP to vessels have relatively small amounts of quota in most cases. Under such a circumstance, it may be that incurring the transaction costs are not worth what is earned from the transfer. Nevertheless, the quota that has routinely gone unused in Alaska has created controversy there, and action is being undertaken to discourage such practices. This provision would force such transfers, ensuring some opportunity for the fleet to harvest all of the available QP.

- Allowing QP To Be Transferred Only to Vessel Accounts

The effect of prohibiting QP transfers other than those directly to and between vessel accounts will be mainly indirect through more effective achievement of the intent of the accumulation limits (described above in the section on the rationale for this provision). Such restrictions may have some minor effect on net benefits by restricting the types of business arrangements through whicH QP are moved through markets. Because of the fishery's multispecies nature and variability in the species mix caught on each trip, it will be difficult to hold the right mix of QP; as the season progresses, it is likely that information on potential buyers, sellers, and prices will be valuable. Such information is essential to the type of well functioning markets that lead to efficient outcomes. Given the value of that information, some entrepreneurs may set themselves up as QP brokers. Brokers provide information and transactions services, but never take ownership of the QP. Broker operations would not be restricted by this provision. Another type of entity that might otherwise be active in the market would be QP traders/distributors. Like brokers, traders provide a market service to those wishing to buy and sell quota. However, quota traders earn profits by taking on some of the risk through their possession of the QP. A QP seller needing funds and unable to find a buyer wanting the type of QP he has might find a trader/distributor willing to buy his quota immediately at a better price than the seller could get in the market at that moment. The price, however, might be lower than he might otherwise receive some other time or with a longer search. By buying the QP and taking on the risk of QP ownership, the trader/distributor provides the seller with a risk sharing and financial service that a broker would not provide. It is uncertain whether this type of trading/distributing operation would come into being in the absence of this transfer restriction. However, if such businesses would have come into existence, it would be because the service they provide would be of value to individuals and the effective functioning of the market. This provision will prevent that type of business service from developing, possibly reducing net benefits.

A-2.2.3.c Temporary Transfer Prohibition

❖ *Provisions and Options*

NMFS may establish temporary prohibitions on the transfer of QS, as necessary to facilitate program administration.

►**Option:** QS will not be transferred in
SubOption 1: the first year
►SubOption 2: the first two years
of the program (QP will be transferable)

❖ *Rationale and Policy Issues*

Two types of temporary transfer prohibitions are covered in this provision:

(1) An annual QS transfer suspension for administrative necessity
(2) A QS trading moratorium at the start of the program to provide an adjustment period

The Council's final preferred option allows NMFS to establish temporary prohibitions on the transfer of QS at the end of the year if administratively necessary. Such a prohibition might be needed to allow accounts to be resolved before QP is issued to the QS accounts for the following year.

An initial moratorium on trading of QS is proposed to allow initial recipients to develop a better understanding of the IFQ system and the trading prices before they make permanent trades. A number of members of the Council family traveled to New Zealand to learn about their program. They reported to the Council that many of the New Zealanders stated that if they could do it again they would have started with a trading moratorium to be in place while participants developed a better understanding of the value of the QS. This provision will keep industry members from making decisions based on fear or lack of understanding of how the system will function.

This initial moratorium will also provide an opportunity to make needed adjustments to the program before QS trading starts to occur. For example, there may still be appeals in progress when the program starts. As those appeals are resolved, the amount of QS an individual has received may change based on the issuance of additional QS to another entity. On one hand, this might be partially resolved by the issuance of QS in some unit other than a percentage. On the other hand, regardless of the units used for the QS, the issuance of additional QS will change the harvest represented by QS already issued. If QS trading has already occurred, the issuance of additional QS may cause some disruption if the prices paid did not fully anticipate the amount that would be issued through appeals. Another example is the potential need to adjust accumulation limits, particularly control limits. During the first years of the program, QP trading will likely provide some indication of the amount of consolidation that is likely to occur and the impacts of that consolidation. If it becomes apparent that accumulation limits are too high, it will be easier to implement downward adjustments before QS trading has started.

While the Council saw these benefits, it also recognized that the prohibition might slow down the generation of benefits, though it was noted that consolidation could still occur during the QS moratorium through the transfer of QP.

NMFS will be overloaded in the first year, and industry should be protected from making decisions based on fear or a lack of understanding regarding how the system will function. There should be a period over which prices are established, and transfer of QP would be allowed. NMFS concurred, citing both the major change that would be entailed in an IFQ program and industry-voiced regrets about quick transfers that occurred early in the implementation of the New Zealand system.

In the process of developing the options and reaching its conclusion, the Council also considered and rejected an option for a two-year moratorium. Ultimately, the Council believed that a two-year period would be of value, both for the industry to become familiar with the program and to provide some opportunity, if necessary, to adjust the program before QS trading begins.

❖ *Interlinked Elements*

There are no direct dependency links between this provision and the effective function of other provisions, except as may be determined in the future with respect to the need for suspension of QS trading at the end of each year to facilitate program administration. There is also a link to the ease with which adjustments may be made to the program in its first two years, particularly with respect to accumulation limits, as described in the above rationale.

❖ *Analysis*

The following are the categories of goals and objectives affected by the decisions on temporary transfer prohibitions.

Section	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Moratorium -- Establishing Market Prices and Adjustments		X	X		X	X					
Moratorium – Delayed Benefits		X				X					
Moratorium -- Effectiveness of the Moratorium					X						X
Moratorium – Administrative Costs										X	X
Annual Trading Suspension		X	X			X				X	X

- Moratorium — Establishing Market Prices

The moratorium is being proposed primarily because it is believed that it will assist QS holders in trading at fair market prices. Most economic literature assumes an established and known market price; little attention is given to how prices are established for entirely new commodities and how institutional arrangements (i.e., the rules of the market in which the commodity is traded) might affect the process by which the prices are established (Anderson 2004). Anderson (2004) experimentally demonstrated that in a market for a new commodity, in which both sellers and buyers advertise their bid and sale prices and trade at will, there is likely to be a high degree of price volatility, and the typical price pattern will be one of price bubble and collapse (technically termed a "double auction"). In such a system, the price one pays is affected more by when one decides to buy than the actual value of the commodity being purchased, thus bringing up concerns about inequities and disruption. It was further demonstrated that early trades would not necessarily result in the transfer of the commodity to the more efficient

producers, thus adversely affecting net benefits and sector health. Comparisons were made to other types of market structures (institutions), and results indicated that a period of leasing prior to free trading tended to stabilize prices and result in prices that are more likely to conform to the actual value of the commodity. Over the long term, appropriate market prices will likely develop regardless of the market structure created to support development of the market; however, the amount of disruption, inequity, and inefficiency encountered during the transition period will vary depending on the structures provided.

The proposed moratorium on QS trading would essentially establish a period of leasing (a time during which only the annual harvest privilege, the QP, could be traded). Based on Anderson (2004), we would expect this to be beneficial for the reasons described in the above paragraph. Lease prices (QP prices) may be helpful to the fishermen in determining the appropriate sale price for the QS in that there should be a relationship between the sale price for the QP and the stream of revenue one would expect from holding the QS and leasing the QP out each year. The Council considered two moratorium options; a one-year, and a two-year moratorium. The difference between the two can be evaluated in terms of the additional information that participants might learn in the second year of the moratorium and the costs to industry from the delay in the start of the period of full transferability. QP prices will likely vary through the first year of the program in response to the changes in knowledge about the trading prices, changing mixes in the catch that occur during the year, and shortages or surpluses that become apparent as the fishery moves through the year. As the participants move through the year, they will begin to understand the value of the QP. It will not be until after the year is over, however, that they will be able to start evaluating what might have been a reasonable price for QP for an entire year. The second year will provide some information on the annual lease prices for QP for an entire year, based on knowledge of the seasonal value of the QP in the previous year. Thus, there is an increment of knowledge to be gained in the second year that is qualitatively different from the first year (i.e., first-year prices are more likely to be based on seasonal demand, while the prices that QP trade for at the start of the second year are more likely to be based on an assessment of the value of the QP across the entire year). The question then is what is the cost of this additional increment of knowledge? First, it may delay QS holders' ability to adjust their QS holdings to the appropriate mix for their businesses (see section on moratorium effectiveness). This will extend the period of uncertainty, make it more difficult to plan, and extend the duration of the transition period. Second, during the period of the moratorium, there will likely be a greater number of transfers of QP, increasing both transaction and program administrative costs. The equal allocation provision will likely ensure that every year, almost every participant will have some allocation for a geographic area outside its normal range of operation that will have to be transferred to those who operate in a different geographic area.

In order for the QS trading moratorium period to be most effective in helping to establish QS market prices, it would be useful for the QP prices to be publically available (see Section A-2.3.2).

- Moratorium — Effectiveness of the Moratorium

While it is hoped that the moratorium will inhibit those who might otherwise transfer QS from doing so, there is little that would prevent QS holders from circumventing the moratorium by signing contracts for the annual transfer of QP to the buyers until the QS transfer moratorium expires and then transferring the QS themselves after the moratorium expires. The moratorium will send a strong message that extreme caution should be exercised in the early transfer of QS, but it will not prevent the effective commitment to a permanent transfer of QS by those determined to do so.

- Moratorium — Delayed Benefits

While QP trading will occur in the first two years of the program and will facilitate consolidation, to the degree that the moratorium is effective, some vessel consolidation and exit may be delayed because of uncertainty about the ultimate QS prices and the harvester's ability to acquire them. To the degree that consolidation is delayed, industry's ability to pay for program costs may be diminished. Higher vessel operation costs could reduce the price that vessels are willing to pay for QP, as compared to a situation in which QS trading was allowed, and consolidation occurred more rapidly.

- Moratorium — Administrative Costs

During the period of the moratorium, there will likely be more transfers of QP than if there is not a moratorium. Once the moratorium ends, there will likely be a period when the number of QS transfers intensifies, perhaps catching up to the number that would have occurred in the absence of the moratorium. Thus, overall administrative costs during the transition period will likely be higher with a moratorium than without.

- Annual Trading Suspension

An annual trading suspension of QS may be implemented, as necessary, to facilitate program administration. Such a short-term suspension might not significantly constrain transactions during the suspension, since nothing would prevent the signing of contracts for the QS during the suspension, with final execution of the contract occurring at the end of the suspension. Under such contracts, it is likely that, when the end-of-year suspension is over, both the QS and QP for the coming year could be transferred from the seller to the buyer. During the QS suspension, the trading of QP would continue to be allowed so as not to interfere with a harvesters' ability to cover their catch.

Depending on the nature of the administrative challenges that a suspension might help address, there may be approaches available that would not require the freezing of QS transfers. For example, suppose it appeared desirable to have a 45-day prohibition on transfers between November 1 and December 15 to determine the QS accounts to whicH QP should be issued for the following year. An alternative might be to issue QP to the holders of QS for a year based on QS account ownership as of November 1. It could be left to private contract for buyers to secure the separate transfer of the attendant QP with respect to transfers of QS occurring after November 1. On one hand, this would put less of a constraint on the market. On the other hand, it might increase administrative costs by increasing the number of transfers of QP independent of QS (any transfers of QS between November 1 and the time the QP are issued would have to be followed up with a transfer of the corresponding QP from the QS seller to the QS buyer, once the QP are issued).

A-2.2.3.d Divisibility

❖ Provisions and Options

QS will be highly divisible and the QP will be transferred in whole pound units (i.e., fractions of a pound could not be transferred).

❖ Rationale and Policy Issues

Blocking shares into indivisible units has been used in other programs to achieve social objectives (such as the west coast fixed gear sablefish tier system and sablefish and halibut IFQ programs in the north Pacific in which QS were blocked). In the north Pacific sablefish and halibut IFQ programs, some shares are blocked, and holders of unblocked QS are limited in their ability to acquire the blocked QS.[83] This is done to preserve small vessel opportunities. However, for this fishery, the divisibility is needed not only to allow vessels to achieve the most efficient scales of operation, but also to allow vessels to achieve the QP mixes needed to match the species mixes encountered in the catch, catch mixes that vary from tow to tow. Because of the need to matcH QP with variable species mixes in the catch and the desire to provide opportunities for new entrants to acquire QS in small increments, little consideration was given to the blocking of shares into larger units and maximum divisibility is emphasized.

QS divisibility might vary by species, but should probably be small enough to allow the transfer of single pounds.

❖ Interlinked Elements

Second to transferability, a high degree of divisibility is central to the IFQ program's ability to achieve many of its goals and objectives. If this provision is changed, a number of other program features would have to be reconsidered, particularly those related to accommodation of new entrants.

❖ Analysis

Divisibility is important with respect to efficiency, sector health, and labor, new entry, and small vessel opportunities. The reduction in flexibility that would result from reduced divisibility may decrease the per pound value of the quota.[84] This reduction in the value of the QS would reflect lost efficiency and reduced net benefits. Requiring that shares trade in larger units would make it more difficult to enter through incremental investments. These results might be somewhat different in a system that included both highly divisible and blocked shares, such as that in the NPFMC sablefish and halibut IFQ program.

[83] The NPFMC restricted the number of these blocks that a person could hold in an area. If the person held any unblocked QS in an area, they could only hold one block of QS for the area. If the person did not hold unblocked QS for an area, then the person could hold up to two blocks for that area. The objective of these blocking rules was to preserve a portion of the QS for the fleet of small part-time operators (Dinneford, *et al.* 1997).

[84] As an example, in the north Pacific, the 1996 average lease price for blocked QS was $0.88 per pound of IFQ, and the average lease price for unblocked QS was $0.97 per pound of IFQ when calculated over all areas and vessel categories (Dinneford, *et al.* 1997).

A-2.2.3.e Accumulation Limits (Vessel and Control)

❖ *Provisions and Options*

This provision restricts the amount of QS and QP that may be held. Three types of accumulation limits are included, control limits, vessel limits, and an unused QP limit for vessels. The control limit would apply to QS; the vessel limit would cap the total amount of QP that may be registered to a single vessel during the year, and would cover both the vessels used and unused QP. Under this limit, a vessel could not have more QPs registered for the vessel than a predetermined percentage of the QP pool. The unused QP limit for vessels would cap the amount of unused QP in a vessel's account.

Limits[85] may vary by species/species group, areas, and sector. See Table A-82, Table A-83, and Table A-84 for the percentage options that were considered for the accumulation limit levels and the Council's final recommendations. The vessel unused QP limits may be revisited in the first biennial specifications process after implementation of the program.

Vessel Use Limit (Vessel Limit): A limit on the total QP that may be registered for a single vessel during the year. This element will mean that a vessel could not have more used and unused QPs registered for the vessel than a predetermined percentage of the QP pool.

► **Option: Vessel Unused QP Limit:** A limit on the amount of unused QP that may be registered to the vessel at any time. As QP are used, permit owners may replenish their QP accounts up to the vessel unused QP limit. This limit applies only for overfished species and Pacific halibut.

QS Control Limit:[86] A person, individually or collectively, may not control QS in excess of the specified limit (unless exempted by the grandfather clause). QS controlled by a person shall include those registered to that person, plus those controlled by other entities in which the person has a direct or indirect ownership interest, as well as shares that the person controls through other means.[87] The calculation of QS controlled by a person will follow the "individual and collective" rule.

> Individual and Collective Rule: The QS that counts toward a person's accumulation limit will include 1) the QS or QP owned by them, and 2) a portion of the QS owned by any entity in which that person has an interest. The person's share of interest in that entity will determine the portion of that entity's QS that counts toward the person's limit.[88]

---

85 In this section, the term "permit" was changed to "vessel" to be consistent with Section A-2.1.3, which indicates that QP go into vessel accounts, not permit accounts. The term "own or control" was shortened to "control" for simplicity. Control includes ownership.

86 In the preliminary preferred alternative, and prior to revisions made in the spring of 2009, the control limit applied to both QS and QP. This was changed so that the vessel limit could be set greater than the control limit. Further explanation of this change is provided in the rationale.

87 It is the Council's intent that control limits should not constrain the formation of risk pools to help the fishermen deal with overfished species constraints, as long as the pools do not undermine the effectiveness of the accumulation limits. A risk pool is one in which two or more people enter into an agreement whereby if one person does not have the QP it needs, the others would agree to provide the QP, if they have them. Whether these kinds of agreements are informal or formal, they may begin to constitute control as other considerations and conditions are added to the agreements. It is the Council's intent to allow for these pooling agreements, so long as they do not become control.

88 For example, if a person has a 50 percent ownership interest in that entity, then 50 percent of the QS owned by that entity will count against the individual's accumulation limit unless it is otherwise determined that the individual has effective control of a greater or lesser amount.

Grandfather Clause and Divestiture:

Option 1: A grandfather clause will apply to (1) vessel accumulation limits and (2) control accumulation limits. This clause allows a person, if initially allocated QS in amounts in excess of the cap, to maintain ownership of the QS. The grandfather clause will expire with a change in ownership[89] of the QS. If the owner divests some of the QS, the owner may not reacquire QS or QP until the owner is under the cap. Once under the cap, the grandfather clause expires and additional QS or QP may be acquired but not in excess of the control caps.

Option 2: Same as Option 1 but the maximum allowed under the grandfather clause will be twice the vessel accumulation limit.

Option 3: There will not be a grandfather clause and there will be no opportunity to receive QS and divest of it.

►**Option 4:** There will not be a grandfather clause for the control limits, however, an adjustment period is provided through the following divestiture rules. QS will be issued for amounts in excess of aggregate and species control limits only for holders of permits transferred by November 8, 2008, if such transfers have been registered with NMFS by November 30, 2008. The holder of any permit transferred after that time will be eligible to receive an initial allocation for that permit of only those QS that are within the aggregate and individual species control limits. Anyone who qualifies for an initial allocation of QS in excess of the control limits will be allowed to receive that allocation but required to divest themselves of that excess QS sometime during years 3 and 4 of the IFQ program (the two years after the QS transfer moratorium specified in Section A-2.2.3.c). Holders of QS in excess of the limits may receive and use the QP associated with that excess, up to the time their divestiture is completed. However, QP for year 5 of the program will not be issued for QS held in excess of the limits. At the end of year 4, any QS still held in excess of the species or aggregate limits in place at the time of the initial QS allocation will be revoked and redistributed to the remainder of the QS holders in proportion to their QS holdings. No compensation will be due for any revoked shares. Divestiture transfers will be allowed in accordance with the provisions established here and the transfer rules and processes implemented by NMFS. Permit transfers will not be limited or required by the divestiture provision.

Calculation of Aggregate Nonwhiting QS Holdings: To determining how much aggregate nonwhiting QS an entity holds, an entity's QS for each species will be converted to pounds. This conversion will always be conducted using the trawl allocations applied to the 2010 OYs, until such time as the Council recommends otherwise. Specifically, each entity's QS for each species will be multiplied by the shoreside trawl allocation for that species. The entity's pounds for all nonwhiting species will then be summed and divided by the shoreside trawl allocation of all nonwhiting species to get the entity's share of the aggregate nonwhiting trawl quota.

Note: Absent guidance otherwise, Options 2 and 3 would be implemented in such a manner as to not alter other provisions of the program. Specifically, QS that is not allocated because of the limit or absence of the grandfather clause will be distributed to other eligible recipients in a manner that maintains the distribution among groups specified in A-2.1.1 and based on the allocation formulas specified in A-2.1.3.

❖ *Rationale and Options Considered, But Not Included*

There is a tension between allowing a sufficient accumulation to improve the efficiencies of harvesting activities and preventing levels of accumulation that could result in a variety of adverse economic and social effects. Excessive accumulation of the control of IFQ can result in changes in the structure of the fishing industry and communities and, in the extreme, possibly reduce net economic benefits (in the unlikely event that those accumulating QS alter total production). While some IFQ programs rely solely

[89] **Change in Ownership definition:** For the purpose of the grandfather clause, ownership of a legal entity is defined to change with the addition of a new member to the corporation, partnership, or other legal entity. Members may leave without causing the grandfather clause to expire for that entity.

on antitrust law to prevent excessive concentration of shares, experience has shown this not sufficient to prevent problems resulting from excessive concentration of IFQ (NRC 1999) (pg. 209). The NRC also notes that concentration limits may not be very effective if ways can be found to circumvent them.

National Standard 4 of the MSA has always required the consideration of excessive shares:

> (4) Conservation and management measures shall not discriminate between residents of different States. If it becomes necessary to allocate or assign fishing privileges among various United States fishermen, such allocation shall be (A) fair and equitable to all such fishermen; (B) reasonably calculated to promote conservation; and (C) *carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privilege.* [Emphasis added]

Additionally, the reauthorized MSA requires that accumulation limits be established within a limited-access privilege program.

> (5) ALLOCATION. — In developing a LAPP to harvest fish the Council or secretary shall—
> (D) ensure that LAP holders do not acquire an excessive share of the total LAPs in the program by—
> (i) establishing a maximum share, expressed as a percentage of the total LAPs, that a LAP holder is permitted to hold, acquire, or use; and
> (ii) establishing any other limitations or measures necessary to prevent an inequitable concentration of LAPs.

There are a number of policy choices associated with the specification of accumulation limits.

1. Should there be a vessel limit (production level limits: vessel or permit limit)?
2. Should there be a control or ownership limit?
3. How should control be defined and what scope of control relationships should be considered? Should both QS and QP count against the limits?
4. Should there be a grandfather clause and is there a need for a control date?
5. If there is no grandfather clause, what should be done with QS that is not allocated to entities because the allocation would exceed the accumulation limit?
6. At what levels should the limits be set?
7. How should aggregate limits be applied as the trawl allocation changes?

Each of these policy choices will be discussed in the following sections along with other options considered but rejected.

Table A-82. Page numbers for sections on accumulations limit rationale and analysis.

	Rationale	Analysis
Vessel Limit (Production Level Limit: Vessel or Permit)	A-287	A-336
Vessel Unused QP Limit	A-288	A-339
QS Control Limit	A-288	A-340
The QS Control Rule and Included Scope of Control Relationships	A-289	A-342
Grandfather Clause, Divestiture and Cut-off Date	A-296	A-346
Percentages for Limits	A-301	A-352
Calculation of the Aggregate	A-335	A-370

♦ *Vessel Limit (Production Level Limit: Vessel or Permit)*

The vessel would limit the total amount of QP a vessel could use each year (both the used and unused QP in the vessel account). Permit limits were considered as an alternative to vessel limits, but rejected.

This section includes the following:

- The reason for including a vessel limit
- The contrast of a vessel limit with a permit limit

The following section covers a different kind of vessel limit: the vessel unused QP limit.

The Council's final preferred alternative contains a vessel limit. The vessel limit applies at the level of the production unit (as compared to the control limit, which does not directly restrict the amount of fish used on a vessel). The vessel limit would be intended to achieve the following:

- Ensure that there is at least some minimum number of fishing vessels in the fleet to support more job positions and the purchase of more equipment, supplies, and support from fishing communities
- Increase the likelihood that harvest would be geographically dispersed
- Serve as a back up to the control limit (control limits may be difficult to monitor and enforce)

The Council is balancing the need to address these objectives with the risk that restrictive vessel limits may decrease potential efficiency gains from consolidation.

A grandfather clause was considered for the control limits and for vessel limits, but was not developed for the vessel limits. On a share of catch basis, vessel limits were set above the maximum historic catches of any individual vessel.[90]

A permit accumulation limit was considered as an alternative to a vessel limit. In order for a permit limit to achieve an effect similar to the vessel limit, there would have to be a prohibition on the stacking of permits and on the rotation of permits through a single vessel. Without such limits on stacking and rotation, the permit based limit would function more like a control limit in that it would not affect the number of vessels in the fleet.[91] The vessel-based limit is simpler than the permit limit because there is no need for provisions related to limiting the stacking or rotation of permits.

[90] A grandfather clause for the vessel limits would present certain implementation challenges. The accumulation limit grandfather clause is generally structured to allow entities to maintain QS they receive in excess of the accumulation limits, but does not address a grandfather level for QP used on a vessel. The grandfather clause would be intended to facilitate initial allocations. QS are issued as part of the initial allocation. QP are not issued until later in the implementation process. Additionally, QS are issued to entities that own permits, not to vessels. Therefore, there is no direct permanent link between a particular permit and vessel. If the Council wanted to grandfather vessels in at certain production levels, an additional provision would be needed to establish the grandfather levels for vessels. A simple approach would be to set the vessel's grandfather level to the amount of QS received for the permit associated with the vessel. A few other decisions would also be needed: the conditions under which the vessel grandfather clause expires (e.g., whether the clause expires with a change in ownership of the permit or vessel) and whether one vessel may be substituted for another without the grandfather clause expiring (i.e., whether the vessel grandfather exemption stays with the vessel or transfers with the permit).

[91] Relative to the vessel-based limit, the permit-based limit would simplify implementation of a grandfather clause because the grandfather clause provisions can be easily applied to the permit: the grandfather level would be determined based on the permit's allocation of QS, and the grandfather clause would expire with a change in ownership of the permit (vessels could be replaced through the transfer of a permit without having the grandfather clause expire).

♦ *Vessel Unused QP Limit*

The Council developed an unused QP limit for incidentally caught overfished species. Under the unused QP approach, a vessel is limited in the amount of unused QP it may hold in its account at any one time, but is potentially free to acquire as much additional QP as is necessary to cover its actual catch of overfished species. The utility of this approach depends on the substantial incentives that vessels have to avoid overfished species: (1) the amount of overfished species QP available will be quite limited, particularly for certain species and, therefore, very expensive to acquire; (2) any overfished species the vessel does not need can be sold, likely at a high price. Absent these incentives to avoid overfished species, the unused QP approach would not work because it would effectively provide no cap on the amount of the species a vessel catches.

Two specific reasons have been identified for considering the unused QP approach:

1. **The Difficulty of Choosing the Right Limit for Incidentally Caught Overfished Species.** An overly constraining vessel QP limit for overfished species could prevent a vessel from accessing its target species QP. Because of variability in bycatch rates along the coast and across different fishing strategies, it is very difficult to pick one QP limit for overfished species that would be large enough to accommodate needs in every geographic area and strategy without providing limits substantially in excess of that needed for others.
2. **Facilitating the Choice of a Lower Limit.** A vessel unused QP limit would not restrict the total amount of overfished species QP a vessel could access to cover the incidental catch taken with its target species. Therefore, the vessel limit could be set at a lower level without constraining vessel's catch of target species (assuming the vessel is able to acquire additional overfished species QP on the market as needed). A lower vessel limit may help maintain QP availability in the market by reducing the opportunity for vessels to sequester overfished species in their accounts on the chance they might need it to cover an unexpectedly high bycatch rate.

The rationale for use of the unused QP approach is discussed further below in the section on the rationale for setting the percentages for the control and vessel limits.

♦ *QS Control Limit*

In this section, we address the following:

- Reasons for having a control limit and reasons for having a control limit instead of an ownership limit
- Rationale regarding whether there should be different control limits for different types of entities

A limit on the amount of QS an entity would be allowed to control is proposed to address requirements of the MSA and a number of goals and objectives. Control limits could achieve the following:

- Contribute to efficiency if the control limits are set at a level that prevents the exertion of market power without constraining operation sizes to below the most efficient levels (MSA – National Standard 5, Groundfish FMP Goal 2 and Objective 7, Amendment 20 Objective 2 and 6)
- Prevent the accumulation of excessive shares (MSA – National Standard 5, 303(c)(5)(B)(ii), 303(A)(c)(5)(D), Amendment 20 Constraint 6)
- Contribute to sector health (Amendment 20, Objectives 2 and 6)

- Help to geographically disperse harvest and landings to the benefit of communities (MSA – National Standard 8, 202A(c)(5)(B); Groundfish FMP Objective 16; Amendment 20 Objective 5 and Constraint 3)
- Contribute to fairness and equity (MSA – National Standard 4(a), 3030(c)(5)(A); Amendment 20 constraint 5);

Please see Table 6-1 for additional description of the referenced guidance.

Consideration was given to relying solely on antitrust laws to address concerns about excessive shares; however, the level of aggregation required to establish the anticompetitive behaviors that are of antitrust concern may be substantially greater than the levels of aggregation that trigger concerns about fairness and equity, geographic distribution, communities, or sector health.

The Council also considered having an ownership limit and a control limit. The term "owner" is used to designate the person with whom the QS is registered through NMFS. In general, *control* includes both the control exerted through ownership of the QS and the control exerted by the ability to direct the use of QS. To address the stated objectives, a limit is needed on the amount of control. A separate ownership limit that is a subset of a control limit would serve little purpose and would add to the complexity of the regulations. Therefore, the Council decided there should be a control limit that subsumes ownership.

Another question to be addressed with respect to the QS control limit is whether there should be different types of control limits for different types of entities (e.g., control limits for harvesters that are different than control limits for crewmembers, processors, or communities). In particular, processors have argued that they should have greater control limits because they handle larger volumes of product. It has also been argued the communities should have larger control limits to address the needs of their entire fleet and that harvester cooperatives should have greater limits to form risk management pools and take advantage of other benefits that may flow from the formation of harvester cooperatives.

When discussed by the TIQC, there were two reasons that setting up different control limit for different groups was rejected. First, the differential limits could be circumvented if an entity would be able to make some simple adjustments and qualify as the type of entity that has the highest accumulation limit. For example, if processor limits would be substantially higher than harvester limits, then harvesting companies might make adjustments that allow them to qualify as a processor (e.g., acquire a processing license and process a small amount of fish or take on a minority processor interest). The second reason for not having different control limit levels for different types of entities was that control limits are less of a direct impediment to operations of other entities, as compared to harvesters. Thus, there did not appear to be a need to provide higher control limits for other groups. However, the Council has expressed its intent to consider a special higher limit for CFAs to facilitate groups of QS holders working together. This would occur as part of a trailing amendment. The rationale would be that these higher limits are needed to allow certain types of group activities that advance Council goals and objectives for the fishery and which would not be possible or as effectively carried out without the higher limits.

♦ *The QS Control Rule and Included Scope of Control Relationships*

The control rule and specification of its scope will affect goals and objectives through its impact on the effectiveness of the limits on control. Control may be exerted directly or indirectly.

PARSING THE QS CONTROL RULE

The full control rule is as follows:

> **Control Limit:** A person, individually or collectively, may not control QS in excess of the specified limit (unless exempted by the grandfather clause). QS controlled by a person shall include those registered to that person, plus those controlled by other entities in which the person has a direct or indirect ownership interest, as well as shares that the person controls through other means. The calculation of QS controlled by a person will follow the "individual and collective" rule:
>
> > Individual and Collective Rule: The QS that counts toward a person's accumulation limit will include (1) the QS owned by them, and 2) a portion of the QS owned by any entity in which that person has an interest. The person's share of interest in that entity will determine the portion of that entity's QS that counts toward the person's limit.[92]

We will now review a number of the key aspects of this rule.

QS Control Limit: A person, individually or collectively . . .

This definition applies to all legal persons, whether they are individuals, partnerships, corporations or other legal entities. By including all legal persons within the scope of the rule (rather than just individuals), this specification acknowledges the abilities of individuals to use partnerships, corporations, and other legal entities to exert control, or for these other types of legal entities, to exert collective control.

Where an individual or group of individuals have collectively formed a legal entity, the individual's influence over the collective legal entity will be taken into account in assessing the control exerted by the individual. Ownership is only one type of influence. The exact formula used to determine the total amount of QS a person controls through ownership is specified below in the "individual and collective rule." This specification will make it more difficult for an individual to circumvent the control cap by exerting influence over a number of different legal entities (e.g., partnerships or corporations).

QS Control Limit: . . . QS controlled by a person . . .

The Council considered applying the control limit to both the QS and QP controlled by a person. However, in order to balance efficiency objectives that require the concentration of harvest on fewer vessels with social objectives related to maintaining a broad distribution of benefits from QS control/ownership, the Council determined that it would be desirable to set the vessel limits at a higher level than the control limits. This created a conflict in that if the control limits applied to QP, and a person was considered to control QP placed on its vessel, then there would be no way to reach the vessel limit without violating the control limit.[93] The Council, therefore, modified the definition of

[92] For example, if a person has a 50 percent ownership interest in that entity, then 50 percent of the QS owned by that entity will count against the individual's accumulation limit.

[93] The possibility that QP might be used on a vessel without placing the QP under control of the owner was discussed. However, this adds complexity both to the tracking of the QP and to the process for crediting catch against QP. For vessels with more QP than the control limit, catch would have to be counted against each of the separate accounts held for the vessel. In addition to adding to the complexity of the tracking system, it would also add a source for error and disagreement and raise questions regarding who is responsible for the various accounts on the vessel. Adding more accounts to the vessel would also require consideration of how

control to exclude explicit control of QP. Not counting QP against the control limit may make it easier for an individual to use indirect methods to exert control without being detected. For example, an individual might use side contracts to acquire QP issued each year for particular QS. Depending on other aspects of the agreement by which the transfers are made, even though the control limit would not apply to QP, a determination could be made that the entity is effectively controlling the QS that is behind the QP. Thus, while a person's control of QP would not automatically be counted toward the control limit, its control of QP could indicate that it also controls the underlying QS. Again, whether the entity acquiring the QP actually controls the underlying QS would largely depend on the circumstances under which the QP are acquired and other aspects of the relationship between the persons receiving and providing the QP.

QS Control Limit . . . shall include those registered to that person . . .

All QS registered with NMFS under the person's name would count against that person's accumulation limit. This language intentionally uses the word "include" so as not to exclude counting QS against a person's limit, even though it is not registered to the person.

QS Control Limit: . . . plus those controlled by other entities in which the person has a direct or indirect ownership interest . . .

The mention of indirect ownership provided here sets up the definition for application of the "Individual and Collective Rule." Indirect ownership might include ownership through intermediary entities, e.g., if Individual A participates in a partnership that has an ownership interest in a corporation that owns or controls QS, some portion of the QS that corporation owns or controls would count against Individual A's limit.

QS Control Limit: . . . as well as shares that the person controls through other means. . .

This language makes it explicit that the term "control" covers means of control beyond ownership. Ultimately, the evaluation of control depends only partially on direct ownership of QS or ownership of some other entity that owns the QS; i.e., one entity may have no direct ownership in another entity or its QS, but still be found to exert control over that other entity and/or the QS it holds.

QS Control Limit. . . The calculation of QS or QP controlled by a person will follow the "individual and collective" rule:

> Individual and Collective Rule: The QS or QP that counts toward a person's accumulation limit will include (1) the QS or QP owned by them, and 2) a portion of the QS or QP owned by any entity in which that person has an interest. The person's share of interest in that entity will determine the portion of that entity's QS or QP that counts toward the person's limit.

This language provides definition and a formula for assessing control through ownership. Note that this rule applies only for the purpose of determining amounts controlled through ownership

the carryover provisions would be applied (which, to this point, have been based on the QP in the vessel account). An assumed constraint in the design of the program has been that once QP are issued for the year we would not track their source. They would be treated similar to bank accounts in that only the total amounts in an account are relevant, not the source of the QP.

and does not cover or restrict the consideration of control through other means in determining the total amount of QS an entity controls. For example, if it was determined that a person who was a partial owner in a corporation effectively exerted complete control over the disposition of QS held by that corporation, all of the QS owned by that corporation might be counted against that person in an evaluation of the "shares that the person controls through other means," depending on case specific circumstances.

OWNERSHIP CALCULATIONS (DOWNSTREAM AND UPSTREAM ACCOUNTING)

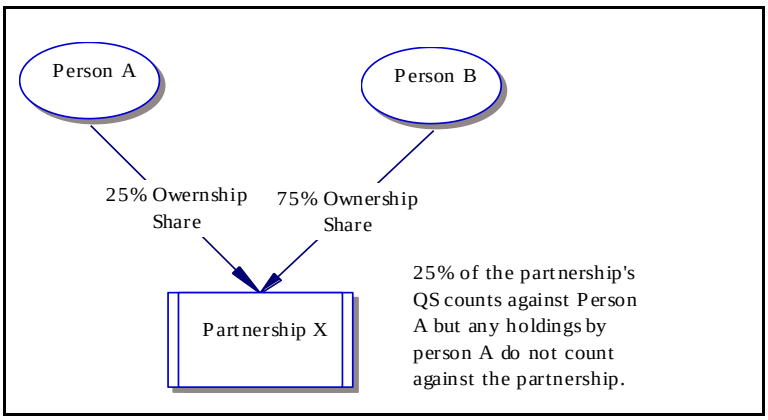

Figure A-96. Downstream accounting for control through ownership.

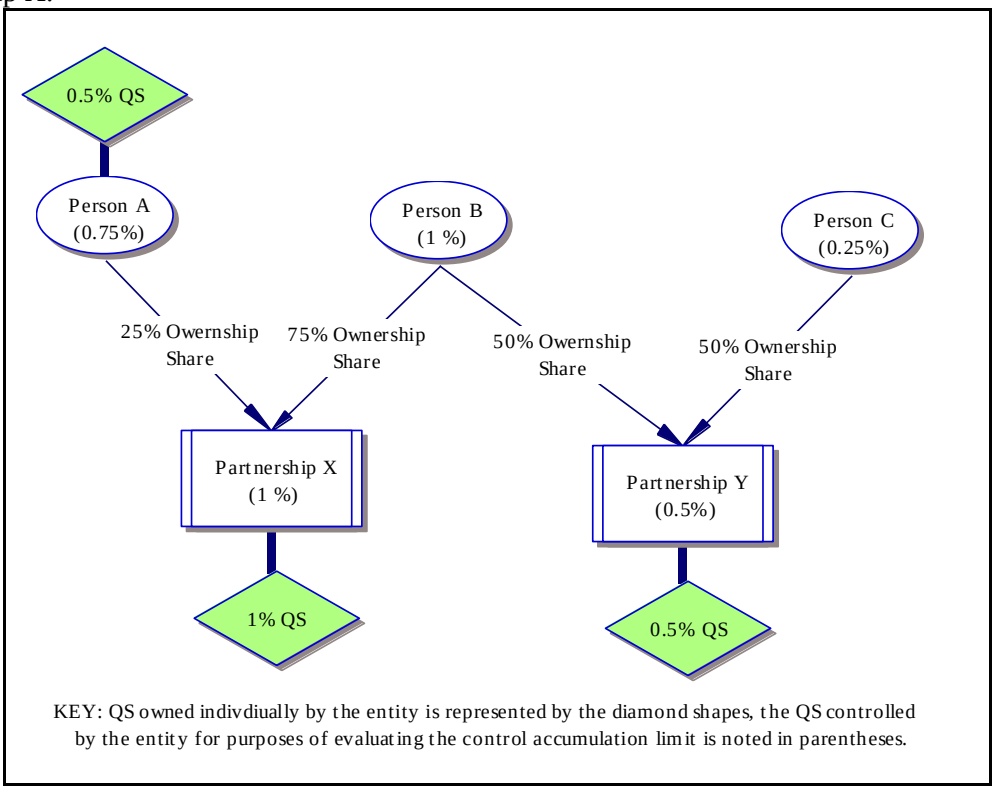
Under the individual and collective rule, persons are considered to control legal entities, but legal entities are not considered to control persons who control the legal entity. The QS owned by downstream entities counts against control limits of upstream owners, but the QS ownership of upstream owners does not automatically count against the QS of downstream entities. For example, in Figure A-118, a portion of the downstream partnership's QS (Partnership X) would count against Person A, but Person A is upstream of the partnership, and any QS owned by Person A separately from the partnership would not automatically count against the downstream partnership.

Consideration was given to automatically counting against an entity all shares owned by individuals who have some ownership in that entity (upstream accounting). Under such a rule, the control limits could become rapidly over-restrictive because the QS of individuals with only a very distant ownership relationship to a particular entity would still count against that entity. Figure A-119 diagrams an example of partnership QS accounting for a rule under which there is only downstream accounting (QS owned by a partner does not count toward the partnership's QS). Figure A-120 diagrams the same relationships for a rule under which there is both downstream and upstream accounting (QS owned by a partner does count toward the partnership's QS). In these figures, the QS owned by an entity is provided in the diamond shapes, and the entities are represented in circles (individuals) or squares (partnerships). The percent of a partnership a person controls is indicated in the arrows pointing to that partnership. The amount of QS counted against an entity is provided in parentheses in the square or circle. In these examples, Persons A, B, and C are individuals. Persons A, B, or C could also be partnerships, corporations, or other legal entities, in which case there would be additional boxes showing the upstream individuals who owned those entities.

Under the downstream accounting illustrated in Figure A-119, Person A is considered to have ownership over 0.75 percent of the QS (Person A's own 0.5 percent and 25 percent of partnership X's 1 percent QS). Person B is considered to own 1 percent of the QS (75 percent of Partnership X's 1 percent QS and 50 percent of Partnership Y's 0.5 percent QS). Person C is considered to own 0.25 percent of the QS (50 percent of Partnership Y's QS). Note that this method and these illustrations are only for determination of control through ownership. For example, it might be determined that

Person B controls all of the QS of Partnership X because of Person B's 75 percent interest in Partnership X.



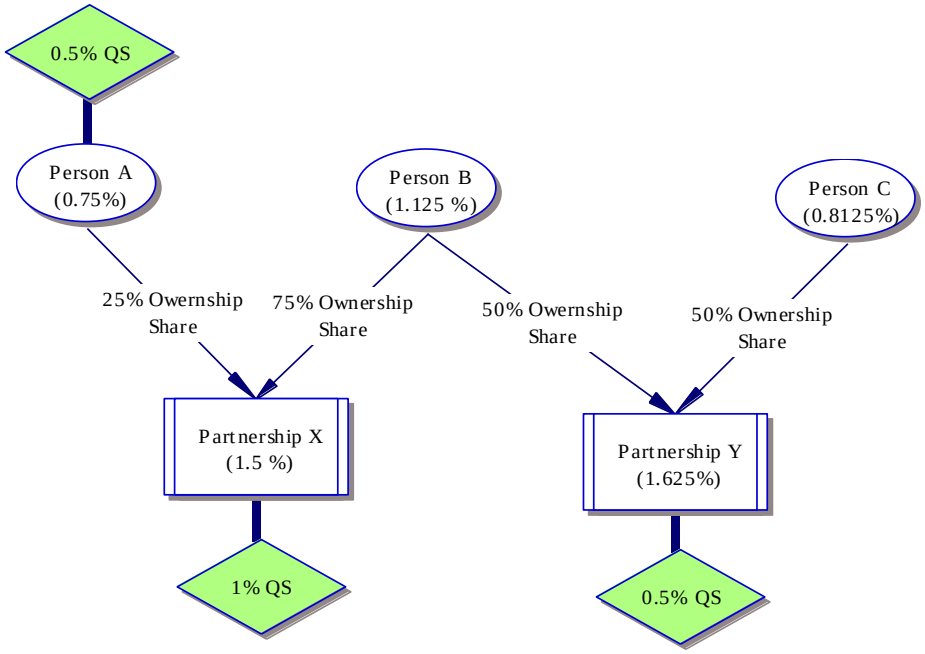


Figure A-97. QS accounting if the QS owned by a partner does not count toward the partnership's QS (downstream accounting only).

As compared to downstream-only accounting, the impact of upstream and downstream accounting illustrated in Figure A-120 is most marked for Partnership Y and Person C. For these two entities, the QS attributed to them more than doubles. Because all of Person A's QS counts against Partnership X, Partnership X has 1.5 percent QS and Person B's 75 percent interest in Partnership X is counted as giving him control over 1.125 percent QS (of which 0.375 percent is that which Person A owns on his own). The QS Person B controls then counts against Partnership Y, which increases that partnership's QS to 1.625 percent (of which 0.375 percent is that which Person A owns on his own, and 0.75 percent is that held by Partnership X). Figure A-120 shows only a partial accounting for upstream ownership. For a full accounting, Person B's ownership of Partnership Y would be counted against Partnership X, increasing Partnership X's QS holdings by 0.25 percent to 1.75 percent. This would then increase Person A's holdings by 0.675 percent (25 percent of 0.25 percent) to 0.8175 percent. Thus, the full effect of upstream accounting is to increase both the extent of the constraint and the complexity of the accounting.

The decision on the downstream/upstream accounting aspect of the control rule draws a balance between a "cascading effect" that may unfairly restrict a person based on the actions of a distantly related entities (Persons A and C in Figure A-120) and the opportunity for an entity to circumvent the limits by a chaining together a number of partnerships that work cooperatively to control QS in excess of limits. It is at this point that the portion of the rule that includes "as well as shares that the person controls through other means" becomes important. Even under a rule that does not automatically count upstream ownership control of QS against limits for downstream entities, if it were determined that upstream ownership and the chaining together of entities was being used to circumvent QS control

limits, such control would still be considered a violation of the limit. Such situations would be evaluated on a case-by-case basis.

KEY: QS owned indivdiually by the entity is represented by the diamond shapes, the QS controlled by the entity for purposes of evaluating the control accumulation limit is noted in parentheses.

Figure A-98. QS accounting if the QS owned by a partner does count toward the partnership's QS (upstream and downstream accounting) (Note: Partnership X's and Person A's QS have not been fully adjusted to account for Person B's separate ownership of Partnership Y. See text for discussion).

An alternative specification of the control rule could count the QS/QP owned by a partner against all entities owned by that partner but not against the other owners of those entities. Under such a rule, in Figure A-120, Partnership X would still be considered to control 1.5 percent of the QS, but Person B would be considered to control only 0.75 percent of the QS (as in Figure A-119), and Partnership Y and Person C would also be unaffected by Person A's ownership of QS (also as in Figure A-119). As compared to a downstream-only rule, this would make it somewhat more difficult to circumvent control limits by chaining entities together, but would not eliminate the problem and would add complexity to the control rule.

Another version of the calculation for the individual and collective rule would have counted 100 percent of the QS held by any entity against each owner of that entity, regardless of the owner's share of ownership. A variation on this approach would count 100 percent of the QS held by an entity against each owner who has at least a 10 percent interest in the entity. Under such an approach, in Figure A-119, Person A would be considered to control 1.5 percent QS. This approach, while making it more difficult to exert covert control over QS, would also constrain a person's ability to participate in multiple partnerships or corporations, or to hold QS and participate in fishing separately from the partnership or corporation in which it also participates. The net effect of the 100 percent approach would likely be to fragment the ownership in the fishery into more distinct units than may now be the case.

From the above discussion, it is apparent that in specifying the control rule, the Council is balancing the following:

- Complexity
- Unintended constraints on business arrangements due to the cascading effect of a more broadly specified control rule
- The effectiveness of the control rule as evaluated based on ownership information alone
- The need and cost of enforcing abuses through investigation of control exerted by means not captured under the rules for evaluating control through ownership

IMPLEMENTATION OF THE CONTROL RULE

In implementing the QS control limit, NMFS would provide a regulatory definition of the Council's intent. With respect to the interpretation of "otherwise controls," the following is the regulatory interpretation that was provided for similar policy language for the North Pacific crab rationalization program[94] *(Note: minor revisions have been made to these examples so that they can be better understood in the context of the IFQ Alternative):*

a) The person has the right to direct, or does direct, the business of the entity to which the QS are registered.
b) The person has the right to direct, or does direct, the delivery of groundfish harvested under a permit registered to a different person/entity.
c) The person has the right in the ordinary course of business to limit the actions of or replace, or does limit or replace, the chief executive officer, a majority of the board of directors, any general partner, or any person serving in a management capacity of the entity to which the QS is registered.
d) The person has the right to direct, or does direct, the transfer of QS.
e) The person, through loan covenants, has the right to restrict, or does restrict, the day-to-day business activities and management policies of the entity to which the QS is registered.
f) The person has the right to control, or does control. the management of, or to be a controlling factor in, the entity to which the QS is registered.
g) The person has the right to cause, or does cause, the sale of QS.
h) The person absorbs all of the costs and normal business risks associated with ownership and operation of the entity to which the QS is registered.
i) The person has the ability through any other means whatsoever to control the entity to which the QS is registered.

The catchall phrase at the end of the definition, "shares that the person controls through other means," restricts ways to circumvent the accumulation limit, but also presents questions as to how the definition should be interpreted in its implementation. Examples include the questions below:

- *If someone is a crewmember of a vessel or a cutting line employee for a processor, should the shares owned by that person be considered within the control of the harvesting/processing company?*
- *If someone is a vessel captain or a plant manager, should the shares owned by that person be considered within the control of the harvesting/processing company?*
- *If someone leases the vessel/facility to the harvesting/processing business, should the harvesting/processing business be considered under that person's control?*
  If there is only one processor in the port, should that processor be considered to control the harvesting operations (and use of quota) of vessels in that port?

[94] NMFS based its examples on the indices used for determining impermissible control by a noncitizen of a U.S. fishing vessel under MARAD regulations at (46 CFR 356.11)

Ultimately, the evaluation of a possible accumulation limit violation would be based on specific situational facts.

♦ *Grandfather Clause, Divestiture, and Cut-off Date*

Grandfather Clause and Divestiture:

Option 1: A grandfather clause will apply to (1) vessel accumulation limits and (2) control accumulation limits. This clause allows a person, if initially allocated QS in amounts in excess of the cap, to maintain ownership of the QS. The grandfather clause will expire with a change in ownership[95] of the QS. If the owner divests some of the QS, the owner may not reacquire QS or QP until the owner is under the cap. Once under the cap, the grandfather clause expires and additional QS or QP may be acquired but not in excess of the control caps.

Option 2: Same as Option 1 but the maximum allowed under the grandfather clause will be twice the vessel accumulation limit.

Option 3: There will not be a grandfather clause and there will be no opportunity to receive QS and divest of it.

►**Option 4:** There will not be a grandfather clause for the control limits, however, an adjustment period is provided through the following divestiture rules. QS will be issued for amounts in excess of aggregate and species control limits only for holders of permits transferred by November 8, 2008, if such transfers have been registered with NMFS by November 30, 2008. The holder of any permit transferred after that time will be eligible to receive an initial allocation for that permit of only those QS that are within the aggregate and individual species control limits. Anyone who qualifies for an initial allocation of QS in excess of the control limits will be allowed to receive that allocation but required to divest themselves of that excess QS sometime during years 3 and 4 of the IFQ program (the two years after the QS transfer moratorium specified in Section A-2.2.3.c). Holders of QS in excess of the limits may receive and use the QP associated with that excess, up to the time their divestiture is completed. However, QP for year 5 of the program will not be issued for QS held in excess of the limits. At the end of year 4, any QS still held in excess of the species or aggregate limits in place at the time of the initial QS allocation will be revoked and redistributed to the remainder of the QS holders in proportion to their QS holdings. No compensation will be due for any revoked shares. Divestiture transfers will be allowed in accordance with the provisions established here and the transfer rules and processes implemented by NMFS. Permit transfers will not be limited or required by the divestiture provision.

There are a number of significant choices within this element. The first is whether to have a grandfather clause (Option 1 or 2 vs. Option 3 or 4) and, if so, the level of the grandfather clause (Option 1 vs. Option 2). If there is no grandfather clause, then a choice is required regarding whether the QS that would be issued in excess of accumulation limits will instead be distributed to all of those under the limits (Option 3), or whether the QS will be issued in accord with the formula and provide those receiving amounts in excess of the accumulation limits an opportunity to divest (Option 4). If there is a grandfather clause or opportunity to divest, will there be a cutoff date beyond which any additional permits acquired will not entitle an initial recipient to receive QS in excess of accumulation limits under any circumstances (Options, 1, 2, and 4)? If there is no grandfather clause, and no opportunity to divest (Option 3), then there is a choice on the order in which the accumulation limits are applied. [96] The order will affect the mix of species an entity receives as part of its initial allocation. Finally is a question as to

[95] Change in Ownership definition: For the purpose of the grandfather clause, ownership of a legal entity is defined to change with the addition of a new member to the corporation, partnership, or other legal entity. Members may leave without causing the grandfather clause to expire for that entity.

[96] Additionally, the order of application of the limits will affect the species mix of the QS issued to any entity that acquires an additional permit after the November 8, 2008, control date, whether or not that acquisition butts the entity over the accumulation limit.

whether the grandfather clause should be applied to vessels. The following subsections take up each of these topics in the order presented here.

GRANDFATHER CLAUSE

The primary purpose of a grandfather clause (Option 1) would be to reduce disruption in the transition to a new program. Fairness and equity are also concerns. The MSA mandates that in order to ensure a fair and equitable initial allocation, the Council consider current and historical harvests in the fishery and participation of fishing communities, employment (harvesting and processing), investment, and dependence. After considering these factors, a broad scope of actions is available for the Council. One possible response is the adoption of a grandfather clause (Option 1). Option 2 would provide a result that is intermediary between the choice of no grandfather clause and a grandfather clause (i.e., a grandfather clause that is capped at twice the QS control limit. On one hand, a grandfather clause could be appropriate if the Council determines there are certain past or existing practices that would not be allowed under a new program, but believes that those practices should not be immediately disrupted. On the other hand, a grandfather clause could delay the full effect and benefit from the program and could create a class of participants with an advantage over other participants. These types of tradeoffs are taken into account in the Council's development of its recommendations.

In addition to the disruption issue, the question of a grandfather clause pits a number of fairness and equity questions against one another. If there is no grandfather clause, and accumulation limits are below what is needed for some highliners to take their historic harvest levels, is it fair that some entities should have their historic practices disrupted (particularly given that the one of the purposes of rationalization is to reduce capital in the fishery and increase efficiency)? If there is a grandfather clause, is it fair that some entities should have advantages over others and that many of those who will benefit from the program will have to wait for the full benefits until the grandfather provisions expire? Finally, there is a fairness question associated with issues of advance notice and the impacts of not having a grandfather clause on those who would receive QS in excess of limits because they have acquired permits during the Council's deliberations on trawl rationalization. This last issue will be discussed below in the section on cutoff dates.

The Council decided that it would not recommend a grandfather clause for those who would otherwise receive an initial QS allocation in excess of limits. The tradeoff in the impacts of this decision was based on the level at which the Council chose to set the QS control limits. These limits were set such that it was not expected that any single permit (or whiting processor) would receive an initial allocation of QS in excess of limits. Therefore, the absence of a grandfather clause would not be expected to impact the ability of such entities to receive the QS that would go to them under the allocation formula. Owners of multiple permits could be adversely impacted in terms of their initial allocations; however, this would not disrupt their ability to continue to operate multiple vessels if they so desires. The result of the QS control limits and absence of a grandfather clause mean that such owners will have to acquire QP from other QS owners each year, rather than relying on QS they own. This result addresses Council concerns about ensuring that there is not excessive accumulation of QS (that the benefits of QS ownership are distributed), while at the same time allowing the generation of efficiency benefits from permitting larger-scale operations. Limiting distribution of QS to maximum levels that reflect that needed by individual permits is expected to better maintain the social character of the industry and its relationship to the communities in which the fleet operates. This result might also have been achieved with a grandfather clause as initial recipients of amounts in excess of limits retire from QS ownership; however, without a grandfather clause the result is achieved earlier in the program. In summary, the absence of a grandfather clause does not constrain the initial allocation to single-permit owners and processors that do not own permits, will not prevent those operating multiple vessels from continuing to do so by relying on QP available from other QS owners, maintains levels of QS ownership aggregation that are expected to be less disruptive to the historic character of the industry and its relationship to communities, and achieves that end earlier than would be the case if there were a grandfather clause.

DISPOSITION OF AMOUNTS IN EXCESS OF LIMITS

In the absence of a grandfather clause, a decision is needed as to the disposition of the QS that would otherwise go to those who would receive QS in excess of control limits. The Council formally considered two options, distribution of that QS to those under the QS limits (Option 3) and allowing those who would receive QS in excess of the limits to receive that QS, but requiring them to divest themselves of the QS within a certain time period (Option 4). There are also other possibilities for disposition of the excess amounts. For example, those amounts could have been redistributed in auctions, through a lottery, or to CFAs. One of the main concerns in moving to a trawl rationalization program is to achieve the move while minimizing disruptive effects and considering recent and historical harvests. In general, because of the averaging effects inherent in most allocation formulas, many participants do not receive amounts sufficient to support their existing activities. This is particularly true with respect to the larger producers (see Section 2.1.3). Therefore, disposition of excess back to the existing operations helps reduce disruption and accounts for recent and historic participation. Options 3 and 4 achieve this end in different ways. Option 3 reallocates the excess back to those who are under the limits in proportion to the allocations they receive under the allocation formula. Option 4 allows those who qualify for that excess to receive an initial capital gain from the initial allocation, but not the long-term security that comes from being able to hold the QS to support their fishery-related operations.[97]

The Council adopted the divestiture provision of Option 4, in part because there had been some confusion in the industry as to whether the November 6, 2003, control date applied to fishing activities or to other activities as well (such as the acquisition of additional permits). Because of this confusion, a number of entities had invested in additional permits anticipating that they would receive benefits from the initial allocations. With respect to fairness and equity, there are two groups to consider, those that chose to buy permits after 2003, and those that did not make that choice. The divestiture provision was viewed as fair to both. It is fair to those who did buy additional permits after that time by allowing them partially to recapture their investment by being given the QS and QP; it is also fair to those who did not additional permits. Divestiture recognizes the decisions being made by those on both sides of this issue.

The following provides some of the rationale for specific elements of the divestiture provision. The November 8, 2008, cutoff for permit acquisition is based on the date on which the Council took its final action making it clear that there would not be a grandfather clause. Since contracts for permit sales may have been signed before that date, but the sales not registered with NMFS until afterward, November 30 was established as a cutoff date for the registration of the sale with NMFS. The Council felt it reasonable to expect that anyone who qualifies for QS in excess of limits based on permits acquired after that date would have had sufficient notice of the risks entailed in their acquisition. Those with QS in excess of limits are allowed to receive QP for their excess QS until they divest because of concern about impacts on the community, the need to avoid major disruptions, and to provide supply to the markets. Absent this provision, the QP associated with the excess would have been redistributed to QS holders throughout the coast in proportion to the amount of QS they hold below the limits. This is more likely to maintain the fishing activity within the community. Further, there is an expectation that some of those who will be forced to divest of their QS will do so in a way that maintains the QS in the local communities. The two-year QS transfer moratorium will apply to those receiving QS in excess of limits. This will allow market prices to develop for QP. Well-developed QP market prices will provide better information for determining the appropriate prices for sale of QS once the moratorium is over. Additionally, during this two-year period, the Council will be considering developing some special provisions for CFA and, in particular, a provision that may provide such associations with higher trip limits. Providing the opportunity for divestiture, but requiring two years before transfers occur, will

[97] The Option 3 redistribution approach could be used in the unlikely event that someone has acquired a permit after November 8, 2008, and that permit puts them over the QS control limits. Under such circumstances, the divestiture option would not apply.

allow the Council to complete such work and determine whether there will be special provisions that may encourage or allow the transfer of QS in amounts in excess of QS control limits to CFAs. After QS trading starts (at the end of the first two years of the program), holders of excess QS would be provided two years (years three and four of the program) to complete their divestiture or forfeit their QS back to NMFS for redistribution. This period of time was considered reasonable, particularly for the purposes of allowing QS market and market prices to be established and to allow CFAs to form and be available to receive QS divestitures (if the special opportunities are eventually provided for CFAs). In anticipation of the possibility that the QS control limits might be increased prior to the time divestiture is completed, the Council specified that the control limits to be applied are those that are in place at the time of initial allocation. This was done to discourage anyone from delaying divestiture of QS in hopes that the QS control limits might be increased and to avoid providing an additional benefit that those below the limits would not have (the benefit of having received an initial allocation in excess of the initial set of QS control limits).

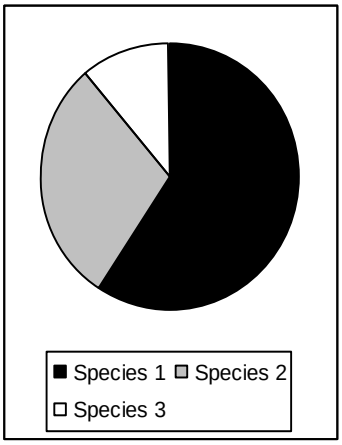
CUTOFF DATE

The above discussion of the divesture provision also covers the November 8, 2009, cutoff date. A control date was published that had the effect of providing fishery participants with advance notice that activities they undertook after that date might not be acknowledged in provisions of the trawl rationalization program under development. In particular, the control date announcement expressed concern that fishermen not increase their fishing activities in order to qualify for more fish. If there is a grandfather clause or no grandfather clause, but a divestiture provision, the question arises regarding whether activities occurring after the control date (in particular, the acquisition of additional permits) should entitle an applicant to a greater allocation. In this regard, there were those who stated that it was not clear that the control date applied to anything more than fishing. They argued that allocations resulting from permit accumulation after the control date should be grandfathered in or they should be allowed to receive the QS and divest themselves of it. As indicated above, ultimately the Council agreed that the control date was not clear regarding whether it would apply to the acquisition of additional permits. This issue is discussed further in the analysis.

APPLICATION OF THE GRANDFATHER CLAUSE TO VESSELS

In the preliminary draft, EIS there was discussion regarding the need for a grandfather clause for vessels. In taking its final action, the Council set vessel QP usage limits well above the shares of harvest that any one vessel had taken in recent years and did not apply control limits to vessels. For these reasons, there was no further work on the development of a grandfather clause for vessels. The preliminary draft EIS covers some of the challenges that would be entailed in developing a grandfather clause for vessels. Some of these challenges are summarized above in the section on vessel limits.

CHOICE ON THE ORDER OF APPLICATION OF QS CONTROL LIMITS

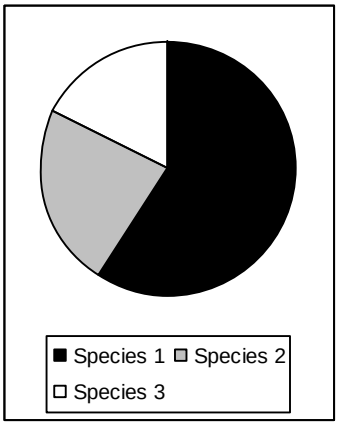


If there is no grandfather clause and no opportunity for divestiture, the species mix of the allocations to entities that would otherwise be over the QS control limits will depend on the order in which the accumulation limits are applied (this could also be true for any entity that, after November 2008, acquires a permit that would result in it receiving an initial allocation in excess of control limits). If the species accumulation limits are applied before the aggregate limits, it is more likely that the ratios will deviate from those that would have occurred in the presence of a grandfather clause. Table A-90 contains a hypothetical three-species example for a single permit scheduled to receive 6.9 percent of the QS if there is no grandfather clause and an aggregate of 3 percent if there is a grandfather clause. The following are the limits applied for each species and the relative size of the OY for each species.

	Accumulation Limits	Relative Weight of OY for Each Species
Species 1	5%	2
Species 2	2%	1
Species 3	3%	0.5
Aggregate Limit	3%	

The first graph contained within Table A-90 shows the allocations to the permit in the presence of a grandfather clause. The second graph shows what happens for the same permit when there is no grandfather clause and the allocations are brought within control limits by first applying the species limit. In this example, when the species limit is applied first, QS Species 2 is cut back by 50 percent (from 0.04 to 0.02). After the species are brought under the accumulation limits, all species are reduced proportionally by another 20 percent to bring the total holdings within the aggregate limit (Species 2 is reduced from 0.02 to 0.16). The third graph shows what happens when the aggregate limit is applied first. All species are cut back by about 50 percent, after which the additional reduction needed to bring Species 2 under the species accumulation limit is only 1 percent. After reducing Species 2 to bring it within the individual species limit, the permit has been reduced to a level below the 3 percent cap so Species 1 and 3 can be increased. The resulting graphs from the two approaches to applying the control limits can be compared to the first graph to see which most closely matches the original species mix. From that, it can be seen that application of the aggregate limit first results in a species mix that better matches the original species mix than application of the species limit first. One objective in developing the QS allocation formulas has been to provide initial recipients with a mix of species that matches their need for prosecuting their fisheries.

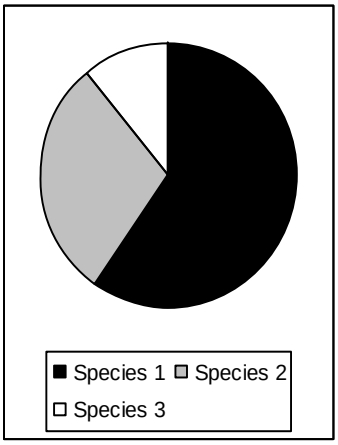
Table A-83. Illustration of the effect of the order in which individual species accumulation limits and aggregate groundfish accumulation limits are applied to limit initial QS allocations (Graphs show the proportion of QS for a single entity with QS allocations for three species under three different scenarios).



Grandfather Clause

Total QS: 6.9%

QS Species 1 = 8%
QS Species 2 = 4%
QS Species 3 = 1.5%



No Grandfather Clause, Species Limits Applied First

Total QS: 3% (weighted total)

QS Species 1 = 4.1%
QS Species 2 = 1.6%
QS Species 3 = 1.2%

No Grandfather Clause, Aggregate Limits Applied First

Total QS: 3% (weighted total)

QS Species 1 = 4%
QS Species 2 = 2%
QS Species 3 = 0.8%

♦ *Percentages for Limits*

The Council's preferred set of control and vessel limits is identified in Table A-82. As highlighted at the start of this section, the task of arriving at these preferred limits a balancing the social objectives behind control and vessel limits against the economic objectives at the center of the rationalization program. In particular, the Council attempted to identify percentage limits that would be low enough to prevent excessive control and use of QS/QP, while at the same time, high enough not to interfere with the objectives of providing for improved operational flexibility for the fleet and a viable, profitable, and efficient groundfish fishery.

The Council's accumulation limits are aimed at more than just preventing market power or other anticompetitive situations from developing in the fishery. The Council views accumulation limits as important tools to use in balancing its broad, and often competing, social, economic, and conservation objectives for the fishery. This broader scope is what Congress seemingly contemplated with section 303A(c)(5)(D) of the MSA. In that provision, Congress chose to use the terms "excessive share" and "inequitable concentration" without defining them and without reference to the Federal antitrust laws or to economic theory. When Congress uses terms without accompanying definitions, the intended meaning comes from the ordinary sense of the words as read within the context of the overall purpose of the statute. Looking to the ordinary meanings of "excessive" and "inequitable" within the context of the MSA national standards and LAPP provisions, it seems clear that Congress granted the Council considerable discretion to determine the levels of quota ownership and usage that would be unreasonable, unnecessary, or unfair considering the Council's overall management objectives for the fishery. This interpretation is consistent with NMFS' nonregulatory guidance on the technical design and use of catch share or LAPPs .

Throughout consideration of control and vessel limits, the Council and its advisors recognized the inexact nature of identifying specific percentage limits for each management unit species. Information on current and historical levels of ownership and control in the harvesting and processing sectors of the fishery is incomplete, as is our understanding of future harvesting efficiency in the trawl fleet. Even with more complete information, there are no analytical methods for pinpointing precise thresholds above which limits become excessive or inequitable. Rather, the process of arriving at percentage limits involved an imprecise balancing of management objectives that left much to the policy discretion of the Council. The task proved especially complex for the nonwhiting trawl fishery because of the many species encountered, the interactions between those species, and the regional diversity in fishing strategies and mix of species for which there is a market.

To help delineate the upper boundaries above which control and use become excessive and the lower boundaries below which limits constrained operational flexibility and efficiency, the Council and its advisory bodies considered several criteria that included the following:

- The initial allocations of QS at the permit and entity level to establish the expected range of starting points in the fishery
- Recent and past levels of vessel performance as an indication of what level of harvest vessels may need to achieve profitability
- The minimum fleet size possible or minimum number of vessels needed to harvest the full trawl allocation for a given species of limits[98]

[98] The minimum number is calculated by dividing the percentage limit into 100 and then adding one vessel or owner for any remainder. For example, the minimum number of vessels needed to harvest a species that was subject to a vessel limit of 3 percent would be 34 (100 ÷ 3 = 33 1/3). Of course, this minimum would be achieved only if participants acquired QS/QP up to the limit. As discussed more below, the more likely result will involve a distribution of QS/QP ownership and usage where only a limited percentage of participants hold

- The minimum number of entities that could control all the harvest in the fishery in comparison to the number of entities that may need some quota to cover catch, including incidental catch
- The maximum amount of revenue a single entity or vessel might receive under a given set of vessel limits

The TIQC developed the first suite of accumulation limits using relatively simple rules focused on past vessel performance. [99] Nonwhiting limits were based on aggregate average catches per permit during the period 1994 to 2003, which was used to allocate QS. Limits for shoreside and at sea whiting were based on the knowledge and recommendations of whiting industry members present at the TIQC meetings. Whiting, as discussed below, was treated differently from the nonwhiting fishery because it is a single-species target fishery with a smaller fleet.

In September 2007, the GAC reviewed the TIQC's initial recommendations and added three options for the Council's consideration (Table A-83). The GAC's options were also based on relatively simple rules using past vessel performance. The GAC's Option 1 would have set control limits at the maximum landings history shares of non-buyback permits for each species, i.e., the 1994 to 2003 average of each nonbuyback permit's annual landings divided by the annual landings of all non buyback permits with an upper limit of 5 percent for all nonwhiting species except for English sole and the Other Flatfish management unit. Option 2 would have set the control limits at 1.5 times the percentages from Option 1. Option 3 was identical to Option 2 for all nonwhiting groundfish control limits except that the aggregate nonwhiting limit would be set at 3 percent. The GAC focused on the 1994 to 2003 period because it matched the window period used for initial allocation of QS and on nonbuyback permits only because those permits represent the performance of vessels most likely to operate in the TIQ program. The intent of Option 1 was to develop caps that were generally above the amounts of QS that will be allocated to most permits based on their history during the qualifying period. Options 2 and 3 were set at levels above Option 1 to explore the effects of higher limit levels. The GAC paid particular attention to the maximum fleet consolidation level, or minimum fleet size, permitted by a particular accumulation limit. For whiting, the GAC followed the GAC recommendations for the purpose of continuing to explore the appropriate level for the limits. The TIQC had recommended exploration of a wide spread of limits for the shoreside, mothership, and catcher-processor fisheries. The low end of the proposed range of limits for the shoreside whiting fishery (10 percent) matched with the maximum 1994 to 2003 landings history shares of nonbuyback permits (i.e., the same data used for the nonwhiting fishery).

QS/QP at the highest level allowed by the accumulation limits.

[99] The first option developed by the TIQC. The limits may vary by species/species group, areas, and sector (see table below).

Sector	Own-or-control Accumulation Limits	Permit Use Limit
Shoreside nonwhiting	All groundfish: 1.5%, 2.1%, 3%, or 5% Individual species: sablefish, 1.7%; Dover sole, 1.95%; Petrale sole, 3.0%; English sole, 7.0%; sanddabs, 27.6%; other flatfish, 9.1%; longspine thornyhead, 2.1%; shortspine thornyhead, 2.0%; widow rockfish, 3.6%; yellowtail rockfish, 3.5%; canary rockfish, 6.0%; and other Sebastes, 6.6%	Double the own-or-control limits
Shoreside whiting	5%, 10%, or 15%.	7.5%, 10%, or 12%
Mothership whiting	10%, 15%, or 25%	20%, 30%, or 50%
Catcher-processor	50%, 55%, or 60%	65%, 70%, or 75%
Whiting sectors combined	15%, 25%, or 40%	25%, 40%, or 50%

Table A-84. Control and vessel limit options: Council preferred alternative.

Species Category	Vessel Limit (Vessel Use Limit)	Vessel Unused QP Limit	QS Control Lim

* Same as Option 2 except for the values indicated below.

For all three original GAC options, the vessel limits would have been set at double the control cap amount, except for whiting. The recommendations for whiting vessel limits differed from the recommendations for nonwhiting vessel limits in that the whiting vessel limits were set at 1.5 times the control caps (again based on recommendations first developed by the TIQC). In general, the GAC recommended setting vessel limits higher than the accumulation limits in order to accomplish the following::

- Allow for potential efficiency gains that may result from the aggregation of catch on fewer vessels, while maintaining a tighter limit on control.
- Provide an opportunity for crewmembers and vessel operators to use their QS on the vessel for which they work.

As explained above in the discussion on the control rule, the GAC envisioned that vessel limits greater than control limits made it possible for QP to be used on a vessel without that QP necessarily counting to the control limit of the vessel owner.

The Council reviewed the GAC's options at the November 2007 meeting and adopted them into the trawl rationalization alternatives for analysis.[100] Analysis of the three options was first presented to the GAC in May 2008. After reviewing that analysis, the GAC requested that the TIQC review the options and make a recommendation to the Council for consideration in June 2008.[101] The TIQC reviewed the analysis and offered corrections and modifications to the whiting limits but did not recommend a particular option.[102] The TIQC recommended reevaluation of the limit, for overfished species like widow rockfish in particular, if the Council were to recommend that shoreside whiting and nonwhiting be combined into a single sector. Taking the TIQC's recommendations into account, the Council adopted all three GAC options, with the TIQC's corrections and modifications, into the PPA for public review and analysis in the preliminary DEIS.[103]

The GAC again considered accumulation limits options, together with the full trawl rationalization PPA, in October 2008. Although the GAC acknowledged the importance of control and vessel limits and the necessity of including them in the program, the committee members were unable to recommend a single option.[104] The GAC did request additional tables, which Council staff presented to the Council in November 2008.[105] In consideration of this additional analysis, and the GAC's inability to produce a recommend set of limits, the Council signaled its intent to include accumulation limits in the program but recommended that the limits be further development and analyzed in a trailing action.[106]

That trailing consideration began, again with the GAC, in January 2009. The GAC reviewed the existing options and recommended two new options, described below. The Council arrived at preferred alternative for target species control and vessel limits at the March 2009 meeting and for overfished species and halibut IBQ in June 2009. The Council's deliberations on target species and overfished species are described separately.

[a] Under the GAC option, the numbers provided for overfished species are for reference only and not part of the GAC option.
[b] The GAP recommended overfished species control limits equal to the maximum initial allocations to an individual permit. Values provided here for overfished species are based on the maximum allocation estimates available at the March 2009 Council meeting. With a single shoreside sector, the allocations would include QS for shoreside whiting and nonwhiting trips. The allocations for QS for whiting trips were not included in the calculation of the maximums for overfished species.

[c] Under the GAC option, the numbers provided for overfished species are for reference only and not part of the GAC option.
[d] The GAP recommended overfished species control limits equal to the maximum initial allocations to an individual permit. Values provided here for overfished species are based on the maximum allocation estimates available at the March 2009 Council meeting. With a single shoreside sector, the allocations would include QS for shoreside whiting and nonwhiting trips. The allocations for QS for whiting trips were not included in the calculation of the maximums for overfished species.

TARGET SPECIES

The Council's March 2009 deliberations on final preferred control and vessel limits for target species centered on the June 2008 PPA, the two new January 2009 options from the GAC (Table A-84), new analysis from the GMT and Council staff on key nonwhiting target stocks, and recommendations and rationale from the GAP.[107]

The GAC's January 2009 options were intended to create a broader range of control and vessel limits for the Council's consideration. Whereas the existing three options for setting control limits were based on the maximum landings values for each species, the GAC's January 2009 options focused on 90th percentile values. The first option would set control limits at the 90th percentile level from the 1994 to 2003 window for each species, effectively bracketing the top 10 percent of annual landings when evaluated together with the existing option 1. The second January 2009 option focused on 90th percentile landings during 2004 to 2006 to give the Council a more recent period for comparison. Both options would set the vessel limits at twice the control limits and include a maximum cap of 10 percent for control limits and 20 percent for vessel limits. The GAC also requested that the GMT review the two new options in time for review at the March 2009 meeting.

The GMT responded to the GAC's request with a suggested framework approach for setting control and vessel limits for the primary nonwhiting target stocks. The approach did not cover whiting, overfished species, or nontarget stocks like lingcod. In summary, the GMT's framework suggested that the Council do the following:

- Focus on a "one vessel, one owner" scenario as a starting point and way of evaluating control limits in terms of harvesting operations.
- Use ex-vessel revenues to gauge what might constitute an "excessive share" or "inequitable concentration" of quota, and on the other hand, what might be overly constraining on vessel operations.
- Consider the regional diversity in target strategies and geographic distribution of each species.
- Identify maximum potential revenues associated with accumulation limits based on regionally important target strategy "bundles" and landings in the fishery (2004 to 2006).
- Consider the market importance substitutability of each species to judge its susceptibility to control.
- Use sablefish and Petrale sole, the two key economic target stocks in the nonwhiting trawl fishery, as benchmarks to set control and vessel limits for the remaining target species.
- Set limits for target species higher than the GAC recommended options to provide for operational flexibility and increased harvesting efficiency among regions and target strategies.
- Employ a relatively small aggregate groundfish control and vessel limits to counter the effect of the relatively higher species limits.

In developing recommendations based on this framework, the GMT first looked at the level of revenue that might be necessary to sustain an efficient operation after the fleet consolidation expected under a trawl rationalization program. A recent study (Lian, *et al.* 2008) of the status quo fleet found that most vessels merely generated enough revenue to cover costs (including a reasonable return on investment) and pay wages without generating an appreciable additional profit (see discussion in Chapter 4). This same study indicated that under a fully rationalized fishery the nonwhiting fleet could consolidate to between 40 and 50 vessels, with the average vessel generating gross revenues on the order of $700,000, compared to a status quo value that is closer to $200,000 (Figure A-121).

[107] PFMC, March 2009 Briefing Book, Agenda Item G.4.b; GAC Report; GMT Report; Supplemental GAP Report; and NMFS Report.

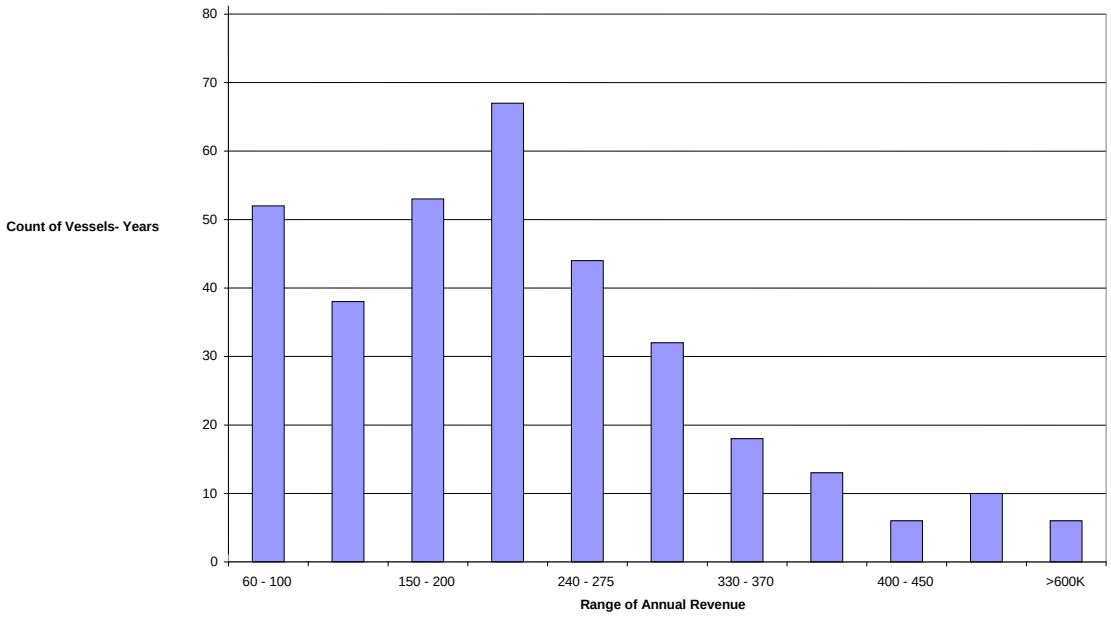

Figure A-99. Count of Vessel-Year Combinations by Annual Revenue Category (2004 - 2006).

The nonwhiting fishery involves considerable diversity in vessels, target strategies, and markets with some species like Petrale sole and sablefish being important to everyone, and other species, like arrowtooth flounder, important only to relatively few vessels. To help the Council identify limits that would most likely accommodate the variety of fishing strategies and opportunities that exist within and across regions, the GMT looked at the species mixes caught by the top three vessels in each region of the coast and identified accumulation limits for the bundles of species targeted by those vessels. These limits were aimed at allowing harvesting entities in each region of the coast to earn at least the $700,000 gross ex-vessel revenue estimate from Lian, et al., 2008.

At the same time, the GMT noted that establishing a suite of species-specific limits intended to accommodate this level of potential ex-vessel revenues in each region would result in limits that could allow for substantially higher levels of consolidation than would be possible under the Council's PPA and the GAC's January 2009 options. Considering the strong preference for accumulation limits that would prevent excessive control and usage expressed by the Council, GAC, GAP, and TIQC, the GMT stressed the aggregate control and vessel nonwhiting groundfish limits as the key means of providing harvesting flexibility among regions and target strategies while maintaining a strong policy against consolidation in quota ownership and usage. Figure A-122 illustrates the expected maximum revenue opportunity by region, depending on the level at which the aggregate limit is set and assuming the suite of individual species accumulation limits developed by the GMT (Table A-84).

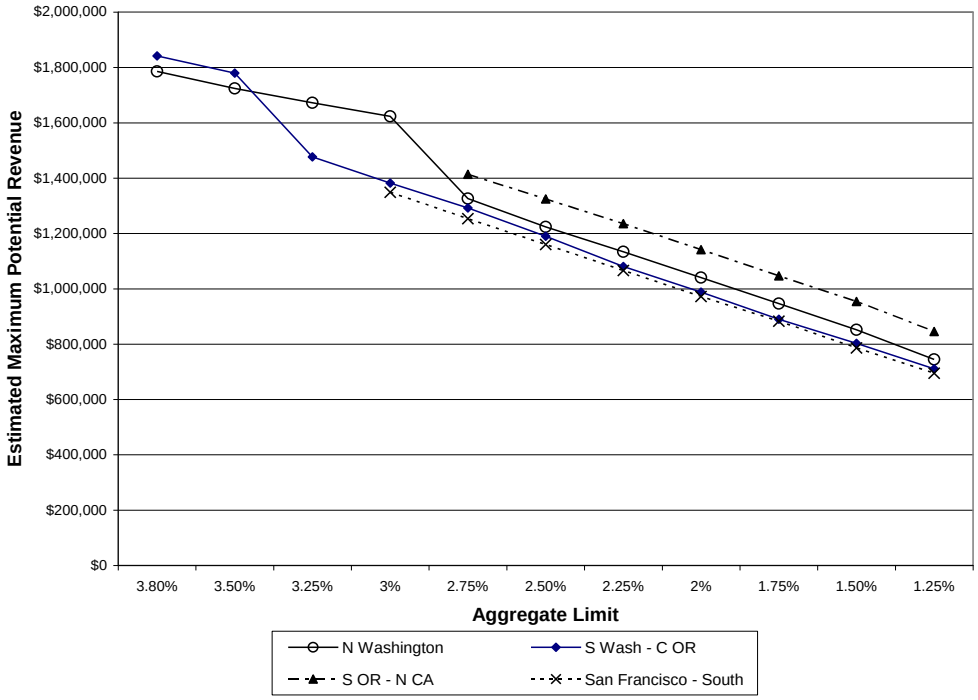

Figure A-100. Estimated maximum potential revenue by regional target strategy and aggregate control limit.

For its recommendations for non-overfished species QS control and vessel accumulation limits, the Council relied principally on the GAP recommendations for the suite of limits it used in the preferred alternative. The GAP had developed its recommendations and rationale taking into account all previous options and analyses, including the suggest framework approach developed by the GMT. The GAP recommendations were focused on accommodating vessel operations for all species at levels that would be at least as great as those identified in the GMT's report, with the exception of Dover sole. Because of Dover sole's market importance and wide spread occurrence in the catch of many vessels, the GAP recommended a limit of 3.9 percent compared to the GMT suggested limit of 5 percent or higher. In addition, the GAP recommendations varied from the GMT on one major principal. The GMT report was based on a principal that each vessel should be able to achieve the target revenue level while relying on QS controlled by the vessel. The GAP approach was to set limits that would allow a vessel to achieve the identified target levels but not necessarily using QP from its own QS. For example, the GMT recommended a Pacific cod control limit of 20 percent. The GAP recommended that the vessel QP limit be set at 20 percent, but that the QS control limit be set at 12 percent. Thus, in order to achieve the revenue and efficiency level that would be accommodated by the 20 percent limit, a vessel will have to rely on QP acquired from other entities. The GAP recommendation was based on concern about excessive consolidation of control for a particular species and the ability of the entities that controlled that species to control not only the targeting for that species, but the harvest of other target species with which that particular species would show up as incidental catch. Based on the GMT analysis, the GAP recommended an aggregate nonwhiting control limit of 2.7 percent. This would accommodate a fairly high level of consolidation (down to as few as about 38 entities controlling QS) and would allow entities to control QS representing up to well over a million dollars of annual ex-vessel revenue (as indicated in Figure A-122).

In general, in developing its recommendations for control limits the GAP used as a starting point the maximum initial QS share allocation to permits and checked that level to ensure that in most cases the

resulting control limit or vessel limit would accommodate the maximum recent share of landings taken by any single vessel in recent years (Table A-84). For many species, the GAP recommended allowing for some growth above the maximum initial allocations to facilitate the desired improvements in harvesting efficiency and in some cases to accommodate recent levels of harvest levels. However, they also went lower than the general approach in situations where a catch of a species was widely distributed along the coast and important to a number of different trawl strategies, as recommended by the GMT with respect to Petrale and sablefish. They did not want to take a chance on one entity developing excess concentration that could potentially affect the entire coast. Occasionally, in the opposite situation, they went somewhat higher when the fishery was very limited geographically. This was also in line with the GMT approach. In these situations, the effect of the concentration would be limited to a smaller geographic area, and they did not believe there was any possibility for expansion of the local fishery to other areas along the coast. Table A-85 provides the GAP recommendation on each species and its rationale. This table also covers GAP recommendations on overfished species. In March 2009, when the Council adopted its final recommendations for non-overfished species, the Council did not adopt the GAP recommendations on overfished species. The limits for overfished species were adopted at a later meeting, as discussed in the following section.

In adopting its preferred QS control and vessel QP limits for non-overfished species, the Council noted that, in general, the ranges of percentages in the accumulation limit options had been relatively consistent since the first set of options was adopted by the Council for analysis at its November 2007 meeting (Table A-83). It was also noted that there will never be perfect information but the Council can still develop a good rationale for setting the accumulation limits while fully recognizing this limitation. In adopting the GAP recommendation, the Council noted its agreement with the rationale provided and indicated that where the GAP recommendations differed from the GMT recommendations, the GAP recommendations were lower (or the GMT had no recommendations). In that regard, the Council deviated from the GAP recommendations for only two species. Starry flounder was the only species for which the GAP recommended a control limit (15 percent) substantially higher than the control limit recommended by the GMT (10 percent). For starry flounder, the Council went with the control limit recommended by the GMT. Additionally, for slope rockfish south, while the GAP recommendation (9 percent) was within the range recommended by the GMT (6 percent to 10 percent), the Council was more comfortable going with the lower end of the GMT's range (6 percent). Neither the GMT nor the GAP provided a recommendation for the aggregate nonwhiting vessel limit. The Council followed the standard approach used for individual species and recommended an aggregate nonwhiting vessel limit of 1.5 times the control limit. The aggregate nonwhiting vessel limit of 3.8 percent could theoretically allow the fleet to shrink to as few as 27 vessels while still taking the entire trawl allocation (or fewer if some of the trawl allocation goes unharvested). However, while the opportunity to trade QP makes it feasible for ownership of QS to contract to as few as 38 entities, it would be very difficult for 27 vessels to take the mix of species necessary such that they could take full advantage of the available harvest opportunities. Lian et al. project an optimum fleet size of 40 to 50 vessels. The fleet size would not be expected to shrink to less than optimum levels.

For shoreside whiting, the Council chose a 10 percent control limit over a higher limit because the 10 percent control limit accommodated the initial allocations and because of concern that a control limit above that (combined with an even higher vessel limit) could concentrate harvest among too few entities and vessels, leaving some coastal plants without enough vessels to maintain operations. Higher limits were set for the mothership co-op program (20 percent ownership and 30 percent usage) because the processing facilities are not tied to coastal communities, and fewer vessels are required to service the motherships.

Table A-87. GAC rationale for recommendations provided to and adopted by the Council (with the exception of overfished species).

Species	Vessel use limit	Control limit	Rationale for limits	Vessel/ Control Ratio (1.5:1.0) (+ =Yes)	Control Limit Greater than (+ =Yes)		In line with GMT Report (+ =Yes)
					Max vessel share of annual fleet landings ('04-'06)	Max Initial Permit QS Allocation	
Pacific Whiting	15.0%	10.0%	Similar to GAC recommendation	+	+	+	
Lingcod	3.8%	2.5%	Limits relatively low because it is a coast-wide species, the catch of which is widely distributed among the fleet.	+	+	+	
Pacific cod	20.0%	12.0%	Higher vessel limits because the distribution is geographically limited, participants few, and opportunities intermittent. Keep the control limits down to prevent excess control. On this basis, provide vessel limits that are greater than the 1.5 to 1 ratio used for other species.	**0**	+	+	
Sablefish N	4.5%	3.0%	Control limit lower than max share because of high dependence on a coast wide basis. Vessel limit is high enough to allow the vessel to achieve the recent maximum share of allocation.	+	**0**	+	+
Sablefish S	15.0%	10.0%	Underutilized; very few vessels operating there now. Potential for gear switching. 10% control limit, in line with GAC 90th percentile recommendation.	+	**0**	**0**	
POP	3.3%	3.3%	*Overfished species rationale.	+	+	+	
WIDOW	2.5%	2.5%	*Overfished species rationale.	+	+	+	
CANARY	5.2%	5.2%	*Overfished species rationale.	+	+	+	
Chilipepper	15.0%	10.0%	On the higher end because it is taken in a smaller area, it s not a coast-wide fishery, and it is under harvested. Similar to GAC recommendations.	+	+	+	+
BOCCACIO	15.0%	15.0%	*Overfished species rationale.				
Splitnose	15.0%	10.0%	Rationale similar to chilipepper.	+	+	+	+
Yellowtail	7.5%	5.0%	Control limit quite a bit higher than initial allocation because it has not been fully utilized in recent years. However, limits should not be too large because the stock is widely distributed and is used in a lot of strategies along the coast.	+	+	+	+

Table A-86 cont. GAC rationale for recommendations provided to and adopted by the Council (with the exception of overfished species).

Species	Vessel use limit	Control limit	Rationale for limits	Vessel/ Control Ratio (1.5:1.0) (+ =Yes)	Control Limit Greater than (+ =Yes)		In line with GMT Report (+ =Yes)
					Max vessel share of annual fleet landings ('04-'06)	Max Initial Permit QS Allocation	
Shortspine N	9.0%	6.0%	Control limits somewhat higher than for Dover and sablefish, for example, because it is underutilized, but at the same time there is need to maintain widespread availability to provide opportunity for many vessels over the majority of the coast.	+	+	+	+
Shortspine S	9.0%	6.0%	The same as limits set for other thornyheads.	+	**0**	+	+
Longspine N	9.0%	6.0%	Similar to shortspine in the north.	+	+	+	+
COWCOD	20.0%	20.0%	*Overfished species rationale.				
DARKBLOTCHED	2.0%	2.0%	*Overfished species rationale.				
YELLOWEYE	5.2%	5.2%	*Overfished species rationale.				
Shelf Rockfish N	7.5%	5.0%	Control limit is twice the maximum initial allocation because the stock has been substantially underutilized in recent years. [Note: While the control limit is less than what is in the GMT report, the vessel limit is in the report's range.]	+	+	+	
Slope Rockfish N	7.5%	5.0%	Rationale similar to shelf.	+	+	+	
Shelf Rockfish S	13.5%	9.0%	South, limits slightly higher than northern rockfish because of fewer vessels participating.	+	+	+	
Slope Rockfish S	13.5%	9.0%	Rationale similar to shelf.	+	**0**	+	
Dover sole	3.9%	2.6%	Lower limit than for many species, because it is widely distributed and caught by many vessels. A large control limit would create opportunities for a few vessels with a relatively lower amount of QS to completely supply the limited market. Even though relatively lower, the control limit is still over twice the maximum initial allocation.	+	**0**	+	
English sole	7.5%	5.0%	Similar to Dover sole (widespread and soft markets) but it is underutilized and more important to a small subset of the fleet (beach boats). Therefore, the limits are larger.	+	+	+	
Petrale sole	4.5%	3.0%	The control limit is similar to sablefish and in line with the GMT report. The limit would constrain the maximum share; however, this maximum occurred in a year in which the OY was exceeded. Similar to sablefish.	+	**0**	+	+

Table A-86 cont. GAC rationale for recommendations provided to and adopted by the Council (with the exception of overfished species).

Species	Vessel use limit	Control limit	Rationale for limits	Vessel/ Control Ratio (1.5:1.0) (+ =Yes)	Control Limit Greater than (+ =Yes)		In line with GMT Report (+ =Yes)
					Max vessel share of annual fleet landings ('04-'06)	Max Initial Permit QS Allocation	
Arrowtooth	20.0%	10.0%	A larger vessel limit is needed because of the smaller number of vessels involved in the fishery and need to allow for expansion of harvest on this underutilized species. Similar to Pacific cod, a control limits is needed that is lower than what is would be if the standard 1.5:1.0 ratio is applied.	**0**	+	+	+
Starry Flounder	30.0%	15.0%	Higher limits because it is one of the fisheries with the lowest number of participants. However, control limit is lower than the maximum initial allocation (30%) because that level would not accommodate enough of the beach draggers.	**0**	+	**0**	
Other Flatfish	15.0%	10.0%	This is a catchall category, which includes sanddabs, rex sole, and true turbots. It has a fairly large aggregate OY. However, a larger control limit is recommended because of the need to specialize in single species within the complex.	+	+	+	
Other Fish	7.5%	5.0%	Lower end of the range of limits because this is a catchall category that everyone might need a little of.	+	+	+	

* Rationale for overfished species control and vessel limits: (1) Control limits are set at the maximum initial allocation under the formula adopted by the Council at this meeting. Of all the species, it is most important to minimize the chance of excessive control of the overfished species QS. The maximum initial allocation level is a reasonable level at which to set the control limit for this purpose. (2) There is significant incentive for vessels to avoid overfished species. The proposed rules for applying the vessel limits will allow any vessel to cover its catch regardless of the level at which the vessel limit is set, if it can find the QP to do it. Therefore, it is recommended that the vessel limit be set at the control limit.

OVERFISHED SPECIES AND HALIBUT IBQ

General Considerations

In March 2009, the Council adopted the GAP recommended accumulation limits levels for overfished species but maintained them as preliminary preferred options. For halibut, the Council adopted a range of options for consideration. The GMT had highlighted reasons why the Council might wish to approach accumulation limits for overfished species differently than target species and raised questions about some of the Council's preliminary choices for overfished species limits.[108] Furthermore, the GAP's recommendations, which the Council used as a basis for its motion, were based on the concept that vessel limits for overfished species would only apply to unused QP with no cumulative limit on annual usage.[109] The Council had not included the unused QP approach when it adopted the limits recommended by the GAP. The GMT had just conceived of this unused QP concept during the meeting

[108] PFMC, March 2009 Briefing Book, Agenda Item G.4.b, Supplemental GMT Report and Supplemental GMT Report 2.

[109] PFMC, March 2009 Briefing Book, Agenda Item G.4.b, Supplemental GAP Report (see footnote).

and had advised the Council that it be scrutinized further before final action was taken. Based on the GMT comments and concerns, the Council maintained the overfished species limit options as preliminary rather than final and requested additional analysis for consideration at the June 2009 meeting.

Three major characteristics of incidentally harvested overfished species (OFS) and halibut (H) (OFS and H bycatch) in the shoreside trawl fisheries ultimately guided the Council in identifying final preferred control and vessel limits for overfished species and halibut IBQ: (1) OFS and H bycatch constrains the harvest of healthy stocks, (2) OFS and H bycatch rates are uncertain, and (3) for target species the incentive is to use QP but for OFS and H taken incidentally the incentive is to avoid the bycatch and conserve QP. In this section, the term bycatch will be used to refer to overfished species and halibut taken incidentally in the groundfish fishery, whether they are retained or discarded. This use of the term varies from the definition of bycatch in the MSA. The MSA uses the term bycatch to refer only to that incidental catch which is discarded.

The first major characteristic to consider is that OFS and H bycatch constrains the harvest of healthy groundfish target stocks. Although individual accountability of the trawl rationalization program is expected to improve individual, and hence fleet, performance in the fishery with respect to OFS and H bycatch, OFS and H are expected to remain scarce relative to healthy target stocks for the near future. OFS and H QP will, therefore, be scarce inputs for harvesting in the rationalized trawl fishery. For some vessels prosecuting certain target strategies in certain regions, QP for particular OFS and H will essentially nonsubstitutable because bycatch will be unavoidable. For example, it will not likely be possible to trawl on the continental shelf, or to target whiting in depths shallower than 150 fathoms, in areas north of 40º 10' N latitude without having the QP to cover incidental catch of canary rockfish. Figure A-123 is a basic, conceptual representation of this point with the diagonal line marking the natural encounter rate between some individual or complex of target species and another species or complex of species that is incidentally encountered as bycatch while targeting those species. Because some rate of encounter will be unavoidable for any given level of target species QP harvested, vessels will need some corresponding amount of bycatcH QP. In the conceptual example provided in Figure 1, vessels would need bycatcH QP at $*B$ in order to harvest at the $*T$ level. This conceptual example assumes that the bycatch rate is fixed and constant. Variability of the bycatch rate will be discussed in the following section.

The importance of OFS and H QS/QP in the trawl rationalization program, and hence its value, will derive from this function as an input. The price fishery participants are willing to pay for OFS and H QP will be related to the target species to which the QP provides access, or more specifically, to the ex-vessel revenue that those target species generate. Harvesters may be able to earn some revenue from the sale of the incidentally caught OFS themselves, yet this revenue could be trivial compared to what the QP is worth in terms of target species revenues. For halibut IBQ, its value will derive exclusively from the value of the target species with which it co-occurs because halibut are a prohibited species that cannot be retained or sold.

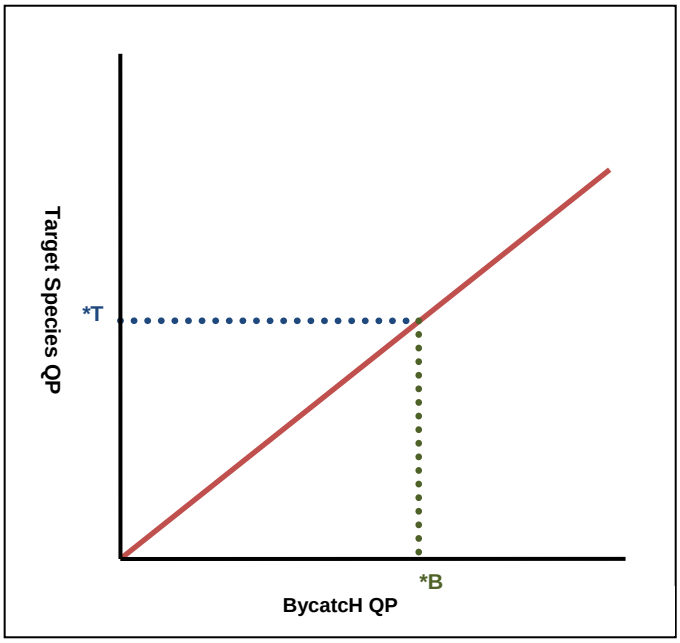

Figure A-101. Conceptual relationship between target and OFS and H bycatch species QP in the TIQ fishery. The diagonal line represents the natural encounter rate between the two species, i.e., the amount of bycatcH QP that a vessel will need to harvest a given amount of target species.

A few implications follow from this first characteristic. Most basically, given that OFS and H QP will be needed to access target species QP, the Council sought to match control and vessel limits for individual bycatch species to the limits for the target species with which they co-occur. That is, the Council sought to set OFS and H quota control and vessel limits high enough to give harvesting operations a reasonable chance at harvesting their target species limits. OFS and H limits that were set too low would unreasonably cap the amount of target stocks that could be harvested by a vessel and would be an overall forced inefficiency on the fleet.

The second implication, somewhat countervailing to the first, arises from the lack of substitutability and relative scarcity of OFS and H QP. Every harvesting operation will need some amount of QP for OFS and H, yet there will not be enough available for everyone to fully harvest their target species holdings. Those that own OFS and H QS, or have other means of directing the use of OFS and H QP, could, therefore, exert considerable bargaining leverage over the fishery. Given that the QS/QP for certain OFS and H will essentially be nonsubstitutable in some cases,[110] concerns about control are as high or higher than for the most economically important targets stocks, such as Petrale sole and sablefish. Again, given that harvesters and processors participate in multiple fisheries on the Pacific coast and in Alaska, that leverage could conceivably extend beyond just activities in the shoreside trawl fisheries. For example, QP for OFS and H might be made available to a vessel contingent on considerations for deliveries in another fishery, such as Dungeness crab.

In consideration of the scarcity and limiting nature of bycatch, the Council's basic approach to setting control and vessel limits was to set them high enough to give harvesting operations a reasonable chance of harvesting the target species limits, yet at the same time, low enough to minimize the risks of allowing entities to gain unacceptable control. Given the central importance of OFS and H bycatch in the fishery, the acceptable margin between limits that are too constraining and those that create

[110] QPs for Dover sole are economically substitutable because if a Dover sole QP is not available (or available in only small quantities), a vessel might earn revenue by targeting on Petrale instead of Dover sole. QP for canary rockfish may not be substitutable because it is needed regardless of the target species that is targeted.

unacceptable levels of control appeared to be much narrower for OFS and H accumulation limits than for target species.

The second major characteristic of OFS and H bycatch is that it is uncertain. This uncertainty, deriving from our limited ability to observe discards and the natural variation in bycatch encounter rates, affected the Council's ability to identify the percentage limits that that best balanced harvest opportunity and concerns about control. The uncertainty of OFS and H bycatch will also be a significant factor influencing fishing and trading behavior in the rationalized trawl fishery.

The best available information on annual bycatch rates in the nonwhiting fishery come from the West Coast Groundfish Observer Program. The WCGOP places observers on board nonwhiting trawl vessels to measure bycatch and discards with a target sampling rate of 20 percent of the annual nonwhiting trawl landings (NMFS, 2006 1700 /id). The bycatch rates produced by the WCGOP are critical for status quo management and have proven effective at assisting the Council with maintaining bycatch within acceptable levels. Yet, as with all statistical estimates, the WCGOP bycatch rates are subject to variation. The estimates used for status quo management are averaged across years and aggregated over all vessels operating in relatively large areas. The "true" bycatch rate varies between vessels, areas, and years meaning that the particular experience of an individual vessel could depend on when, where and how it fishes and could be considerably different from a different vessel operating in the same area. Even with perfect information about current bycatch rates, ratios between target species catch and bycatch are variable at any given time and change over time together with the factors that influence the encounter rate (e.g., fish abundance, ocean conditions, fishing gears and strategies). Fishing strategies, for one, are expected to change in the rationalized trawl fishery under the influence of individual accountability for total catch. The WCGOP rates, although the best available information on bycatch, are, therefore, not necessarily representative of what vessels will experience in the rationalized trawl fishery.

Natural variation in bycatch rates also means that setting control and vessel limits based on an average rate, no matter how precise or unbiased the estimate of that average, would create a situation where some harvesters experience bycatch rates above the average. This point is illustrated in Figure A-124, which represents the same conceptual relationship as in Figure A-123 yet with a variable encounter rate between the target and OFS and H bycatch species. The vertical line at *B represents the average or mean encounter rate and the lines at B_{upper} and B_{lower} mark the tails of the hypothetical probability distribution. In this Figure 2 example, to access target stocks at the QP amount marked by the horizontal line at *T, some vessels would end up needing QP near the B_{lower} level while others may encounter amounts closer to the B_{upper}. Figure A-124 can represent the variability in bycatch experienced at the level of a tow or trip or over the course of the fishing year for an individual vessel. It can also represent the different bycatch encounter rates experienced across vessels and operators, seasons and areas, and between years.

As described in detail below, there are some species in the fishery for which a single trawl tow can bring up a significant percentage of the OFS and H bycatcH QP.[111] Fishery managers have referred to these types of bycatch events as "lightning strikes" because of their relatively low probability of occurrence and large magnitude of the catch. Under status quo management, lightning strike tows in the whiting fisheries have contributed to early closures of the fishery in 2007 and 2008. In the trawl rationalization program, a single lighting strike tow of certain OFS and H species could conceivably place a vessel over the vessel limit. For other species, such risks exist more on the scale of the fishing year because it would take multiple "B_{upper}" type tows or trips to put a vessel in jeopardy. The Council is relying on the individual accountability of the trawl rationalization program to push vessels to change their fishing behavior, minimizing their risk of lightning strikes and lowering their individual average bycatch rates.

[111] See also section A-2.2.1 for a discussion of how a "lightning strike" bycatch event can place an individual in an overage situation.

However, the nature of trawl fishing is such that harvesters only have so much control over what they catch. Even the most skilled and experienced vessel operators cannot be expected to completely eliminate randomness from bycatch.

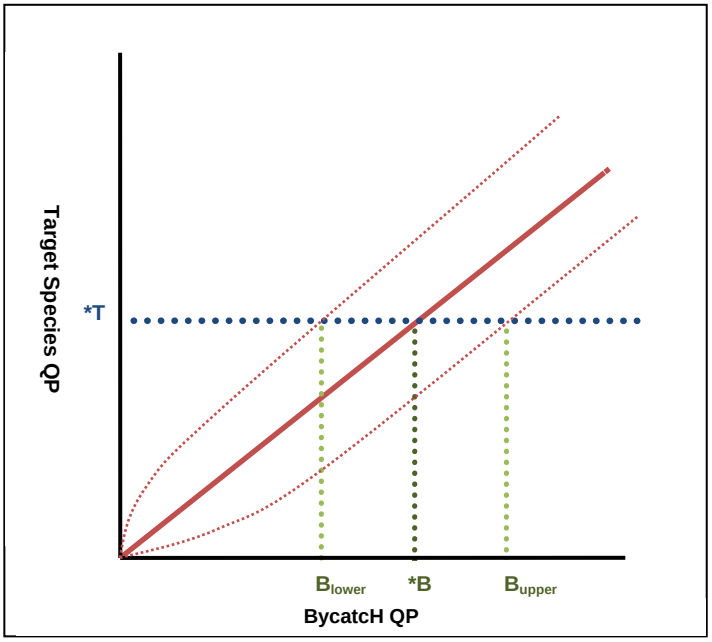

Figure A-102. The same conceptual relationship shown above in Figure A-113 yet with a range of natural encounter rates meant to illustrate the uncertainty and variation involved with bycatch. The amount of bycatch needed to harvest a given amount of target species will vary between vessels, areas, years, etc. For and individual vessel, the rate will vary between tows, trips, and years.

This uncertainty, randomness, and risk involved with bycatch will influence the behavior of harvesters in the trawl rationalization program and the dynamics of the OFS and H QS/QP market. Harvesting operations will have imperfect information about their annual bycatch needs and a perception of risk that they face from high bycatch. This then creates an incentive for harvesting operations to hold onto or acquire enough OFS and H QS/QP to cover their perceived risk. The OFS and H QS/QP would not be needed unless the bycatch is actually encountered, yet in a climate where most in the fishery are uncertain and concerned, harvesters may have little confidence that OFS and H QP would be available on the market at a reasonable price when needed. Therefore, if the control limits are set high enough to permit harvesting operations to cover their perceived margin of risk, then those allocated or with the means of to acquire QS up to the limit may be less likely to sell or lease their QS/QP except at a premium until they gain a better understanding of their OFS and H bycatch needs. This potential chilling effect on market trading is not too dissimilar to the uncertain conditions affecting consumer spending and bank lending in the global financial crisis and recession that existed at the time of the Council's consideration of these limits. Additionally, if harvesting operations are able to cover their margin of risk on their own, then they might be less likely to cooperate with others in risk pools or other arrangements.[112] The tradability of QS/QP will be the main engine of improved harvesting efficiency. Conditions that hamper the trading or cooperative sharing of OFS and H QS/QP could, therefore, be detrimental to the performance of the trawl rationalization program.

[112] For more analysis of the relationship between control limits and risk pools, *see* p. 5-7 of PFMC, June 2009 Briefing Book, Agenda Item E.11.b, GMT Report.

Therefore, as with the first characteristic, the uncertainty of bycatch creates countervailing dynamics to consider in the setting of accumulation limits. The Council looked to set accumulation limits high enough to allow some flexibility for the low probability, high-magnitude bycatch events, yet at the same time, not so high as to reduce quota trading and cooperation between harvesters.

The third major characteristic of bycatch is that the incentives created by the IFQ system are somewhat different than for target stocks, particularly when it comes to the use of QP. Put simply, there is no purpose of using OFS and H QP other than to access target stocks, thereby generating revenue.

Vessel limits are, in effect, a secondary rationing mechanism for QP with the trawl rationalization program itself as the primary mechanism ("IFQ mechanism"). The Council included this secondary rationing mechanism as a measure against the fleet consolidation that will result from the pure market-based rationing of the trawl rationalization program. As detailed in Chapter 4 of this FEIS, the IFQ mechanism is expected to drive those harvesters able to operate most profitably to acquire QP up to their vessels' optimal harvesting capacity. As vessels that are more efficient acquire QP from the less efficient, the fleet consolidates towards some optimal fleet size. Yet, this optimal fleet size is only optimal in terms of harvesting efficiency and may be too small to be considered optimal in light of the Council's other management objectives for the fishery. The vessel limits were thus included in the program in case the IFQ optimal fleet size is undesirably small.

For OFS and H, the IFQ mechanism also creates an incentive for harvesters to acquire an optimal amount of QP. However, there is a key difference in that the optimal amount of OFS and H QP is a direct function of the optimal amount of target species. As discussed above, OFS and H QP will function as an input in the fishery rationalized under an IFQ program, or in other words, as a cost of harvesting. As with all profit-seeking enterprises, harvesters will seek to minimize costs and maximize revenues. The optimal level of OFS and H QP can thus be thought of as the amount that allows vessels to access their target species and no more. The market is expected to set a high price for OFS and H QP, and in turn, there will be a high opportunity cost to using OFS and H QP inefficiently. In a well functioning QP market where each harvesting operation has sufficient information about its OFS and H need, the IFQ mechanism would ration OFS and H QP efficiently, and vessel limits on the use of OFS and H QP would be unnecessary because the Council's policy objectives on fleet size would be achieved solely by the vessel limits placed on target stocks. In other words, in a well functioning market vessel limits on bycatch would be redundant to those on target species.

Figure A-125 illustrates this concept with the horizontal line I representing the vessel limit on target species QP. Again, if the simple diagonal line from Figure A-123 represents the ratio or natural encounter rate between the target and bycatch stock for a particular vessel, that vessel would need OFS and H QP at the *B level in order to harvest the target species vessel limit. In such a scenario, a vessel limit set at *B (vertical line B) or higher (e.g., vertical line C) would, therefore, have no impact to the vessel. If Figure A-125 represents the fleet in aggregate, a vessel limit set at *B or higher would have no influence on fleet consolidation above what is accomplished by the target species vessel limit I. On the other hand, if the Council were to set the vessel limit below *B, the vessel would be prevented from harvesting the full target species limit. In the Figure A-125 example, a vessel QP limit for a bycatch species set at vertical line A would create a de facto target species limit depicted by horizontal line II. Over the aggregate, a vessel QP limit for a bycatch species set below the average encounter rate would be expected to allow less fleet consolidation than contemplated by the Council's target species vessel limit. In sum, in this simplistic example the limit on the amount of QP a vessel is allowed to have to cover OFS and H bycatch either has no effect on fleet consolidation, or it permits less consolidation than desired.

Vessel limits for OFS and H may be redundant in a well functioning, simple IFQ fishery, yet the same cannot realistically be said for shoreside trawl fisheries. For the reasons highlighted above in the discussion of the first two major characteristics of bycatch uncertainty, it would be unreasonable to

assume that the QS/QP market will function optimally, especially in the early years of the program. QS/QP to cover OFS and H could be so scarce and limiting on harvest that many harvesters will be unable to achieve target species vessel limits. Variability in bycatch rates means that harvesters would likely hold on to OFS and H QP on the chance that they might need it. Further, some may see acquisition of OFS and H QP in excess of their needs as a means to capture profits for groundfish, and possibly nongroundfish, harvest of vessels needed the OFS and H QP. The OFS and H vessel limits may be more influential on the number of vessels operating in the fishery than the target species vessel limits. In addition, as discussed above in the section on target species, the Council did not set vessel limits for target species envisioning that the limit would result in some precise fleet size. Instead, the Council, in its best judgment, attempted to set vessel limits at a level that best balanced the need for individual harvesting efficiency and the desire to minimize the risk of over consolidation in the fleet. The interaction between target species vessel limits and vessel limits for OFS and H cannot be represented by the conceptual diagrams shown in this section; the multispecies, regionally diverse, shoreside trawl fishery is just too complex for the Council and its advisors to predict the effect of any one particular vessel limit. The Council, therefore, included limits on the use of OFS and H QP not just because of their effect on fleet consolidation, but also to promote the overall social, economic, and conservation goals and objectives of the trawl rationalization program. Nonetheless, the fundamental point to make related to this third major characteristic of bycatch is that IFQ mechanism creates a strong disincentive against inefficient use of QP. Further implications of this disincentive are explored below in the context of the unused QP limit.

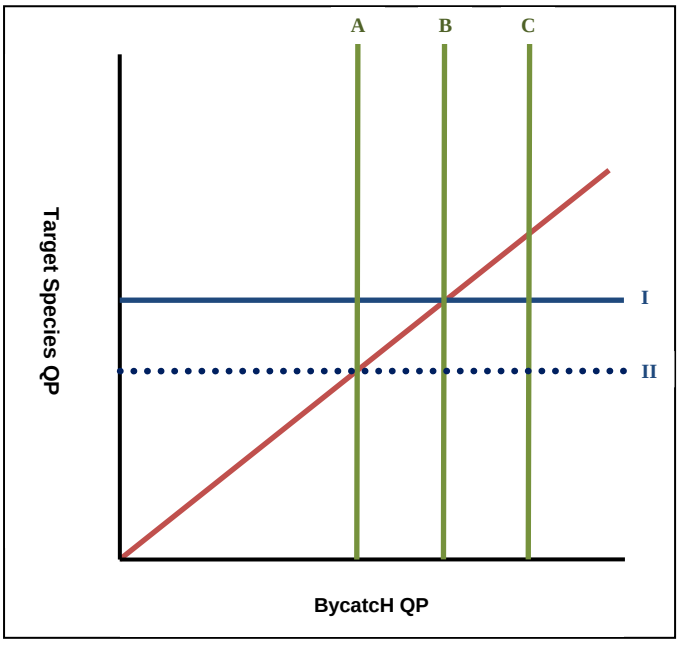

Figure A-103. Same conceptual relationship as in Figure A-113 with a vessel limit on target species marked by the solid horizontal line *I* and three possible vessel limits on bycatcH QP depicted by the three vertical lines *A*, *B*, and *C*. The dotted horizontal line, *II*, represents the effective target species limit that would result if the bycatch vessel limit were set at vertical line *A*.

Approach for Setting Control Limits for Overfished Species and Halibut

The Council set its preferred control limits for overfished species and halibut IBQ at the level of the estimated maximum initial allocation to an individual permit.[113] The Council determined that this method appropriately matched the control limit for a particular overfished species to those for co-occurring target species while also keeping limits low enough to minimize issues of control.

The initial allocation formulas for overfished species and halibut IBQ is described in detail in section A-2.1.3.a and Appendix C. The most important feature of the formulas for analysis of control limits is that they are based on WCGOP bycatch rates and designed to accommodate current spatial fishing patterns in the fishery. For overfished species QS, the initial allocation formula applies area-specific WCGOP bycatch rates for each overfished species to the target species QS allocated to each permit, with the appropriate area-specific bycatch rate assigned to a permit based on the permit's logbooks. The formula for halibut IBQ is structured similarly, except that it uses a broader area stratification and applies the WCGOP bycatch rates only to each permit's allocation of arrowtooth flounder and Petrale sole, the two species most closely associated with Pacific halibut.[114] The estimated maximum initial allocation for a particular species is, therefore, made to a permit with a relatively high initial allocation of target species and a record of fishing in an area where the WCGOP bycatch rate for that species is also relatively high. For example, the maximum initial allocation of halibut IBQ is made to a permit receiving substantial amounts of arrowtooth flounder and Petrale sole and with history operating in an area where the WCGOP rates predict halibut to be abundant.

The GAP believed that of all the species in the trawl fishery it was most important to minimize the chance of excessive control of the OFS and H QS.[115] In its reports to the Council at the March and June 2009 meetings, the GAP recommended the maximum initial allocation level is a reasonable level at which to set the QS control limit for such a purpose.

In a June 2009 report, the GMT team noted that the approach's use of area-based bycatch rates and permit-specific logbook was the most reasonable method of those considered for identifying control limits that would accommodate expected bycatch needs across the different target strategies and regions of the coast. [116] That same report noted that, although the maximum initial allocation approach would set control limits for many species above the expected need of the vast majority of fishery participants, the control limits would still be expected to encourage cooperative risk pooling among vessels operating in regions of the highest bycatch species abundance, which are the areas where such arrangements will be needed most.[117]

---

[113] The Council could only set the control limit based on the *estimated* maximum initial allocation to individual permits because the final initial allocation will not be known until NMFS freezes the database and issues the QP. However, permit-level allocations are not expected to change substantially from what was estimated in this analysis.

[114] For more explanation, *see* Appendix C and PFMC, June 2009 Briefing Book, Agenda Item E.11.a, Attachment 1, Issue Summary and Analysis: Accumulation Limits, Divestiture and Related Provisions.

[115] PFMC, March 2009 Briefing Book, Agenda Item G.4.b, Supplemental NMFS Report.

[116] PFMC, June 2009 Briefing Book, Agenda Item E.11.b, GMT Report.

[117] An overfished species or halibut control limit that is set high relative to the amount needed for target species would allow an individual harvester to acquire enough QS to cover a reasonable range of its expected bycatch need, leaving it with a low likelihood of need to acquire overfished species or halibut bycatcH QP during the fishing year. A control limit that is closer to the average vessel need (for a vessel that has the maximum amount of QS for target species) leaves harvesters in a position where there is a greater probability that they will have to acquire overfished species or halibut QP during the year. This, then, might encourage those entities to enter into risk sharing pools with other harvesters.

The Council was confident in this method's ability to produce control limits that are not unduly constraining on an entity's ability to control the OFS and H QS needed to access target species because the limits are based on the best available information on the expected need of large producers operating in areas where bycatch is most abundant. In other words, the control limits set at the maximum initial allocation should only be constraining to those harvesting operations that own QS at or close to the target species control limits and that wish to operate in areas where bycatch rates are high. Those owners harvesting below the level allowed by the target species, or in areas where lower bycatch rates can be achieved, should not be constrained by the control limits.

The Council was also confident that the method would produce control limits that minimized the ability of entities to exert unwanted control over the fishery because the maximum initial allocation used to set the control limit is at the permit-level and not the entity-level. As discussed elsewhere in this FEIS, permit-level allocations are most representative of the operation of a single vessel. Entities wishing to operate multiple vessels using only the QS they control will have to do so by achieving a lower bycatch rate than that on which the rate used to produce the control limit is based. Likewise, entities receiving an initial allocation of OFS and H QS at or near the control limit will also have to improve upon their bycatch performance if they wish to increase their target species harvest to the levels allowed by the target species control and vessel limits. Overall, the Council's final preferred control limits will make it difficult for entities to control more OFS and H QS than needed by a single vessel operating in areas where bycatch is most needed.

The Council's control limits for overfished species and halibut IBQ are discussed on a species-by-species basis below.

The Unused QP Limit and General Approach to Vessel Limits for Overfished Species and Halibut IBQ

For overfished species and halibut, the Council's final preferred alternative includes both a vessel QP limit and a limit on unused QP in a vessel account. For these species, the Council set the unused QP limit equal to the control limit and identified vessel limits for each species based on the GMT and Council staff analysis of bycatch patterns in the status quo fishery.

The vessel limit and unused QP limit were originally considered as alternative approaches for governing bycatcH QP with both having apparent advantages and disadvantages. Further analysis and consideration between March and June 2009 revealed that the two concepts could be complementary. In light of the central importance of bycatch, the Council believed its management objectives would be best served by employing both in the trawl rationalization program.

The central challenge with OFS and H QP is, again, to prevent excessive use and counterproductive holding of QP while also providing individuals with some flexibility for unexpected bycatch performance. Identifying limits that would accomplish both objectives proved especially difficult because of the many factors and countervailing dynamics discussed above.

The first method considered by the Council and its advisors was to set vessel limits above the control limits. This would allow harvesting operations to acquire QP above what could be derived from the QS allowed under the control limit via the market or some cooperative arrangement like a risk pool.

The major disadvantage to this approach is that higher vessel limits would allow entities to acquire and hold more QP in their vessel accounts than what is contemplated by the control limits. The GMT used canary rockfish to illustrate the potential implications of this in a June 2009 report.[118] To accommodate

[118] PFMC, June 2009 Briefing Book, Agenda Item E.11.b, Supplemental GMT Report 2.

rare but likely bycatch of canary rockfish, the GMT recommended setting the vessel limit at 10 percent. Few vessels would encounter canary bycatch of this magnitude, yet the vessel limit would allow any entity to acquire and place up to 10 percent in a vessel account. This raised concerns, particularly with the GAP, that the benefit of providing flexibility to the relatively few vessels that might need higher vessel limits in any given year might be outweighed by the overall risks to the fishery associated with allowing QP to be held in higher concentrations on fewer vessels. These risks, outlined in more detail above, include potentially less QP on the market for those that need it to cover actual catch and entities exerting control over other fishery participants by directing the use of substantial amounts of QP.

The GMT originally conceived of the unused QP limit concept because it would only allow entities to acquire QP above the control limit if needed and because it would eliminate the need to identify specific vessel limits that best balanced the need for flexibility and concerns over control.[119] The unused QP limit instead relies on the QP market to regulate individual use. Vessels that encountered OFS and H would be allowed to replenish their QP accounts back to the unused QP limit thereby providing flexibility to cover any bycatch overage as long as the QP was available from other fishery participants. The price of acquiring the additional QP would be set by the market, and as highlighted above, the cost of acquiring QP could be substantial.

The major disadvantage to the unused QP limit was that it places no ultimate limit on use of OFS and H QP. The GAP was not concerned by this, believing instead that the unused QP limit would improve functioning of the QP market, and in turn, that the QP market incentives would be enough to prevent fishermen from engaging in a strategy that relies on serial replenishment of OFS and H QP. The unused QP approach would allow harvesters to cover bycatch overages as long as the QP was available. However, the QP would have to be obtained through the market at potentially high cost or through a cooperative arrangement where the ability of would be limited. The GAP was most concerned with the potential issues of control and QP availability associated with the higher vessel limit approach. The GAP endorsed the unused QP limit concept in March 2009 and reiterated its support during the Council's final consideration of accumulation limits in June 2009.

The Council recognized the market forces at play, yet remained concerned that, under the unused QP approach, the lack of an upper limit on bycatcH QP would weaken the incentive, even if marginally so, and send the wrong message to fishery participants about the necessity of improved bycatch performance to the success of the trawl rationalization program. Bycatch is so limiting in the fishery that unreasonable use of QP by a small number of actors could have negative impacts, including less overall harvest and fewer vessels operating in the fishery. For this reason, although the Council accepted the GAP's recommendation and rationale for employing the unused QP limit, it also capped cumulative annual usage with the vessel limits analyzed by the GMT and discussed below species-by-species.

Another concern that has been expressed regarding the unused QP limit concept was that it might induce early season fishing activity by vessels concerned about the availability and price of OFS and H QP later in the year. The degree to which this issue is a concern depends on the degree to which there is seasonality in the price of bycatcH QP. Theoretically, the anticipation of higher prices later in the year should be self-dampening. Those with OFS and H QP anticipating higher prices later in the year will be more likely to hold QP to sell late in the year. This dynamic will tend to make more QP available then, reducing the degree of the price rise. If enough people hold out hoping for a higher price, in the extreme there could be a late season glut and reduction in price. At the other extreme, if enough fishermen fish early in order to use their OFS and H QP and make room to acquire more, the early season demand will rise, increasing early season OFS and H QP prices. Together, these two dynamics would be expected to flatten out the initial expectation of a price swing during the year. In systems such as the New Zealand

[119] PFMC, March 2009 Briefing Book, Agenda Item G.4.b, Supplemental GMT Report.

system, where there are constraining species in a multispecies fishery, strong late season increases in price are not typical. The Council will monitor patterns in fishing activity and QP trading early in the trawl rationalization program and revisit the unused QP limit if necessary.

Development of Specific Limits for Overfished Species and Halibut IBQ

This section describes how the general approaches to setting control and vessel limits were applied to each overfished species and halibut. The analysis detailed below was presented to the Council by the GMT and Council staff in June 2009.[120] The figures describing the distribution of QS initial allocations for each species are also discussed above in Section A-2.1.3.a. Discussion of the different bycatch characteristics of each species is based on observations from the WCGOP, monitoring of the shoreside whiting fishery, and the GMT and Council staff's experience managing the status quo trawl fisheries. Control and vessel limits are equated to pounds of fish using 2010 OYs and Amendment 21 ISAs or status quo sector catch proportions for species not included in Amendment 21 ("2010 catch scenario"). Again, the actual pounds associated with QS/QP could be considerably different at the start of the trawl rationalization program because stock abundance, and our understanding of stock status, changes over time. Likewise, the amount QP deriving from QS will undoubtedly fluctuate throughout the trawl rationalization program from biennial cycle to biennial cycle, and in some cases, from year to year. Given the uncertainty in the data and questions about how fishing behavior and bycatch rates and needs might change, the Council recommended that vessel limits for overfished species and halibut IBQ be reviewed during the first biennial management process after implementation of the trawl rationalization program.

Yelloweye Rockfish

The maximum initial allocation of QS for yelloweye rockfish is 5.7 percent. Under the current shoreside trawl catch of 0.6 mt per year, this would equate to 75 pounds of fish. As the distribution in Figure A-126 shows, only a few entities that operate in the areas of highest yelloweye abundance would be expected to need this amount of yelloweye to access their target QS holdings.

Although most harvesting operations should be more than accommodated by the control limit, the Council also recognized that a single trawl tow can bring up enough yelloweye to put vessels at jeopardy. The WCGOP data includes discard events of yelloweye rockfish as large as at least 150 pounds, which under catch levels, would represent 11 percent of the QP, or almost twice what would be allowed by the control limit.

The Council also recognized that a vessel experiencing a tow of this magnitude would almost certainly encounter additional yelloweye during the year. The Council, therefore, chose to set the vessel limit at 15 percent, which would equate to 200 pounds under a shoreside trawl allocation of 0.6 mt.

[120] PFMC, June 2009 Briefing Book, Agenda Item E.11.a, Attachment 1 Issue Summary and Analysis: Accumulation Limits, Divestiture and Related Provisions; and Agenda Item E.11.b, GMT Report

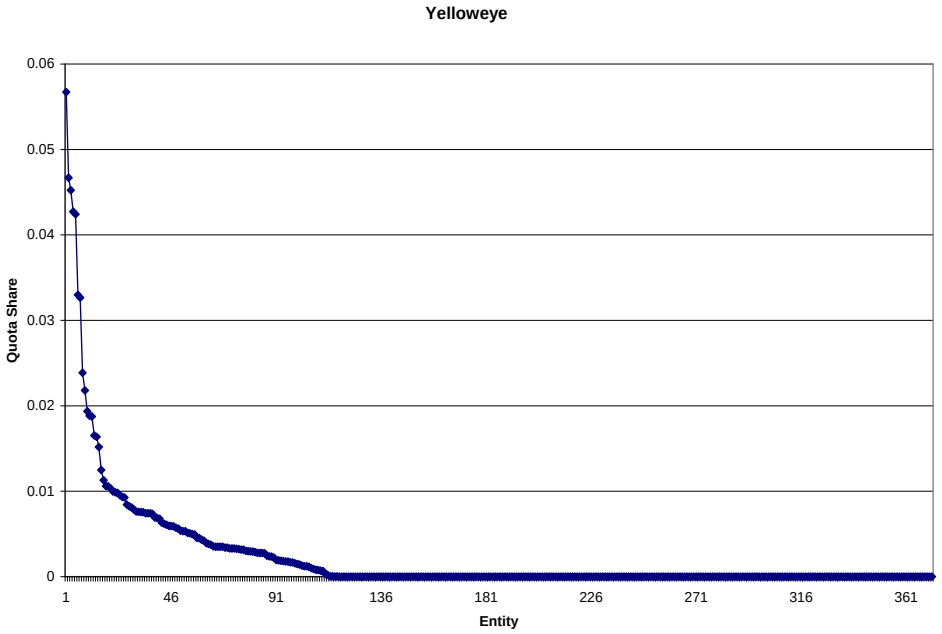

Figure A-104. Estimated distribution of yelloweye rockfish QS to individual vessel permits and processing entities.

Canary Rockfish

Canary rockfish is one of the most important bycatch stocks in the shoreside trawl fisheries. The canary rockfish initial allocation plots are fairly similar to those for yelloweye in that a handful of receive initial allocations that are noticeably larger than others. The highest initial allocation of canary rockfish is 4.4 percent, which at existing catch levels, would equate to 1,571 pounds of canary in the 2010 catch scenario. Canary rockfish are also highly important in the whiting fishery; thus, the initial allocation is a product of the weighted average of the whiting and nonwhiting initial allocation formulas. The Council, therefore, expects that a control limit of 4.4 percent will adequately meet the needs of harvesting entities that have prosecuted both whiting and nonwhiting strategies under the status quo.

In November 2009, the Council revised its final preferred alternative with respect to the allocation of canary rockfish. Before the revision, canary would have been allocated entirely based on the bycatch method, which applies a permit's logbooks to fleet bycatch rates and the permit's initial allocation of target species QS. The revision made was to allocate 45 percent of the canary rockfish equally among all permit holders (amount based on the amount of canary landed by the permits that were bought back). As a result of this revision, the maximum initial allocation was reduced from 4.4 percent to 3.8 percent. However, this reduction does not alter the rationale for setting a canary control limit at 4.4 percent. The revision to the allocation formula was based on the lack of an initial allocation provided to certain ports along the coast. The accumulation limits are "one size fits all" for the entire coast, and they govern not just the initial allocation, but the amount of canary that an entity will be able to control over the long term. Therefore, it is important that the individual species limits be set in proportion to the target species limits. Without an equal allocation element for overfished species, the maximum allocation of canary (4.4 percent) was driven by the allocations of target species to individual entities and the application of logbook and bycatch rates to those target species allocation. Changing the allocation formula for canary to include an equal allocation element does not alter the balance between the target species QS accumulation limits and the best estimates of the corresponding amounts of canary QS needed. Therefore, despite the revised method for making an initial allocation of QS, it continues to be

appropriate, based the control limit on the balance between the target species QS and the need for canary as determined entirely by permit logs and bycatch rates. No adjustment is needed in response to the revision made to the canary allocation formula.

Canary rockfish have also been caught in lightning strike tows of considerable magnitude. Available data from the WCGOP shows that discard events of canary have occurred as large as at least 150 pounds. These data are truncated at 150 pounds, meaning larger events may have occurred. Data from the Washington Arrowtooth Flounder EFP show that some vessels incidentally caught as much as 1,000 pounds of canary over the year. This EFP was conducted under conditions similar to a rationalized fishery and in an area where canary are relatively abundant. Shoreside whiting vessels have also encountered nearly 1,000 pounds of canary rockfish during the 2004 to 2007 seasons. The Council, therefore, chose to set the vessel limit at 10 percent, to accommodate vessels that participate in both the whiting and nonwhiting target strategies. At current catch levels, this would permit vessels to use roughly 2,000 pounds of canary QP over the year.

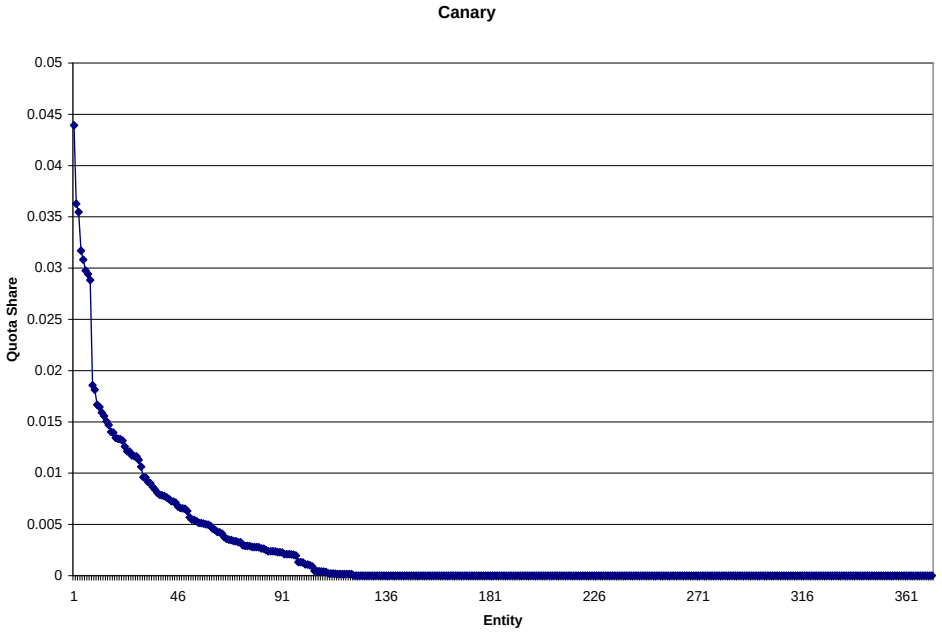

Figure A-105. Estimated distribution of canary rockfish QS to individual vessel permits and processing entities.

Darkblotched Rockfish

Darkblotched rockfish are also allocated based on the nonwhiting and whiting allocation formulas. The highest initial allocation is expected to be 4.5 percent, which equates to 25,000 pounds of fish scenario. Darkblotched rockfish do not appear to create the same "disaster tow" risk as canary and yelloweye. This may be attributable to the fact that darkblotched aggregate to a lesser degree than other types of rockfish (Parker, pers. comm., 2005). Without the same concern about lightning strike catch events, the Council chose to set the vessel limit for darkblotched rockfish at 1.5 times the control limit, or 6.8 percent, using the convention used for most nonwhiting target stocks.

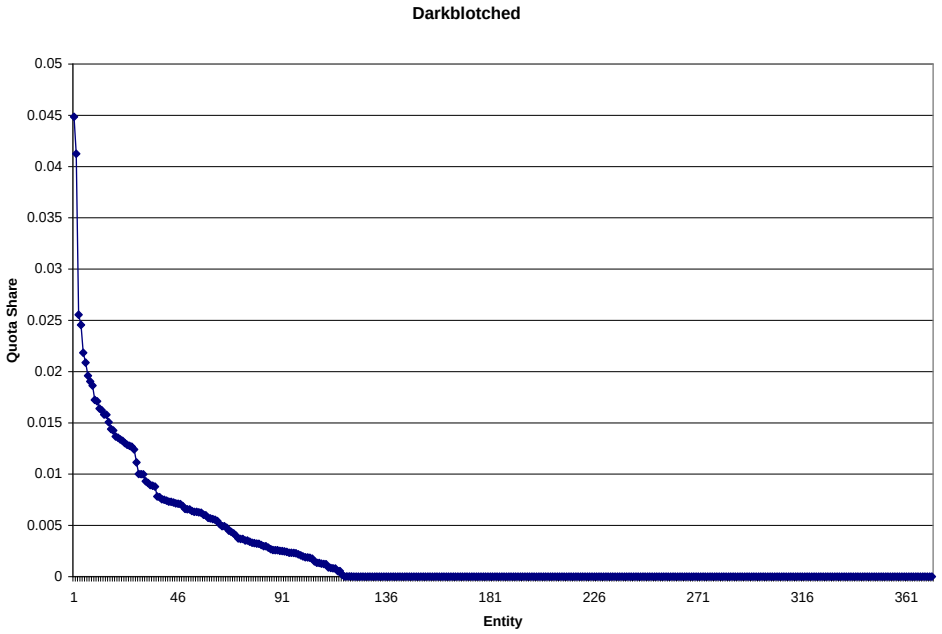

Figure A-106. Estimated distribution of inital allocation of darkblotched rockfish QS to individual vessel permits and processing entities.

Pacific Ocean Perch

The maximum initial allocation of Pacific Ocean perch is estimated to be four percent. This percentage equates to 14,374 pounds of fish in the 2010 catch scenario. Pacific Ocean perch are similar to darkblotched rockfish in that they are less subject to lightning strike tows. The Council, therefore, chose to set the vessel limit at 1.5 times the control limit or six percent.

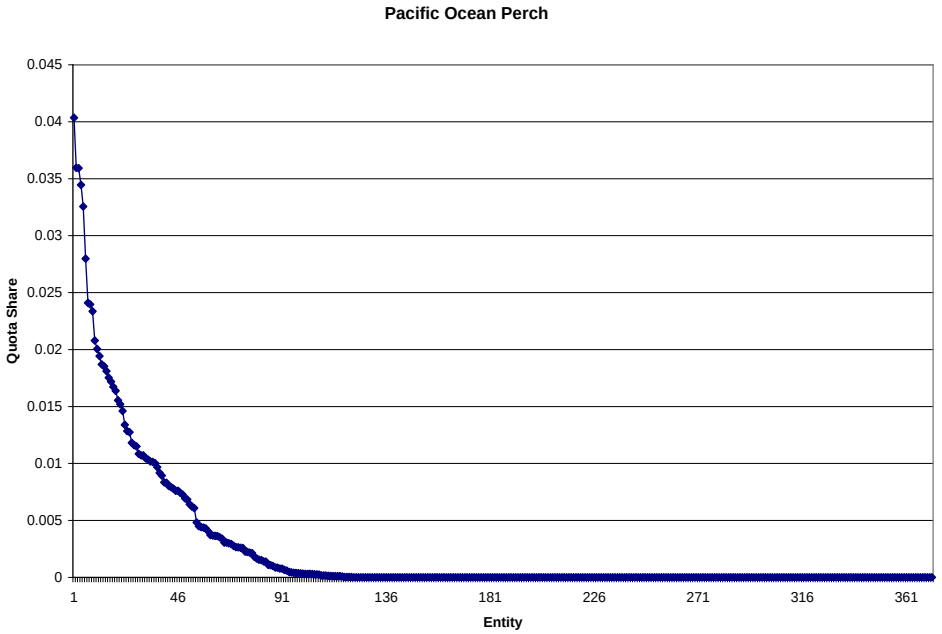

Figure A-107. Estimated distribution of initial allocation of Pacific ocean perch QS to individual vessel permits and processing entities.

Bocaccio

Even more so than for yelloweye and canary, the initial allocation bycatch formula results in a highly skewed distribution of QS with some entities receiving amounts that are orders of magnitude larger than others. The estimated maximum allocation of bocaccio is 13.2 percent. Under the 2010 catch scenario, this percentage would equate to 3,579 pounds of fish.

The Council considered this number closely because it is large compared to other overfished species. At the suggestion of the GMT, the Council also considered disregarding the highest allocation amounts and setting the control limit at 8 percent. However, given that bocaccio is highly constraining to a relatively small geographic area, the Council believed 13.2 percent was an appropriate control limit. The Council did not believe the percentage was so high as to raise concerns over excessive market control or to justify a deviation from the methodology used for the other overfished rockfish stocks. In addition, the Council also noted that few vessels are likely to operate in the area where the overfished bocaccio stock is encountered in large numbers and that larger control limits were natural in such circumstances.

With few trawl vessels operating in southern areas, the WCGOP data are more limited for bocaccio than for other species. The available WCGOP data do record individual discard events as large as at least 150 pounds, yet, as with canary, the data are truncated, and larger catch events may have occurred. West coast research landings have taken more than 4,000 pounds of bocaccio on a single trip in recent years. Under current shoreside trawl catch levels, 4,000 pounds of bocaccio equate roughly to 16 percent of the QP. However, given that research data are not reflective of commercial fishing practices, the Council did not believe vessel limits should accommodate unintended catch of this magnitude. Instead, the Council chose to set the vessel limit at 15.4 percent, which would permit vessels an additional 2,000 pounds above what is permitted by the control limit under current shoreside trawl catch levels.

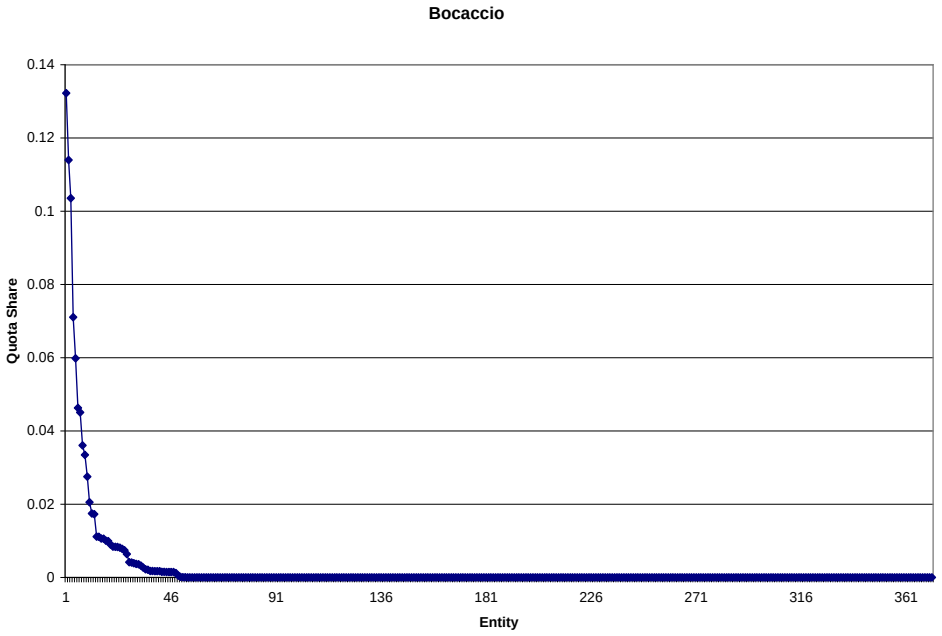

Figure A-108. Estimated distribution of initial allocation of bocaccio QS to individual vessel permits and processing entities.

Cowcod

Cowcod raised similar concerns as bocaccio as it is also highly constraining to the trawl fleet in a relatively concentrated area in the south. The bycatch rate allocation again results in a few entities receiving initial allocations of cowcod QS that are orders of magnitude larger than most others, with the maximum initial allocation estimated to be 17.7 percent. As with bocaccio, the Council determined that this was an appropriate control limit despite being high relative to other species because of the small number of vessels expected to fish in areas where cowcod are encountered. Like yelloweye, cowcod is relatively rare with 17.7 percent translating into only 507 pounds of fish under current shoreside trawl catch levels.

The WCGOP data are also limited for cowcod because of the few trawl vessels operating from ports in the south in recent years. However, the available observer data again indicate that some encounters of cowcod have exceeded 150 pounds. Yet the data also show that most of the larger cowcod discard events have been less than 100 pounds. Based on this information, the Council determined that the 507 pounds of fish allowed by the control limit was sufficient to protect vessels from unexpected cowcod bycatch events and, therefore, set the vessel limit equal to the control limit.

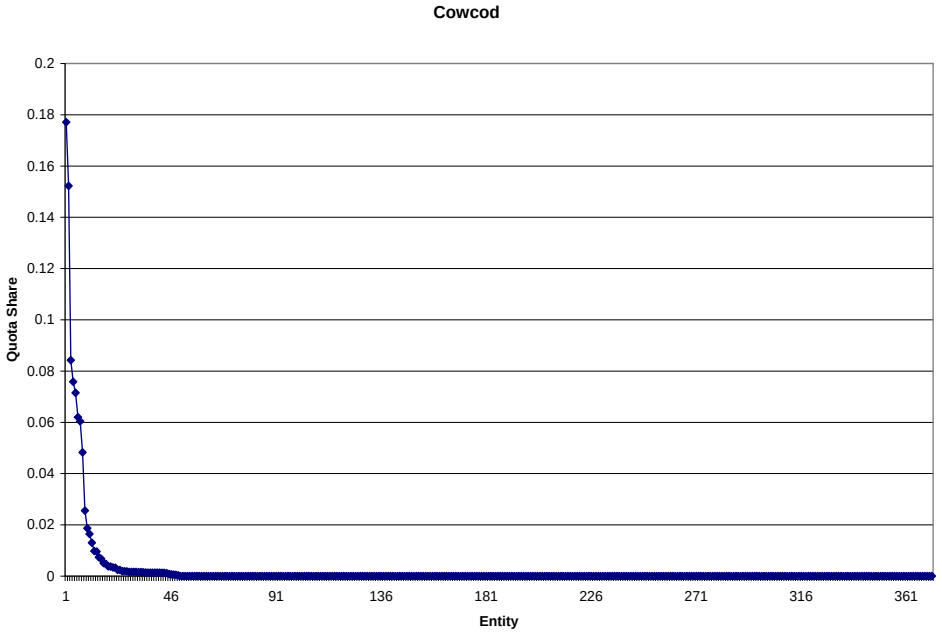

Figure A-109. Estimated distribution of initial allocation of cowcod QS to individual vessel permits and processing entities.

Widow Rockfish

Widow rockfish are caught by both whiting and nonwhiting vessels, although they have become particularly important to whiting vessels under rebuilding. The maximum initial allocation of widow rockfish produced by the whiting and nonwhiting bycatch allocation formulas is estimated to be 5.1 percent. This percentage would equate to 33,000 pounds of fish under the 2010 catch scenario.

In recent years, individual shoreside whiting vessels have encountered the largest lightning strike catches of widow, with some tows bringing up more than 20 metric tons of fish. Under the 2010 catch scenario, 20 mt would equate to nearly 7 percent of the QP. Most vessels, however, have not encountered catch evens of this magnitude. In consideration of the whiting data, the GMT

recommended 10 mt as a reasonable margin for large bycatch events. The Council accepted the GMT's recommendation and set the vessel limit at 8.5 percent, which amounts to 54,989 pounds under the 2010 catch scenario.

The Council also recognized the possibility that widow rockfish could be declared rebuilt by the start of the trawl rationalization program. In the scenario that the stock is rebuilt, the Council recommended setting the vessel limit at 1.5 times the control limit in line with the convention used for most nonwhiting target stocks. The Council chose to maintain the 5.1 percent control limit under either scenario. The overall amount available to the shoreside trawl sectors could be four times higher than what is available under rebuilding, meaning the control limit of 5.1 percent could represent more than 130,000 pounds of widow. Based on the widow rockfish stock assessment adopted by the Council at the September 2009 meeting, widow will not be rebuilt before the 2011/2012 management period.

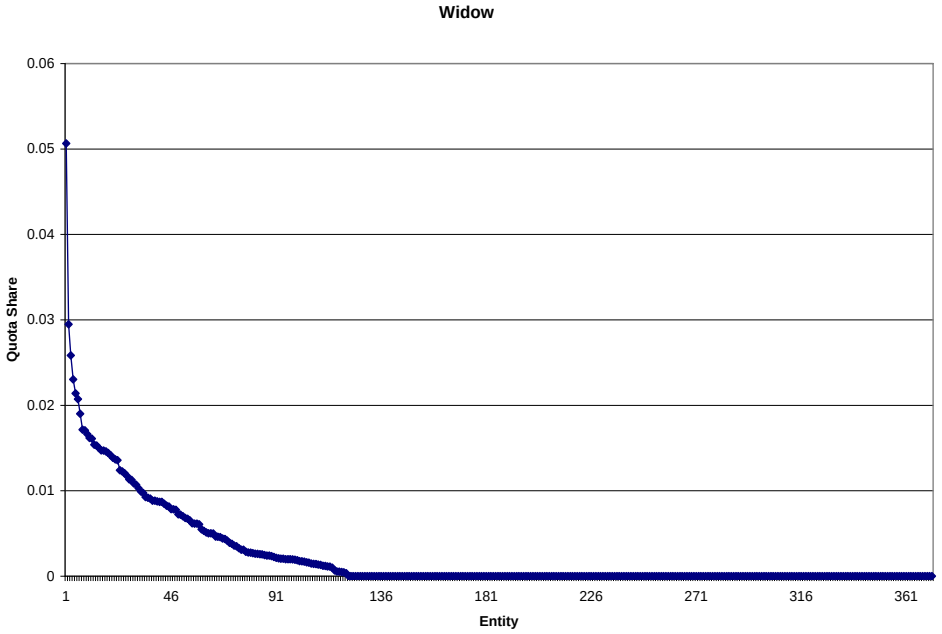

Figure A-110. Estimated distribution of initial allocation of widow QS to individual vessel permits and processing entities.

Pacific Halibut

Pacific halibut is not overfished, yet allowable levels of trawl bycatch could potentially constrain trawl targeting of flatfish, primarily arrowtooth flounder and Petrale sole, depending on the status of the stock and available harvest in the PFMC management area. In addition, halibut is a prohibited species in the groundfish trawl fisheries that cannot be retained or sold. For this reason, the Council has signaled its intention to progressively limit the trawl take of halibut in the future to allow for more catch by the recreational and commercial hook and line sectors.

The expected maximum initial IBQ-QS allocation to a single permit is 5.4 percent. Figure A-133 shows the strong relationship between halibut IBQ and allocations of Petrale sole and arrowtooth flounder. Analysis of this relationship between arrowtooth flounder and Petrale sole was presented first to the GAC in May 2009, then to the Council in June.[121] The Council established the control limit at this

[121] PFMC, June 2009 Briefing Book, Agenda Item E.11.a, Attachment 1 Issue Summary and Analysis: Accumulation Limits, Divestiture and Related Provisions.

maximum initial allocation level despite setting control limits that were 60 percent higher for Petrale sole and 75 percent higher for arrowtooth flounder than the maximum initial allocations of those species. Harvesting operations that want to operate using only their own QS will have to better the bycatch rate used in the initial allocation formula to achieve the higher harvest levels allowed by the control limits.

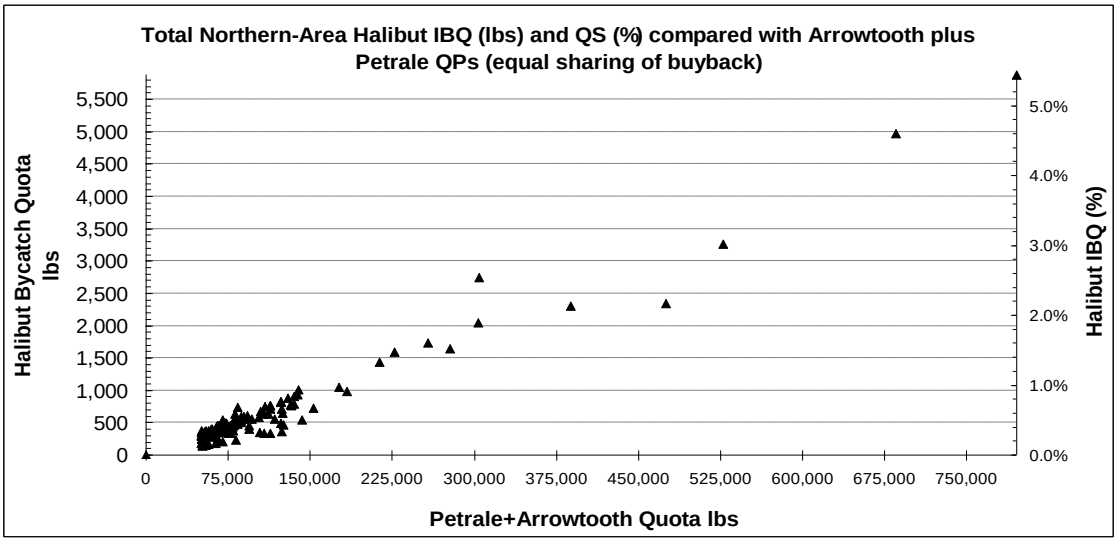

Figure A-111. Amount of halibut IBQ QPs (left vertical axis) and QSs (right vertical axis) by permit (permits are arrayed from the smallest to greatest based on amount of Petrale sole and arrowtootH QPs allocated assuming 2006 OY levels.

The Council also relied on an analysis of Petrale sole and arrowtooth flounder bycatch ratios in setting vessel limits for halibut IBQ. Based on 2008 CEY for halibut and OYs for Petrale and arrowtooth, the Council evaluated halibut IBQ vessel limits by using the following methods:

1. Calculating the maximum pounds of a target species that can be harvested for each target species vessel limit
2. Evaluating the amount of halibut that might be needed to achieve that target species catch
3. Determining the percent of the total trawl bycatch represented the pounds of halibut needed

Because the allowable harvest for halibut is set by the International Pacific Halibut Commission, the evaluation did not use the 2010 catch scenario, but instead used 2008 OYs for Petrale and arrowtooth, with the available halibut IBQ determined based on applying the Council's Amendment 21 trawl halibut bycatch formula to the 2008 halibut total Constant Exploitation Yield (CEY) (Table A-86).

The first calculation determined the pounds represented by each vessel limit, provided in the first two columns of Table A-87. Second, the WCGOP bycatch data were applied to determine an amount of halibut needed, with a range of rates considered (Table A-88). Bycatch rates were originally reported by the observer program in round pounds of legal and sublegal halibut catch per round pound of arrowtooth and Petrale catch, but were then converted to account for discard survival and measurement in dressed weight (Table A-88). Figure A-134 and Figure A-135 illustrate the degree of variation in the bycatch rates observed for halibut.

Full harvest of the 2008 arrowtooth and Petrale OYs would require average bycatch to be reduced to 0.006 pounds per pound of target species. At this assumed rate, a halibut vessel limit set at 1.4 percent

would allow full harvest of the Petrale limit, and a halibut vessel limit set at 14 percent would allow full harvest of the arrowtooth limit. At the lowest average bycatch rate in the WCGOP data of 0.17, the halibut IBQ vessel limit would have to be 3.8 percent to fully harvest the Petrale vessel limit and 39.2 percent to fully harvest the arrowtooth vessel limit (Table A-87).

In light of this analysis, the Council established the vessel limit at 14 percent following the rationale recommended by the GAC.[122] This is the level that would permit harvest of the full vessel limit for either arrowtooth or Petrale sole by vessels able to achieved the halibut bycatch mortality rate of 0.006 pounds of legal and sublegal halibut per pound of arrowtooth or Petrale. Data from the Washington EFP fisheries suggest that such reductions in halibut bycatch rates may be achievable.

Table A-88. OYs and halibut mortality limits based on 2008 fishery conditions.

2008 Halibut Mortality Limits (Trawl)	**Pounds (thousands)**
a. Total 2008 CEY (Legals)	940
b. Trawl Bycatch Calculation: 15 percent of CEY	141
c. Trawl Bycatch Mortality Max (not more than 130,000)	130
d. The greater of b and c = amount available for legal and sublegal trawl bycatch (dressed weight total mortality)	130
e. Set-aside for South of 40 10 (5 mt) and At-sea (5 mt)	22
f. **Trawl Halibut IBQ**	108
2008 OYs	
Petrale OY	5,509
Arrowtooth OY	12,787
Petrale + Arrowtooth	18,296
2008 Catch	
Petrale OY	4,873
Arrowtooth OY	5,887
Petrale + Arrowtooth	10,761

[122] PFMC, June 2009 Briefing Book, Agenda Item E.11.b, GAC Report: GAC Recommendations on Accumulation Limits, Divestiture and Related Matters.

Table A-89. Target species vessel limits and halibut needed to take those limits based on various assumed bycatch rates.

	Vessel Limit	Vessel Limit (thous pounds)	Assumed Lbs Halibut Mortality (Mty) /Target Species LB Caught	Halibut Mty Needed to Take Vessel Limit (thous pounds)	Halibut Needed as % of Available Halibut
Petrale	4.5%	248			
Minimum average bycatch rate strata			0.017	4	3.8%
Closest to midpoint average bycatch rate strata			0.039	10	8.9%
Maximum average bycatch rate strata			0.065	16	14.8%
Average bycatch rate to achieve full target species harvest a/ b/			0.006	1	1.4%
Arrowtooth	20.0%	2,557			
Minimum average bycatch rate strata			0.017	42	39.2%
Closest to midpoint average bycatch rate strata			0.039	99	91.5%
Maximum average bycatch rate strata			0.065	165	153.0%
Average bycatch rate to achieve full target species harvest a/ b/			0.006	15	14.0%
Total					
Total halibut required to take maximum vessel limits of Petrale and arrowtooth using assumed average bycatch mortality rate b/			0.006	16	15.4%

a/ The rate of 0.006 represents the bycatch mortality rate that would have to be achieved for the fleet to take the entire Petrale and arrowtooth harvest in 2008. It is the total halibut that would have been available based on the Council's Amendment 21 recommendations (108,000 pounds) divided by the total Petrale and arrowtooth available (18,296,000 pounds).

b/ If a rate of 0.006 is achieved, then a vessel would require the percent of the total trawl halibut IBQ indicated in the last column in order to take the vessel limits for this target species. The last rows of the table (total) show the amount of halibut a vessel would need in order to take the vessel limit for both Petrale and arrowtooth.

Table A-90. Observer program halibut bycatch rates by strata ((legal plus sublegal halibut lbs)/(Petrale + arrowtooth lb)) (2003-2006).

	North-South Area Strata	Depth Strata	
		<115 Fm	>115 FM
Catch Round	North of 47°05' N Lat	0.117	0.061
Discard Mortality (dressed wt)		0.065	0.034
Catch Round	South of 47°05' N Lat	0.07	0.03
Discard Mortality (dressed wt)		0.039	0.017

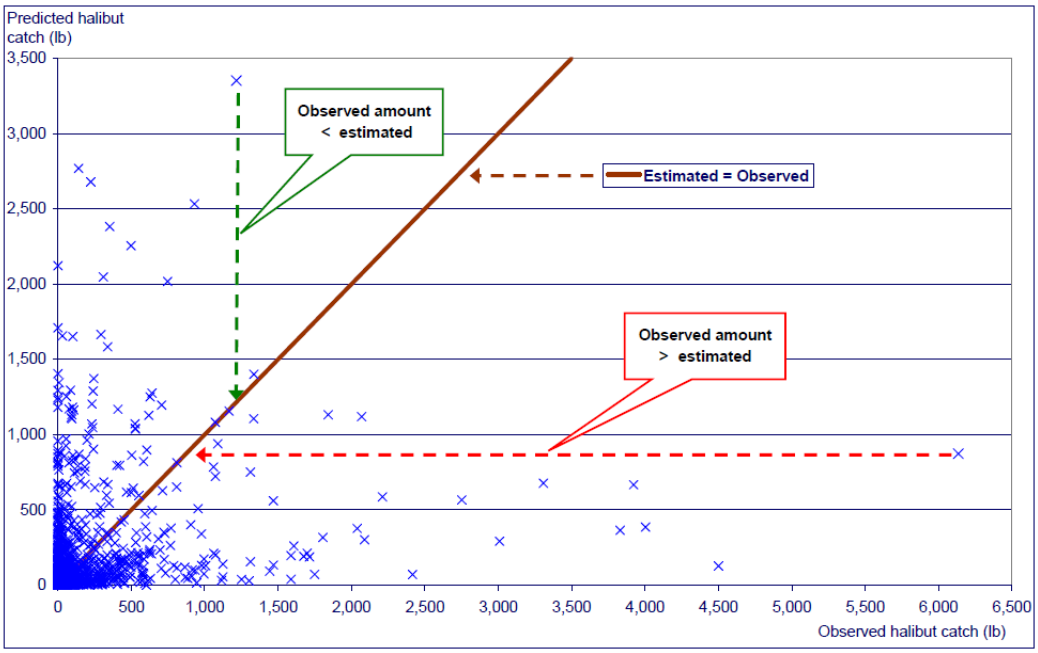

Figure A-112. Plot of observed vs. predicted Pacific halibut catch, using the mean stratum rate of Pacific halibut pounds per pound of Petrale sole and arrowtooth flounder caught in the area north of 47.5º N. lat. in depths less than 115 fathoms.

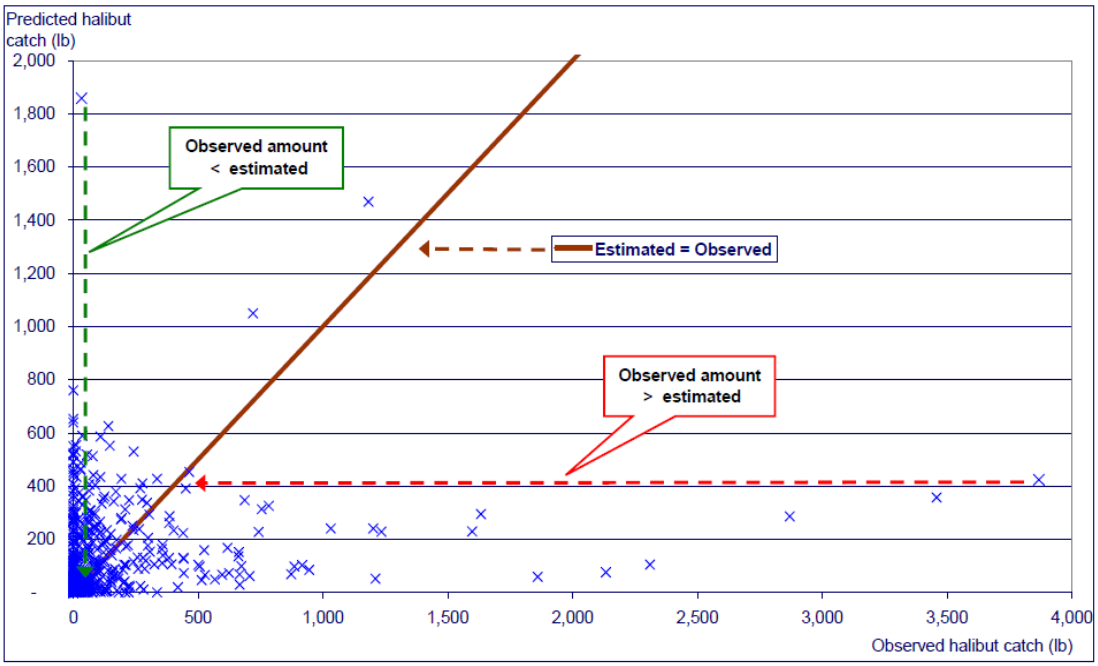

Figure A-113. Plot of observed vs. predicted Pacific halibut catch using the mean stratum rate of Pacific halibut pounds per pound of Petrale sole and arrowtooth flounder caught in the area north of 47.5º N. lat. in depths greater than 115 fathoms.

♦ *Calculation of the Aggregate*

Calculation of Aggregate Nonwhiting QS Holdings: To determining how much aggregate nonwhiting QS an entity holds, an entity's QS for each species will be converted to pounds. This conversion will always be conducted using the trawl allocations applied to the 2010 OYs, until such time as the Council recommends otherwise. Specifically, each entity's QS for each species will be multiplied by the shoreside trawl allocation for that species. The entity's pounds for all nonwhiting species will then be summed and divided by the shoreside trawl allocation of all nonwhiting species to get the entity's share of the aggregate nonwhiting trawl quota.

The control limits apply to each individual species, and there is an aggregate limit for all nonwhiting species. Increases or decreases in the OYs for individual species would not affect a QS owner's standing relative to being above or below the QS control limit for an individual species. However, an entity's aggregate QS holdings would be calculated by converting QS to QP and determining the entity's share of the total QP for all nonwhiting species. If this were done based on each year's trawl allocation, a change in the OY for an individual species could push someone who is close the aggregate nonwhiting limit above it, as is explained in the following paragraph. Because of concern that a person's aggregate QS holdings would fluctuate with changes in the OY, the Council decided to establish a more stable approach for this calculation. Under this approach, the method of calculating QS will be fixed until explicitly changed by the Council. This method anticipates using the trawl allocations coming out of the Amendment 21 process and applying those allocations to the 2010 OYs to determine a weighting for the QS of each species.

Example of Calculating the Aggregate and Effects of OY Changes. An entity's aggregate nonwhiting QS is evaluated by weighting the QS of each species using the expected trawl allocations and summing the results. Under this approach, for example, if the trawl allocation of Dover sole is 10,000 mt, and the trawl allocation of Pacific cod is 1,000 mt, then an individual who holds 1 percent of the Dover sole QS and 2 percent of the Pacific cod QS would hold QS for 120 mt of a total 11,000 mt (1.09 percent of the combined Dover sole and Pacific cod QS). In this example, either an increase in the Pacific cod OY or a decrease in the Dover sole OY would increase the combined QS holdings, as illustrated in the following table.

Table A-91. Example calculations showing how increases or decreases in the OY (represented as changes in the amounts allocated to the trawl fishery) may increase an entity's aggregate holdings.

	Trawl Allocation	Entity's QS Holdings	Entities QP
Starting point for the trawl allocation and entity's holdings (aggregate holdings 1.09%).			
Dover Sole	10,000 mt	1%	100 mt
Pacific cod	1,000 mt	2%	20 mt
Aggregate	11,000 mt	**1.09%** (120/11,000)	120 mt
Entity's aggregate increases with an **increase** in Pacific Cod OY (from 1.09% to 1.13%)			
Dover Sole	10,000 mt	1%	100 mt
Pacific cod	1,500 mt	2%	30 mt
Aggregate	11,500 mt	**1.13%** (130/11,500)	130 mt
Entity's aggregate increases with a **decrease** in Dover sole OY (from 1.09% to 1.17%)			
Dover sole	5,000 mt	1%	50 mt
Pacific cod	1,000 mt	2%	20 mt
Aggregate	6,000 mt	**1.17%** (70/6,000)	70 mt

The Council considered two methods for calculating an entity's nonwhiting aggregate QS in a manner that would hold a person's aggregate nonwhiting QS constant.

Under one method, **QS for all species would be weighted the same.** For example, the aggregate holdings of someone with 2 percent of the Dover sole QS and 1 percent of the Pacific cod QS would be the average (1.5 percent of the combined Dover sole and Pacific Cod QS). This would provide a more stable system and make it easier for QS holders to determine their aggregate. There would be no need to deal with situations in which QS holders are forced over the aggregate limit through no action of their own. However, there was also some reason to believe it could distort QS markets, putting a premium on the QS and participation in those strategies that require fewer different types of QS.

Under the method adopted by the Council, **relative weights of the QS for each species would be set at a certain point in time, but would be changed only through direct Council action** (i.e., would not automatically change whenever the OY or trawl allocation changes). This would provide a hybrid that uses the relative weighting system while providing the stability of the equal weighting approach. Such an approach is expected to reduce the frequency with which QS holders are faced with an externally imposed change in their aggregate holdings, but the approach would still require QS holders to multiply their shares of each IFQ management unit by a factor to determine their aggregate holdings.

❖ *Interlinked Elements*

The accumulation limits and decisions on the grandfather clause will have a strong but indirect impact on the results of the allocation formulas. The allocation formulas do not directly rely on provisions of the accumulation limits.

The vessel QP limits and unused QP approach rely heavily on the restriction that allows QP to be transferred only from QS holder accounts directly to vessel accounts (i.e., prohibits the transfer of QP anywhere other than to and among vessel accounts). Without such a requirement, once QP are issued at the start of the year, an entity could acquire addition QP in amounts exceeding both the QS control and the vessel limits.

❖ *Analysis*

The analysis of the accumulation limits is subdivided into sections that parallel the sections used to describe the rational for the limits (see Table A-80 on page A-286).

- Vessel Limit (Production Level Limits: Vessel or Permit Limit)

The following are the categories of goals and objectives affected by the decision to have vessel limits (independent of the level of those limits or the size of the vessel limits relative to the control limits) and the section in which each is addressed.

Section	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Social Versus Net Benefit Trade-off		X			X	X	X	X			
Impact on Labor							X				
Impact on Processors						X					
Impact on Harvester						X					
Impact on the Public										X	

♦ *Social Benefits versus Net Economic Benefit Tradeoff*

The vessel limit is designed to ensure that there is at least some minimum number of vessels in the fleet, so that benefits are more likely to be distributed across more individuals and a broader geographic area. Ensuring this distribution may come at the cost of a lost opportunity for greater efficiency (lower net economic benefits). Absent a vessel accumulation limit, the fleet would be expected to shrink in size to a number that would be determined based largely on efficiency. Control limits alone will not maintain fleet size because several QS owners that are at their control limits might work together to take their QS from a single vessel. Maintaining a larger fleet diverts money from profits to payments for the parts, equipment, supplies, labor, and support services needed to maintain and operate the larger fleet. The diverted profits represent lost efficiency and will likely have a downward influence on the QS price. Had the profits not been diverted they would have been spent or invested on goods and services elsewhere in the economy and overall production in the economy would be greater. While net national benefits may be lower as a result of the vessel limit, the higher expenditures needed to maintain the fleet are likely to occur in the coastal communities, potentially increasing local benefits.

The actual effects of the accumulation limits will depend on whether the fleet would have consolidated to numbers lower than that allowed by the vessel limits. For example, in an analysis based primarily on maximization of efficiency, it was estimated that the nonwhiting fleet would decline to between 40 and 50 vessels. The aggregate nonwhiting vessel limit was set at 3.2 percent, implying that at maximum consolidation if the full trawl allocation was harvested, the fleet might decline to as few as 32 vessels (100 percent/3.2 percent). Thus, in the case of the aggregate limit, the floor on the minimum number of vessels would not directly constrain the maximum efficiency result.[123] While the aggregate limit may not constrain achieving the most efficient fleet size, it may be that vessel limits for individual species could constrain efficiency in particular targeting strategies. For example, the vessel limit for Petrale

[123] The decline could be greater if not all of the allocation can be taken due to limits (such as overfished species constraints). However, it would also be difficult to have 32 vessels that were able to harvest the exact mix of species that would allow each of them to achieve the 3.2 percent accumulation limit and fully exhaust the trawl allocation. For these reasons, a 3.2 percent vessel limit would likely imply a minimum number of vessels at least somewhat greater than 32. The other issue is whether the trawl allocation would end up being taken by full-time trawl vessels or vessels that participated in multiple fisheries. The latter case would also lead to an expectation of more than 32 trawl vessels.

sole is set at 4.5 percent, but it may be that all Petrale sole could be harvested most efficiently with a fleet of fewer than 23 vessels (100 percent / 4.5 percent).

♦ *Impact on Labor*

If vessel limits result in more vessels than would be the case without such a limit, this could result in more job positions, but might not result in an increase in the payments to vessel labor. With more vessels, the annual pay per job position on a vessel might be lower than if there were not a vessel accumulation limit. Under similar circumstances in other systems, individual crewmembers and vessel operators have sometimes rotated between vessels so that crewmembers earn a greater annual income, and the harvesting companies gain the benefit of a more experienced crew.

♦ *Impact on Processors*

For processors that do not own vessels, the vessel limit might help ensure that they have more potential suppliers than if there were not such a limit. In the absence of a vessel limit, as many QS owners as is economically efficient might work together to harvest their QS off a single vessel. Individual QS owners operating off the same vessel might negotiate with processors independently of one another or collectively. Their use of a single vessel would reduce their flexibility for independent negotiations.

For processors that do own vessels, the effect of the vessel limit will depend on where it is set relative to the control limit and whether or not there is a grandfather clause. If there is a grandfather clause for the control limits, or if there is no grandfather clause but the control limit is greater than the vessel limit, the vessel limit will force the processor to operate more vessels to take its QS (or to pay other vessels to harvest its QS). If the control limit is lower than the vessel limit and there is no grandfather clause (the preferred alternative), the vessel limit will not have a direct effect on processors owning vessels.

	Grandfather Clause	**No Grandfather Clause**
Control Limit Greater than Vessel Limit	Processors with more QS than allowed under the vessel limit or grandfathered vessel level forced to operate more vessels to take their QS.	Processors with more QS than allowed under the vessel limit forced to operate more vessels to take their QS.
Control Limit Less than or Equal to the Vessel Limit	Processors grandfathered in at a QS levels higher than the vessel limits may be forced to operate more vessels to take their QS.	Vessel limit will have no effect on the number of vessels the processor operates using its own QS (the processor will be able to take all of its QS on one vessel).

♦ *Impact on Harvesters*

As discussed in the section on net benefits, the vessel QP limit could effectively require that a greater number of vessels operate in the fishery, increasing the costs to harvesters and reducing their benefits. The existence of a vessel limit reduces the opportunity for multiple QS owners to gain efficiency by taking their QP from the same vessel. As with processors that own vessels, the effect of the vessel limits on the number of vessels operated by a particular harvesting company will depend on where the vessel limit is set with respect to the control limit and whether or not there is a grandfather clause (see the matrix in the section on processors). Under the preferred alternative, the vessel limit is higher than the control limit, so it would not require that a harvesting company operate more than one vessel to take its allocation of QS and could provide independent harvesters some opportunity to cooperate by fishing their QP from the same vessel.

♦ *Impact on the Public*

Vessel limits could negatively affect the general public through both lower overall net benefits than might be achieved without a vessel accumulation limit and increased program administrative costs. The effect on net benefits was discussed above. With a vessel accumulation limit, program administration, tracking, monitoring, and enforcement costs may be higher than they would be with a greater degree of fleet reduction. The fleet can be charged fees of up to 3 percent of ex-vessel value. Additional cost recovery may occur through the collection of royalties through means such as auctions, though no such mechanisms are included in the Council's PPA. Some costs may be paid directly by the fleet, such as the cost of carrying an observer. Any program-related expenses that are not covered through the fee, royalty collection, or direct payment by industry would be covered by taxpayers.

● Vessel Unused QP Limit

The following are the categories of goals and objectives affected by the decision to have vessel unused QP limits for overfished species and Pacific halibut and the section in which each are addressed.

	Related Category of Goals and Objectives										
Section	**Conservation**	**Net Benefits**	**Disruption**	**Excessive Shares**	**Fairness and Equity**	**Harvester and Processor Sector Health**	**Labor**	**Communities**	**Small Entities and New Entrants**	**General Public**	**Program Performance**
Impact Mechanism and Conservation	X										
Net Benefits		X								X	
Other Impacts			X	X	X	X	X	X			

♦ *Impact Mechanism and Conservation*

The unused QP limit has its impact through the flexibility it allows for the Council to set lower vessel limits for overfished species and halibut without directly limiting a vessel's ability to achieve the harvests of target species allowed under the vessel limits. Absent this approach, the Council may have had a more difficult time in determining the appropriate balance between setting overfished species and halibut vessel limits that are high enough to accommodate the ranges of bycatch rates that a vessel might reasonably be expect to encounter and low enough so that QP is not sequestered on vessels, possibly making it less available on markets.

The unused limit approach could generate a conservation concern in that, absent an annual cap on total QP an individual vessel could use, there might be greater potential for the fleet to exceed its limits for these species. However, the trawl rationalization program does not end the governmental responsibility to ensure that the fleet stay within its limits. Full observer coverage (100 percent) combined with rapid catch reporting should allow NMFS to impose additional fishery restrictions as necessary to ensure that individual vessel overages do not result in a fleet overage. Additionally, the Council has backed up the unused QP limit with a vessel QP limit to ensure that fishermen who regularly encounter overfished

species and halibut at high rates and who have the money to acquire the needed QP do not cause the fleet to prematurely consume its annual allotment of QP for overfished species and halibut.

♦ *Net Benefits*

As described above, and in the rationale for this provision, it is hoped that low unused QP limits will increase the availability of QP on the market during the year and improve market function, contributing to higher net benefits from the program. Whether this happens depends the degree to whicH QP transfer commitments are made before actual transfers occur. Harvesters will be able to control their own QS for all species, but not up to the maximum of the vessel limits. Therefore, for vessels that want to harvest amounts of QP in excess of what the harvester can hold under the QS control limits, some transfers will be required. For nonoverfished species, these transfers can happen at the start of the year. However, for overfished species or halibut, if the vessel is already at the unused QP limit, the transfers must wait until some of the overfished species or halibut QP are used. Given harvester concern about having adequate amounts of overfished species and halibut QP, it seems likely that they will try to lock up as much as they can early in the year. This could be done through side agreements under which the QP transfers are not registered with NMFS until there is room on the vessel account. If it is not possible to limit such side agreements, and if they are used extensively, the unused QP approach could have limited effect. Another circumvention tactic could be the use of surplus trawl permits. As the fleet shrinks under trawl rationalization, it is expected that there will be numerous surplus permits of limited value. A vessel owner might acquire one of these permits, place it on some other vessel, and then transfer overfished species and halibut QP to that vessel until they are needed by the trawl vessel.

There was some concern that the unused QP limit itself could encourage vessels to fish early so they could recharge their accounts before QP prices increased. This could cause a race for fish and higher bycatch rates. Analysis provided to the Council indicated that seasonality in the prices might self-correct so that there would not be large fluctuations during the year; however, the result is not certain. Because of concern over how the overfished species and halibut vessel limits will perform, the Council will review these limits during the first management cycle after the program is implemented

♦ *Other Impacts*

Sector health, labor, and communities will benefit if the unused QP approach is successful in increasing the availability of QP on the market. However, there was a concern about not having any annual limit on the total amount of QP a vessel could take. This concern went to questions of fairness and equity, as well as the effective function of the program with respect to encouraging bycatch avoidance. In particular, without an annual limit, a vessel that regularly experienced higher than normal bycatch rates and had sufficient wealth to remain in the fishery (perhaps as a lifestyle choice) could adversely affect function of the trawl rationalization system through individual accountability mechanisms. By combining the unused QP approach with a straight vessel limit on overfished species, the ability of such vessels to impact the remainder of the fleet and those dependent on it adversely is limited.

● Control Limit

The following are the categories of goals and objectives affected by the decision to have control limits. The level at which such limits are set, whether there is a grandfather clause, etc., are discussed in other sections.

Section	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Market Power and Efficiency		X				X					
Geographic Dispersion								X			
Fairness and Equity					X						

♦ *Market Power and Efficiency*

Market power is the ability to influence prices away from the competitive equilibrium to the favor of the entity(ies) exerting that power. Exerting such power redistributes wealth and, in some cases, may result in market distortions that reduce overall efficiency of the economy. This issue is discussed in detail in Appendix E.

With respect to relative market power advantage between harvesters and processors, the initial allocation will set the starting point. The initial allocation is (1) an allocation of wealth and (2) an allocation of advantage to certain firms, if there is a grandfather clause. The grandfather clause would allow firms to retain QS they receive as part of the initial allocation that exceeds accumulation limits. However, over time, the accumulation limits will have more of an effect than the grandfather clause or the initial allocation. If the accumulation limits are set sufficiently low, they will limit the opportunity for individual firms to use QS to exert market power. If set too low, they will constrain efficiency to the degree that firms can be develop more efficient operations based on the certainty provided through ownership of QS (i.e., not having to rely on buying QP each year).

When the Council decided not to apply control limits to QP, there was a dramatic change in the implications of the control limits for the size of the harvesting operation and processors' ability to vertically integrate. When control limits applied to QP, harvesting companies could not take more fish than the control limits, and processing companies could not have more vertical integration than allowed under the control limits. By not applying control limits to QP, harvesting companies are free to harvest as much fish as they can so long as none of their individual vessels exceeds the vessel limits. Harvesting companies are only restricted in the amount of QS they can control, not the amount of QP that they can acquire and place on vessels they own during the year. Similarly, with this change processing are able to operate as many vessels as they desire and can support through the acquisition of QP from QS holders, after the QP for each year is issued. Options for the level at which accumulation limits would be set are discussed in the section on Percentages for Limits.

♦ *Geographic Distribution*

With respect to geographic distribution, the control limit does not directly result in greater geographic distribution of the harvest. While requiring that QS be distributed among more entities does not guarantee that those entities will be geographically dispersed, allowing QS to be concentrated into the

hands of only a few would make geographic concentration of harvest, landings, and benefits more likely.

♦ *Fairness and Equity*

Some view the accumulation of large amounts of wealth as unfair. Others view it as fair as long as everyone is under the same rules. The accumulation limits would constrain an entity's ability to accumulate wealth through use of QS, but all would be playing by the same rules (have the same limit), depending on the Council decision with respect to the grandfather clause.

● The Control Rule and Included Scope of Control Relationships

A narrower control rule allows for circumvention of the limits through means outside of the scope of the rule, frustrating achievement of the objectives related to the accumulation limit provision (objectives identified in previous sections). A broader control rule may inhibit relationships that are useful and beneficial for the efficient organization of the seafood industry (e.g., the formation of co-ops to manage overfished species QP or exclusive marketing agreements to encourage entry by a new processor). The analysis of impacts is organized into the following sections:

- Market Power
- Efficiency
- Alternative Organization of Production
- Administrative and Enforcement Costs
- Fairness and Equity

A bullet summary is provided at the end of this section.

♦ *Market Power*

The control rule is specified to take into account the exertion of control beyond the boundaries of ownership. This is required to effectively prevent the exertion of market power and the adverse effects that the exertion of such power would have on the economy and socio-economic conditions. Without a broadly specified control rule and the associated percentage limits, anti-trust law would provide the next level of protection against the adverse effects of excessive control. Anti-trust laws are more difficult and costly to enforce than a control rule with a specified threshold (the accumulation limit percentage).

Effectiveness of the control rule in evaluating the amount of QS under an entity's control may be limited by not taking into account QS that owners of an entity hold separately (not accounting for upstream ownership). See the rationale for this provision for further explanation of "upstream" (page A-292). Not including upstream ownership as part of the calculation of ownership control does not prevent that ownership from being taken into account in the application of the more generalized restrictions that entail "other means of control."

♦ *Efficiency*

The extension of the control rule to means of control beyond ownership could inhibit the formation of relationships that are useful to maintaining an efficient industry. One example is the potential inhibition of the formation of risk control co-ops. This is discussed further in a following section. Another example might be exclusive marketing agreements. On one hand, exclusive marketing agreements can

be a means of exerting control. On the other hand, such agreements may also be used to limit risk and encourage new investment, including the development of new markets. For example, if vessels in a particular port wanted to encourage entry by a new processor, they might reduce that processor's risk by offering an exclusive marketing agreement for a period. If the number of competing buyers in the local area is limited, ability to encourage new entrants via marketing agreement may lead to more competitive pricing in the raw fish markets and a more efficient distribution of resources.

Counting QP against the control limit could have had an adverse impact on processors' ability to vertically integrate. All catch must be covered by QP placed in a processor's vessel accounts. That QP would have counted against the processor's control limits, even if the processor did not own or otherwise control the associated QS. In its final preferred alternative, the Council adjusted this provision so that QP in a vessel account does not automatically count toward the vessel owner's control limit. This adjustment allows processors to use their own vessels to catch a volume of fish that exceeds QS control limits.

♦ *Alternative Organization of Production*

The control rule may affect the ability to effectively form other types of organizations that would benefit the fishery, such as harvester co-ops or regional fisheries associations.

One of the difficulties that harvesters will face under the IFQ program is covering their catch witH QP when they encounter an unexpected high bycatch of an overfished species ("lightning strike" or "disaster tow") for which the amount of QP available is very limited. There has been talk that industry members might form risk pools or risk management co-ops. Such types of arrangements may be established as contractual agreements that place obligations on and provide benefits to the parties to the agreement; or it may be established as an entity unto itself (for example, a co-op established as a corporation). Under a contractual agreement, members might simply agree that, whichever of them encounters a "disaster tow," all parties of the agreement will transfer to that member a proportion of their holdings of the species sufficient to cover the tow. Or, a risk management co-op might be established to which the members transfer certain species and a co-op manager monitors members and transfers QP to the member accounts in accordance with the co-op rules. Under the rules of the IFQ program, in order for such a co-op actually to hold QS or QP, it would have to be incorporated or otherwise take on a legal identity that makes it eligible to own a U.S. documented fishing vessel (the requirement for QS/QP ownership). In the case of an entity eligible to own a vessel, there is clearly an entity to which the control rule would apply. In the case of a contractual agreement, the question may become one of whether or not the contract effectively establishes control of one entity over another.

If consideration is given to exempting risk management pools from the accumulation limits, the types of pools for which such exemptions are provided, and the consequences that would be incurred if attempts were made to use such a pool to circumvent accumulation limits, should be taken into account. Under a contract-based risk management pool for vessel overages, the consequences to the vessel for exceeding the limits would limit the ability of anyone routinely to use the contract to circumvent the control rule. Even if parties entered into a risk management contract, no one party to the contract could start with more QS than allowed. If a vessel experienced an overage, the needed QP would be transferred to that vessel. If the amount needed by the vessel exceeded the QS accumulation limit, the vessel would not be prevented from receiving the QP needed to cover its overage. However, the vessel would have to stop fishing until the end of the year. The requirement that the vessel acquire the needed QP and then stop fishing for the remainder of the year would apply regardless of whether the QP were transferred from the risk management pool or through transactions on the open market. Thus, there would be some limit on the opportunity to abuse an interpretation of the control rule that allows QS control limits to be exceeded by a risk management pool contract entered into for the purpose of covering a vessel overage. On the other hand, it might be easier to abuse a control rule that is interpreted, as an example, to allow

processors to establish contingency contracts to mitigate the risk that they will not be able to keep a plant in operation year-round. Such a contingency contract might specify that if a processor runs short of product, QP would be transferred to vessels that are not under its control, but are under contract to deliver to that processor. So long as the vessels are not at their individual accumulation limits, there would be no disincentive for the exercise of such a contract. The processor would be able to continue processing even if the risk management contract resulted in the transfer of amounts of QP to vessels delivering to that processor that exceeded the accumulation limits. In contrast, for the example of a vessel risk management pool for an overfished species overage, the vessel would be forced to stop fishing if the exercise of the contract gave it more QP than allowed under the accumulation limit. Thus, a determination as to whether contracts that support risk management pools are within or outside the scope of the control rule should consider not only the nature of the control entailed in that contract, but also the consequences that might flow from the abuse of the interpretation.

The control rule may also present challenges in the development of RFAs or CFAs. Specifically, unless an exemption is provided that allows RFAs or CFAs to exceed the general limits, RFAs/CFAs that involve amounts of QS in excess of the accumulation limits will have to be structured such that they cannot be construed as an entity "controlling" the QS/QP of its members. To be eligible to participate in an IFQ program, an RFA must meet criteria developed by the Council (MSA, 303A(c)(4)(A)). At this time, there are no provisions in the IFQ alternative that would establish the criteria needed for creation of RFAs.[124] The Council has indicated its intent to consider special accumulation limit rules for CFAs as part of a trailing action.

As with other types of entities, the problem with providing exemptions or higher limits for co-ops and RFAs is the potential for such entities to be formed as a front for private interests whose main goal is to control QS in excess of the accumulation limits. In response to uncertainty about the application of control rules, the Council provided the following policy statement:

> It is the Council intent that control limits should not constrain the formation of risk pools to help the fishermen deal with overfished species constraints, so long as the pools do not undermine the effectiveness of the accumulation limits. A risk pool is one in which two or more people enter into an agreement whereby if one person does not have the QP it needs, the others would agree to provide the QP, if they have them. Whether these kinds of agreements are informal or formal, as other considerations and conditions are added to the agreements, they may begin to constitute control. It is the Council's intent to allow for these pooling agreements, so long as they do not become control.

[124] When rules are established for RFAs, to minimize the chance that RFAs are established to circumvent the accumulation limit rules, the Council might impose certain restrictions and requirements. The following is an example of the type of language that might be considered as part of the criteria for an RFA:

An RFA plan shall:

(a) not be approved if the Council or NMFS determines that
  (1) the primary purpose or effect is to allow an entity to control quota shares in excess of the accumulation limits which apply to entities that are not part of RFAs or co-ops;
  (2) it will in any way allow the RFA or its members to exert market power with respect to ex-vessel price negotiations between processors and harvesters.

(b) be revocable at any time based on a Council or NMFS determination that the RFA is not meeting the terms and conditions on which the agreement was approved or that the RFA is otherwise being used to circumvent the intent of the trawl rationalization program.

♦ *Administrative and Enforcement Costs*

The control accumulation limit restricts the acquisition of excessive shares, including acquisition by means other than through purchase of QS. "Ownership" and potential violation of such limits would be tracked on an ongoing basis in a NMFS database. The need to track indirect ownership will add to the amount of information NMFS collects about the entities that nominally own QS (as compared, for example, to the information collected on ownership of a trawl LEP). NMFS might also require that additional information be submitted to assist in assessing levels of control not reflected in ownership records. Investigation and prosecution of potential violations of control limits would likely require information beyond that contained in the regular submissions to NMFS. Such investigations would likely be instigated based on substantiated citizen complaints or other sources of information. Adequate enforcement resources would be needed to follow up on substantiated allegations.

♦ *Fairness and Equity*

Full application of the control rule will require case-by-case investigations and evaluation of the situations. If those who are adversely harmed by entities that are alleged to exert excessive control do not believe those violations are being adequately investigated, they may believe that the program is not fair and equitable, or that someone is getting away with violating the program. For this reason, it will be important to ensure that there are resources available to follow up adequately on allegations of violations for which there is some supporting evidence. On the other hand, those who are the subject of such allegations will likely think that the program is not fair and equitable if control is not being evaluated consistently against all participants. In particular, the consistent application of the language "shares that the person controls through other means" will be important. Further, the vagueness of the language may leave some uncertainty about what is and is not allowed. Ultimately, the standard of evaluation might be "Is or isn't control being established that adversely impacts program objectives?"

♦ *Summary*

- A control rule that extends beyond ownership control is necessary to effectively limit control and achieve related program objectives.
- Depending on its interpretation, the control rule may hamper the ability of harvesters to form risk management co-ops or other types of beneficial business arrangements.
- The control rule will hamper the ability of processors to vertically integrate.
- The operation of RFAs/CFAs could be hampered by control rules (the current alternative does not include criteria for formation of RFAs, and the Council will address special limits for CFAs in a trailing amendment).
- Direct and indirect ownership will be monitored on an ongoing basis. Monitoring indirect ownership will add to program costs.
- Control that is not based on ownership will be enforced on a case-by-case basis and will require additional enforcement resources for investigation.
- Perceptions of fairness and equity may be affected by whether it is perceived that nonownership control is being adequately investigated and applied consistently across all QS/QP holders.

● Grandfather Clause, Divestiture, and Cutoff Date

The following are the categories of goals and objectives affected by the decision on the grandfather clause and implications of the control date and the section in which each are addressed:

Section	Related Category of Goals and Objectives										
	Conservation	**Net Benefits**	**Disruption**	**Excessive Shares**	**Fairness and Equity**	**Harvester and Pro-cessor Sector Health**	**Labor**	**Communities**	**Small Entities and New Entrants**	**General Public**	**Program Performance**
Grandfather Clause, Divestiture, and Disruption			X			X					
Grandfather Clause and Fairness and Equity				X	X						
Permit Acquisition Cutoff Date and Disruption, Fairness and Equity			X		X						
Program Performance	X	X									X
Net Economic Benefits		x				X					

The analysis of impacts is organized into the following sections:

- Grandfather Clause, Divestiture, and Disruption
- Grandfather Clause and Fairness and Equity
- Permit Acquisition Cutoff Date, and Disruption, Fairness, and Equity
- Program Performance
- Net Economic Benefits

♦ *Grandfather Clause, Divestiture, and Disruption*

Disruption is often associated with change, and greater disruption is likely to adversely affect sector health over the short term. The grandfather clause and divestiture provisions affect the speed and mechanisms through which the change to an IFQ trawl rationalization system occurs, but have a lesser effect on the total amount of change. In particular, these provisions affect the path by which the QS distributions are brought into line with the long-term rules on accumulation limits, specifically, QS control limits.

With no grandfather clause and no divestiture provision, the initial distribution of QS will comply with the QS control limits, the reallocation of amounts of QS that would have otherwise been issued to entities in excess of the limits will occur administratively (distributed to those below the limits in accordance with the allocation formula), and the initial distribution of the wealth represented by the QS that would have otherwise been issued in excess of the limits will go to those who are under those limits. The amount of the redistribution would depend on the level at which the limits are set. The

number of entities over control limits, and the amount by which they are over, is provided in a following section as part of the analysis of the options for setting percentages for the control limits. With no grandfather clause, there may be some disruption to the degree that those who had made investments in permits that entitled them to QS in excess of limits would not receive QS for those permits. After the initial allocation, the value of those permits would decline, but they would receive no QS in compensation for the reduction. The possibility that they might sell those permits in advance of the initial allocation is discussed below. In addition to the potential disruption from the loss of value of the permits, to the degree that their investment in permits was accompanied by capital investments in harvesting they will experience a sudden change in their annual operating costs, represented by their need to purchase additional QP each year.

With no grandfather clause and a divestiture provision (the PPA), the initial distribution will not be compliant with the QS control limits, but will be brought into compliance over a relatively short time (four years). The reallocation will occur through market transactions instead of administratively (as would occur without a divestiture provision). Those selling the QS will have an opportunity to direct their QS sales to entities with which they may have an ongoing long-term relationship (e.g., a harvester might sell to someone with whom they might enter into an overfished species risk sharing pool, a processor might sell to a vessel from which it expected to receive deliveries, or either of these entities might choose to sell in a manner that maintains the QS in their local community). The opportunity to maintain QS for a few years will provide the divesting entities more opportunity to adjust their cost structures and finances in anticipation of the need to purchase QP annually to replace those from the QS that they divest (if such purchases are necessary to maintain their operations, as would be the case for harvesters but not processors). The revenues from sale of the QS should provide them with sufficient funds to make annual QP purchases for a number of years.

If there were no grandfather clause and no divestiture opportunity, those with permits that place them in excess of accumulation limits could also generate revenue through the sale of those permits prior to initial allocation. By doing so, they could direct the distribution of their harvest privileges and buffer the disruption caused by the move to the IFQ program in a fashion somewhat similar to what they could achieve through divestiture after initial allocation. However, prior to initial allocation there may be uncertainty about whether and when the program will be implemented, its final form, the actual amount of history and QS that will be assigned to a particular permit, the trading value of the QS, and whether the program will be successful and survive over the long term. These uncertainties are likely to result in a lower price for the permit prior to QS allocation than for the permit and QS after initial allocation and initial experience with the program. Additionally, prior to initial allocation, a permit with its entire suite of QS must be traded as a lump to someone who may be more interested in some of the associated species than other species. After the initial allocation, the QS can be divided and sold separately to those who place the highest value on each particular species.

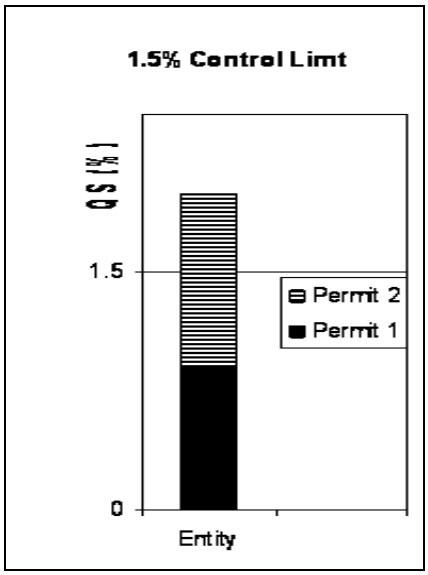

Figure A-114. An entity with two permits selling one permit to get under the control limit may end up being far below the control limit.

If there is no divestiture provision, the opportunity to sell permits provides substantially less flexibility for a permit holder to get under the control limits than with divestiture after initial QS allocation. For example, if two permits put an entity over the limit, selling one permit might put them well under the limits, as illustrated in Figure A-136.

With a grandfather clause, the result is similar to the result without a grandfather clause and with divestiture except that the redistribution is spread out over a substantially longer period. Rather than being forced to come into compliance with the accumulation limits over a relatively short time, those with QS in excess of limits would be able to maintain that QS until they retire from QS ownership. Their retirement from QS ownership might occur substantially later than their retirement from active participation in harvesting or processing activities. On one hand, the ability of some entities to own QS in excess of the QS control limits may have provided those entities a long-term competitive advantage over those whose initial allocation was less than the control limits. In addition to having lower long term operating costs, these entities would have had greater bargaining strength relative to those with lesser amounts of QS. On the other hand, the fact that they qualified for QS in excess of limits indicates the possibility that their operations were larger-scale and that being forced to QS ownership levels within limits would have been disruptive. The exception would be for those that are over limits only because they speculated in permits based on their expectation of receiving QS and not because of their need for that QS to support their harvesting operations.

The impacts of the decision on whether to have a grandfather clause was changed substantially as a result of the Council's decision that control limits would not apply to QP. Application of the control limit to QS and QP would have created a situation in which harvester production was constrained by the control limit but not by processor production. Under such circumstances, the absence of a grandfather clause might have disrupted some harvesters, but would have had less effect on processors (except those owning vessels). The level of production by harvesting companies would have been restricted by QP limits, but not the level of production by processors. However, since QP placed on vessels would have counted against their total quota holdings (regardless of the source of those QP), processors owning vessels might have found themselves needing to reduce their level of vertical integration (ownership of vessels) in order to come into compliance with the control limits.

♦ *Grandfather Clause and Fairness and Equity*

Another major objective affected by the grandfather clause issue is the perception of fairness and equity. If there is no grandfather clause and no opportunity for divestiture, those who do not receive an amount of QS that they would have otherwise received may believe they been treated unfairly (that, unlike those under the limits, they would not have been entitled to receive QS in proportion to their investment in the fishery). With the opportunity to divest after QS issuance, they would be able to receive a capital return through the sale of their QS. The degree of difference in impact between having and not having the opportunity to divest is reduced by the opportunity permit holders have to benefit from the selling before the initial allocation those permits representing an excess. As discussed above, they would have

less flexibility in making those sales and would likely receive lower returns compared to being able to receive the initial allocation and then divest themselves of it. If there is a grandfather clause, those who are unable to accumulate as much QS as those who were grandfathered in above the limit may feel unfairly disadvantaged by the protected competitive position provided to those who are grandfathered in at levels in excess of the accumulation limits. Those below the limits would have no opportunity to buy themselves up to the same level of QS as those who received the initial allocation in excess of accumulation limits.

♦ *Permit Acquisition Cutoff Date, and Disruption, Fairness, and Equity*

Not providing a grandfather clause, but providing an opportunity to divest raises fairness and equity questions. As indicated in the previous section, there are two sides to this issue, one being the fairness of providing rewards to those who have been accumulating permits in anticipation of the issuance of QS (through a grandfather clause or divestiture provision) and the other being the fairness of reducing the opportunity to reap those rewards (through the absence of a grandfather clause).

Related to the balance of perceived fairness is the advance notice provided regarding policy development and its implication for investment while policy was being developed. In regard to a cutoff on permit acquisition and issues of disruption and fairness and equity, the issues to be addressed here are the importance of effective control dates in reducing disruption, whether the November 6, 2003, control date applied to permit acquisition, and the degree to which permits were, in fact, accumulated during Council deliberations on this program.

The Council's final recommendation includes a divestiture opportunity for those with permits, qualifying them for more QS than the QS control limit, but it also provides a cutoff date such that prevents the divestiture opportunity from being applied to permits acquired after that date. In this section, we will address the importance of the control date in setting the cutoff date, providing a sense of fairness and equity, and minimizing disruption; arguments pertaining to whether the control date announced by the Council can be construed as applying to the acquisition of additional permits; and the number of entities affected and the degree of effect of the Council's recommended cutoff date for new permit acquisition.

Provision of advance notice of policy changes has a major impact on the perception of fairness and equity. If there is not a grandfather clause, then it is likely a program will be perceived as more fair and equitable if those making investments during policy deliberations were on advance notice that they might not receive benefits from those investments. On the other hand, if advance notice has been provided, and there is a grandfather clause or an opportunity to divest, then the program may be perceived as less fair and equitable if those who made investments despite the notice are rewarded for those investments. Additionally, when policy makers disregard the advance notice they have provided (e.g., allocations are provided based on activities occurring after announced control dates), the probability increases that future announcements will be less effective in minimizing disruption.

While control dates can contribute to a sense of fairness, a major purpose is to reduce disruption. This reduction occurs through two mechanisms. First, it discourages speculative activities that may have adverse effects on the fishery during deliberations on rationalization programs (discourages "fishing for quota"). Second, if those speculative activities have been minimized by the control date, there is less disruption during implementation (assuming that the policy adheres to the control date). To maintain the ability to announce control dates that are effective in their intent, the resulting policy must generally adhere to the control date. Failure to do so will result in disregard for future control dates. Maintaining the ability to credibly announce control dates is important for controlling the speculation that can have

disruptive effects, both during policy deliberations and when the management system changes as a result of those deliberations.

On November 6, 2003, the Council took action to adopt a control date for the trawl rationalization program. The November 6, 2003, control date was published in the *Federal Register* on January 9, 2004, and the public was put on notice that a trawl rationalization system that could alter their future opportunities in the fishery was under development. One point of discussion around the issue of a cutoff date for the acquisition of additional permits and need for a grandfather clause on accumulation limits is whether the November 6, 2003, control date covers activities such as the acquisition of additional permits. The control date notice stated that "The control date for the trawl IQ program is intended to discourage increased fishing effort in the LE trawl fishery based on economic speculation while the Pacific Council develops and considers a trawl IQ program." There are many ways an individual can increase fishing effort, including more intense use of existing permits and vessels, or aggregation and use of additional permits and vessels. The notice further states that "The control date announces to the public that the Pacific Council may decide not to count activities occurring after the control date toward determining a person's qualification for an initial allocation or determining the amount of initial allocation of QSs." Use of the general term "activities" indicates that the scope of the notice goes beyond fishing activities such that it discourages any activity that might potentially entitle an individual to a greater allocation. Therefore, strictly interpreted, the control date could be applied the acquisition of additional permits. However, in terms of the interpretation applied by the general public, the Council found there was substantial room for alternative views. Therefore, the Council chose to use as a cutoff date a point at which there was little doubt that a grandfather clause would not be provided for QS control limits (the date on which it adopted its final recommendations in this regard).

There has been change in ownership of permits since the November 6, 2003, control date was set. The main data set used in this analysis is based on records held by NMFS on permit ownership as it stood in the fall of 2006 and an examination of state data on the identity of buyers associated with fish ticket records. To evaluate how ownership of permits has changed since the control date, we examined NMFS data on LEP ownership changes, comparing permit ownership information from the start of 2004 with the fall of 2006, the start of 2008, the Council's cutoff date for permit acquisition (November 30, 2008, for registration of the transfer with NMFS), and the most recent date available for this analysis (June 22, 2009). Our assessment of ownership and ownership changes is based on an examination of name and address changes on permit records in consultation with agency personnel and members of industry. We lack information on control other than ownership or on changes in ownership that may not be reflected in the NMFS data set. We were unable to evaluate changes in ownership of processors over that period. From the start of 2004 through the November 30 2006, there were 26 entities that acquired permits, and 45 entities that divested themselves of permits (Table A-90). Most of the divestitures and acquisitions occurred between the start of 2004 and the fall of 2006. After the November 30, 2008, date and through June 22, 2009, three entities divested themselves of permits, and these permits were acquired by two entities. In neither case did the additional permit acquisitions put the entity over the aggregate nonwhiting control limit of 3.2 percent. After the fall of 2006, only one entity acquired additional permits that put it further over the aggregated nonwhiting accumulation limit. However, these conclusions are limited by the limited ownership data available for the analysis. More complete ownership and control information would be collected during program implementation and the Council could review ownership relationships and impacts that we were not able to detect.

Table A-92. Shoreside aggregate nonwhiting QS allocations to business entities acquiring or divesting permits between January 1, 2004, and June 22, 2009 (QS allocations based on a 90 percent allocation to permits, combined shoreside sector, equal sharing of buyback portion).

	Permit Ownership Dates					Change in Permit Ownership							
						2004 to 2006		2006 to 1/1/2008		1/1/2008 to 11/30/2008		11/30/2008 to 6/22/2009

QS for 36 entities departing after Jan 1, 2004 (not listed above)	17.12%	-	-	-	-	-	-	-	-	-	-	-	-
QS changing hands compared to previous period		17.12%	2.58%	4.22%	1.13%								
Number of entities acquiring permits	-	21	4	4	2								
Number of entities divesting permits	-	36	4	7	3								

♦ *Program Performance*

Much of the overall performance of the program relies on the transfer of QS from less efficient to more efficient producers and from those with higher bycatch rates to those with lower bycatch rates. If there is a grandfather clause, firms that are grandfathered in at higher accumulation limits will be less likely to sell their QS than others because they will not be able to buy back any QS they sell, as long as they are above the limit. Further, these firms are less likely to change ownership because the grandfather clause will expire with change in ownership, and advantages of the grandfathered levels of QS will be lost. Therefore, it would be difficult to find buyers willing to purchase the firm for an amount that fully compensates the grandfathered owners for what they can earn if they maintain ownership of the firms. The absence of a grandfather clause would eliminate these impediments to the transfers needed for a rationalization program to succeed, with respect to both its efficiency effects and reduction of bycatch rates for overfished species. The divestiture provision may forestall some transfers for a few years (no transfers would be allowed in years one and two, and all divestitures would have to be completed by the end of year four).

♦ *Net Economic Benefits*

In the PPA, control limits applied to both QS and QP such that the control limit grandfather provision had the potential to affect the size of harvesting operations and, therefore, efficiency. In the Council final preferred alternative, the control limit applies only to QS. Therefore, the question of whether there should be a grandfather provision does not affect the size of the harvest operation (size of harvest operation is affected by the vessel limits, and the vessel limits were set to accommodate recent harvest levels). The absence of a grandfather clause will encourage the transfer of QS to the most efficient producer. The delay in those transfers that results from the divestiture provision might delay some of the expected efficiency benefits; however, the delay would be short relative to the duration of the program.

● Percentages for Limits

♦ *Vessel Percentage Limits*

The following are the categories of goals and objectives affected by the decision on the level at which vessel accumulation limits are set and the section in which each are addressed.

Section	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Initial Endowments (Allocations Compared to Vessel Limits)			X	X	X	X					
Structure of the Fleet (Vessel limit effect on historic fleet structure)		X	X			X					
Efficiency		X				X					

The vessel percentage limits will determine the minimum size to which the fleet may shrink while still taking all of the groundfish and will cap the degree to which vessel efficiency may increase (assuming efficiency consistently increases with the amount a vessel can harvest). Because the regulatory focus of concern here is the vessel, this section concentrates on the permits and vessels rather than the firms owning them or the processors. Effects of the allocation on firms, including processors, are addressed in the following section on control limits. The rationale for using vessel limits is discussed above in the section on vessel limits. Here the focus is on the actual percentages chosen for those limits.

INITIAL ENDOWMENTS (ALLOCATIONS COMPARED TO VESSEL LIMITS)

Vessel limits will not constrain initial QS allocations or constrain the acquisition of QS. QS holdings are constrained by the QS control limits. However, there is some relationship between the per permit initial allocations of QS and the historic production levels of vessels operating under the permit, particularly for those permits with greater production history. Therefore, a comparison of the initial QS allocations per permit to the vessel limits provides a sense of the degree to which the vessel limits might constrain a permits historic share of harvest. If QS allocations exceed the vessel limits, the impact of the vessel limits would depend on whether there is a grandfather clause for QS control limits and vessel limits. Such a clause would allow permit owners receiving QS in excess of those limits to use their QS on a single vessel. If there were a grandfather clause, the main issue would be whether there is a perception of inequity because some permits/vessels are able to operate at higher levels of production and efficiency than others. If there were no grandfather clause, the issues would be whether there are inequity, disruption, and reduced efficiency because of the reduced opportunity for permits/vessels that have a history of making greater amounts of deliveries.

In its final preferred alternative, the Council did not provide a grandfather clause for either the vessel QP limits or QS control limits. However, vessel limits were set higher than control limits and higher than the unconstrained initial allocations (allocations without QS control limits applied). Table A-91 shows that, under the FPA, there would be a potential initial allocation that is greater than the vessel limit for only one non-overfished species (starry flounder). With respect to overfished species, there would be an initial allocation of cowcod in excess of the vessel limit; however, the allocation would be only slightly over the limit and only because the vessel limits would be rounded to the nearest tenth of a percent. There were some combinations of QS allocation and vessel limit options considered during the

process for which there could have been more initial QS allocations in excess of the vessel limits. For example, with permit holders allocated 100 percent of the QS using an allocation formula based entirely on landings history (with no equal allocation component) and using the most constraining vessel limits (Option 1), for 18 of 37 potential IFQ management units, some permits would have been eligible for more QS than the most restrictive accumulation limits (Option 1 in Table A-92). In many of these cases, however, the QS allocations in excess of vessel limits would be for management units that the Council exempted from the scope of IFQ program as part of its final preferred alternative, or for overfished species, for which a different allocation formula was used in the final preferred alternative. Under the 100 percent to permit owner option and Option 1 vessel limits, initial allocations would have exceeded vessel limits for only six IFQ management units that are within the scope of the program and are not overfished.

Table A-93. Combined (whiting and nonwhiting) QS allocations to permits based on Council's final preferred alternative (FPA* June 2009).

* Gray rows indicate management units not included in the scope of the final preferred alternative.
Rows with a single gray cell indicate an overfished species. In this table, a history-based approach was used for calculating the allocation of overfished species. In the Council's final preferred alternative, an approach was used that applied bycatch rates and logbook information to initial allocations of target species.

STRUCTURE OF THE FLEET (VESSEL LIMIT EFFECT ON HISTORIC FLEET STRUCTURE)

This section addresses how the vessel limits will affect the structure of the harvesting and processing sectors. Specific questions include the following:

- What levels of concentration of harvest on vessels have we experienced recently and in the past?
- What size of fleet has been active in the fishery?
- How do the vessel accumulation limits compare to those levels of concentration and will they allow consolidation or constrain the fleet as compared to the past?

There are a number of ways to look at recent past and historic data. One way is to look at permit/vessel recent and historic shares of annual harvest to determine whether a particular vessel limit option will allow lesser, similar, or greater levels of concentration as compared to that of the past. Comparison to permit shares is most relevant to the proportional sharing of harvest within the fleet, distribution, and equity issues.

Per-vessel recent and historic shares are evaluated in two ways. One approach is that taken by the GAP, in which each permit's catch was compared to its share of the fleet allocation (Table A-84 and right-hand column of Table A-93). If, under an IFQ program, the fleet is able to more fully harvest its allocation (or individual vessels are able to take the entire amount of QP allowed under the vessel limit), then comparison of the vessel limits to recent and historic maximum individual vessel shares of the trawl allocation in recent years may best reflect the impact of the vessel limits. Under such circumstances, the vessel limits would be less than the maximum share of the trawl allocation take by a vessel from 2004 to 2006 (evaluated annually) only for sablefish south, minor slope rockfish south, Dover sole, and Petrale sole (comparing the last column of Table A-93 to the final preferred alternative vessel limits). Thus for most species, the vessel limits would not constrain vessel operations, again assuming overfished species can be avoided as markets develop.

An alternative look compares the permit shares to actual landings for two periods: 1994 to 2003 and 2004 to 2006 (Table A-93). While this approach may not reflect the actual opportunities that may be present under the trawl rationalization program, it allows us to evaluate the vessel limits against the shares of harvest that vessels were taking during the allocation period 1994 to 2003 (for which it is difficult to determine what the trawl allocations might have been). Additionally, to the degree that the vessel limits are not constraining in comparison to vessel share of landings, they would be even less constraining when considered in comparison to vessel share of the trawl allocation, since a vessel's share of fleet landings will be greater than the share of the trawl allocation if the allocation is not fully harvested. Therefore, the share of landings comparison provides an upper bound for the degree of constraint that vessel limits might impose, in comparison to vessel harvest shares for recent and historic periods. In Table A-93, values are provided for the maximum share of landings achieved by any single vessel in a year during the period and for the 90th percentile vessel (i.e., values exceeded by only 10 percent of the fleet). An accumulation limit set at the 90th percentile would accommodate past landing shares of 90 percent of the fleet but not the top 10 percent. The maximum share of nonwhiting species landings taken by any one vessel in any single year from 1994 to 2003 or 2004 to 2006 was 4.9 percent. The aggregate nonwhiting vessel accumulation limits under Options 1, 2, and the final preferred alternative are 3 percent, 4.4 percent, and 3.2 percent, respectively. There was a third accumulation limit (not shown in this table) for which the vessel limit would have been 6 percent (Table A-83). Thus, only under Option 3, would vessels be able to achieve that maximum share of landings reflected in this table. On the other hand, 90 percent of the vessels did not take more than 1.5 percent of the total landings, and such levels of performance would be more than accommodated by Option 1 and the Council final preferred alternative. Additionally, the maximum vessel landings as a

share of the allocation was only 1.8 percent, a value more than accommodated by the most restrictive vessel limit (Option 1). Looking at the results for single species, and taking northern sablefish as an example, the proposed vessel accumulation limits are 4 percent, 6 percent, and 4.5 percent. The maximum share achieved by any vessel from 1994 to 2003 was 2.4 percent, and the maximum for 2004 to 2006 was 5.7 percent. Thus, if Option 2 were selected, with respect to sablefish, the fleet could rationalize to the point where every vessel had slightly more than the maximum share achieved by any one vessel from 1994 to 2003. The Council's final preferred alternative is for a 4.5 percent limit. While less than the 2004 to 2006 5.7 percent maximum, it is well above the 1.5 percent that would accommodate 90 percent of the fleet and also above the 2004 to 2006 maximum share (4.3 percent) as evaluated against the trawl allocations.

For both these approaches (the comparison to trawl allocation and comparison to landings), vessel landings are evaluated rather than vessel catch. Information is not available on individual vessel catch. To the degree that vessel catches exceed reported landings, the share of the trawl allocation required to support historic landings will be greater than indicated in these tables.

Another way to evaluate the accumulation limits would be to determine whether they would allow lesser, similar, or greater poundage of harvest as compared to the past (Table A-94). Where the previous comparisons are relevant to distribution and equity issues, this comparison may be more relevant to the efficiency that individual harvest operations will be able to attain under the trawl rationalization program as compared to the past. For the individual harvesters, the pounds of fish they can catch relate more to their costs and earnings than their share of harvest. This becomes rapidly apparent if we consider, for example, northern slope rockfish. The same maximum share of landings from the mid-1990s applied to northern slope rockfish OY for 2010 would yield one third less harvest. For most of the important target species that are not under rebuilding plans, the vessel limits of the Council's final preferred alternative would allow vessels to catch volumes of fish equal to or exceeding the amounts taken by the single largest annual production by any vessel in any year from 1994 to 2003. For those non-overfished species for which the historic maximum cannot be reached (lingcod, whiting, splitnose, northern and southern shelf and slope rockfish) the 90th percentile harvest levels can be reached. These results seem to indicate that the levels of harvest allowed by the Council's final preferred alternative for vessel limits have a reasonable chance of allowing vessels to increase their annual harvest to levels that match or exceed levels taken when the fleet was believed to be in better economic health. The overfished species could constrain this result until they are rebuilt. In terms of current target species, the primary exception with respect to the opportunity to achieve past harvest levels might be for directed vessels whiting. However, for the shoreside vessels, the vessel limit would allow a vessel to come within 1 percent of the maximum annual landings observed for any one vessel from 1994 to 2003. For the mothership fishery (which will be managed under a co-op system), the vessel limit would allow a vessel to come within 5 percent of the maximum observed from for any one vessel 1994 to 2003. Overall, the vessel limits appear to provide good prospects for increased efficiency and economic health of the trawl fishery.

The number of vessels catching each species/species group also suggests a minimum vessel accumulation limit that might be set if one wanted to ensure that the fishery could accommodate as much consolidation as there has been in the past. For example, if the minimum number of vessels participating in a segment of the fishery in the past is 20 (catching a particular species), an accumulation limit of 2 percent would require that 30 more vessels participate than in the past in order to take the entire available catch (a 2 percent limit requires that at least 50 vessels take part if the entire trawl allocation is to be harvested). Table A-95 provides the accumulation limit options, the minimum limit required to accommodate the minimum number of vessels catching each species in 2004 to 2006, the minimum fleets implied by the vessel accumulation limit options, and the minimum annual number of vessels taking each species for two past periods (1994 to 2003 and 2004 to 2006). There is only one

species for which the vessel limits may force more vessels into the fishery than have participated in recent years, if the full allocation is to be taken (sablefish south). There are a number of species that appear to be taken broadly in the fishery, but for which the vessel limits could allow substantial consolidations (e.g., Pacific cod, northern slope rockfish, and English sole).

Summary

For most species, the Council's final preferred alternative vessel limits would accommodate recent permit/vessel shares of landings and shares of the trawl allocation.

For most species, the maximum poundage landed by a permit in a single year from 1994 to 2003 could be achieved under 2010 OYs and the Council's final preferred alternative for vessel limits. The most important exceptions would be overfished species and target species for which harvest has been dramatically reduced to protect overfished species, including shelf and slope rockfish.

For some species that are broadly taken by many vessels, it appears that the vessel limits would allow levels of consolidation that would leave less than 20 percent of the vessels as compared to recent periods.

In general, it appears that the final preferred alternative vessel limits would provide substantial opportunity for vessels to improve their efficiency and economic performance as compared to levels from the 1990s, if they can develop markets and avoid overfished species.

- The vessel limit for sablefish south is such that the fleet could have to expand to fully take the allocation.

EFFICIENCY

This section addresses how the vessel accumulation limits will affect efficiency. For most of the objectives, we do not have the quantitative information needed to make exact predictions about how the objectives will be affected by the level at which accumulation limits are set, therefore, we rely on comparisons to historic experiences. However, we do have some general quantitative results indicating the effect of the accumulation limits on overall fleet efficiency. These will be discussed below.

A quantitative analysis by Lian et al. (2008) indicates an expectation that optimal size of the nonwhiting fleet under rationalization might be between 40 and 50 full-time vessels of approximately 60 to 70 feet in length. While it may be that the unconstrained fleet size will be larger if vessels choose to maintain multifishery strategies, aggregate accumulation limits in the range of 2.0 to 2.5 percent would be sufficient to allow a fleet of this size. Lian et al. also indicated that an aggregate accumulation limit of 1 percent would increase the minimum fleet size to 100 vessels, reduce benefits by about $3.8 million, and substantially increase the number of 50-foot vessels. Based on this model, it does not appear that the aggregate limits under consideration by the Council, even under Option 1, would necessarily constrain an efficient outcome.

♦ *Control Percentage Limits*

The following are the categories of goals and objectives affected by the decision on the level at which to set QS control limits and the section in which each is addressed.

Section	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Initial Endowments (Allocations to Firms Compared to Control Accumulation Limits)			X	X	X						
Structure of the Harvesting Sector (QS Control Limit Relative to Past Harvest Levels)		X	X			X					

The control limits will determine the minimum number of firms that may control all the QS and cap the profit levels firms may achieve through QS ownership. Efficiency of firm level fishing operations may also be constrained to the degree that ownership of the QS provides efficiency advantages (see Appendix E for a discussion of possible efficiency benefits from vertical integration through QS ownership[125]).

[125] Summary of information on vertical integration from Appendix E: Under the IFQ program, in addition to other inputs, a harvester must also acquire QP each year to cover its catch. The QP becomes a new required input or "factor of production." QP is issued each year to QS holders. The harvester might be considered vertically integrated with respect to the QP if it owns the QS needed to meet its annual needs for QP. The

We evaluate control limit percentages from the perspective of how they affect the distribution of the initial endowments and the magnitude and degree of concentration as compared to our historical experience.

INITIAL ENDOWMENTS (ALLOCATIONS TO FIRMS COMPARED TO CONTROL ACCUMULATION LIMITS)

This section addresses how the control limits compare to the QS allocations to fishing businesses. It evaluates the specific levels at which the control limits will be set. As discussed in the general sections on QS control limits and cutoff dates (see pages A-340 and A-346), QS that would be issued to entities over the QS control limits would be treated as follows:

- Redistributed to those under the limits (if there is not a grandfather clause)
- Allocated to entities in excess of the limits; those entities will then be required to sell them within four years (if there is not a grandfather clause, but there is a divestiture provision).
- Allocated to entities in excess of the limits; those entities will then be entitled to retain them until they retire from QS ownership (if there is a grandfather clause)

Table A-96 shows the number of entities over the QS accumulation limits and the amounts of their overages under Option 1, Option 2, and the Council's final preferred alternative. In general, under the final preferred alternative, not more than three entities are over the limit for any one species or species group. For about two-thirds of the species, at least one entity is over the limit. Then number of entities directly affected by the control limits may be greater than three if different entities are affected by different individual species limits. The amount potentially available for reallocation, retention and sale, or retention until retirement is greater than 10 percent for many species groups with a southern distribution (sablefish south, bocaccio, shortspine south, cowcod, minor slope rockfish south). The only other species for which the total amount allocated in excess of limits could be more than 10 percent is starry flounder. The greatest amounts potentially available to be redistributed, retained and sold, or kept until retirement are sablefish south, bocaccio, and cowcod (more than 25 percent for each). For bocaccio and cowcod, the entire amount in excess of the control limits may go to a single entity. If these amounts are considered excessive, the control limits will reduce the initial allocation below excessive levels, either immediately or over time. To the degree that businesses have corresponding physical capital invested in harvesting at levels reflected by those initial allocation, the absence of a grandfather clause or requirement to divest may be somewhat disruptive. However, since the control limits do not apply to QP, those entities unable to retain the QS they would otherwise receive under the initial allocation will not be prevented from continuing to operate at their existing production levels by acquiring QP each year from the market.

On one hand, for large initial allocation in excess of limits, the program could be viewed as unfair if there is no grandfather clause to allow those who have acquired assets entitling them to the allocation to also acquire and hold or acquire and sell the initial allocation. On the other hand, others may view the program as unfair if entities are allowed to keep the QS in excess of the limits (if there is a grandfather clause). Table A-97 shows how the amount going to a single entity has varied since discussions of the trawl rationalization program began. For January 1, 2004 (two months after announcement of the November 6, 2003, control date), there was not more than one entity that held permits for any species or species group that would entitle it to QS in excess of the limits. Moreover, the amount by which any

harvester might also vertically integrate by acquiring a processing operation. Similarly, a processor might vertically integrate by acquiring QS or a harvesting operation. Vertical integration through ownership provides certainty about the price that will be paid for each year's QP, reducing the QS holder's price risk and increasing its ability to plan and maximize efficiency.

entity's initial allocations would exceed the limits was less than 1 percent, with the exceptions of sablefish south and starry flounder.

For whiting, the Council selected the lowest control limit it had under consideration (10 percent). In contrast to nonwhiting species the amount of QS going to any single entity, for shoreside whiting is not in excess of the whiting QS control limit and has not changed during the time the Council has been deliberating on the initial allocation (Table A-98).

The amounts by which individual allocations are over the limits would vary by the initial allocation formula. Table A-99 shows amounts of aggregate nonwhiting QS in excess of the initial allocation, as that amount varies depending on whether there is an equal allocation and on the amount of the initial allocation going to processors.

All data provided in this section are based on ownership information as best as it can be determined based on name and address records from the LEP Office. During program implementation, additional ownership information will be collected and may result in determination that existing levels of concentration are higher or lower than indicated here.

Table A-98. Combined (whiting and nonwhiting) shoreside entity-level QS and halibut IBQ allocations compared with the Council Final Preferred Control Limit Alternative and Control Limit Options 1 and 2 from the October 2008 EIS (based on November 30, 2008, permit ownership).

Initial allocations notes:
Non-whiting spp in non-whiting fishery (90% allocation to permits):
Non-OF spp: 1994-2003, relative lbs, drop 3 years, equal allocation of buyback permits' catch history.
OF spp: Alloc. based on finer area bycatch rates and 2003-2006 logbook target spp history (Average distribution was used in cases where logbook unavailable).
(Canary allocations include equal sharing component)
Whiting in shoreside fishery (80% allocation to permits, 20% to processors):
Permits: 1994-2003, relative lbs, drop 2 years, equal allocation of buyback permits' catch history.
Processors: 1998-2004 (at least 1 mt in any two years 1998-2004), relative lbs, drop 2 years.
Non-whiting in shoreside whiting fishery: allocated to permits in proportion to whiting QS, 90% allocation to permits.

Table A-99. Combined (whiting and nonwhiting) shoreside entity-level QS and halibut IBQ allocations under different permit ownership date scenarios based on Council Final Preferred Alternative (June 2009).

Initial allocations notes:

Non-whiting spp in non-whiting fishery (90% allocation to permits):

Non-OF spp: 1994-2003, relative lbs, drop 3 years, equal allocation of buyback permits' catch history.

OF spp: Alloc. based on finer area bycatch rates and 2003-2006 logbook target spp history (Average distribution was used in cases where logbook unavailable).
(Canary allocations include equal sharing component)

Whiting in shoreside fishery (80% allocation to permits, 20% to processors):

Permits: 1994-2003, relative lbs, drop 2 years, equal allocation of buyback permits' catch history.

Processors: 199**8**-2004 (at least 1 mt in any two years 1998-200**4**), relative lbs, drop 2 years.

Non-whiting in shoreside whiting fishery: allocated to permits in proportion to whiting QS, 90% allocation to permits.

Table A-100. Maximum Pacific whiting allocations to entities under different permit ownership control dates (QS allocation formula uses: 80/20 permit-processor split, equal sharing, and shoreside processor recent participation requirement).

Note: Data in this table are based on ownership information available in the fall of 2006.

STRUCTURE OF THE HARVESTING SECTOR (QS CONTROL LIMIT RELATIVE TO PAST HARVEST LEVELS)

As mentioned in the introduction to this section on QS control limits, these limits may constrain efficiency gains by restricting the degree to which a vessel can support its operation with QS under its personal ownership. In this section, the control limits are compared to past vessel performance levels to evaluate the degree to which a vessel owner might support operations with QS owned (the degree to which the owner can vertically integrate through QS ownership relative to his or her total production level). The section on vessel limits compared those limits to past operations of individual vessels to determine the degree to which vessel limits might directly constrain vessel operations. Here QS control

limits are compared to the same vessel level data to determine the degree to which an owner's ability to control the QS available to support production might be constrained. In general, because QS control limits are about two thirds of the vessel limits (vessel limits are generally 1.5 times greater than control limits) the QS control limits interfere with the amount of QS a vessel might like to have to support operations to a greater extent than the vessel limits interfere with past vessel operation. As an example, Table A-100 shows that for 10 nonwhiting species, the control limits are below the 90th percentile level for vessel landings as a share of 2004 to 2006 fleet landings. This compares to only four nonwhiting species in this category when comparing past performance to the vessel limits Table A-93. This evaluation covers the single vessel case. Harvesters owning multiple vessels could be more constrained in their ability to support those vessels with QS than is indicated in this table.

Table A-102. Comparison of control limits to vessel (permit) share of annual landings (1994 to 2003 and 2004 to 2006. Values in gray cells are greater than the Council's final preferred alternative).

- Calculation of the Aggregate

The Council decided to establish a fixed formula for calculating an entity's aggregate nonwhiting QS. This formula weights QS based on the 2010 trawl allocation for each IFQ species. As the trawl allocations change over time, there may be more need to adjust the calculation of the aggregate to bring the calculation into line with the intent for the level at which the control limit is set. Because the approach remains fixed until explicitly changed, when such a change appears needed, the amount of adjustment required could be substantial compared to what would have occurred if incremental adjustments were made every two years. However, the approach adopted by the Council will provide more stability for planning and a simpler program for administration.

A-2.3 Program Administration

A-2.3.1 Tracking, Monitoring, and Enforcement

A-2.3.1.a Discarding

❖ *Provisions and Options*

It is the Council's intent to provide NMFS flexibility sufficient to design and implement a tracking and monitoring (T and M) program that will achieve the goals and objectives of the trawl rationalization program.

►T and M Program Alt 1: Nonwhiting – Discarding of IFQ species allowed, discarding of IBQ species required, discarding of non groundfish species allowed.

T and M Program Alt 2: Nonwhiting – Discarding of IFQ species prohibited, discarding of non IFQ commercial species prohibited, discarding of IBQ species required, discarding of non groundfish species allowed except retention of non IBQ prohibited species would be required.

►T and M Program Alt 1 and 2:

Shoreside whiting
Maximized retention vessels: Discarding of fish covered by IFQ or IBQ, and non groundfish species prohibited.
Vessels sorting at sea: Discarding of IFQ allowed, discarding of IBQ required, discarding of non groundfish species allowed.

At-sea whiting
Discarding of IFQ allowed by processors, discarding of IBQ required by processors, discarding of non groundfish species allowed by processors, mothership catcher vessels prohibited from discarding catch.

❖ *Rationale and Policy Issues*

Alternatives 1 and 2 are identical for the shoreside whiting and nonwhiting fisheries. Options are provided for vessels that supply nonwhiting groundfish to shoreside processors.[126] It is expected that the tracking and monitoring program will be able to provide accurate estimates of each vessel's discards of IFQ and IBQ species. Non-marketable species can also be discarded. As a disincentive to IBQ catch, the current policy of mandatory discard of halibut would continue. [127] Allowing discards of IFQ species gives vessels the flexibility to determine what species are retained for landing or discarded. In determining what to discard, vessel captains would review a variety of factors including ex-vessel prices, marketable sizes of fish, and vessel storage space. Allowing discard provides flexibility to the vessels. Discarding will also require changes in vessel operations and the purchase of new equipment to have onboard and at sea. In addition to observers, vessels would need to have scales on board to allow for accurate weighing of fish. To use observer time efficiently, vessel crew will have to aid the observer in the sorting of fish and with other functions associated with sorting, weighing, and identifying discarded fish species.

[126] The shoreside whiting and at-sea mothership and catcher-processors sectors do not bottom trawl; they mid-water trawl for whiting.
[127] Halibut is currently the only IBQ species.

❖ *Interlinked Elements*

IFQ discards have to be accounted for witH QPs. The accuracy and timeliness of IFQ discard estimates will affect all those elements associated with comparing QPs with catch and QS.

❖ *Analysis*

Allowing discards would change the nature of the tracking and monitoring system. Observers will have to focus their efforts on estimating discarded catch and not on estimating retained catch. However, implementation of a full retention program where there is zero discarding of IFQ species would be difficult. Full retention might require keeping everything from tires and derelict fishing gear to bottom items like mud, clams, and sea anemones. For example, the shoreside whiting fishery has evolved from the concept of "full retention" to a "maximized retention" fishery to account for operational discards and safety issues. Maximized retention would apply to the relevant species of the fishery and would not prevent the discard of rocks, seaweed, and plastics, for example.

A-2.3.1.b Monitoring

❖ *Provisions and Options*

At Sea Catch Monitoring

T and M Program Alt 1: Nonwhiting – The sorting, weighing and discarding of any IFQ or IBQ species must be monitored by an observer with supplemental video monitoring.

►T and M Program Alt 2: Nonwhiting – The sorting of catch, the weighing and discarding of any IBQ and IFQ species, and the retention of IFQ species must be monitored by the observer. *(The preferred alternative matches this with T and M Program Alt 1, discarding allowed. Therefore, discards would also have to be monitored.)*

►T and M Program Alt 1 and 2:

Shoreside whiting - *For maximized retention vessels*: video monitoring as proposed under Amendment 10.

►Suboption: Observers would be required in addition to or as a replacement for video monitoring.

For vessels that sort at sea: The sorting, weighing, and discarding of any IFQ or IBQ species must be monitored by an observer with supplemental video monitoring.

At-sea whiting: *Catcher vessels.* Observers would be required in addition to or as a replacement for video monitoring. *Motherships and catcher/processors*: The sorting, weighing and discarding of any IFQ or IBQ species must be monitored by an observer.

►**Shoreside Landings Monitoring** (T and M Program Alt 1 and 2)
Nonwhiting and whiting - The sorting, weighing, and reporting of any IFQ must be monitored by a catch monitor (IBQ will have been discarded at sea).

❖ *Rationale and Policy Issues*

More accurate estimates of total mortality through better catch accounting would help achieve stock conservation goals.

Shoreside whiting and nonwhiting: A monitoring and tracking program is necessary to ensure that all catch (including discards) is documented and matched against QP. For shoreside nonwhiting trips, there is a proposed requirement for 100 percent observer coverage on vessels and for shoreside whiting trips, observers in addition, to or as a replacement for, video monitoring. Note that the Council's preferred alternative is for the shoreside whiting and nonwhiting fisheries to be managed under an IFQ system and as a single combined sector. In its PPA the Council specified that if Congress provided the needed legislation, the shoreside whiting fishery might be managed as a co-op with processor linkages rather than with IFQs. In addition to 100 percent observer coverage, 100 percent shoreside monitoring is also being proposed because the sorting, weighing, and reporting of any IFQ or IBQ species must be monitored by a catch monitor.

At-Sea Sector: Under status quo, mothership processing vessels and catcher-processors currently carry two observers. This monitoring requirement would remain for these vessels. However, a new requirement would be the placement of observers, possibly supplemented by cameras, on catcher-vessels that deliver to motherships. [Note that for the 2009/2010 groundfish harvest specifications and management measures, the Council is proposing video monitoring for these vessels.] See Appendix B, Section 1.4 on at-sea observers and monitoring for information regarding this sector.

❖ *Interlinked Elements*

Overall Program Execution: Implementation of the trawl rationalization program hinges on individual and co-op catch accountability, which in turn hinges on complete observer coverage. Should 100 percent observer coverage not be retained as part of the trawl rationalization preferred alternative, the entire proposed program would have to be rethought.

General Management and Trawl Sectors (A-1.3): The decision whether to manage the shoreside whiting fishery as a co-op or an IFQ fishery will affect the determination whether observers are more appropriate than cameras for the shoreside whiting fishery. As mentioned above, shoreside co-ops with processor linkages will require congressional approval.

❖ *Analysis*

Cameras are currently employed as an electronic monitoring system (EMS) in the shoreside whiting fishery, and EMS is used as a monitoring tool. The EMS system employed under the EFP for Pacific whiting permits shoreside vessels to dump unsorted catch directly below deck and allows this unsorted catch to be landed, if an EMS is used on all fishing trips to verify retention of catch at sea. The EMS is an effective tool for accurately monitoring catch retention and identifying the time and location of discard events. However, current video technology is not good enough to use cameras in trawl fisheries to measure the amount of fish discarded or to determine the species of fish discarded. Therefore, observers are deemed a superior monitoring tool for the nonwhiting trawl fishery given the number of species and need to have accurate estimates of IFQ discards. If the shoreside whiting fishery is managed as an IFQ fishery, observers rather than the current cameras will also be needed for the same reason. The option of requiring cameras in addition to observers (should human observers be deemed necessary to ensure compliance) is a potential cost-cutting measure compared to requiring a second human observer. The purpose of having catch monitoring in the shoreside nonwhiting fishery is to ensure that all IFQ and IBQ species are accurately weighed, sorted, and reported. Catch monitors are already employed in the shoreside whiting fishery. See also the discussion under program costs, below.

A-2.3.1.c Catch Tracking Mechanisms

❖ *Provisions and Options*

►Catch Tracking Mechanisms (T and M Program Alt 1 and 2)

Electronic vessel logbook report
Nonwhiting, shoreside whiting and at-sea whiting: VMS-based electronic logbook required to be transmitted from vessel. At-sea entry by vessel personnel required including catch weight by species and if retained or discarded.

Vessel landing declaration report
Nonwhiting and shoreside whiting: Mandatory declaration reports.

Electronic IFQ landing report
Nonwhiting and shoreside whiting: Mandatory reports completed by processors and similar to electronic fish ticket report.

Processor production report
Nonwhiting, shoreside whiting and at-sea whiting: Mandatory reports (possible inclusion of proprietary data included to be recommended as option is fleshed out).

❖ *Rationale and Policy Issues*

Other than the declaration reports and the processor production reports, these catch tracking mechanisms are largely the conversion of existing state paper-based systems. Converting to electronic reporting is seen as an aid for improved accuracy of reported data and better quota monitoring at the individual vessel, co-op, and sector level. Declaration reports and processor production reports are seen as tools that improve the ability to enforce regulations. One of the issues facing the implementation of these reporting systems is how best to adapt the existing state paper-based systems to the needs of the trawl rationalization program.

❖ *Interlinked Elements*

All of these reports address directly or indirectly address the needs for total catch accounting, biological and management data, socioeconomic data, economic data (including data for anti-trust), excessive share assessments, cost recovery, and program performance measures.

❖ *Analysis*

All trawl sectors (shorebased nonwhiting, shorebased whiting, mothership catcher vessels and processors, and catcher-processors) will require VMS-based electronic logbooks. Nonwhiting and whiting vessels that deliver shoreside will also have to submit declaration reports. Shorebased processors will have to submit the electronic IFQ landing reports in the form of the electronic "fishtickets," and processors will also have to supply mandatory production reports.

Compared to the status quo, the only new reports are the vessel declaration reports and the processor production reports. As cited above, there are many conservation and management reasons for these reports. In addition, electronic reporting will aid vessels, processors, and all QS and QP holders in making real-time decisions. Currently the Pacific States Marine Fisheries Commission (PSMFC) is working with the states on converting their paper-based fish ticket and trawl logbook systems into electronic systems. Electronic fishtickets are now being experimented with in the shoreside whiting

fishery. The actual design of these reports are under development and most likely will be more fully analyzed for public comment under the rulemaking process that converts the Council's preferred alternative into regulation. This process includes addressing reporting issues under the Paperwork Reduction Act process and under the Regulatory Flexibility Act (regulatory reporting burden on small businesses). One of the issues in the design of these systems and the integration with observer, catch monitor, and QP/QS tracking systems concerns lining up the coding systems so that all IFQ species are reported consistently on a species and species group basis. Another issue is understanding when changes are needed. As the Council and Federal management tracking and monitoring needs change, states will have to convert their systems to meet these needs.

A-2.3.1.d Cost Control Mechanisms

❖ *Provisions and Options*

Shoreside landing hour restrictions
T and M Program Alt 1, Nonwhiting and shoreside whiting: Landing hours not restricted.
T and M Program Alt 2, Nonwhiting and shoreside whiting: Landing hours restricted.
►T and M Program Alt 3, Nonwhiting and shoreside whiting: Landing hours may be restricted.

Shoreside site Licenses
►T and M Program Alt 1 and 2, Nonwhiting and shoreside whiting: Mandatory license for shoreside deliveries. License can be issued to any site that meets the monitoring requirements.

Vessel Certification
►T and M Program Alt 1 and 2, All Trawl Sectors: Mandatory certification. Certificate can be issued to any vessel that meets the monitoring requirements.

❖ *Rationale and Policy Issues*

The certification of vessels, licensing of shoreside processing plants, and restricted shoreside landing hours support management and enforcement objectives and potentially reduce costs by restricting the number of shoreside processing plants and the hours under which plant monitors have to be present in the plant.

❖ *Interlinked Elements*

Among other requirements to receive certification or licensing will be the need for accurate scales to be used, thus aiding many of the catch tracking mechanisms discussed above. Tracking and monitoring costs will be affected by the certification requirements and by decisions to limit shoreside landing hours.

❖ *Analysis*

All trawl sectors (shoreside nonwhiting, shoreside whiting, mothership catcher vessels and processors, and catcher-processors) would require certification or licenses that show they meet the monitoring requirements. To reduce costs, landing hours could be restricted. In addition to the options to restrict or no restrict landing hours, a third option was added and selected as the final preferred alternative, which states that landing hours *may* be restricted. This option provides for greater flexibility to provide solutions as issues arise, rather than preemptively limiting landing hours.

Many of the other requirements will be similar to those currently specified as part of the 2008 Pacific Whiting Shoreside Fishery Maximized Retention and Monitoring Exemption Program (see http://www.pcouncil.org/bb/2008/0308/F1a_SUP_ATT2.pdf). This program outlines the reporting

requirements, equipment needs, and vessel and plant responsibilities including relationships with plant monitors, notification and declaration procedures, and the requirement of a NMFS monitoring plan. For IFQ and co-op fisheries, these elements would have to be expanded to include existing observer requirements, together with safety requirements, as well as the responsibilities of the crew to assist the observer in the weighing and sorting of catch and responsibilities of the captain to ensure that vessel operations do not hinder observer efforts. For IFQ vessels, there is likely to be a need to purchase appropriate scales to meet these requirements. The actual design of these reports is under development and would be more fully analyzed for public comment under the rulemaking process that converts the Council's preferred alternative into regulations. This process includes addressing reporting issues under the Paperwork Reduction Act process and under the Regulatory Flexibility Act (regulatory reporting burden on small businesses).

A-2.3.1.e Program Performance Measures

❖ *Provisions and Options*

►**T and M Program Alt 1 and 2,** All Trawl Sectors: integrate into the tracking and monitoring program the collection of data on cost, earnings and profitability; Economic efficiency and stability; capacity measures; net benefits to society; distribution of net benefits; product quality; functioning of quota market; incentives to reduce bycatch; market power; spillover effects into other fisheries; contribution to regional economies (income and employment); distributional effects/community Impacts; employment in seafood catching and processing; safety; bycatch and discards; administrative, enforcement, and management costs. [See A-2.3.2., Socioeconomic Data Collection.]

A-2.3.2 Socioeconomic Data Collection

❖ Provisions and Options

The data collection program will be expanded and submission of economic data by harvesters and processors will be mandatory. Random and targeted audits may be used to validate mandatory data submissions. See footnote for a full description. Information on QS transaction prices will be included in a central QS ownership registry. *NOTE: Data collection started before the first year of implementation would be beneficial, in order to have a baseline for comparison.*

Footnote from IFQ Program provisions:

- Mandatory submission of economic data for LE trawl industry (harvesters and processors)
- Voluntary submission of economic data for other sectors of the fishing industry
- Include transaction value information in a centralized registry of ownership
- Formal monitoring of government costs

Mandatory Provisions: The Council and NMFS shall have the authority to implement a data collection program for cost, revenue, ownership, and employment data, compliance with which will be mandatory for members of the West Coast groundfish industry harvesting or processing fish under the Council's authority. Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA.

A mandatory data collection program shall be developed and implemented as part of the groundfish trawl rationalization program and continued through the life of the program. Cost, revenue, ownership, employment, and other information will be collected on a periodic basis (based on scientific requirements) to provide the information necessary to study the impacts of the program, including achievement of goals and objectives associated with the rationalization program. These data may also be used to analyze the economic and social impacts of future FMP amendments on industry, regions, and localities. The program will include targeted and random audits as necessary to verify and validate data submissions. Additional funding (as compared to status quo) will be needed to support the collection of these data. The data collected would include data needed to meet MSA requirements (including antirust).
The development of the program shall include the following: A comprehensive discussion of the enforcement of such a program, including discussion of the type of enforcement actions that will be taken if inaccuracies are found in mandatory data submissions. The intent of this action will be to ensure that accurate data are collected without being overly burdensome on industry in the event of unintended errors.

Voluntary Provisions: A voluntary data collection program will be used to collect information needed to assess spillover impacts on nontrawl fisheries.

Central Registry: Information on transaction prices will be included in a central registry of QS owners. Such information will also be included for LE permit owners/lessees.

Government Costs: Data will be collected and maintained on the monitoring, administration, and enforcement costs related to governance of the rationalization program.

❖ Rationale and Policy Issues

The goal of the Council's rationalization alternatives involves several economic components. The stated goal of the program is presented below:

> *Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.*

The Act also contains a monitoring requirement to determine whether a LAPP is meeting its goals. Sec. 303A (c)(1)(G) states that any LAPP shall do the following:

> *include provisions for the regular monitoring and review by the Council and the Secretary of the operations of the program, including determining progress in meeting the goals of the program and this Act, and any necessary modification of the program to meet those goals, with a formal review 5 years after the implementation of the program and thereafter to coincide with scheduled Council review of the relevant FMP (but no less frequent than once every 7 years).*

The MSA (as amended through January 2007) also places importance on social and economic outcomes resulting with a rationalization programs. Sec. 303A(c)(1)(C) states that any LAPP to harvest fish submitted by a Council or approved by the Secretary under this section shall promote social and economic benefits. The Council has also enumerated several objectives and constraints for the program that involve economic components and monitoring of the program (see Chapter 1).

In order to meet the monitoring requirements for the economic goals, improved and expanded economic data would be needed for the trawl IFQ fishery. The Council's PPA provides for a mandatory economic data collection provision. Regardless of whether the economic data collection is mandatory or voluntary, the types of data necessary to monitor the effects of the program are the same. However, the choice of mandatory or voluntary data collection will likely have a large effect on the Council's and the NMFS' ability to consistently and systematically collect the necessary data.

Despite the NWFSC's recent progress in voluntary economic data collection, economic analysis of the LE trawl fishery historically has been severely constrained by a lack of economic data. Incomplete cost-earnings data on vessels and processors have been a particular problem. While PacFIN provides data on most, but not all, earnings sources for LE trawlers, little data on the cost of operating harvesting vessels have been available. Data on the costs and earnings of processing plants have not been available to NMFS or Council economists. This lack of economic data has hampered attempts to measure economic performance, build regional economic input-output models, assess overcapacity, and build models that predict economic behavior.

The first of recent attempts to collect economic data from LE trawl vessel owners occurred in 1999 and 2000. This mail survey used a lengthy questionnaire asking for considerable fishery-specific information, but obtained a response rate well below 20 percent. Because of the low response rate and nonrespondent bias, data collected through this survey were of limited value. A processor survey conducted at about the same time obtained an even lower response rate.

A second voluntary economic survey of LE vessel owners was conducted from 2005 to 2007. In order to obtain higher response rates, this second survey used a much shorter questionnaire and collected data

through in-person interviews. This survey obtained a fairly high response rate of more than 70 percent, but at the cost of considerably less data collected from each respondent due to the shorter questionnaire. While this second survey provides much data of value for assessing industry economic performance and regional economic impacts, our ability to evaluate the contribution of individual fisheries (such as groundfish) to vessel economic performance is limited by the reduced questionnaire length. Collecting data through in-person interviews helped to substantially increase the response rate, but at considerably increased survey cost.

Mandatory economic data collection offers the advantages of reduced nonresponse bias, the ability to collect more detailed fishery-specific data, and reduced survey fielding costs. These advantages would apply to data collection from both the harvesting sector and the processing sector.

❖ *Interlinked Elements*

The program inherently relies on data collection. These provisions include requirements for data needed to adequately monitor program performance (see Section A-2.3.4).

❖ *Analysis*

The collection of such data are related to several aspects of MSA and groundfish FMP guidance on rationalization that will be discussed in the analysis. These include the categories of net benefits, fairness and equity, and harvester and processor sector health. To a large degree, these broad categories are addressed by data collection because such data collection allows for the measurement of these categories. The measurement of these categories may help inform future decisions on the part of the Council.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Data Collection		X			X	X				

An economic data collection program will increase the ability to monitor and measure the economic performance of the industry, as described in the rationale above. It will also increase the burden on agencies involved in the data collection and analysis and the burden on industry members in the form of time spent reporting data.

The NWFSC has gone through two voluntary survey efforts. The first effort resulted in a relatively low response rate, which minimized the ability to use the survey. The second effort used face-to-face interviews and resulted in a response rate of more than 70 percent. This relatively high response rate has resulted in several pieces of analysis utilized in the rationalization process and may prove useful for other means as well. While this survey has largely been considered successful, the face-to-face

interview technique is estimated to have cost somewhere approximately $700 to $800 per interview. This cost does not include the time and cost of developing the survey and analyzing the data. Given that the trawl fishery is over 100 vessels, the field cost of conducting a voluntary survey using a face-to-face technique could be approximately $100,000 to the agency each year it is conducted.

On the other hand, a mandatory survey may obviate the need for face-to-face interviews. Face-to-face interviews were used in the voluntary survey for several reasons including obtaining a favorable response rate. If a survey is mandatory, a face-to-face technique may not be necessary. However, differences may exist between a mandatory and a voluntary survey, which can make the burden on the industry greater for a mandatory survey than a voluntary survey.

Factors affecting the response rate of a voluntary survey include the length of the survey and the difficulty of the questions. If a survey is viewed as overly lengthy and/or requests information that is not readily available and that may take time to uncover, the response rate is likely to suffer. The response rate from a mandatory survey may not suffer in the same fashion. Therefore, it is reasonable to expect that a voluntary survey may (at least at times) be simpler and shorter than a mandatory survey simply to get a favorable response rate. If this is the case, a mandatory survey may impose a larger burden on industry than a voluntary survey. In the worst-case scenario (one where the survey is highly burdensome), industry members may at times respond with a "protest response" or information that is of poor quality. Such protest response might be an indication of issues related to the program's costs, fairness, and equity. This can affect the ability to use the survey responses even if the response rate is high.

The collection of economic data relates to several aspects of policy guidance from the MSA, the Groundfish FMP, and Amendment 20 goals and objectives. If better data collection leads to more informed decisions relating to net benefits and efficiency, then data collection is related to MSA National Standard 5, MSA – 303A(c)(1)(B), Amendment 20 objectives 2 and 6, and potentially others. In particular, Amendment 20 objective 6 (promote measurable economic benefits) is related to data collection, because data collection allows economic benefits to be measured. Many benefits may not be measurable without the acquisition of additional economic data. If additional data collection helps in the development of sound policies that benefit the industry, then such data collection may also relate to policy guidance on sector health including Amendment 20 objectives 2 and 6, groundfish FMP goal 2, and groundfish FMP objective 7 and 15. Finally, data collection is directly related to several aspects of policy guidance on program performance monitoring and modification. MSA – 303A(c)(1)(G) calls for a regular review and monitoring of the program for progress in meeting goals.

A-2.3.3 Program Costs

A-2.3.3.a and b, Cost Recovery and Fee Structure

❖ Provisions and Options

Cost Recovery
►Option 1: Fees up to 3 percent of exvessel value, consistent with 303A(e) of the MSA may be assessed. Cost recovery shall be for costs of management, data collection, analysis, and enforcement activities.

Option 2: There will be full cost recovery. Cost recovery will be achieved through landing fees plus privatization of elements of the management system. In particular, privatization for monitoring of IFQ catch (e.g., industry pays for their own compliance monitors). Stock assessments will not be privatized and the electronic fish ticket system will not be privatized.

Fee Structure
To be determined. TIQC recommends a fee structure that reflects usage. A fee structure that allows for equitable sharing of observer costs for smaller vessels may be developed.

❖ Rationale and Policy Issues

Fees would be used to recover costs associated with management, data collection and analysis, and enforcement of the IFQ program. The limit on fees will be 3 percent of ex-vessel value, as specified in the MSA, shown below.

The MSA states in Sections 303A (e):

> (e) COST RECOVERY.—In establishing a LAPP, a Council shall—
>
> > (1) develop a methodology and the means to identify and assess the management, data collection and analysis, and enforcement programs that are directly related to and in support of the program; and
> >
> > (2) provide, under section 304(d)(2), for a program of fees paid by LAP holders that will cover the costs of management, data collection and analysis, and enforcement activities.

In Section 304(d)(2)(A) of the MSA:

> (2)(A) Notwithstanding paragraph (1), the Secretary is authorized and shall collect a fee to recover the actual costs directly related to the management, data collection, and enforcement of any—
> (i) LAPP; and
> (ii) community development quota program that allocates a percentage of the total
> allowable catch of a fishery to such program.
>
> (B) Such fee shall not exceed 3 percent of the ex-vessel value of fish harvested under any such program, and shall be collected at either the time of the landing, filing of a landing report, or sale of such fish during a fishing season or in the last quarter of the calendar year in which the fish is harvested.

The policy issues associated with cost recovery include aligning the Council's preferred alternative to be consistent with MSA by including enforcement costs as required by the MSA and adjusting the provisions of tracking and monitoring program so that the three percent fee covers the costs of management, data collection and analysis, and enforcement activities.

Preliminary cost projections are higher than the maximum fee of 3 percent of ex-vessel value of fish harvested that is allowed for direct cost recovery. Some costs, such as payment for observers, will be paid directly by industry to the observer companies. These costs would not come under the 3 percent limit. However, cost projections are preliminary and will be refined during the regulatory process that converts the Council's preferred alternative into regulation. During this period, it is also expected that there may be several public meetings. These meetings would include the affected industry to determine how costs can be reduced. These discussions would also cover the Council's recommended use of limited landings hours for shoreside processors to limit program costs. NMFS will also be meeting with the states to discuss state needs and integration of the tracking and monitoring elements of this program with existing state programs. In this depressed economy, there are state budget concerns about maintaining existing programs, let alone expending programs. State resources may need augmentation to complete status quo projects (electronic fish ticket system) and address budget needs associated with the trawl rationalization program (e.g., personnel to carry out the program implementation).

Fees collection based on "usage" and any special provisions such as "equitable sharing of observer costs for small vessels" is pending further development of tracking and monitoring cost estimates and Council discussion of these issues.

❖ *Interlinked Elements*

The interlinked elements are all the tracking and monitoring elements discussed above, as well as all elements that affect the costs of management, enforcement, or are associated with data collection and analysis. Almost all elements affect costs. These elements include permits, endorsements, IFQ and co-op allocation and transfer rules, adaptive management rules, excessive share monitoring, gear switching regulations, and regional and area management and allocation rules.

❖ *Analysis*

NMFS presented the preliminary estimates below at the November 2009 Council Meeting. (See November 2009 Briefing Book: Agenda Items G.8.B Supplemental NMFS Presentations, Lockhart and Freese.) NMFS has updated these estimates based on April 2010 Council actions. These estimates can be found in Appendix H. These estimates will be updated again during the regulatory processes that convert the Council's preferred alternative into regulation. Through these and Council processes, we expect to address public comment on how costs can be lowered. NMFS is also proposing to partially fund the costs of observers and compliance monitors for the first three years of this program. It should also be noted that there are state budget concerns regarding upholding existing programs, let alone expanding these programs, given the current state of the economy. State resources may have to be increased to establish the electronic fish ticket and logbook programs or to hire personnel for port sampling, enforcement, and other purposes.

Below are tables that show the existing tracking and monitoring system, current tracking and monitoring costs by sector, and what the costs of additional observers, and plant monitors. In addition to these costs, other state, federal, and Council costs are also listed. Total cost projections are then compared with alternative revenue estimates.

Status Quo Tracking and Monitoring Systems (see Table A-103): VMS are used by all vessels except motherships. Paper logbooks are used by all harvest sectors. Logbooks are mandatory for shoreside vessels but voluntary for the at-sea motherships and catcher-processors. PSMFC combines the state fish tickets and logbooks into a single database. This database is funded federally; states contribute personnel and other resources. Shoreside whiting trawlers are monitored with cameras. The industry pays for the cameras, and NMFS pays for review and analysis of the resulting video. Observer coverage in the nonwhiting fishery is approximately 25 percent, which is funded by NMFS, while the at-sea motherships and catcher-processors use hired observers from a private company. Shoreside whiting plants also pay a private company for compliance monitors. The equipment, training, data collection, and analysis associated with these observers and monitors are paid for by NMFS. Electronic fish tickets are now used in the shoreside whiting fishery.

Table A-103. Status quo observer coverage and monitoring for all sectors.

Status Quo	Shorebased Nonwhiting Trawl	Shorebased Whiting Trawl	At-Sea Mothership Trawl	At-Sea Mothership processor	At-Sea Catcher-Processor
VMX	X	X	X		X
Logbooks	X	X	X	X	X
Cameras		X			
Observers	25% WCOP		0	2	2
Compliance Monitors		100%			
Fish Tickets	X	X			
Electronic Fish Tickets		X			

The Council's preferred alternative would result in the following:

- Increase the observer coverage to 100 percent in the shore based nonwhiting trawl fleet.
- Replace the cameras used in shore based whiting trawl sector with 100 percent observer coverage.
- Expand the whiting compliance monitor program to 100 percent coverage of the shore based nonwhiting trawl program.
- Institute 100 percent coverage to the at-sea mothership trawl fleet.

In comparison to status quo management, rationalization will require increases in NOAA Fisheries' Northwest Region, NOAA General Counsel, Northwest Fisheries Science Center, and the Northwest/Southwest Offices of Law Enforcement staff. State fisheries management and enforcement staff will also have to be increased. Additional equipment, training, and information technology resources (hardware and software) will also needed by both state and federal agencies. The Council will also incur additional costs in the early years of the program.

Listed below are examples of anticipated additions to state and federal staff levels due to rationalization:

- Staff for cost recovery, permitting and, quota tracking and appeals processes
- Staff and contracting for performance monitoring including mandatory economic data collection
- Observers, debriefers, and, port samplers
- Law enforcement officers, technicians, equipment, and training
- Lawyers, policy analysts, and regulation writers to adopt federal and state regulations in support of the program and address enforcement issues
- IT resources (FTEs, hardware, and software) to support electronic reporting (logbooks, fish tickets, observers, compliance monitoring, etc.)
- State and Federal outreach

Based on the preferred alternative, NMFS has developed the following preliminary estimates of potential costs.

Implementation Costs (One-time costs to develop the tracking and monitoring programs.)

State management and enforcement $300,000 to $500,000 per state
NMFS management and enforcement $2.1 million
NMFS (NWFSC) Observer Program and
Economics Data Collection Programs $3.150 million

Total: Approximately $6.5 million

Annual Costs (State, Council, and federal costs associated with running the Program when fully implemented.)

State management and enforcement$750,000 to $1.5 million per state
NMFS management and enforcement $1.7 million
NMFS (NWFSC) Observer Program and
Economics Data Collection Programs$3.15 million

Total: Approximately $8 million

Direct Observer and Monitoring Costs (Daily costs associated with hiring observers and plant monitors.)

Shoreside nonhake trawl fishery$3.5 million
Mothership Processors$243,000
Mothership Catcher Vessels$253,000 to $362,000
Catcher-Processor$415,000
Shoreplant Compliance Monitors non hake$950,000
Shoreplant Compliance Monitors hake$300,000

Total: Approximately $5.7 million

Total Annual Costs and Direct Observer and Monitoring $14 million

These costs are preliminary, and the direct observer and monitoring costs depend heavily on operational decisions by industry (both fishing vessels and processors) to reduce costs. In addition, it is impossible to predict how much consolidation will occur, especially in the initial years of program implementation. For these reasons, this analysis makes broad assumptions about industry behavior to frame the range of costs. At one extreme, annual observer costs could rise to $18 million if a 100-vessel fleet needed observers 365 days a year at a cost of $500 per day. The industry could reduce costs by imposing voluntary limits on the number of vessels that can be at sea at any one time or agreeing to share observer coverage between multiple vessels. These and other costs could decline as the number of participating vessels decline, when the fleet consolidates because of the program. A quantitative analysis (Lian *et al*., 2008) indicates an expectation that there will be a fleet of 50 to 60 vessels of a size of 60 to 70 feet after rationalization. If this were to happen, one would expect the costs to be significantly lower and approximately half of the estimated costs for the current fleet.

Table A-104 below shows harvest, revenue, and price dimensions of the fishery. The 2007 fishery earned $57 million in ex-vessel revenues with the nonwhiting groundfish components earning $27 million while the whiting components earned $30 million. Between 2004 and 2007, there were

rising whiting and fuel prices. In 2008, these fisheries earned approximately $90 million in ex-vessel revenues mainly based on the size of the whiting quota and continued high prices for whiting. The total estimated annual cost of the Trawl Rationalization Program, including the direct observer and monitoring costs, is estimated to be $14 million. These costs can be addressed by a combination of industry fees, congressional appropriations, or state/federal reprogramming of existing resources. Additionally, as has been stated, these cost estimates can be reduced via industry adoption of operational changes to lower cost tracking and monitoring alternatives.

Table A-104. Economic comparison of 2004 and 2007 revenues.

Economic Comparison		2004	2007
Harvests Metric Tons			
Total Non-Tribal Whiting		191,793	180,056
Total Nonwhiting Groundfish		17,238	22,253
Total Groundfish including Whiting Tons		209,031	202,309
Ex-vessel Revenues Million $			
Total Non-Tribal Whiting		$26.1	$29.7
Total Nonwhiting Groundfish		$16.2	$27.2
Total Groundfish including Whiting Tons		$42.3	$56.9
Ex-Vessel Prices			
Ex-Vessel Price Whiting		0.046	0.075
Ex-Vessel Price All flatfish	$/lb	0.425	0.43
Ex-Vessel Price Thornyhead Compl.	$/lb	0.609	0.627
H&G Whiting Export Price	$/lb	0.55	0.75
Marine Diesel Fuel Costs Newport, Oregon, June	$/gal	1.65	2.5

Regardless of how these costs are addressed, it is likely that the industry will be paying the maximum recovery fee of 3 percent. (NMFS will discuss fee collection processes with the Council and industry when it undertakes cost-recovery rule-making.) All industry borne compliance costs would be expected to reduce the value of QS prices by corresponding amounts. For those having to buy into the fishery, higher compliance costs would be expected to reduce what they have to pay for QS.

However, for perspective, according to the Council's SSC review of the Lian Analysis (this analysis included an estimate of $350 per day observer costs.) (See: http://www.pcouncil.org/bb/2008/0608/F6d_SUP_SSC_0608.pdf), the following is noted:

The TIQAT (Trawl Individual Quota Analytical Team) used a fleet consolidation model to estimate the size and profitability of the groundfish trawl fleet that may result from the TIQ program....

A standard econometric methodology was used to estimate the economic efficiency of individual trawl vessels based on vessel cost and earnings data collected for 2003 and 2004 by the Northwest Fisheries Science Center (NWFSC). Results from the analysis, based on 2004 costs and harvests, indicated considerable consolidation, with the fleet being reduced to 40 to 60 vessels and with cost savings in the range of $18 to 22 million. The cost savings would arise from a shift in fleet composition to vessels with lower costs, which were estimated to fall in the 50- to 60-foot size range, and a reduction in fixed costs due to the operation of a smaller fleet.

Nonwhiting Trawl (Table A-105***):*** According to the Lian-Weninger analysis (Lian, *et al.* 2008), there were 117 vessels operating in the nonwhiting trawl fishery, taking 2,699 trips in 2004. Based on average of three days per trip, these vessels operated just over 8,000 days. Based on observer cost estimates used in NMFS's Alaska Region and Northwest Region analyses of $350 per day, 100 percent

observer coverage would require the industry to pay approximately $2.8 million in observer costs. If, in addition to observers, cameras were also required, industry costs would be about $700,000 based on the industry estimate of $6,000 per camera per vessel. It is not known how many vessels already have the proper scales that may cost in the neighborhood of $5,000 to $10,000 each. Processors would have to pay plant monitors to monitor the landings from the 2,699 trips. Assuming that each trip requires one day of plant monitoring, the costs to the processors will be approximately $945,000 for 100 percent monitoring. Currently, vessels and processors do not have observer and monitoring coverage, so the status quo estimate is zero. The costs of observers and plant monitors are estimated to be approximately $3.8 million. Note that there will be operational costs to both the plants and vessels as they adjust their operations to account for the observers and monitors. There are no available estimates of these adjustment costs. If, in addition to observers, vessels also are required to carry cameras, this option raises the estimated cost of monitoring to approximately $4.5 million.

Table A-105. Nonwhiting trawl sector observation and monitoring costs at sea and shoreside.

Nonwhiting Trawl				
Catcher Vessels	**Current**			
Number	117			
Trips	2,699			
Days per trip	3			
Observer days	8,097			
Observer variable cost per day	$350			
Observer cost		$2,833,950		
Camera unit cost	$6,000			
Camera cost	$702,000	$702,000		
Additional equipment costs	Discard option may require vessels to have motion-compensating scales			
Processors				
Number	29			
Trips	2,699			
Number of trips per day	1			
Operating days	2,699			
Number of monitors	1			
Monitor variable cost	$350			
Total monitor variable cost		$944,650		
Status Quo			**0**	
T&M Alternative 1 Observers and Monitors			**$3,778,600**	
T&M Alternative 2 Observers, Monitors, and Cameras			**$4,480,600**	

Shoreside Whiting (Table A-106***):*** Based on recent participation rates, a whiting fishery prosecuted by 30 vessels with a season length of 60 days leads to 1,800 observer days at an industry cost of $630,000. The current camera costs are $180,000, and the current processor monitoring costs are about $294,000 for a combined status quo cost of $474,000. If cameras are replaced with observers, the costs rise to $924,000; if cameras are used to supplement observers, the costs rise to $1.1 million. These cost estimates will be updated based on information on the 2008 fishery, the first year in which plant monitors were employed in this fishery. It is unknown if these vessels will have to purchase scales, and the operational adjustment costs of these vessels to the use of observers are also unknown.

Table A-106. Shoreside whiting trawl sector observation and monitoring costs at sea and shoreside.

Shorebased Whiting				
Catcher Vessels	**Current**			
Number	30			
Season length	60			
Observer days	1,800			
Observer variable cost per day	$350			
Observer cost		$630,000		
Camera unit cost	$6,000			
Camera cost	$180,000	$180,000		
Additional equipment costs	???			
Processors				
Number	14			
Season length	60			
Operating days	840			
Monitoring cost per day	$350			
Total monitor variable cost		$294,000		
Status Quo			**$474,000**	
T&M Alternative 1 Observers and Monitors			**$924,000**	
T&M Alternative 2 Observers, Monitors, and Cameras			**$1,104,000**	

Mothership Whiting (Table A-107***)***: This analysis follows a similar approach to the shoreside whiting analysis above. Under status quo, mothership processors are required to carry two observers, and the catcher vessels have no direct monitoring; therefore, the costs are about $250,000. Adding observers to the catcher vessels increases the costs to $672,000, and adding observers and cameras further increase costs to $828,000.

Table A-107. Mothership sector observation and monitoring costs.

Mothership Whiting				
Catcher Vessels	**Current**			
Number	20			
Season length	60			
Observer days	1,200			
Observer variable cost per day	$350			
Observer cost		$420,000		
Camera unit cost	$6,000			
Camera cost		$120,000		
Processors				
Number	6			
Season length	60			
Operating days	360			
Number observers	2			
Observer cost per day (1)	$350			
Total Monitor variable cost		$252,000		
Camera unit cost	$6,000			
Camera cost		$36,000		
Status Quo			**$252,000**	
T&M Alternative 1 Observers Catcher Vessels and Processors			**$672,000**	
T&M Alternative 2 Observers, Monitors, and Cameras			**$828,000**	

Catcher-processor Whiting (Table A-108***):*** Unless cameras are required, there would be no change to industry costs of tracking and monitoring because catcher-processors already carry two observers. If cameras are also required, industry costs would rise from $378,000 to $432,000.

Table A-108. Catcher-vessel sector observation and monitoring costs.

Total Monitor variable cost		$378,000		
Camera unit cost	$6,000			
Camera cost		$54,000		
Status Quo			**$378,000**	
T&M Alternative 1 Observers			**$378,000**	
T&M Alternative 2 Observers and Cameras			**$432,000**	

State and Federal agency costs for program enforcement, data collection and analysis, and administration are outlined in the following paragraph and in Chapter 4. The costs in Table A-109 on the following page are 'incremental' costs of the IFQ program compared to the status quo. The shift from dockside enforcement to enforcement through auditing-reported data as a result of IFQ was discussed by the Enforcement Committee. With the presence of 100 percent observation and monitoring on vessels, the need for dockside enforcement is greatly reduced, and restricted landing hours may not be crucial for cost reduction purposes. Consequently, state/Federal enforcement estimates ranged from no additional costs above the status quo to $500,000. Camera program costs are based on scaling up the costs NMFS is currently incurring for the whiting EMS camera program and scaling up to the entire trawl sector. Estimates of the At-Sea Observer Program are based on scaling up the estimated current costs of managing the trawl portion of the West Coast Observer Program to 100 percent of the fleet. The $3 million estimate for scaling up the observer program includes the costs of administration, observer training, and program infrastructure. It does not include the observer services. Data quality assurance would result from the periodic substitution of industry-paid-for observers with those paid by NMFS. The catch monitoring program cost estimate is based on the scaling up of the current costs of catch monitoring in the current shoreside whiting fishery. [These estimates will be updated based on analysis of the 2008 season, the first year catch monitors were employed in the whiting fishery.]

The IFQ/Co-op Permits, Quota Program estimate is based on doubling the current size of the NMFS NWR Permit Staff (supervisor, computer specialist, permits specialist, and permits assistant) plus one staff person devoted to the cost-recovery process. The appeals costs were based on requiring the services of a lawyer and a paralegal. It is expected that the PSMFC will continue working with the states, NMFS, and industry in developing electronic fish ticket and logbook reporting. There will be costs in the collection of data to monitor the performance of the fishery and developing various reports. In sum, these estimated costs total $5.2 million.

Table A-109. Program enforcement, data collection and analysis, and administration estimated costs.

	Total Costs	
State/Fed Enforcement	$500,000	Incremental cost – 4 staff support, 1 uniform officer **could be $0
Camera Program	$500,000	Tape review and analysis
At-Sea Observer Program	$3,000,000	Scale up current observer programs to 100% and data quality assurance
Catch Monitor Program	$300,000	Monitor, computer specialist, training and equipment, logistical
ITQ/Coop Permits and Quota Program	$500,000	Permits staff plus cost-recovery specialist
Appeals/GCF/GCF	$200,000	Lawyers and para-legal
E-Reporting Support	$100,000	Working with industry/states
Performance monitoring data collection and reporting	$100,000	Collect data and draft reports
TOTAL	**$5,200,000**	

To provide an economic comparison, Table A-110 below shows current harvest, revenue, and price dimensions of the fishery. It shows the recent variation in landings, revenues, ex-vessel prices, fuel prices, and wholesale whiting prices. The 2007 fishery generated $57 million, approximately $27 million of which was associated with nonwhiting groundfish, and $30 million of which was generated by the whiting fishery. Over the 2004 to 2007 period, the whiting fishery experienced a significant increase in prices, while all sectors experienced rising fuel costs.

To provide a summary of the comparison of costs to revenues,

Table A-110 below compares the status quo to costs of a trawl rationalization program that requires 100 percent observer coverage for all trawl sectors and 100 percent monitoring coverage in shoreside plants (T and M Alternative 1), as well as costs if cameras are also used to supplement observers (T and M Alternative 2). Again, the costs of observers are divided between government and industry, with government requiring about $3 million for administration, observer training, and program infrastructure and industry paying for observer services. The largest increase in industry costs occurs in the nonwhiting fishery with change in costs of $3.8 million over the status quo. This change is due to the fact that the industry currently neither pays for the 25 percent observer coverage, nor is it required to have plant monitors. Program management costs under T and M Alternative 1 are about $4.7 million. The total costs of T and M Alternative 1 are about $10.5 million. However, funds currently received by NWFSC for observing the trawl sector would continue to be used, thus reducing the total new costs related to the program to $8.2 million. If ex-vessel revenues in the fishery were $57 million, then the total costs of management would be about 14 percent. The industry would pay $10.5 million directly to contractors to obtain the services of observers and plant monitors required by the program. This would leave 4 percent needed to cover Federal government management costs, which is higher than the maximum fee level of 3 percent. Therefore, in developing this program, such aspects as limited landing hours have to be explored to see if program costs can be reduced enough to match up with the 3 percent maximum cost recovery level.

However, as the fishery adjusts to the IFQ and co-op programs, it is expected that costs will be reduced, because consolidation will create fewer, more-productive vessels earning greater revenue by catching more target species. If industry costs are reduced 25 percent, and revenues are increased by $20 million, then the resulting program costs fall to 3 percent. If program costs also fall, then possibly the cost recovery fee will fall below 3 percent.

The revenue estimate includes estimates of ex-vessel revenues associated with the whiting fishery. In 2007, the catcher-processor sector accounted for about 40 percent of the fish landed or about $12 million. If the catcher-process cooperative is not a LAPP then the cost recovery fee would not apply. The 2007 industry revenue estimate would have to be adjusted to $45 million. The program cost ($2.4 million after the offset) to industry revenues ($45 million) percentage is about 5 percent. After the projected industry adjustment to IFQs, the program costs would be 3.5 percent of industry revenues ($68 million).

Fees collected from industry to cover program costs will reduce the value of the QS initially allocated and the price at which QS and QP is traded by an amount that reflects the additional costs of participation in the program.

Table A-110. Summary comparison of tracking and monitoring costs.*

Summary Totals (Millions $)	Status Quo	T&M Alt 1	T&M Alt 2	Change from Status Quo T&M Alt 1 - Status Quo
Non-Whiting Trawl	-	3.8	4.5	3.8
Shoreside Whiting	0.5	0.9	1.1	0.4
Mothership Whiting	0.3	0.7	0.8	0.4
Catcher Processor	0.4	0.4	0.4	-
Program(s) Management	2.3	4.7	5.2	2.4
Grand Total	3.5	10.5	12.0	
NWFSC Observer Program Offset	2.3	2.3	2.3	
Net Grand Total	1.2	8.2	9.7	7.0
Ex-vessel Revenue Millions $	57	57	57	
% Net Grand Total		14%	17%	
% Direct Payments by Industry		10%	12%	
% Program Management		4%	5%	
Assume: IFQs reduce costs by 25% because it leads to few more productive vessels				
Assume: IFQs lead to $20 million in nonwhiting revenues as educed bycatch allows greater target catch				
Adjusted Costs		6.15	7.28	
Adjusted Revenues		77	77	
% Net Grand Total		8%	9%	
% Direct		6%	7%	
% Program Management		3%	4%	

* These values are provided for the purpose of providing an initial estimate of the magnitude of the impacts for the environmental impact assessment. The RIR/IRFA produced in conjunction with publication of the propose rule provides more refined estimates and an assessment of impacts on the fishing industry.

A-2.3.4 Program Duration and Modification

❖ Provisions and Options

Preliminary Preferred Language: Four-year review process to start four years after implementation. Community advisory committee to review IFQ program performance.

► **Final Preferred Language:** The Council shall begin a review of the IFQ program no later than five years after implementation of the program. The review will evaluate the progress the IFQ program has made in achieving the goal and objectives of Amendment 20. The result of this evaluation could include dissolution of the program, revocation of all or part of QSs, or other fundamental changes to the program. Holders of QSs should remain cognizant of this fact when making decisions regarding their QSs, including buying selling, and leasing of these shares.

The Council shall consider the use of an auction or other nonhistory based methods when distributing QS that may become available after initial allocation. This may include quota created when a stock transitions from overfished to nonoverfished status, quota not used by the AMP, quota forfeited to "use it or lose it" provisions, and any quota that becomes available as a result of the initial or subsequent reviews of the program.

The specific form of the auction or other method of distribution shall be designed to achieve the goals of Amendment 20, specifically including minimizing the adverse effects from an IFQ program on fishing communities to the extent practical.

After the initial review, there will be a review process every four years. A community advisory committee will take part in the review of IFQ program performance.

❖ Rationale and Policy Issues

Within five years of implementation, a quadrennial review cycle would begin. The four-year review is more frequent than that required by Section 303A(c)(1)(g) of the act. The act only requires that the review occur within five years of implementation and thereafter in conjunction with the Council's scheduled review of the groundfish FMP, but not less frequently than once every seven years. The Council wanted to ensure regular review but, for workload management purposes, to time the review around its biennial management cycles.

A community advisory committee would review IFQ program performance. At its November 2005 meeting, this provision was added when the Council considered provisions to ensure full consideration of community concerns.

Options were considered to provide a sunset provision for the program as a whole. Early on, the Council rejected the automatic program sunset provision because of the uncertainty it would introduce into the program and the mandated need it would create to reenter an extensive and controversial process when there might not be a need to do so. The program performance review process is expected to ensure adequate consideration regarding whether the program is meeting its objectives and the appropriateness of its continuation.

A closely related issue is whether the terms of the QS should be limited. The MSA mandates such a provision with a term of no more than 10 years, but specifies it in such a way that the term is effectively limited only for those who violate the program. The Council has not identified any specific acts in this program that would be the cause for QS revocation (Section 303A (f)) and has not specifically identified

a limit on the term of the QS. The MSA type of fixed term for QS is discussed in this section in the context of a discussion of provisions for program modification and the limited nature of the QS privileges issued. In Section A-6, the Council considers an approach for fixed term QS under which QS owners might lose some of their QS even if they have not violated the program. This provision is considered in combination with an auction. The provisions, analysis and the rationale for the Council's decision not to include the option are provided in Section A-6.

❖ Interlinked Elements

This provision could be modified by the fixed term option included in Section A-6 and analyzed in Appendix F. However, the Council chose not to recommend the fixed term and auction option analyzed in Section A-6. The Council did include consideration of a sunset and auctions as part of the quadrennial program review.

❖ Analysis

The following are the categories of goals and objectives affected by the decisions on program duration and modification.

Section	Related Category of Goals and Objectives										
	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Schedule for Program Review											X
Program Modification		X	X			X					
Auction										X	

Schedule for Program Review

The Council's current schedule requires more frequent review than that required by the MSA. It entails higher administrative costs than one that is less frequent. By timing the review process to occur every four years, the Council can set the review up to coincide with either the on-year or the off-year for the biennial groundfish specifications process. Depending on the degree of work entailed and modifications to be considered, reviewing the program at the same time the biennial specifications are developed could be more efficient or could create untenable workloads. The specification of a flexible review period could provide the Council with an opportunity to better prioritize and manage its workload.

Program Modification

The IFQ program may be modified at any time through Council action. QS do not constitute a property right. An IFQ program does not change the resources public ownership status. It is a public resource managed by the government as a public trust. Under the current management system, the government

manages the resource to the public benefit by controlling catch (directly or indirectly) and allowing catch taken under the management rules to be converted to private property sometime between when it is caught and when it is sold to a fish buyer. IFQs are an alternative way for the government to control and organize harvest activity. IFQs do so by creating a catch privilege. A catch privilege is different from ownership of the resource. The following MSA language pertains to the limits on this catch privilege:

> Sec. 303A(b) NO CREATION OF RIGHT, TITLE OR INTEREST.—LAP, QS, or other limited access system authorization established, implemented or managed under this Act—
>
> (1) shall be considered a permit for the purposes of sections 307, 308, and 309;
>
> (2) may be revoked, limited or modified at any time in accordance with this Act, including revocation if the system is found to have jeopardized the sustainability of the stock or the safety of fishermen;
>
> (3) shall not confer any right of compensation to the holder of such LAP, QS, or other such limited access system authorization if its revoked, limited or modified;
>
> (4) shall not create, or be construed to create, any right, title, or interest in or to any fish before the fish is harvested by the holder; and
>
> (5) shall be considered a grant of permission to the holder of the LAP or QS to engage in activities permitted by such LAP or QS.

> Sec. 303(d)(3) "An individual fishing quota...
>
> (B) May be revoked or limited at any time in accordance with the MSA.
>
> (C) Shall not infer any right of compensation to the holder of such individual fishing quota, if it is revoked or limited.

The MSA requires that QS be set with specific fixed terms. However, the MSA specifies that QS must be automatically renewed at the end of those terms, unless an individual has violated the program or the program has been modified. This effectively makes the MSA mandated fixed term more like an unlimited or indefinite term with the possibility of modification or termination, but not on any particular schedule.

The explicit statement that the program may be modified has an indirect effect on all objectives as it makes clear that the privileges conferred by the IFQ program are not open-ended. If it becomes apparent that conditions in the fishery could be improved by the modification or termination of this program, there would no doubt be objections by some based on capital expenditures in expectation that the program was expected to continue unchanged, the disruptive effects of those changes, and related fairness and equity arguments. While this provision will not end or eliminate these arguments, the explicit advance notice should reduce the amount of disruption that occurs if a change is made (to the extent that people take the possibility of change into account when making investments) and reduce the weight of such arguments against changes.

While the specification of IFQ as harvest privileges that may be changed to the point of revocation introduces some uncertainty into the system, private markets are generally able operate effectively under such circumstances. Industries often rely on key inputs for which they do not secure long-term rights of access. For example, airlines rely on fuel as a key input, but most do not try to secure their access to fuel through ownership of oil companies. If they believe it necessary, there are other ways they can mitigate risk due to changing fuel costs (e.g., futures trading). In fisheries, changing resource conditions always create uncertainty about future harvest opportunity. While industry members cannot necessarily plan on continuation of their QS privileges, it is highly likely that some form of access to the fishery will be provided, to the degree that conservation objectives allow. Thus, it is unlikely that, even with

termination of the IFQ program, a firm necessarily would totally lose access to the resource. A firm's ability to secure tenure over a key input is a form of vertical integration. Such vertical integration can contribute to a firm's profitability, increase efficiency, and improve net benefits (see discussion of vertical integration in Appendix E). Whether the IFQ program might generate more net benefits if the QS were issued with no statement about their limited tenure depends on the extent to which people take the possibility of change into account and modify their investments. If a greater possibility of change is taken into account, there may be some reduction in private efficiency gains. The effect on net benefits also depends on whether losses occur as a result of not clearly preserving the opportunity to make changes to the program, i.e. a loss could occur if failure to explicitly identify the limits on QS tenure creates opposition to change that cannot be overcome despite identification of some socially and/or economically desirable improvements that might result from the change.

In summary, explicitly maintaining limited tenure (as mandated by Congress) creates some uncertainty that may have some negative effect on industry efficiency, but makes it more likely and less costly to implement program changes that may increase net social and economic benefits. No limit on tenure might create more efficiency but there would be less opportunity for program change, and change would be more costly. Finally, limited tenure over some key input is something that almost every sector of most industries deals with to some degree. At issue here is the government specification of limited tenure as a quality of the asset that is to be created.

While this section addresses in general the possibility that the IFQ program may be modified and, thus, the terms of the QS issued may be limited, Section A-6 and Appendix F present and analyze an option that would explicitly limit the duration of the terms of the IFQ program and provide for an auction of shares returned to the government. The effect of a fixed term of this type, accompanied by certain revocation and an auction, would be different than the type of fixed term mandated by the MSA (described above).

- Auction Provisions

This provision gives notice of the Council's intent to consider implementing an auction if QS become available that have to be redistributed. The public, industry, and in particular those who acquire QS should be aware that the program could be changed at any time and an auction implemented, after going through the appropriate process for amending the FMP. If the Council considers such an auction, a full regulatory amendment and rule making process would accompany that decision. That process would include a complete analysis of the specific proposal and an opportunity for public comment. Auctions are a way to secure for the public royalties representing a portion of the resource rents that would otherwise be received by the sellers of QS.[128] Other impacts would depend on the source of the QS for the auction and other specifics of the proposal. An analysis of one auction proposal is provided in Appendix F to this document.

[128] QS owners who purchase QS may or may not gain rents when they sell the QS but rather, under stable price and resource conditions, may recover their original investment plus some normal level of return. If resource abundance levels or prices change, they may lose or gain relative to their original investment when selling the QS, depending on the effect of those changes on profitability in the industry.

A-2.4Additional Measures for Processors (All Options – Not Adopted)

❖ Provisions and Options

No options from this section were included as part of the preferred alternative.

Option 1: Any QS received for processing history as part of the initial allocation will expire after a certain period of time (to be determined prior to final Council action). At that time all remaining QS will be adjusted proportionally so that the total is 100 percent.
Option 2: The accumulation limit grandfather clause of Section A-2.2.3.e will not apply for processing history. Regardless of the percent of the total QS designated for processors, processing history will not entitle a person to receive QS in excess of the accumulation limits.
Option 3: The Adaptive Management allocation and process (Section A-3) will be used to compensate processors for demonstrated harm by providing QP to be directed in a fashion that increases benefits for affected processors.

❖ Rationale and Options Considered but not Analyzed Further

Note: In this section and for these options the impacts of the not having a grandfather clause provision assume that there is not an opportunity for divestiture. Under divestiture entities that according to the allocation formulas would receive QS in excess of accumulation limits are allowed to receive and sell such QS within a specified time. Without a divestiture provision QS not allocated because of accumulation limits would be redistributed among other the QS recipients in proportion to the QS they received.

These options were considered as possible ways to address processor concerns short of a full allocation of QS to processors. In Section A-2.1.1.c, we focused on reasons for allocating or not allocating to all groups. The focus of this section is on measures that might be adopted in addition to, or in lieu of, an allocation to processors. In the spring of 2007, we compiled and received public comment on a list of the reasons provided for allocating and not allocating to processors. A summary of that compilation is provided here.

Reasons to Allocate to Processors	Reasons Given for Not Allocating to Processors
Compensate for stranded capital.	Stranded capital will not occur for processors. Long-term compensation should not be given for a short-term problem.
Processors are fishery participants that are invested and dependent on the fishery (303A) and have contributed to the development of the fishery.	National Standard 4 says allocations, when necessary, should be to "fishermen." No precedence for allocating IFQ to processors.
Keep balance of market power and flow of product to existing plants.	Will create a market power imbalance.
Facilitate communication and coordination of fishing activity between plants and vessels, including management of total harvest, bycatch, and participation among co-ops.	Such communication and coordination occurs under status quo and processors do not need an initial allocation to continue. If processors do not receive an initial allocation they can still participate in co-ops by acquiring QS in the market place.
There is a conservation benefit whether you give QS to permit holders or processors.	Degrades conservation benefit.
Maintain diversity and competition in the processing sector.	The processing sector will be consolidated and new entry will become more difficult.
Processor buy-in is needed to move the program forward.	Consolidation among permit holders not associated with processors will increase.
	An allocation to processors does not take into account the permit owner's obligation to repay loans from the buyback program. Those loans bought up permits representing nearly 50 percent of the fleet's landing history.

The following option was considered but rejected from the list of possibly additional measures related to processors:

> As needed, a fee will be established to provide financial compensation to processors for demonstrated harm. A process will be established for the demonstration of harm.

Establishing the fee and using it to provide direct financial compensation would require congressional action.

The Council adopted none of the options provided in this section. Rationale for its action on each of these options is provided below. Rationale for the Council's decision on the amount of QS it would allocate to processors is provided in Sections 2.8.7 and A-2.1.1.a.

Limited Duration QS. Option 1 would provide processors with QS for a limited period. Under the Amendment 6 program, limited duration permits ("B" permits) were issued to provide an adjustment period for those to whom "A" permits were not granted. One reason that limited duration QS might be considered would be if the primary rationale for granting QS to processors were the concern that QS holders may capture a portion of processor profits. This may be a possibility if processors are overcapitalized, the processing side of the market is structured competitively, and QS holders are able to exert market power. The period might be set such that it is believed excess processing capital will have left the fishery when the QS expire or that any processors who had taken out loans to finance their investment would be able to pay that investment back. Holding QS for that period would provide leverage in the market place while the QS is active.

As explained in Section 2.8.7, the strongest argument that IFQs would create excess processing capital applied to the shoreside whiting sector. For the nonwhiting sector, no QS was provided; therefore, this provision could not be applied. For the whiting sector, harvesters and processors reached a compromise agreement in which processors would receive 20 percent of the whiting QS and no QS for bycatch species. Given the compromise reached by the parties, the Council did not consider limitations on the duration of the QS issued.

No Grandfather Clause. Option 2 would place caps on the amount of QS a processor receives at the time of initial allocation. It is relevant only if the Council adopts a grandfather clause as part of the accumulation limit option. This option might be adopted to pursue at least two different ends:

(1) To provide another balance the Council could strike in trying to establish the appropriate distribution of QS between processors and harvesters
(2) To alter the balance of program impacts between small and large processors (independent of issues related to the harvester/buyer split of the initial allocation)

If a grandfather clause had been included in the program, this option would provide more QS to smaller processors and less to larger processors and would not affect the split between harvesters and processors (assuming that the intent of the option is to preserve the split of QS between harvesters and processors established in section A.2.1.1.a, e.g., a 75/25 split). [129] Part of the rationale for a grandfather clause for harvesters is that they must have QP to operate, and a grandfather clause allows them to achieve certain historic scales of operation. Processors do not need the grandfather clause to preserve their historic scale of operation because they do not have to hold QP to buy groundfish. The grandfather clause might

[129] An alternative interpretation of this option could be that any QS that is not issued to a processor because it exceeds the accumulation limit would be distributed as part of the initial allocation to QS holders.

be needed to provide for historic scale of operations with respect to processor owned permits; however, this option is phrased such that QS allocations issued for processor owned permits would still be grandfathered in.

This provision was rejected when the decision was made that no grandfather provision would be provided for any QS recipient.

Adaptive Management. Option 3, like Option 1, is focused primarily on the issue of compensation for harm to processors. Option 3 would establish that it is the Council's specific intent to use the AMP to compensate processors for harm. Under this option, no special action would be taken to benefit processors until after such harm has been identified. At that time, the Council would have to decide if the holdback program would be used to benefit all processors, a certain class of processors, or just those specific entities that demonstrate they have been harmed by the program.

The Council's final action on the adaptive management essentially includes this option as a possible purpose for using the QP provided for adaptive management (Section A-3). The specific related objective included in the program is "Processor Stability." While processor stability does not necessarily imply some form of direct compensation for loss, to the degree that it is necessary to use adaptive management QP for this purpose, there may be some benefit to processors that have experienced harm.

❖ *Interlinked Elements*

Depending on the rationale for considering these options, each of these may be linked with the decision on the amount of QS allocation to give buyers (processors) as part of the initial allocation (Section A-2.1.1.c).

Options 1 and 2 are interlinked with the accumulation limit decision on whether to include a grandfather clause. Option 2 only makes sense if such a clause is provided in Section A-2.2.3.e. Option 1, in particular, would require some additional considerations with respect to specification of the grandfather clause. Specifically, when the QS issued to processors expires, and the result is that all other QS increase proportionally, are those who control QS allowed to keep the additional QS they receive that is in excess of the accumulation limits? If there is a vessel grandfather clause, will the grandfathered levels for vessels be increased?

Under a previous version of the AMP (Section A-3), Option 3 of this section would have applied to relatively few processors if it was adopted in conjunction with Option 5 of Section A-2.1.1.a (Option 5 allocated to processors and specifies a set-aside for the AMP). The previous version of the AMP specified that, if the Council were to allocate QS to processors (adopt Option 5 in Section A-2.1.1.a), those processors who receive an initial allocation would not be eligible to receive QP issued through the AMP. Option 3 of this section allocates only to those processors able to demonstrate harm. Presumably, in order to demonstrate harm from an IFQ Program, the processor would have to exist at time of program implementation. Since if there were an allocation to processors most processors would receive an initial allocation, the only processors eligible for QS under Option 3 would be those that had entered the program relatively recently (i.e., after 2003) or are preexisting, but did not meet the recent participation criteria of Section A-2.1.2.

❖ *Analysis*

These options impact goals and objectives related to net benefits and efficiency, disruption, excessive shares, fairness and equity, and sector health. The impacts will be reviewed here in the context of the effect of the options on processors and harvesters. There may be some indirect impacts to communities

and labor related to the amount and duration of the QS issued to processors or the distribution of QP under adaptive management. These impacts are discussed in Section A.2.1.1.a and A-3. Whether communities benefit more by a provision that benefits harvesters or one that provides more benefits to processors depends in part on the degree to which each of these entities tends to be tied to communities.

Limited Duration QS (Option 1)

Impacts on Processors

One of the rationales for allocation to processors is that during the post-implementation transition period, those who hold QS will be able to capture profits from the harvesters or processors that would otherwise go to a return on investment and possibly repayment of debt. In Section A-2.1.1-a, we identified that the opportunity for QS holders to capture such profits would be limited to the time and the sectors for which overcapitalization exists. If, prior to implementation of the IFQ program, processors competed for vessel deliveries primarily on the basis of the prices offered, then under IFQs, processor profits should not vary substantially from what is observed under status quo. If, under status quo, processors competed for deliveries at least partially based on their ability to handle product volume during an Olympic fishery, then profits that might otherwise go to return on investment might be captured by QS holders under an IFQ program. That ability to capture such profits should be limited to the period during which overcapitalization remains in the sector. Thus, whether this measure would address the concern about capture of processor profits by QS holders would depend on when QS issued to processors are set to expire, the time over which the processors capture adequate return on capital, and the time required to repay debt on the capital investment.

With respect to the difference between capturing adequate return and paying off debt, adequate return is that return needed to compensate the owners of capital for their investment, and it should be comparable to the return for investments of similar levels of risk in other sectors of the economy. When such compensation is not available, it discourages future investments in the sector. Adequate return should be taken into account, whether the capital investment is financed through the firm's own assets (e.g., cash on hand) or through a bank loan. The period required to cover debt is an important consideration with respect to the effect of the IFQ program on financial stress and potential bankruptcies. Banks generally require that most fishery-specific equipment investments be paid off within 5 to 10 years.

Another reason for providing QS to processors is to affect the balance of market power in the fishery. Those initially receiving QS will receive resource rents and be in a better position to thwart an attempt by those on the opposite side of the market to exert market power. If processors are given QS over concern about harvesters' ability to exert market power, limiting the duration of the QS will cut short the achievement of this objective. It would provide processors with a grace period during which they might move to a better position to maintain their profits (assuming that harvesters would otherwise exert market power) and that period could provide an opportunity for them to acquire QS from harvesters (QS that will not expire). Under this option, at the start of the program, the QS available from harvesters may be somewhat less expensive relative to their value after expiration of the QS issued to processors. At the same time, those holding the QS may be more reluctant to part with them because they know their value will increase substantially as the time at which the QS issued to processors approaches. Additionally, an initial moratorium on the transfer of QS (an option in Section A-2.2.3.c) would also make it more difficult to accumulate QS.

An initial allocation of QS will provide an infusion of wealth to the initial recipients, which may give them a leg up in the growth and expansion of their operations, including the accumulation of additional QS (see Section A-2.1.1.a). If the intent of an initial allocation to processors is also to provide them with this advantage, or an advantage more on a par with harvesters, that advantage will be substantially decreased if the QS are set to expire after a certain period.

The initial allocation will also create a competitive advantage for existing businesses compared to new entrants (a barrier to new entry, see Section A-2.1.1.a). Over the long run, sectors are able to exert market power only to the degree that a barrier to entry prevents new competitors attracted by higher profits. Limiting the duration of the initial allocation will reduce this affect.

Impacts on Harvesters

If processor QS is to expire after a time, and all QS that were originally issued to harvesters expanded, the expiration will cause QS prices to increase as the expiration approaches, and there will be a second transition period. The effect of the expiration on price and QS availability on the market is described above in the section on processors. After QS are issued, it is expected that the individual quota will migrate into the hands of the most efficient producers (whether as QS they own or as QP they acquire from other QS holders). It is, however, likely that the initial distribution will affect the vessels to which the QS/QP migrates. The QS issued to permit owners will likely migrate through the market to the most efficient vessels, some of which may be owned by harvesters and others owned by entities that also process.[130] Processors may be more likely to use QS on their own vessels (taking advantage of vertical integration opportunities) and accumulate additional QS to make those vessels more efficient;[131] or they may decide it is more efficient not to operate vessels, but rather to use the QS they own to influence deliveries of independently operated vessels. Depending on this choice and the decision to allocate to processors, the rationalization process may leave a different set of active vessels. Either way, however, if a substantial degree of rationalization is achieved within the "lifespan" of the limited duration QS, once those limited duration QS expire, some vessels may find themselves with more QS than they need and others with less than they need (those who depended on QS issued to processors). Vessels owners may use a variety of contracting mechanisms to arrange in advance to minimize the disruptive effects of the second transition period. However, this will require additional transaction costs.

Impacts on Net Economic Benefits

The need to track QS originally issued to processors separately from other QS will add some cost to the QS tracking program. The second adjustment period occurring when limited duration endorsements expire will also have an effect on net benefits by increasing transaction costs as QS owners prepare for the repositioning required by the expiration.

No Grandfather Clause (Option 2) *(and no opportunity for divestiture)*

Impacts on Processors

The absence of a grandfather clause for processors (in the presence of a grandfather clause for permits) would not affect any QS issued to a processor based on the history of a LEPs owned by that processor. However, a processor that would receive for its LEPs an amount of QS in excess of the accumulation limits would not be eligible to receive QS for its processing history (assuming no divestiture is allowed). QS it would have otherwise received will be redistributed to the remaining processors in accordance with the allocation formula. Thus, if there were a grandfather clause, excluding processors from the grandfather clause provision may have evened the distribution of QS among processors. However, it is likely that those processors with permits that would put them over accumulation limits would sell those permits to gain some financial benefit related to the QS they represent. To the degree that excess permits would be transferred away, the absence of a grandfather clause would cause less redistribution

[130] In some cases, it will be the QP that migrates, while others retain ownership of QS.
[131] Up to accumulation limits.

among processors than would otherwise be the case. This effect has been discussed in Section A-2.1.1.a.

To the degree that there is an allocation to processors and no grandfather clause or opportunity for divestiture, some of the smaller processors could be made relatively better off by this provision in that they would have more QS and thus potentially more bargaining power in their interaction with harvesters. Relative to larger processors, they are likely to have greater strength, as compared to what they would have had if there had been a grandfather clause.

Impacts on Harvesters

As compared to a processor allocation in which a grandfather clause is applied to processors, harvesters are more likely to face a buying sector that has a greater number of buyers and smaller buyers with relatively more bargaining power.

Impacts on Net Economic Benefits

The impact of Option 2 on net benefits, relative to a processor allocation without a cap on the accumulation limit, is uncertain and likely depends on whether there would be any greater or lesser reason to expect that market function would be hampered (i.e., that one side or the other could be effective in exerting market power). As compared to Options 1 and 3, the transition/implementing costs of Option 2 are lower.

Adaptive Management (Option 3)

Impacts on Processors

Under Option 3, QP issued through the AMP would be used to compensate processors for demonstrated harm. If adopted, the exact impacts of this provision would depend on the process by which the provision is activated and how the QP issued for this purpose are distributed.

With respect to activation of the provision, the first step is demonstration of harm. If, prior to implementation of the IFQ program, there were no further development of this option, there would be several implicit lags in its activation. First, the harm would have to be identified, and someone, the industry or government, would have to collect the information and provide it in a Council forum. The Council would then develop criteria for evaluating the information and harm, conduct the evaluation, identify a remedy, and complete the Council decision process, at which time NMFS would evaluate the Council recommendation and take appropriate action. Alternatively, the matter of developing criteria, evaluating the harm, and determining a remedy could be delegated to NMFS discretion. In either case, the action would require a public process. The first QP would likely be issued in the year following completion of that process.

On one hand, leaving the program completely open with respect to criteria and response provides the maximum flexibility for appropriate adaptive management in response to harm to processors. On the other hand, that flexibility results in a time lag for taking action. Depending on the length of that lag and the degree of harm, processing companies could go out of business prior to remedial action. Alternatively, some criteria and remedial actions might be developed in advance, so they are ready to support a rapid initial response using the AMP QPs. The Council's consideration of this possibility and final recommendations are described in Section A-3.

Option 3 of this section and Option 5 of A-2.1.1.a (Option 5 allocates QS to processors and provides for an AMP) could both be adopted; in that case, however, the only processors able to benefit from Option 3 of this section would be those entering the fishery after 2003 or those disqualified by recent participation criteria (Section A-2.1.2). This is because the AMP (A-3) prohibits allocation of QP to processors that received an initial allocation.

Impacts on Harvesters

As with the processors, the impact on harvesters will depend on how the program is implemented. If adaptive management QP are issued to processors, depending on the criteria for usage, it may be more likely that a processor will use the QP on its own vessel rather than an independent harvester. This would cause a direct disruption in the flow of QP among vessels; by definition, however, the AMP will likely alter either product flow or the prices at which raw fish are sold. While issuing QP to processors for use in balancing bargaining power might alter product flow among harvesters, issuing QP to harvesters as a reward for delivering to the same processors that they had in the previous year would stabilize product flow. Issuing the QP to harvesters in this fashion would also stabilize the rationalization process. Alternatively, if the fleet rationalizes, adjusting operation sizes to QS holdings, and QP is diverted for use to compensate for processor harm and not available to the same harvesters (e.g., processors that receive the QP want to use it on their own vessels), then harvesters would go through another adjustment.

Impacts on Net Economic Benefits

There will be some management costs associated with the AMP, and, depending on how the program is implemented, there may be some additional transaction costs if the QP available to particular harvesters are reduced and they have to adjust their QS holdings in order to re-optimize. For example, in the first year of the IFQ Program, all AMP pounds will be passed through to harvesters. If harvesters adjust to those initial levels of QP, and then QP is diverted to other harvesters through AMP mechanisms, some may have to readjust.

In general, imposing a restriction on a properly functioning market system results in some inefficiency. However, if market power is being exerted, and adaptive management is used to counter that effect, the effect on efficiency may be minimal. It might be possible to distribute the QP in such a way as to change the balance of market power, essentially redistributing the profits without changing who harvests and processes the fish. If this end were achieved, the effect on efficiency would be lower than if the program resulted in an actual redistribution of the product flow. In order for the distribution to redistribute profits without redistributing the flow, it would be the threat of the potential redistribution that would cause a different outcome in the bargaining process, rather than an actual shift.

A-3 ADAPTIVE MANAGEMENT (OPTION)

❖ *Provisions and Options*

Preliminary Preferred Language. During the biennial specifications process, up to 10 percent each year's QP available for the trawl IFQ program will be set aside for use in an AMP that could create incentives for developing gear efficiencies, or community development or to compensate for unforeseen outcomes from implementing the IFQ program. Examples of unforeseen outcomes include, but are not limited to, unexpected geographic shifts in the distribution of catch or landings, unexpected effects on certain segments of the industry (e.g., processors), or an unexpected barrier to new entry into the fishery. Should the Council adopt initial allocation of **fishing QS** to processors, those processors receiving an initial allocation would not be eligible to hold QP issued through an AMP. This provision will apply to the overall trawl sector (whiting and nonwhiting) but the QP set-aside from each trawl sector would be specific to that sector.

►**Final Preferred Language.** Ten percent of the nonwhiting QS will be reserved to facilitate adaptive management in the shoreside nonwhiting sector. Therefore, each year 10 percent of the shoreside trawl sector nonwhiting QPs will be available for use in adaptive management (adaptive management QP). The set-aside will be used to address the following objectives.

- Community stability
- Processor stability
- Conservation
- Unintended/Unforeseen consequences of IFQ management.
- Facilitating new entrants.

Years 1 and 2. During the first 2 years in which the IFQ program is in place,

- The method to be used in distributing QP in years 3 through 5 is to be determined, including.
    - The decision making and organization structure to be used in distributing the QP set-aside135F[132]
    - The formula for determining community and processor eligibility, as well as methods for allocation, consistent with additional goals.
    - The division of QP among the states.
    - Whether to allow the multi-year commitment of QP to a particular project.

Years 3 through 5.
QP will be distributed through the organizational structure, decision process, formulas and criteria developed in years 1 and 2 and implemented through subsequent Council recommendation and NMFS rule making processes. Consideration will be given to the multiyear commitment of QP to particular projects (3 year commitments).

Review and Duration. The set-aside of QP for the identified objectives will be reviewed as part of the year 5 comprehensive review and a range of sunset dates will be considered, including 10, 15, 20 year and no sunset date options.

[132] The following are three options for the sequences of agency involvement in decision making for the distribution of adaptive management QP after year 2:
1. NMFS
2. State → Council →NMFS
3. Council →NMFS

❖ Rationale and Policy Issues

Rationalization of the trawl LE fishery could have unforeseen or unanticipated consequences. The QS set-aside for an AMP provides a tool to adaptively deal with these unforeseen issues. For example, if unforeseen harm to processors or communities occurs, adaptive management QPs could be used for compensation. The Council intends that the adaptive management holdback for each sector would be specifically for use in that sector. The Council's adaptive response would not be limited just to the use of the QS set aside for this purpose. See Section A-10 for additional discussion of adaptive response.

The Council may choose to build flexibility into the management of the rationalization program by providing incentives to harvesters to shape fishing behaviors. Adaptive management could be used to rewarded low bycatch rates/amounts, low prohibited species catch rates/amounts, or to encourage conversion to fixed gear.

The Council intends that the adaptive management QP be fished. Any QP not allocated through the adaptive management provision would be redistributed to all the QS holders in proportion to the amount of QS they hold. In this manner, no QP in the AMP would remain unallocated. It is not the intention of the Council to remove 10 percent of each sector's allocation from use.

Vessels receiving adaptive management QP in addition to QP already held in a vessel account could cause the vessel to exceed a vessel accumulation limit. The Council would have to address this issue of excessive shares/pounds caused by allocation of adaptive management QP. If adaptive management QP count towards the accumulation limit, then for those vessels that are at the maximum, there is no way to provide them with the incentives. If AMP QP are not counted towards the vessel's accumulation limit, that would add a small amount of complexity to the tracking and monitoring of accumulation limits. The Council could consider this issue as part of the trawl rationalization program, or leave it as a modification to be made upon implementation.

If the Council were to allocate QS to processors (adopt Option 5 in Section A-2.1.1.a), those processors who receive an initial allocation would not be eligible to "hold" QP issued through the AMP, according to the way the adaptive management provision is written. It may be difficult to track indefinitely which processors were initially allocated QS, and whether they are processors that CAN or CANNOT hold adaptive management QP. The Council may wish to address this issue by changing the term "hold" to "cannot initially receive." In other words, processors would not be able to initially be awarded adaptive management QP, but could later in the year buy them, hold them, and fish them. This alternation to the provision would substantially reduce the amount and cost of tracking adaptive management QP beyond the initial receiver. Another possible approach might be to put a sunset date on processors that are ineligible to hold adaptive management QP.

Depending on the final purpose and structure of the Adaptive Management provision, the goals and objectives addressed include the following: promote fishery conservation and assist in rebuilding of overfished species (MSA 303A(c)(1)(A) and (C)); address concerns over excessive geographic or other consolidation in the harvesting or processing sectors (MSA 303A(c)(5)(B)(ii)); avoid unnecessary adverse impacts on small entities (Groundfish FMP Objective 15); and assist fishing communities, entry-level and small vessel owner-operators, captains, and crew through set-asides or assistance in the purchase of quota (MSA 303A(c)(5)(C)).

Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
X			X			X	X	X		

❖ *Interlinked Elements*

Quota shares allocated to processors – Adaptive management QP would not be allocated to processors that received an initial allocation of QS.

Tracking and Monitoring – Adaptive management QP may have to be tracked separately from other QP, if they cannot be transferred to processors that receive an initial allocation.

Accumulation limits – Adaptive management QP may or may not count against an individual's, an entity's, or a vessel's accumulation limit.

Transferability – Adaptive management QP may or may not be transferable, depending on the purpose of the awarded QP.

Program costs – Adaptive management would add some complexity and increase the cost of execution of the rationalization program.

Additional measures for processors – A particular use of the adaptive management QP is specified in Section A-2.4, Option 3.

❖ *Analysis*

A Council staff paper was presented at the April 2009 Council meeting (Agenda Item F.5.a, Attachment 1, April 2009) to assist decision-making. The paper outlined the following general principles:

- The decision-making process will be governed by one or more goals identified by the Council, providing boundaries on what activities or entities will be eligible to receive AMP quota.[133]
- The decision-making process will most likely involve the Council, but states may play an independent role in decision-making (for example, by pre-screening proposals).
- NMFS will be involved in the decision-making process, at a minimum reviewing Council/state decisions.
- For legal reasons it is likely that NMFS will retain control of AMP QS while distributing the associated QP to program participants.[134]

[133] It is expected that the program goal or goals could be modified from time to time to address changing socioeconomic or environmental conditions.

[134] Note that this is somewhat at odds with the language in the Council's motion.

- The AMP could be "proposal-driven" or "formulaic." In a proposal-driven process, the use of AMP quota will be identified by individuals or entities that apply to receive quota. A decision-making process then evaluates proposals to determine which "applicants" should receive quota, and how much quota each applicant should receive. In a formulaic process, very specific criteria or performance standards determine who receives AMP quota and the allocation is based on a formula rather than case-by-case decisions.
- The Council and NMFS will not be directly involved in structuring local entities that may receive AMP quota, such as regional fishery associations, community stability plans, or other entities that might receive quota, although evaluation criteria could favor certain types of entities or limit eligibility to certain types.

Up to 10 percent of each trawl sector's allocation would be distributed to those harvesters that meet the criteria established for the AMP. The Council may choose to utilize the AMP QP trawl fishery (including processors) so that trawl rationalization is consistent with the goals, objectives, and guiding principles laid out by the Council (see Chapter 1 in the FEIS); Groundfish FMP goals and objectives; National Standards listed in §301 of the MSA; and requirements of limited access programs listed in §303A(c) of the Act. A truly adaptive program would respond to unforeseen and adverse effects from trawl rationalization stemming from implementation.

Establishing program goals is an important part of program design. Goals could be kept broad, essentially relying on the language from the MSA, FMP, and EIS cited above. This would give the Council the greatest flexibility to consider particular activities or proposals for the use of AMP quota on a case-by-case basis. As an alternative or in addition, specific program goals could be enumerated, focusing on particular issues that are anticipated to arise. In that case, the specific goals would be translated into (ideally measurable) standards and evaluation criteria used to decide what specific activities, projects, and entities should receive AMP quota. If more specific goals are identified, the overall AMP framework could incorporate enough flexibility to allow the Council to change the goals from time to time.

The following examples program goals were presented in the staff white paper:

Vulnerable communities: *Protect vulnerable communities from the adverse effects of trawl rationalization*. A program with this goal would distribute AMP quota to harvesters or others (e.g., government or nongovernment organizations) to ensure landings in specified vulnerable communities or communities that can demonstrate harm resulting from trawl rationalization. Objectives could include preventing the loss of fishing-dependent businesses and related employment and tax revenues supporting port infrastructure. This would approximate the competitive grant program of the Groundfish Development Authority (GDA) in British Columbia, Canada. In that program, 10 percent of the quota is available to harvesters if they have an agreement with a processor for delivery. The criteria for this program favor Canadian processors and favor more established or stable processors. The Canadian program is not intended to help new entrants into the fishery, but rather is intended to act as a stabilizing factor for processors. The GDA was set up as the alternative to allocating processor QSs.

Stabilizing harvester-processor relationships: *Support existing business relationships between harvesters and processors*. A program with this goal would distribute AMP quota to processors and/or harvesters that commit to continue an existing business relationship. Objectives could include preventing the closure of a processing plant or providing an incentive for processors to develop new product forms or markets. As noted in Section A-2.4 on processor measures, QP issued through the AMP also could be used to compensate processors for demonstrated harm, which would have to be evaluated in any decision-making process.

Encouraging conservation benefits: *Favor harvesting techniques and technologies that reduce environmental impacts*. A program with this goal would distribute AMP quota to harvesters that use gear and methods producing conservation benefits. Activities could include testing new gear and methods to determine the conservation benefits or supporting the switch to gear and methods that have proven conservation benefits. Objectives could include reducing incidental catch of depleted species or reducing habitat impacts.

Another goal not discussed in the staff white paper is to facilitate entrants into the fishery. To address this goal, the AMP QP could be distributed to applicants based on certain criteria that must be met. These criteria might include a certain amount of time as crew on a U.S. commercial fishing vessel or on a west coast groundfish trawl vessel. For example, the halibut/sablefish fishery in Alaska has a 150-crew-days-in-any-U.S.-commercial-fishery requirement for new entrants to become quota shareholders.

AMP QP would not be retired or held back from use in the fishery. All AMP QP would end up with vessels; however, the distribution would not necessarily be equal among all vessels. Depending on how the adaptive management provision is structured, all vessels may have an equal shot at competing to receive adaptive management QPs (e.g., a QP bump would be given to vessels delivering to same processors as the previous year, or vessels that achieve a certain reduction in bycatch over the previous year). The adaptive management provision could be structured in a way that would benefit certain vulnerable communities; therefore, some vessels would be positioned to access adaptive management QPs, while other vessels would not be positioned well to compete. Note also that control of AMP QP could be given to communities or regional fishing associations.

In designing the decision-making process, the central question is the role that the states, the Council, and NMFS will play in deciding the distribution of AMP quota. The staff white paper identified four possible decision-making structures:

1. **States → Council → NMFS (Proposal Evaluation Process)**: Under this structure, first a state would prescreen proposals from applicants within their state or work with applicants in developing proposals. Proposals accepted by the state would then be forwarded to the Council. The Council would review all proposals submitted and make a recommendation to NMFS on the allocation of AMP quota among the proposals.

2. **States → NMFS (Proposal Evaluation Process)**: This structure is similar to the first except that there would be no direct Council role. States would submit proposals directly to NMFS with the Council having a broad oversight role. For example, the Council's role would be confined to specifying program goals, periodically evaluating program performance, and modifying the program as necessary.

3. **NMFS (Proposal Evaluation Process)**: Under this structure, individual applicants would submit proposal directly to NMFS. The Council would have the type of broad-scale involvement described above (e.g., setting program goals).

4. **NMFS (Allocation by Formula)**: This structure would substantially reduce or eliminate regular decision-making. At its simplest, there would be no proposal process as suggested in the first two structures. Any entity that meets specific criteria, which could be defined as a performance standard, would automatically receive AMP quota, divided up among recipients according to a pre-set formula. For example, anyone who delivers to a specified port or processor would receive quota. Alternatively, as in the previous two decision structures, applicants could be selected but the allocation of AMP quota would then be made formulaically.

The overall decision-making structure could still accommodate varying degrees of state involvement. For example, the framework could be open enough so that each state could decide what role they want to play in selecting recipients. This approach is similar to how the Council currently reviews groundfish exempted fishing permit (EFP) applications, found in Council Operating Procedure 19. In some cases, a state will work with applicants to bring forward proposals, while in other cases applicants bring proposals they have developed independently to the Council without state agency involvement.

Any decision-making process involving the Council would require at least a two-Council-meeting process with full public participation. Production of a regulatory package, including an environmental assessment, might be needed in some circumstances. From a process perspective, environmental review requirements could possibly be folded into the groundfish biennial specifications process, although this is already a complex decision-making process, and adding new elements could increase the difficulty in implementing regulations in a timely manner.

There are two basic ways to view AMP quota that influence how AMP quota use would be monitored. One perspective is to see AMP quota as a reward for past behavior or as an incentive for committing to a particular course of action in the future (i.e., the coming year). For example, any harvester who delivers to specified ports would receive a portion of AMP quota in the following year; alternatively, if he commits to those deliveries in the current year, he could receive the AMP quota at the beginning of the year.[135] In an incentive-oriented program, there is little need to monitor how AMP quota is used; if recipients wish to sell the AMP quota, that should not be a problem, as long as they engage in the behavior that AMP was designed to encourage. Another perspective is to direct AMP quota to specified uses. For example, a harvester requests AMP quota to experiment with a new fishing method that has a high risk-reward ratio. In this case, the AMP distributes quota for specified activities that will occur in the future, and there is, thus, a greater need to monitor its use because the receiver of AMP quota should not do anything with it other than use it for a stated purpose. However, since QP will be fungible (one unit of quota is indistinguishable from all other units of the same type), it will be difficult to determine whether the AMP quota (separate from any other QP in a vessel account) was used for the stated purpose, was sold, or remained unused.

Another consideration is whether AMP quota receivers would be exempted from accumulation limits up to the amount of AMP quota received. This is especially an issue with vessel limits. If vessels at their limits cannot exceed them with AMP quota, it will be difficult to use AMP quota to influence the largest harvesters' actions.

How frequently AMP quota will be allocated has to be considered. Ultimately, AMP quota will be used in the form of QP in vessel accounts, and QP will be of one-year duration. However, allocation decisions do not have to occur that often. For example, allocation could be made to an activity or project that has a multiyear time span. This could provide recipients more certainty about their future operations, which some entities may find beneficial, but may reduce the flexibility to make adaptations to the program (although periodic review could be built in). A proposal-driven program structure would have to specify how frequently proposals would be accepted and AMP quota allocated.

If AMP QP can be held elsewhere than in vessel accounts, the Council may wish to establish eligibility criteria for AMP quota receipt different from the general IFQ eligibility requirements.

[135] In either case there would need to be a mechanism to check whether the behavior actually occurred.

The Adaptive Management provision could be used in many different ways. If the QP is used to protect vulnerable communities by ensuring that landings are delivered to those locations, the following will occur:

An AMP program will likely require several different monitoring and evaluation elements:

- If proposal-driven, a framework for evaluating proposals and deciding which ones to "fund"
- If AMP quota is allocated for a specified activity, a monitoring element to ensure that AMP quota is actually used in that way; if the AMP quota is provided as a reward or an incentive for a particular action, a monitoring or auditing element may be needed to verify that the action was taken (e.g., use of a particular gear)
- Periodic review of the overall AMP to decide if goals are being met and whether those goals have to be changed

In a proposal-driven process, if the amount of AMP quota available is lower than the amount requested, evaluation criteria could be a way to better match the total amount of AMP quota requested with the amount available. Criteria would likely be matched with program goals (for example, making only vulnerable communities, processors, or harvesters eligible). Measurable, minimally subjective criteria would be preferable to make it clear what a proposal has to focus on to successfully receive AMP quota. In these situations, the Council could decide in advance on a maximum number of recipients based on the amount of available quota. Alternatively, if proposals specify the amount of AMP quota needed, the Council would use that information when screening proposals so that the total amount did not exceed the total amount of AMP quota available.

If the program is set up so that AMP quota use must be monitored, as discussed above, there are two monitoring issues: checking whether the AMP quota was transferred (sold) to someone else outside the terms of the proposal and whether it is fully utilized, at least in preference to any other quota the recipient may possess. Figuring out whether this happens does not necessarily require AMP quota to be tracked separately from other quota but would rely on a year-end accounting of the use of quota. However, the need to account for AMP quota in this way could be difficult and could reduce the overall efficiency of IFQs. If the terms of the AMP proposal have been violated, then sanctions could be applied, such as loss of the future eligibility or reduction in the amount of AMP quota received in subsequent periods to make up for unused quota.

The Council's motion states that "up to 10 percent of the non-whiting QS will be reserved for" the AMP. The "up to" language reflects the Council's intent that any unused AMP quota will be redistributed back to QS holders based on the percentage value of their QS holdings. [Figure A-137 illustrates the general process for the allocation of AMP QP based on this model.]

The decision on the amount of AMP quota to be reserved would have to be synchronized with the harvest specifications process and the resulting distribution of QP into vessel accounts. First, the Council could decide in advance the amount of quota to set aside, once OYs and sector allocations have been set. Then the AMP quota could be allocated under whatever mechanism is established. Finally, if there is any unused AMP quota after the allocation process it could be returned to all QS holders. The allocation of AMP quota and any subsequent redistribution of unused AMP quota to QS holders does not necessarily have to occur before the beginning of the fishing year as long as deposits to vessel accounts is timely enough to allow its use at some point during the year and/or for the specified purpose.

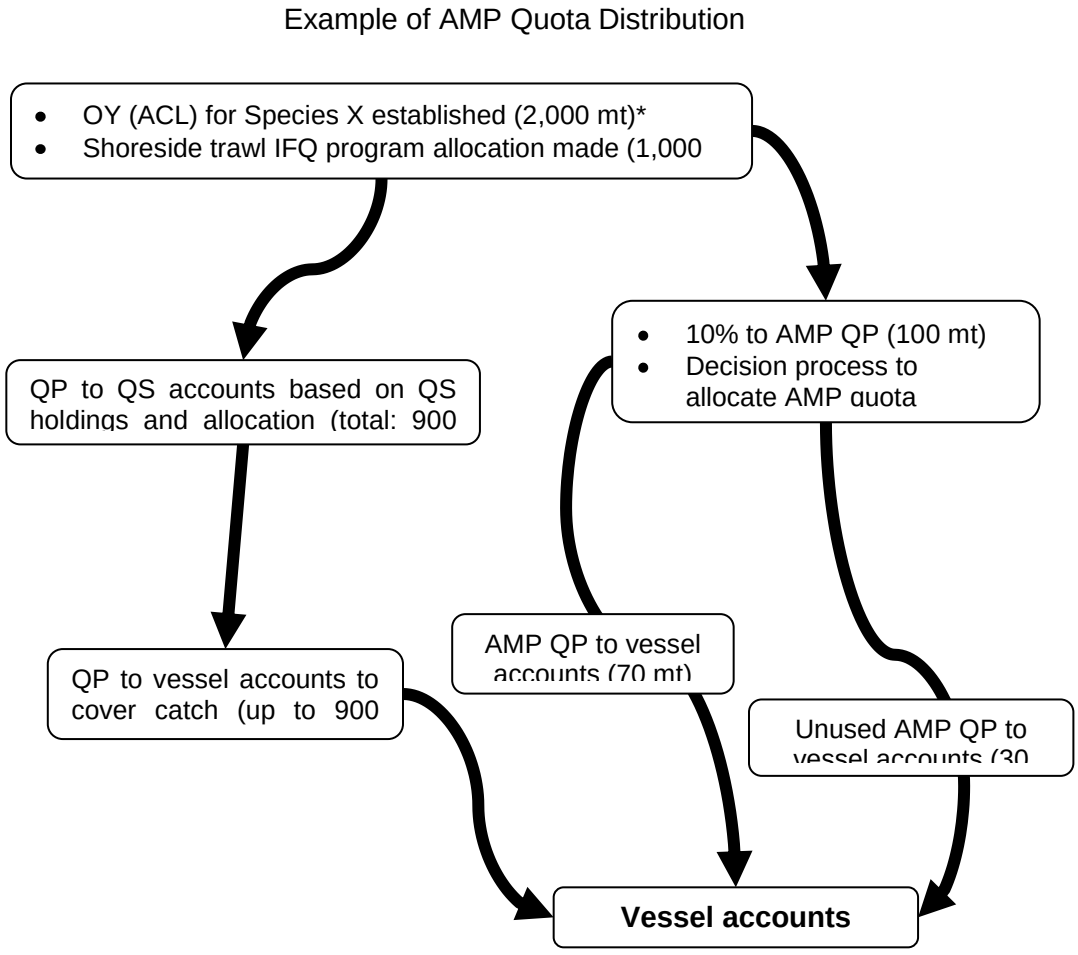

Figure A-115. Schematic of likely process for distribution of AMP quota.

The Council chose to wait to implement the adaptive management provision until year three of the trawl rationalization program, both to reduce the complexity of initial program implementation and to allow more time to develop the AMP. In the first two years the AMP, QP would be distributed pro rata to QS holders ("pass through"). This delay in implementation could cause some disruption and uncertainly for harvesters because the specifics of a future program have not been worked out. Although uncertainty may have a marginal effect on QS prices, the stated intention to implement the program in year three gives notice to QS holders that an adaptive management holdback will occur at a future date. Although the intent in delaying the AMP was to make implementation of both the overall trawl rationalization program and the AMP easier, it may also allow more effectively addressing unforeseen issues in the new management program. By definition, these cannot be determined a priori, but are likely to become apparent in the first two years. On the other hand, delay in implementing the AMP will mean that disruptions in the short term due to transition to the new management program cannot be addressed through the AMP.

A-4 PACIFIC HALIBUT INDIVIDUAL BYCATCH QUOTA (IBQ) – NONRETENTION

❖ *Provisions and Options*

Preliminary Preferred Alternative Language. IBQ for Pacific halibut bycatch in the trawl fishery will be established. Such IBQ will be issued on the basis of a bycatch rate applied to the target species QS an entity receives in a manner similar to that described in Section A-2.1.3.a, Overfished Species Option 2. Area specific bycatch rates may be used for allocation but halibut IBQ will not be geographically subdivided.

►**Final Preferred Alternative Language:** IBQ for Pacific halibut bycatch in the trawl fishery will be established. IBQ limit will be required to cover legal and sublegal sized Pacific halibut bycatch mortality in the area north of 40°10 N latitude. It is the intent of the Council that halibut IBQ mortality be estimated on an individual vessel basis. Such IBQ will be issued on the basis of a bycatch rate applied to the target species QS an entity receives in a manner similar to that described in Section A-2.1.3.a, for overfished species caught incidentally. Area-specific bycatch rates may be used for allocation but halibut IBQ will not be geographically subdivided.

❖ *Rationale and Policy Issues*

Under the status quo trawl fishery, the trawl sector bycatch of halibut constrains directed halibut fisheries. As in all IPHC management areas, Area 2A (off Oregon and Washington) has a total constant exploitation yield[136] (TCEY). Trawl caught halibut bycatch is estimated each year by the WCGOP and is taken off the top of the Area 2A TCEY. The trawl caught halibut subtracted from the TCEY is expressed in pounds of legal-sized halibut mortality. Currently the trawl fleet has no cap on the amount of halibut caught, discarded, or killed. Under the trawl rationalization program, actual bycatch of all sizes of halibut would be capped. Under Amendment 21, it is proposed that the trawl caused halibut mortality be reduced, increasing the amount of halibut that would be available for directed halibut fisheries. This reduction would be achieved through the individual vessel accountability provided by the IBQ program.

Pacific halibut IBQ would function in a manner similar to IFQ for other species, except that retention and landing of halibut would be prohibited, and only pounds of dead halibut would be counted against the IBQ. Discard at sea of Pacific halibut would be required; before discard occurred, observers would estimate the halibut bycatch mortality on that vessel (average mortality rates would be applied based on the condition of the halibut in a particular tow) to provide greater individual accountability and incentives for harvesters to control halibut mortality. Minimization techniques by the individual harvester might include taking short test tows to explore what fish are present in the area (and avoiding areas with high halibut rates), taking shorter tows or smaller amounts of groundfish so that halibut bycatch is less likely to be crushed in the cod end, and helping the observer to the extent possible in order to minimize halibut time on deck ,thereby improving the fish's condition at the time of discard. If a vessel were held accountable for catch instead of mortality, a fleetwide discard mortality rate would be applied, and there would be little incentive for the individual harvester to change his/her fishing behavior to reduce mortality rates. Therefore, the Council specified that under the trawl rationalization program discard mortality should be estimated on a vessel-by-vessel basis to encourage conservation-oriented behaviors in harvesters.

[136] TCEY is expressed in terms of legal-sized halibut, since the primary commercial target halibut fishery (using gear other than trawl) can only retain and land legal-sized halibut.

Consideration was given to requiring IBQ only for legal sized halibut. However, this option would not encourage harvesters to avoid sub-legal sized halibut and would not do as good a job of achieving the objective of reducing bycatch and bycatch mortality.

In order to allocate IBQ, the LE trawl sector cap must be specified; this has not been done in the past. Defining the sector total allocation would allow that amount to be divided up into individual QSs. There are various ways to define the trawl sector allocation, and those methods are described as options in the ISA EIS (Amendment 21). In its final action under Amendment 21, the Council decided to "allocate" 15 percent of the Area 2A (i.e., all waters off Washington, Oregon, and California) TCEY of Pacific halibut to the LE trawl sector, not to exceed 130,000 for the first four years and not to exceed 100,000 pounds for years five and beyond of the trawl rationalization program.

Halibut IBQ would be required only in the area north of 40° 10' north latitude line. At the start of program development, IBQ would have been required for the entire west coast (i.e., anywhere in Area 2A); however, as the trawl rationalization program evolved towards the final preferred alternative, the Council recognized that halibut bycatch in the at-sea sectors and south of 40° 10' north latitude line were negligible and could be managed with set-asides rather than IBQ. Tracking IBQ by sub-area would add an additional tracking and monitoring feature to the rationalization program. Therefore, the Council decided instead to use set-asides for at-sea and the southern management area. This approach requires monitoring of bycatch but does not manage the fishery with IBQ. The 10-mt set-aside for these two fisheries comes off the trawl allocation described in the previous paragraph.

The method for the initial allocation of halibut is described in Appendix C and is similar to that used for overfished species. The Council decided to base initial allocation of IBQ on the different rates of bycatch in different areas or in association with various target species (e.g., arrow tooth flounder and Petrale sole). Halibut cannot be allocated based on individual vessel records because halibut mortality is estimated based on fleet averages; there is no data set of per vessel halibut catch. For a similar reason, there is no history for buyback permits; thus, equal allocation of a portion of the QS related to the buyback fleet is not possible.

❖ *Interlinked Elements*

IFQ Management Units – The management unit options would not apply to IBQ, unless specified by the Council.

Initial Allocation – Initial allocation of IBQ would be similar to the allocation of overfished species IFQ in the nonwhiting fishery (Option 2). That method includes determining a fleet average halibut bycatch rate and then tying that to the target species QS allocations. Initial allocation of IBQ could not be based on landings of halibut, because Pacific halibut is a prohibited species and is not landed in the trawl fishery.

Annual Quota Pound Issuance – Surplus or deficit IBQ would not likely be carried over

Tracking, Monitoring and Enforcement – IBQ discard would be required in all options

Adaptive Management – Adaptive management would not likely be applied to IBQ

In general, most of the IFQ program provisions for groundfish would also apply to halibut bycatch. Notable exceptions include the following:

- Tracking, Monitoring and Enforcement – IBQ discard would be required in all options.
- Adaptive Management – Adaptive management has not been applied to IBQ.

❖ *Analysis*

The IBQ provision addresses the following goals and objectives: reduce nongroundfish mortality (FMP Objective 4); reduce bycatch (Amendment 20, Objective 3); and account for total mortality (Amendment 20, Constraint 4).

	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
Conservation	X									X	
Initial Allocation and Accumulation Limits		X		X	X						
Net Benefits, Sector Health and Communities		X				X		X			

Conservation

The International Pacific Halibut Commission (IPHC) manages the conservation and sustainability of the Pacific halibut resource by conducting an annual coast-wide stock assessment and developing and setting directed fishery catch limits. IPHC accounts for bycatch mortality in an area prior to setting the catch limits for the directed halibut fisheries program. The estimate of discard mortality of trawl caught halibut potentially would be based on observed condition upon release, if observer coverage were at 100 percent, as proposed under rationalization. For Area 2A, the fleetwide discard mortality rate (DMR) had previously been estimated at 50 percent of total catch. IPHC studies have found that discard mortality in trawl fisheries is depends on the size of the fish, the target fishery, and the duration and size of the trawl haul. Under the status quo fishery, the percentage of observer coverage was not extensive enough to estimate a DMR based on condition/release data collected by observers prior to 2007. After 2007, observer viability data were used to estimate the halibut mortality rate, which turned out to be higher (56 percent) than the 50 percent fixed mortality rate. In British Columbia, where the trawl fleet has near 100 percent observer coverage, the DMR is based on observed condition, and, in some instances, is lower than 50 percent. A similar circumstance has the potential to occur in the U.S. groundfish trawl fishery, if individuals have the incentive to behave in a more conservation-oriented way, such as helping the observer to minimize halibut time out of water.

The IFQ program requirement for 100 percent monitoring will increase assurance that total halibut mortality is being properly estimated. Halibut individual bycatch quota (IBQ) would provide incentives to reduce halibut bycatch in the trawl fishery. Bycatch reduction is an objective of the trawl rationalization. The broader experiences of our Canadian counterparts are relevant to this trawl rationalization analysis. Up until 1995, before Canadian groundfish trawl rationalization, the B.C. trawler fishery was estimated to have taken 1.5 to 1.7 million pounds of halibut bycatch mortality annually (all sizes). At the onset of the Canadian IVQ program in British Columbia, a cap of 1 million

pounds was set by Canada's Department of Oceans and Fisheries for the B.C. trawl sector. In 1996, after implementation of the trawl IVQ management program and an IBQ program for managing the halibut bycatch, bycatch was just less than 300,000 pounds. Reasons for this large reduction include the concurrent decline of the cod fishery, avoidance behavior by harvesters, and more deliberate conduct of fishing operations. In addition, 100 percent observer coverage allowed quick and accurate feedback to the skipper of pounds of halibut caught and discarded each trip.

Observed Catch of Pacific Halibut in the Trawl Fishery

The bycatch rate estimates are generated by NMFS Northwest Region using West Coast Groundfish Observer Program (WCGOP) halibut bycatch information, stratified by season, depth, latitude, and amount of arrowtooth flounder and multiplied by effort in each stratum using Oregon and Washington logbook information. Halibut bycatch rates may be different in different areas; however, according to the IPHC, there is no biological reason to divide Area 2A into finer scales of management.

Observations of Pacific halibut bycatch in the west coast LE trawl fishery show some distinct patterns. In particular, Pacific halibut bycatch tends to be closely associated with the catch of arrowtooth flounder, Petrale sole, lingcod, and skates. The association with arrowtooth, Petrale, and skates is not unexpected as these species exhibit similar habitat preferences and have similar life-history characteristics as with Pacific halibut. However, the association with lingcod is somewhat surprising and unexpected. Other patterns clearly exist, including associations with depth and with latitude. Pacific halibut tend to be encountered more frequently by vessels fishing off the northern Washington coast (north of 47.5° N. lat), and differences exist on a depth basis. The majority of Pacific halibut observed in the trawl fishery was caught at depths less than 115 fathoms, though a large percentage was caught at deeper depths as well. This information is illustrated in the following table.

Table A-111. Amounts of species catch (retained + discard weight) and bycatch ratios between Pacific halibut and two flatfish species on observed limited entry bottom trawl hauls during 2003 to 2006.

	Depth Stratification		
	< 115 fm	**> 115 fm**	**All depths**
Area North of 47.5₀ N. lat Number of observed hauls	1,487	724	2,211
Observed catch of species (lbs) Petrale sole	314,471	450,562	765,033
Arrowtooth flounder	1,648,667	753,976	2,402,643
Petrale + Arrowtooth	1,963,138	1,204,538	3,167,676
Pacific halibut	230,090	73,092	303,182
Ratio of halibut lbs to arrowtooth lbs	**0.140**	**0.097**	**0.126**
Ratio of halibut lbs to combined Petrale + arrowtooth lbs	**0.117**	**0.061**	**0.096**
Area between 40₀10' and 47.5₀ N. lat Number of observed hauls	4,646	4,395	9,041
Observed catch of species (lbs) Petrale sole	1,353,420	1,457,496	2,810,916
Arrowtooth flounder	958,221	1,361,180	2,319,402
Petrale + Arrowtooth	2,311,642	2,818,676	5,130,318
Pacific halibut	161,217	85,553	246,769
Ratio of halibut lbs to arrowtooth lbs	**0.168**	**0.063**	**0.106**
Ratio of halibut lbs to combined Petrale + arrowtooth lbs	**0.070**	**0.030**	**0.048**
Total Area North of 40₀10' Number of observed hauls	6,133	5,119	11,252
Observed catch of species (lbs) Petrale sole	1,667,891	1,908,058	3,575,949
Arrowtooth flounder	2,606,889	2,115,156	4,722,045
Petrale + Arrowtooth	4,274,780	4,023,214	8,297,993
Pacific halibut	391,307	158,645	549,952
Ratio of halibut lbs to arrowtooth lbs	**0.150**	**0.075**	**0.116**
Ratio of halibut lbs to combined Petrale + arrowtooth lbs	**0.092**	**0.039**	**0.066**

Observer information also indicates that Pacific halibut bycatch occurs south of the 40° 10' north latitude line. The tool for allocating Pacific halibut bycatch (described in Appendix C) does not provide a mechanism for allocating Pacific halibut to vessels in this southern area, due in part to the lack of observations for informing a bycatch rate calculation. However, in the final preferred alternative, a set-aside of Pacific halibut was made for the fleet in this southern area and the at-sea sector.

Initial Allocation and Accumulation Limits

Like overfished species, halibut will be allocated using a formula intended to provide QS to those who most need it to cover their bycatch while pursuing target species. Providing an initial allocation to these entities is expected to reduce disruption and related costs, thereby increasing overall benefits. To achieve this end, halibut IBQ will be allocated proportionally to arrowtooth flounder and Petrale. Information on the initial allocation and accumulation limits for halibut is provided starting on page A-330. The control and vessel limits for Pacific halibut are covered in Section A-2.2.3.e.

Net Benefits, Sector Health and Communities

It is anticipated that the bycatch of Pacific halibut will decrease under trawl rationalization due to the incentive for individual vessels to avoid bycatch and based on observations of the B.C. fishery. Reduction of trawl bycatch of Pacific halibut would provide more yield for directed Area 2A halibut fisheries. This would increase net benefits, positively impacting net national benefits and the fishing and processing sectors, as well as the communities that depend on them. The overall effect on net benefits, sector health, and communities will depend on whether enough halibut is provided for trawlers to access all of the available and marketable target species. If the amount of halibut is not sufficient for this purpose, net benefits may still be higher under the IBQ system if the value of the additional halibut directed fishing opportunities is greater than the value of the target groundfish harvest forgone because of IBQ constraints.

A-5 ALTERNATIVE SCOPE FOR IFQ MANAGEMENT (OPTION)

❖ *Provisions and Options*

Option: IFQ will be required to cover all groundfish catch except for bycatch species taken on whiting sector trips.

If this option is selected sections above would be modified as follows.

Section A-1. Replace "QP will be required to cover catch of all groundfish (including all discards" with "for nonwhiting trips, QP will be required to cover catch of all groundfish (including all discards), for whiting trips, QP will be required to cover catch of all whiting (including all whiting discards but not incidental catch of nonwhiting groundfish species)." If the three sector option is selected in Section A-1.3, then in the previous sentence replace "nonwhiting trips" with "shoreside trips" and replace "whiting trips" with "trips delivered at sea."

Section A-1.3 Under the three sector option (shoreside, mothership, and catcher-processors) this alternative scope does not apply to the shoreside sector. For all catch destined for shoreside delivery QP would be required, including catch on trips targeted on whiting. For catch destined for at-sea delivery, QP would be required for whiting but not bycatch species. Under the four sector option, shoreside whiting trips would be included among those for whicH QP is required to cover whiting and not required for bycatch species.

Section A-1.5. Whiting trip bycatch species will not be managed with IFQ but will be pooled and managed with bycatch caps. Select one of the following options for incorporation in Section A-1.5:

Bycatch Management Option 1: A single bycatch caps covering all whiting sectors. All sectors and co-ops will close as soon as the whiting fishery bycatch cap is reached for one species; a controlled pace may be established if the sectors choose to work together cooperatively, potentially forming an intersector/interco-op cooperative.

Bycatch Management Option 2: A single bycatch caps covering all whiting sectors and seasonal releases. Same as Option 1, including the potential for forming co-ops, except there will be seasonal releases of bycatch allocation.[137]

[137] At the outset, it is envisioned that the seasonal approach will be used to manage widow rockfish bycatch; for canary rockfish and darkblotched rockfish, status quo management will be maintained (i.e., no sector allocation and no seasonal apportionment). A seasonal release bycatch management program will be implemented through regulation. For reference, a similar program is used to manage halibut bycatch in NPFMC-managed flatfish and Pacific cod fisheries, see 50CFR679.21(d). In practice, seasonal releases protect the next sector entering the fishery. For example, a May 15 to June 15 release will be used by the catcher-processors and motherships, but it protects the shoreside fishery; the June15 to September release will be used by shoreside and whichever catcher-processors and motherships are still fishing whiting and to protect a fall at-sea season after September 15; the final release in September will again be shared by the catcher-processors and motherships, assuming shoreside is done.

For example:

1. No sector bycatch allocations.
2. Status quo for canary and darkblotched rockfish; i.e., no seasonal or sector allocation.
3. May 15 to June 15; 40 percent of widow hard cap released.
4. June 15 to August 31; an additional 45 percent of widow hard cap released.
5. Sept. 1 to December 31; final 15 percent of widow hard cap released.
6. Once a seasonal release of widow rockfish is reached, the whiting fishery is closed to all three sectors for that period. The fishery reopens to all three sectors upon release of the next seasonal release of widow rockfish.
7. Unused amounts from one seasonal release rollover into subsequent release periods.

(Note: percentages are for illustration purposes only, actual release percentages will be developed through the PFMC process).

Bycatch Management Option 3: A separate bycatch caps for each sector. Each sector closes when its bycatch cap is reached.

Bycatch Management Option 4: A separate bycatch cap for each sector and a roll-over. Each sector closes when its bycatch cap is reached. Unused bycatch may be rolled over from one sector to another if the sector with unused bycatch has used its full allocation of whiting or participants in the sector do not intend to harvest the remaining sector allocation.

❖ *Rationale and Analysis*

The rationale and analysis covering this topic are included in Section A-1 and within Appendix B. Therefore, the reader is referred to these analyses when considering the effect of this alternative scope.

❖ *Interlinked Elements*

Interlinked elements are identified in the text of the option.

A-6 DURATION: FIXED TERM (AND AUCTION) (OPTION – NOT PREFERRED)

❖ *Provisions and Options*

Fixed Term Option: The term of all QS issued will be limited to 15 years (except that the Term-1 QS may last 15 or 16 years, depending on when the biennial specification period ends). Starting with Term-2 of the program, **Reallocation Option 1:** QS will be reallocated to holders at the end of the term, unless the program is otherwise modified. **Reallocation Option 2:** Starting with Term-2 of the program, every two years up to 20 percent of all QS will be returned to NMFS for reissuance via an auction, unless the program is otherwise modified.

If the fixed term option is selected, sections above would be modified as follows.

Section A-2.3.4. Add the following. The initial allocation of QS will be valid for a period of 15 or 16 years (ending at the end of the second year of the biennial specification period). Thereafter, in the absence of actions to end or amend the program, QS will be issued for 15 year terms (i.e., all QS will expire every 15 years) on the following basis.

Section A-2.1.6. Add the following.

Reallocation Option 1: After initial issuance, for the start of each subsequent term of the program, QS will be reallocated to current QS holders (those holding the QS on the day the term expires), in proportion to the amounts they held on the day of expiration, unless the program is otherwise modified,

Reallocation Option 2: After initial issuance, for the start of each subsequent term of the program, up to 20 percent of the QS will be reallocated in an auction with the remainder going to the current QS holders (those holding the QS on the day the term expires), in proportion to the amounts they held on the day of expiration, unless the program is otherwise modified. Additionally, every two years during the term up to 20 percent of each holder's QS will return to NMFS for redistribution via an auction. All auctions for the QS to be redistributed will be held at least one year in advance of the actual redistribution. When the redistribution occurs, the QS will come from those holding it at the time of the redistribution and go to the winners of the auction.

The specific form of the auction will be decided by the Council in the period between trawl rationalization implementation and the first auction. It will be designed to achieve the goals of the trawl rationalization program, including reducing bycatch, increasing operation flexibility, measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.

❖ *Rationale and Policy Issues*

An initial auction is not proposed because of the need for a transition during a period of economic stress. It is unlikely that many of the participants in the current fishery have structured their operations financially in a manner that would allow them to effectively compete in an auction. After 15 years, the fishery should be in much better shape, and 15 years would provide fishermen a long time to get used to the IFQ program without having to pay for the QS. It would also provide a substantial amount of advance notice to allow existing firms an opportunity to position themselves financially to effectively compete in an auction. The general reason for 15 years is to provide a substantial amount of stability for industry to make fishing decisions. The term of 15 years was also chosen because of the rebuilding periods for overfished species. Within 15 years, Boccaccio, canary, POP and widow would all be rebuilt. With the exception of darkblotched, the other species are not projected to rebuild for a

substantially longer period. An auction should not be included in the period during which the Council is exploring how it will handle allocation when species are rebuilt.

Holding an auction every year would result in too much annual change and increased administrative costs; therefore, it was proposed that the auction occur every two years in conjunction with the biennial specifications. There should be a transition at the end of the 15 years; therefore, an auction of 20 percent of the QS every two years was specified. The Council could choose to auction less than 20 percent, and that decision could come out of the analysis conducted when the auction is designed. The auction could be designed to provide for new entrants and protect communities by setting aside specific amounts to go to small fishermen, communities, etc.

The 15-year limit and auction were also intended to add to the assurance that IFQ would not be viewed as property rights. The largest investors in the fishery are the citizens of the U.S., and that had to be more strongly recognized, at least as an option for analysis. There are various other public natural resources for which use rights are auctioned.

Funds collected in the auction would go into the new fund specified in the MSA, which, subject to appropriations, could come back to the fishery.

The rationale for the Council's final action on the auction option is provided in Appendix F.

❖ *Interlinked Elements*

The option is a variation on Section A-2.3.4Program Duration and Modification.

❖ *Analysis*

Analysis is provided in Appendix F.

A-7 GEAR CONVERSION (OPTION – NOT PREFERRED)

❖ Provisions and Options

The scope of the IFQ program allows trawl vessels to use other types of gear to harvest groundfisH QPs. At its June 2008 meeting, the Council added the following option for consideration. ***This option is not necessarily a preferred option.***

Gear Conversion Option: allow a permit holder to use an alternative legal gear for a two-year period after which the permit holder decides whether to continue to use the alternative gear or trawl gear.

❖ Rationale and Policy Issues

When trawl vessels use a nontrawl gear in the current groundfish fishery, their groundfish catch is attributed to the trawl sector allocation. Section A-1.1 specifies the scope of the trawl rationalization program, which implicitly allows vessels to switch back and forth between trawl and other gears. The purpose of a gear conversion provision would be to make a permanent reduction in the amount of groundfish catch taken with trawl gear, change the fishing footprint on bottom habitat, and provide an additional option to harvesters on gear usage. Gear conversion would be voluntary. Permanent gear conversion would not change the scope of the IFQ program but, depending on how it is implemented, gear conversion would not allow vessels to convert back to trawl gear. In other words, some of the trawl permits, vessels, and/or QS/QP would be prohibited from use with trawl gear.

Gear switching and gear conversion would both allow harvesters to have greater flexibility, though to differing degrees. To achieve gear conversion, incentives would likely be required to encourage trawlers to permanently convert gear types. Adaptive management QP in the shoreside nonwhiting trawl sector could be used to reward or encourage bottom trawlers to convert to fixed gears.

The Council decided against this option based on its preliminary specifications. Additional guidance would have been needed to fully specify this gear conversion provision. Specifically there was a question as to what would be constrained or converted to "fixed-gear only" after the two-year period. Choices appeared to include the following:

- The permit
- The vessel
- All QS/QP used with the vessel (including QS/QP taken with trawl gear)
- Only certain QS/QP used with the vessel (partial conversion)

With respect to the question of "what would be constrained," constraint of the permit would be unlikely to achieve the purpose of the provision until enough permits had been converted to constrain the fleet's ability to use trawl gear to take the full amount of the available harvest. Until such time, QS could be moved from the converted trawl permits (trawl IFQ sector permits) to regular trawl permits, such that no permanent conversion to nontrawl gear is achieved. Constraint of the vessel would be even less likely to achieve the desired end because there are even more substitute vessels available than there are trawl permits. Requiring the conversion of all QS/QP used with the vessel would provide a substantial disincentive for a vessel to opt for conversion unless it was the vessel's intent to use only nontrawl gear. In addition to the constraint on the vessel's activities with full conversion of all a vessel's QS, the loss of flexibility to use those QS with trawl gear would reduce the market value of those QS. Partial conversion, requiring the conversion of only those QS representing the QP used with the converted gear, would substantially reduce the disincentive for participating in conversion at the end of the second year.

The vessel choice between conversion and returning to the use of a trawl gear would likely depend on the benefits the vessel experienced by using the nontrawl gear compared to the amount of time it would be required to forgo use of that gear before it would be once again allowed to engage in gear switching.

Both the complete and partial QS conversion approaches could present tracking problems with determining what QS would be converted. First, the QP used on a vessel may not be from QS owned by the harvesting company. Second, the QS from which a vessel receives its QP may be different from one year to the next. One possible approach would be to require that QS to be converted be assigned to the vessel, along with the QP, and left there for two years in order to trigger the conversion provision. For this approach to work, there would have to be an incentive for harvesters to want to permanently convert their QS to nontrawl gear, otherwise most harvesters would probably prefer to take advantage of the gear switching opportunities without committing to permanent conversion. There may be some possibility that at-sea monitoring with cameras instead of observers is more feasible with nontrawl gear than with trawl gear. If this were the case, providing an opportunity to fish their QS without having to pay observer costs (an opportunity that using converted QS might allow) would provide an incentive for some harvesters to commit to the conversions. Another incentive might be to use some of the adaptive management QP to bump up the QP allocated to QS that have been converted. Another approach for addressing the tracking problem would be not to require the identification of the QS to be converted, until the end of the two-year period. At that time, if the harvester wanted to continue to use nontrawl gear, it would be required to submit QS to NMFS for conversion.

Because the gear conversion option needs further development, two analytical options are provided. These options focus on the conversion of QS rather than the vessel or permit. Under these options, vessels would either be provided a positive incentive to permanently switch QS from trawl to nontrawl gears (Option 1), or a disincentive for not switching after using a nontrawl gear for two years (Option 2). Under the second gear conversion option, the disincentive would be a restriction on a vessel's ability to switch gear types for a period. The design of these options takes into account that, under the program as it is currently designed, only QP is associated with a vessel (QS is held in separate accounts that may be held by processors, crewmembers, and communities, as well as individuals that happen to be vessel owners).

Analytical Option 1: Incentive for Permanent Gear Conversion, No Constraint on Gear Switching

Adaptive management QPs could be utilized as an incentive to convert permanently to fixed gear. Gear conversion is a long-term prospect. To provide sufficient incentive, either the amount of the adaptive management QP provided as incentive would have to be high enough to compensate for the longer-term commitment, or there would have to be a longer-term commitment of the adaptive management QP. If the 10 percent set-aside of adaptive management QP is to be fished only by vessels that have permanently converted to fixed gear, this would require an extra element of tracking of adaptive management QP to make sure it was caught with fixed gear.

Analytical Option 1a: QS Acquired In Advance and Designated for Conversion

At the start of a two-year period, a harvester interested in permanent conversion would assign to a vessel the QS it intends to convert to another gear. At the end of the two-year period, the harvester would be required to choose between permanently converting those QS to an alternate gear or not receiving the incentives in the following period. Incentives would be provided for permanent conversion of all QS the vessel designated for conversion. Examples of possible incentives include additional quota for the following two-year period and/or ability to use some lower cost at-sea monitoring technologies (e.g., electronic monitoring) if deemed to meet the program's monitoring standards. Vessels that gear

switch but do not assign QS to the vessel for purpose of conversion would not have to make a gear conversion choice after two years, but would receive no incentives for switching.

All other provisions of the IFQ program would continue to apply, including the requirement that a trawl permit must be held in order to fish in the rationalization program. Harvesters who assign QS for conversion but opt out within two years must wait two years before having an opportunity to again take advantage of the conversion incentives.

Analytical Option 1b: QS Acquired At End of Two-year Period

Option 1b is the same as Option 1a except that instead of acquiring the QS in advance to receive the incentives, a vessel would acquire the QS at the end of the two-year period and submit the request to NMFS for permanent conversion of that QS. The amount of QS a vessel would be required to acquire and designate for permanent conversion would be the amount that is equivalent to the average amount of QP it used with nontrawl gear during the previous two-year period.

Analytical Option 2: Disincentive for Not Switching After Two Years

Option 2 is the same as Option 1b except that there would be no incentives and a vessel that used nontrawl gear and, at the end of that period, did not permanently convert the required amount of QS would be prohibited from using the nontrawl gear again for two years.

❖ *Interlinked Elements*

Tracking and Monitoring (A-2.3) - At the permit level, NMFS may have to track which permits/QS/QP had permanently converted to fixed-gear usage. Tracking of the specific gear type used to catcH QPs would not necessarily occur. Observer coverage and compliance monitoring coverage are necessary elements for the trawl rationalization program.

Adaptive Management (A-3) - Adaptive management QSs could be utilized to develop gear efficiencies, which might include incentives for permanent gear conversion in the shoreside nonwhiting fishery.

Regional Landing Zones (A-8) – The need to track additional types of QS is multiplicative. If regional landing zones are adopted, the 30 different IFQ management units would be subdivided, possibly resulting in well over 100 different categories to track. If some QS and QP were designated as "converted," that number would double.

❖ *Analysis*

The goals and objectives addressed by the gear conversion provision include the following: reduce bycatch and minimize adverse impacts on EFH; contribute to reducing capacity; maximize the value of the groundfish resource by providing further flexibility to harvesters; and minimize negative impacts resulting from localized concentrations of fishing effort if fixed gear users access different locations than trawl gear users.

Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Sector Health	Labor	Communities	Small Entities and New Entrants	General Public	Program Performance
X	X				X		X			

The conservation consequences of gear conversion include a potential reduction in bottom trawl contact in areas where trawl gear is allowed to fish; a potential increase in fixed-gear bottom contact, both in areas where trawlers can fish and in areas where only fixed-gear types are allowed to fish; and a change in the volume and species mix of fish taken by the LE trawl fishery. Fixed gear is better able to avoid certain bycatch species, but fixed gear can also access and impact more sensitive (rocky relief) habitat, upon which trawl gear cannot fish. Should 10 percent of trawl gear be converted to fixed gear, there would likely be a decrease in bottom disturbance from trawl gear and a corresponding (but not equivalent) increase in bottom disturbance by fixed gear.[138] Fixed-gear impacts benthic habitat differently than trawl gear.

As noted in the "gear switching" analysis in Section 4.7.2.1, some trawlers in southern-central California coast have expressed an interest in using fixed gear due to public demand for fixed-gear-caught product. Fishing effort could increase south of Eureka, an area where there currently is little trawling, if fixed gear is utilized to a greater extent because fixed gear is more workable in that area of the west coast. That analysis also suggests that harvesters in areas that encounter constraining bycatch species at a higher rate than other areas of the west coast may be more likely to utilize gear switching (and perhaps, by extension, gear conversion) to avoid those stocks. Those areas of higher constraining species bycatch rates are northern Washington and southern Oregon.

The Chapter 4 gear-switching analysis states that market prices of certain species – like fixed-gear-caught sablefish – may incentivize the switch to fixed gear. Gear switching would also provide flexibility to the harvester to catch all of the QP in a vessel account in a given year (modifying the mix of gear used based on conditions and the mix in the trawl harvest in a particular year). However, these advantages for gear switching would not be incentives to commit to permanent gear conversion.

The permanence of gear conversion may deter some trawlers who want to use fixed gear but do not want to fully convert with no provision to convert back. A Natural Resources Defense Council funded study (Jenkins 2008) of west coast trawlers regarding gear conversion, noted that "because of the long-term commitment, some trawlers, especially those with the highest volume, are not likely to convert to an alternative gear." Absent adequate incentives, the likelihood of trawlers permanently converting to fixed gear may be low because nonpermanent gear switching would already be allowed (see Section A-1). Without an incentive or prohibition otherwise, trawlers could use fixed gear for two years, come to the point of making a decision whether to convert to fixed gear, choose not to, and still use whatever gear type they choose. If a requirement were specified that after two years of using an alternative gear a

[138] The 10 percent switching number is mentioned because the Council requested an analysis based on the assumption that there would be a 10 percent switch from trawl to other gears. Unfortunately, we are not able to provide quantification of the impacts from this switch.

trawler chose not to permanently convert, then the vessel would have to fish only with trawl gear, trawlers would be forced to use trawl gear when they might have preferred to continue to use nontrawl gear. This could reduce the amount of gear switching and the associated benefits.

While permanent conversion to fixed gear would provide less flexibility than gear switching, it may provide other advantages. For example, camera monitoring could be more feasible with fixed gear than with trawl gear. Incentives could also be provided by charging different annual renewal fees or transaction fees for QS that has been converted or by providing a supplemental amount of QP from the AMP. These differences and incentives could contribute to differences in the overall cost and revenue of fishing with the alternative gear, encouraging use of that gear.

Gear conversion may create imbalances in the multispecies mix necessary for prosecution of the trawl fishery. Species targeted by trawlers include flatfish and the Dover sole-Thornyhead-Sablefish (DTS) complex. Flatfish cannot be effectively harvested by fixed gear, and that market would be sacrificed by trawlers that convert to fixed gear. Sablefish caught by fixed gear could yield a higher price than sablefish caught by trawl gear. For example, in response to multiyear-duration, cyclical swings in price, relative availability, and/or species mixes, conditions may favor the conversion of some of the trawl sablefish QS to nontrawl gear, reducing its availability for use in the DTS fishery. If conditions then reversed, favoring targeting of the sablefish harvest with trawl gear, the switch back would not be possible without a regulatory change. This could reduce the net economic value derived from the fishery. While permit holders or vessel owners may consider that conditions in the fishery vary over time, the effect of those conditions on their decisions will depend on their planning horizon. The planning horizon needed to appropriately organize production in the fishery may be longer than that of the individual fishermen, (i.e., decisions based on short-term conditions may be suboptimal as fishery conditions change).

A-8 REGIONAL LANDING ZONE (OPTION – NOT PREFERRED)

❖ *Provisions and Options*

Under the preferred alternative, the Council will choose between creating a split in the management units at 40°10' N latitude and the regional landing zones option (see Section A-1.2). The following describes the regional landing zone option as presented in the WDFW proposal:[139]

Regional Landing Zone Option:

1. Two basic types of QS would be issued for target species:
   (a) zone-specific QS and
   (b) zone-free QS.
   Zone specific QS would not be required for incidentally caught overfished bycatch species.
2. The Council would decide the overall split between zone-specific and zone-free QS (e.g., 80 percent zone-specific, 20 percent zone-free). Each permit owner or processor would be allocated the same split of zone-specific and zone-free QS.
3. Zones would be limited in number (i.e., two to six per state with a coast wide maximum of ten), designed and nominated by the states, and approved by the Council. The states could design individual zones to encompass a single port or group of ports.
4. QP from zone-specific QS could only be landed in the zone for which the QS is issued. However, the zone designation would not restrict the catch area. Zone-specific QS would be transferable to holders outside the zone, but the QP associated with that QS would have to be landed within the specified zone.
5. QS would be issued to permit owners and processors based on the allocation formulas specified in Section A-2.1. These formulas use a 1994-2003 allocation period. The QS issued to each recipient would be designated for a particular zone based on the recipient's landings history over a time period chosen to reflect recent conditions (e.g., 2005-2007). For each target species, zone-specific QS would be issued to a recipient based on the proportion of landings history in each zone during the recent period.
6. The Council could adaptively manage the system by varying the split of zone specific to zone free QS, redistributing QS among zones, permitting limited transfers between zones, adding or subtracting zones, etc.

❖ *Rationale and Policy Issues*

Rationale for the Option

The Council added the regional landing zone option for consideration alongside the June 2009 PPA out of concern over the negative impact that consolidation in the nonwhiting fleet could have on fishing communities. The option was proposed as a means of directing landings towards communities that have traditionally participated in the nonwhiting trawl fishery.

The option was proposed with both short- and long-term social objectives in mind. The short-term objective would be to provide stability to communities by preventing quota recipients from completely transferring their QS/QP out a region. Quota holders could transfer their QS/QP, yet any zone designated QS/QP-transferred would remain subject to the landings restriction. Over the long term, the zone landings requirement could be used as a tool to prevent excessive geographic consolidation of quota, to promote sustained participation from fishing communities, and to ensure that the economic benefits of the program were dispersed coast wide.

[139] PFMC, June 2008 Briefing Book: Agenda Item F.6.f, WDFW Supplemental WDFW Attachment 1.

The Council did not include the regional landing zones option in the November 2008 preferred alternative. Many Council members expressed their concern about fleet consolidation and the impact to communities. However, the Council's discussion and motion in November 2008 focused on the AMP as the tool for addressing those concerns.

Policy Guidance and Previous Consideration of Area Landings Requirements

Section 303A(c)(5) of the MSA requires the Council to do the following:

> (B) consider the basic cultural and social framework of the fishery, especially through—
>
> > (i) the development of policies to promote the sustained participation of small owner-operated fishing vessels and fishing communities that depend on the fisheries, *including regional or port-specific landing or delivery requirements*; and
> >
> > (ii) procedures to address concerns over excessive geographic or other consolidation in the harvesting or processing sectors of the fishery (emphasis added).

The Council's consideration of regional area management and landing requirements began even before Congress added Section 303A to the MSA. Indeed, the need for such policies was a major topic of discussion during the NEPA scoping process:

> The question has been raised as to whether or not an IFQ program might increase the need for regional area management to address biological or socioeconomic concerns. Without area management, it has been suggested that under an IFQ program there may be a greater potential for effort to be concentrated within some areas than there would be under other types of catch control tools. . . . Assigning area-specific OYs may prevent regional depletion of stocks, which is an issue of biological concern to the extent that mixing or migration of stocks between areas is not occurring. Maintenance of fishing opportunities and protection of local community interests and processing infrastructure could be potential socioeconomic reasons for dividing OYs by area.[140]

The scoping process identified three key objectives for of regional area management:

- Preventing regional depletion and set catch levels for areas based on stock assessments
- Distributing economic benefits of catch along the coast
- Ensuring that certain communities receive economic benefits

The scoping process also drew a distinction between biological and social objectives and the appropriate methods for achieving the two:

> Catch area restrictions on IFQs would more precisely address biological concerns and would likely keep landings more geographically dispersed than might be the case without such restrictions. Landing area restrictions on IFQs would more precisely address socioeconomic

[140] PFMC. 2005. NEPA Scoping Results Document: Individual Fishing Quotas (A Kind of Dedicated Access Privilege) and Other Catch Control Tools for the Pacific Coast Limited Entry Trawl Groundfish Fishery.

All quotations and references made to the scoping document in this section can be found in Appendix A, Section A.1.0.

> concerns and would likely keep catch more geographically dispersed than might be the case without such restrictions.

At the end of scoping, the TIQC rejected any type of landings area endorsement and concluded that area management measures "should be based solely on the need to address stock conservation concerns." The TIQC's recommendation was based on concerns about possible constraints on the fleet's operational flexibility:

> Minimizing restrictions, such as catch area restrictions, will increase operational flexibility and increase the value of the IFQ. Given flexibility, vessels will go to areas where they can fish the cleanest.
>
> Landing area endorsements should be rejected. With respect to protection for ports, the TIQC felt that there are not enough groundfish to support processing facilities in every port that has historically had such fisheries. The economics of the trawl fishery do not allow vessels to travel far from the fishing grounds to deliver their catch. Where fish should be landed cannot be accurately forecasted and is worked out through negotiations between vessels and processors. The potential for geographic redistribution is a reality for market driven systems. Nothing in the current system prevents vessels from migrating between ports.

In October 2008, the GAC considered the regional landings zone option but did not recommended that it go forward as part of the Council's preferred alternative.[141] The GAC had concerns about the task of tracking the additional types of quota that would be created by the option. Members of the GAC and its advisors raised questions about the landings requirement's potential effectiveness given that fish can just be landed in a port and trucked elsewhere. Some members of the GAC stated their belief that adaptive management would do a better job of providing community stability. The GAP discussed the regional landings zone option in November 2008 and was not in favor of its inclusion in the trawl rationalization program.[142]

❖ *Interlinked Elements*

The regional landings zone option shares overlapping objectives with the proposed AMP. However, the structure and approach of the two are substantially different and, therefore, potentially compatible. The proposed latitudinal area management option described in Section A-1.2, in contrast, would potentially be redundant to this option. An area management program that combined the biological objectives of the latitudinal area management option with the socioeconomic objectives of the regional landings zone option would have to be carefully designed.

[141] PFMC, November 2008 Briefing Book, Agenda Item F.3.e, GAC Report.
[142] PFMC, November 2008 Briefing Book, Agenda Item F.3.f, Supplemental GAP Report.

❖ Analysis

This analysis examines how a regional landing zone option would modify and integrate into the IFQ system. There are several design elements, which we identify and discus in this section. There are many possible configurations of these design elements, making it difficult to analyze anything but broad dynamics.

Design elements of the regional landings zone option that would have to be considered by the Council:

- Number and location of the regional landing zones
- Method for assigning zone restricted QS/QP to the zones and for tracking and enforcement of the landings obligation
- The overall ratio between zone free and zone restricted QS/QP
- Identifying the IFQ management units to be covered by the landings restriction
- Adaptive features

Assigning and Tracking QS/QP under a Regional Landings Zone Program

Assigning Zone Restricted QS/QP

This regional landings zone option would divide QS issued for a set of IFQ management units in the shoreside nonwhiting trawl fishery into two categories: zone-restricted QS and zone-free QS. Zone-free QS would be identical to the IFQ management units described in Alternative A.1-2. QS would have a restriction on the zone where the associated QP can be taken, but it would not otherwise alter the IFQ Management Units.[143]

Zone-restricted QS would be marked with a zone designation at initial allocation and would "run with" the QS through transfers. This means that zone-restricted QS/QP would be transferable subject to the IFQ Transfer Rules chosen in Alternative A-2.2.3, yet transferees would still be bound by the landings requirement. The zone designations would remain in effect until extinguished through regulation.

Table A-110 illustrates the basic process of how the zone assignment would occur at initial allocation. In the first step, the QS for each IFQ management unit covered by the option would be designated either as zone-free or zone-restricted based on the percentage of QS the Council desired split. The example in Table A-110 uses a 40/60 split so that 40 percent of all QS is zone-free, and 60 percent is zone-restricted. Each QS recipient would receive the same overall amount of QS they would obtain under the Initial Allocation and Direct Reallocation rules chosen under Alternative A-2.1. In Table A-110, the hypothetical Company X stands to receive 0.02 of the *Sablefish N. of 36* QS. Using the 40/60 split, 0.008 of Company X's QS would be zone-free, and 0.012 would be designated as zone-restricted.

In the second step, each permit's zone-restricted QS would be assigned specific zone designations based on the permit's landings history. The assignment would be based on a window or "zone assignment"

[143] The IFQ management units are based on stocks and catch areas and ensure that acceptable levels of fishing morality are not exceeded. The landing area restrictions placed on the QS will not alter the amount of QP issued or directly change the areas where the harvest is taken. However, harvest areas could be indirectly influenced by the zone restrictions because trawl vessels tend to operate close to where fish are landed.

period chosen by the Council. In the Table A-110 example, the zone assignment period is 2006 to 2009; in those years, Company X made 6 percent of its *Sablefish N. of 36* landings in Zone 1, 83 percent in Zone 2, and 11 percent in Zone 3. Applying the percentages to Company X's overall zone-restricted QS (0.012) would then yield Company X's QS for each zone.[144]

Table A-112. Illustration of the process for assigning a quota recipient's ("Company X") zone-restricted QS/QP. The example is based on a 40/60 split between zone-free/restricted QS. Initial QS, landings history, and "Trawl OY" data are hypothetical.

Company X -- "Sablefish N. of 36" IFQ

[Step 1] QS Split

Initial QS
0.0200

Zone Free QS
40% *x 0.0200*
= 0.008

Zone-restricted QS
60% *x 0.020*
= 0.012

[Step 2] Zone Assignment
(based on window period 2006-2009)

		Zone 1	Zone 2	Zone 3
Total Landings			*150 mt*	
Landings by Zone		*Zone 1* 8.4 mt	*Zone 2* 125.1 mt	*Zone 3* 16.5 mt
			÷ 150 mt	
% of Total Landings		*= 6%*	*= 83%*	*= 11%*
	⟶		*x 0.012*	
Zone Restricted QS		***= 0.00067***	***= 0.01001***	***= 0.00132***

[Step 3] QS/QP Portfolio in Year

	Zone Free	Zone 1	Zone 2	Zone 3
QS	***0.00800***	***0.00067***	***0.01001***	***0.00132***
Trawl OY in Year	7,000 mt			
QP for Year	123,458 lbs	10,370 lbs	154,445 lbs	20,371 lbs

Additional zone assignment rules may be necessary to address the issuance of *de minimis* amounts of zone restricted QS to quota recipients. The amount of zone-restricted QS resulting from this minor amount of landings could be so small that the quota holder would not bother to land within the zone and may even have difficulty trading it on the market. A minimum threshold percentage (e.g., 5 percent) would be one method of addressing the issue. Landings not meeting this percentage threshold could be assigned to an adjacent zone or designated as zone-free QS.

[144] The zone assignment could be based on species-by-species basis, as shown in Table A-110, or based on all groundfish landings in aggregate during the window period.

After initial allocation of QS, the next step would involve translating the zone-restricted QS into an annual landing requirement. In this step, the zone-restricted QS would either (1) be converted into QP using the same IFQ Annual Issuance process chosen under Alternative A-2.2.2 used for all IFQ management units, or (2) converted into zone assignment QS ratios depending on how the zone landings requirement was tracked (discussed below). Neither method would involve an annual sub-allocation of the trawl sector OY to the regional zones. Unless altered through the Council process, the QP received by each zone would be based solely on QS assigned to the zone at initial allocation.

Tracking Zone Restricted QS/QP

There are two potential methods for tracking zone restricted QP. The first would track zone-restricted QP in the same manner contemplated for tracking QP without the zone landings option in place. Doing so would require zone-restricted QP to maintain its species-zone identity throughout the year as a special type of QP. For example, a vessel account could contain multiple types of Dover sole QP: zone-free Dover sole QP, Zone A Dover sole QP, Zone B Dover sole, and so on. The Permit/IFQ Holding Requirements described in Alternative A-2.2.1 would apply to eacH QP type. If a vessel landed a particular species in a particular zone, QP for that species-zone combination would be required. Zone-free QP could be used as well. If the vessel account had both types, the owner could designate which type and the amount to deduct from the vessel account.

The second approach—which would have to be worked out in more detail—would fashion the option as an annual requirement. QS account owners would be given zone assignment QS ratios at the start of the fishing year. At the close of the fishing season, account owners would have to show documentation that proved their annual landings achieved or bettered the zone assignment ratios (e.g., Company X show that 1.32 percent of its *Sablefish N. of 36* landings were made into Zone 3.

The potential downside to the first method is that there would be significantly more types of QP categories to track than there would be in the absence of the zone landings requirement. The potential number of QS/QP combinations is explored below. Under the second method, data collection would be the same as it would be absent the regional landings requirement. Quota holders would only have to know the amount and location of each landing to track their cumulative landings in each zone. However, the review of landings documentation at the end of the year would create another administrative task for NMFS.

Design Elements and Other Considerations

IFQ Management Units Covered by the Regional Landings Zone Requirement

As described in the WDFW proposal, the regional landings zone requirement would apply to all nonwhiting groundfish IFQ stock management units except the overfished stocks. The potential universe of stocks is identified in Table 2-5. Table A-111 provides a list of those species that tend to be trawl targeted and were included within the scope of the Council's PPA.[145]

[145] See section A.1-2 for details on the IFQ management units. The Council's preliminary preferred alternative would not have required QS/QP for longspine thornyhead south of 34°27' N latitude, minor nearshore rockfish north, minor nearshore rockfish south, black rockfish (WA), black rockfish (OR-CA), California scorpionfish, cabezon, kelp greenling, shortbelly rockfish, other rockfish, and spiny dogfish. In June 2009, the Council recommended adding the Other Fish category to the list.

Table A-113. The shoreside nonwhiting IFQ stock managed units that would potentially be subject to the regional zone landings restriction under the Council's PPA.

1	Lingcod N of 42º	12	Dover Sole
2	Lingcod S of 42º	13	English Sole
3	Pacific Cod	14	Petrale Sole
4	Sablefish N of 36º	15	Arrowtooth Flounder
5	Sablefish S of 36º	16	Starry Flounder
6	Chilipepper Rockfish	17	Other Flatfish
7	Splitnose Rockfish	18	Other Fish
8	Yellowtail Rockfish	19	Longnose Skate
9	Shortspine Thornyhead - N of 34º27'	20	Minor Rockfish North
10	Shortspine Thornyhead - S of 34º27'	21	Minor Rockfish South
11	Longspine Thornyhead - N of 34º27'		

The total number of QS units in the zone landings option would depend on the configuration and number of zones and actual landings into those zones during the zone assignment window period. The number of QS units would be something less than the following:

> [(*the # of IFQ management units subject to the zone restriction*) * (*the # number of zones* + 1)] + [the # of *overfished stocks management units* / *other stocks not subject to the restriction*].[146]

It would be "something less than" the number produced by this equation because not all IFQ management units would have coast wide landings history. Very few stocks (e.g., Dover sole, Petrale sole) would have landings history for every zone. Several stocks are already subject to some geographical subdivision. In addition, other stocks like arrowtooth flounder and Pacific cod are not geographically subdivided as management units yet would only have landings history within a limited number of zones because of the natural geographic distribution.

Even so, the regional zone landings option would likely add a considerable number of stock-zone QS units. If the Council designated eight zones, all 21 stock units in Table A-111 were subject to the zone restriction, and (on average) those stock units had landings history in four different zones, then the zone landings option would create 105 QS units for a total of 112 management units (including 7 QS/QP units for the overfished stock).[147] If the average number of zones were five instead of four, then the number of QS units created by the option would increase to 126 for a total of 133 management units. For comparison, the latitudinal area management option in Alternative A-1.2 would increase the number of management units from about 35 to 58. This number is comparable to the B.C. IVQ program, which involves eight groundfish management areas and 27 stocks that are managed for a total of 55 species area quota units.[148]

Another factor to consider in subdividing QS into regional units would be the potential risk posed by the pools of quota becoming too small. In other words, for species with a relatively small trawl sector

[146] The "plus 1" accounts for the zone free QS.

[147] 105 = 21 * 5 = (# of stock management units) * (average # of zones + 1 zone free).

[148] The B.C. trawl IVQ species area units can be viewed in Appendix 8 of the 2008/2009 Groundfish Trawl Commercial Harvest Plan: Fisheries and Oceans Canada, Pacific Region Amended Integrated Fisheries Management Plan: Groundfish, March 8, 2008 to February 20, 2009. (http://www-ops2.pac.dfo-mpo.gc.ca/xnet/content/mplans/mplans.htm#Groundfish).

allocation to begin with, the subdivision of pools of zone-restricted quota might create thin market conditions and potentially erode some of the efficiency gains expected under an IFQ program (see discussion of thin markets in Section 4.7.2.3).

To reduce the number of stock-zone QS combinations, the Council could choose to designate only a subset of stocks with the zone restriction. Given that a relatively few target species drive the nonwhiting groundfish trawl fishery, the outcome of the regional landings zone option could be more or less the same if only those key target species were covered. Still, even a limited number of target stocks would still have the potential to create a considerable number of new species area management units. Covering the top five target stocks would be similar to the area management by geographical subdivision option in terms of the total number of additional QS/QP units. For example, assuming 8 zones and an average of 6 zones per stock (target stocks tend to be more widely distributed), the total number of management units would be 58.

Table A-112 identifies the most economically significant stocks based on approximate average annual ex-vessel value from 2004 to 2006.[149]

Another potential way of reducing the number of QS units in the program would be to endorse certain zone-restricted QS units with multiple zone designations (e.g., Dover sole QS eligible for landing Zone 1, 2, or 3).

Table A-114. Top 12 nonwhiting, groundfish species in terms of average ex-vessel value, 2004 to 2006 (PacFIN).

	Species	Approx. value (thousands $)
1	Sablefish	~$6,200
2	Dover sole	~$5,200
3	Petrale sole	~$5,200
4	Shortspine thornyhead	~$1,000
5	Pacific cod	~$900
6	Longspine thornyhead	~$700
7	English sole	~$700
8	Arrowtooth Flounder	~$500
9	Rex Sole	~$500
10	Lingcod	~$450
11	Pacific sanddab	~$300
12	Unspecified. Skate	~$300

Designating the Regional Landings Zones

The configuration of the regional landings zones—their number and location—is perhaps the key design element of the option. The zones would redefine the geographic scope of the quota market. In addition, the ultimate configuration of the zones would be the primary factor determining the option's impact on

[149] There may be other significant target species that have been targeted in the past, and may again be targeted under the IFQ system, that do not have recent landings history because of overfished species constraints (e.g., chilipepper rockfish, yellowtail rockfish).

harvesting efficiency and operational flexibility. Some configurations might be highly constraining to some areas of the coast, whereas other configurations might have negligible impact on overall efficiency and flexibility.

As described in the WDFW alternative, the regional landings zones would be designed and nominated by the states and approved by the Council. The proposal suggests that there should be no more than 10 zones. The borders of each zone would be delineated by a north and south latitude line. Zone borders could either coincide with state borders or cross them. In addition, a regional landing zone could conceivably be designed to cover a single port to provide strong protection to that community. Alternatively, zones could be designed to encompass multiple ports to increase competition and operational flexibility. Overlapping zones would also be possible. Overlapping zones could make a single port or port group eligible to receive multiple sets of zone restricted QS/QP.

Multiple sections in this document could be used to guide the design of the zones. The regional comparative advantage analysis in Section 4.7.2.1 and Appendix C discuss some of the initial conditions (e.g., distribution of QS/QP at initial allocation) that are expected to influence geographic shifts in fishing effort and landings under an IFQ program. The regional geography of processing infrastructure is examined in Section 4.10.2.2. Possible impacts to fishing communities from the proposed action fleet are detailed in Section 4.15.2. Section 3.7 discusses the current status and vulnerability of individual fishing communities based on their dependence on and engagement in the groundfish fishery and other fishing activities.

Designating the Zone-Free/Restricted QS Split

As highlighted in the Table A-110 example, the Council would determine the overall split or ratio between zone-free and zone-restricted QS. The WDFW proposal suggested that the percentage split would be uniform across the program; however, it would also be possible to vary the split between IFQ stock management units (e.g., 40/60 for Dover sole, 25/75 for Petrale sole).

While the configuration of the zones defines the geography of the quota markets, the zone-free/zone-restricted QS split essentially determines the degree of independence between those markets. Competition between zones would be limited to the zone-free QS/QP, so the degree of independence would be proportional to the percentage of zone-restricted QS/QP designated by the Council: the higher the percentage, the lower the QS/QP competition between zones. At the same time, the independence of zone QS/QP markets would remain limited as long as overfished stocks were tradable coast wide.

Again, the objective of the option is to provide community stability by preventing quota from shifting geographically. Buyers and processors within regional landings zones could leverage the zone-restricted QS/QP to attract zone-free QS/QP. To remain "whole" in the IFQ program, each zone would have to leverage its zone-restricted QS/QP up to the amount of the zone-free QS ratio. The chances of this happening would presumably increase with higher percentages of zone-restricted QS. At the same time, restricting QS to a zone would not necessarily mean that all the associated QP would be landed every year. As is the case with the status quo, harvesters may not be able to access the full trawl sector OY because of overfished species constraints or they might not have a market for the fish.

Designating the Zone Assignment Window Period

As also discussed and illustrated in Table A-110, the Council would need to identify a zone assignment window period for assigning each quota recipient's zone-restricted QS to specific zones.

To achieve the goal of providing community stability during the IFQ program, this window period should be chosen to reflect recent landings patterns. A window period that went too far back might increase restrictions on operational flexibility because it would increase the chances that permit holders receiving the initial allocation of QS may have purchased the permit, or changed the location of their operations, outside or at the tail end of the window period.

Given that the zone assignment window would not influence the overall amount of QS issued to quota recipients, and that the objective of the option is to mitigate against substantial disruption to the fishery, the Council could consider designating a window period that extended to the present and beyond (e.g., 2004 to 2010). Doing so would allow those eligible to receive QS some influence over their potential portfolio of zone-restricted QS.

Further examination of potential window periods or alternative zone assignment rules would likely reveal a need for additional procedures for assigning the initial allocation of QS to zones. For example, if a recent window period is chosen, there may be permits receiving an initial allocation of QS/QP that have no landings history. There are known latent LEPs that will receive little QS/QP other than what may be distributed from the buyback history.

Adaptive Features of the Regional Landing Zones Option

The WDFW proposal suggests that the regional landings zone program could be managed adaptively by altering the design elements of the program. As seen above, there is considerable flexibility in the design elements of the program. For example, IFQ management units could be added to or subtracted from the zone requirement; the zone-free/zone-restricted QS percentage split could be decreased or increased; the boundaries of zones could be redesignated to add or subtract ports, etc. The Council would presumably make such changes in response to new information about the performance of the fishery.

Changing the design elements would involve varying administrative complexity and costs. The simplest change to the program would involve converting zone-restricted QS to zone-free QS, either wholesale or for a certain percentage (e.g., converting 25 percent of zone-restricted Dover sole QS to zone-free).[150] This conversion to zone-free could be made on a permanent basis or temporarily in response to inseason conditions. Increasing the number of zones in which a QS unit could be landed (e.g., permitting Zone 1 QS to be landed in Zone 2 as well) would also be relatively simple in terms of administrative complexity. In contrast, redesignating zone boundaries or increasing the amount of zone-restricted QS from the pool of zone-free QS would be more administratively complex and would require use of a zone assignment window period or other formula.

Biological effects of the Regional Landings Zones Option

Although the objectives of the regional landings zones option are exclusively socioeconomic in nature, any shift in fishing activity induced by the landings restrictions could have biological implications as well. Many of these implications are discussed in the analysis of the latitudinal area management provision in A-1.2. The biological effect of the regional landing zones option would be similar to that of the area management provision—i.e., precautionary and expected to decrease the likelihood of localized stock depletion—to the extent that the regional landing zone provisions were successful at preventing geographic consolidation of fishing activity. If, however, the design of the zones somehow increased concentration of fishing effort in certain regions, then the risk of localized depletion in those

[150] If the regional landings boundaries coincided with the 40° 10’ N latitude line (e.g.. if Zones 1-4 were north of 40, and Zones 5-8 south), then it would also be relatively simple to convert to the area management option.

regions would be higher. A major difference between area designations and the landing zone provisions is that the landing zone designations do not necessarily force vessels into particular catch areas if the fish are not there. The vessels can fish anywhere along the coast as long as they meet the landing area requirements for zone designated QP.

Influence of the Regional Landings Zone on the IFQ system

The regional landings zones option would not amount to a fundamental alteration of the IFQ mechanism. Therefore the tradability of QS/QP and individual accountability for total catch and discards would still be expected to change the behavior and composition of the fleet. The regional zones would, however, be expected to alter the scale at which these dynamics operate, and in turn, to impact the geographic redistribution of landings under the program. Again, markets for zone-restricted QS/QP would maintain some degree of independence from one another, yet would remain connected through trade for zone-free QS/QP. Competition for overfished species QS/QP in particular would be expected to remain high.

Potential Benefits to Fishing Communities

By creating landings restrictions based on recent conditions in the fishery, the regional zone provision would preclude wide-scale redistribution of QS/QP under the IFQ program. Over the long run, the regional zones would be expected to prevent excessive geographic consolidation of landings and promote broader distribution of benefits from the IFQ program. However, the degree to which individual ports and communities would benefit from these protections would depend largely on the configuration of the zones. The option could also provide communities disadvantaged under the IFQ system some protection by reducing coast-wide competition for QS/QP and by dampening down the influence of initial conditions (e.g., port infrastructure) on the redistribution of QS/QP. The converse of this, of course, is that communities that stood to gain the most from increased coast-wide competition would lose some of their advantages under the zone requirement.

Ports and communities within zones would still face competition from one another; thus, fishing activities and zone-restricted QS/QP could still shift within zones. If a port were placed into the same zone as a major competitor, then the zone provision might not provide much protection to that community. From the point of view of individual buyers and processers, nothing in the regional landings zone option would prevent new entrants from competing for landings. As happens under status quo, competitors could enter a zone with little or no capital investment in the community by sending mobile buyers into a zone to purchase fish and transport them to another area for processing.

The regional landings zones option would also present some risk of undermining overall economic efficiency and long-term benefits to the fishery. In 2004, the GAO evaluated landings restrictions as part of a report evaluating various community protection measures for IFQ programs and reached the following conclusion:

> *Requirements to bring catch into ports in a particular geographic area . . . may not be healthy for a community's economy in the long term. For example, such a requirement may subsidize inefficient local fish processors that cannot compete on the open market. With reduced competition, these processors may offer less money for the catch, thus reducing the fishermen's income and ultimately harming the community. According to Shetland Islands fishery managers we spoke with, had fishermen been required to land their catch in the Shetland Islands, they would have been forced to sell their catch at a*

> *price far below the market value and the processor would have had no incentive to restructure into the competitive business it is today.(GAO, 2004)*[151]

Although conditions on the west coast are much different than those in an isolated archipelago like the Shetland Islands, the potential for the zone landings provision to reduce competition within zones would still exist. As discussed elsewhere in Appendix A and in Appendix E, there are issues of market power and competitiveness in the processing and harvesting sectors related to the transition to an IFQ system and the initial distribution of QS/QP. These would be important factors for the Council to consider during the design of the regional zones.

Potential Impacts in the Harvesting Sector

The IFQ program would be expected to produce gains in harvesting efficiency over the status quo even with the regional landings zone option in place. Any additional costs associated with the landing restriction would be internalized into the IFQ mechanism, and the price harvesters are willing to pay for QS/QP will remain connected to the potential profits earned through harvesting the fish. As explained in Section 1.3.1, given that the zone-restricted QS/QP would still be divisible and tradable, harvesting efficiency within each zone would improve over time as the quota accrues to those able to harvest and land fish within the zone most profitably.

At the same time, there is some risk that economic improvement in the fishery would be lower than it would be without landings restrictions in place. This risk can be weighed by examining the potential impact of the landings restriction on the two sources of expected economic improvement under the proposed IFQ system: (1) reductions in overall and per-vessel harvesting costs and (2) increased access to target species from improved avoidance of overfished species bycatch. The risks posed by the regional landings zone option to improvements in these two areas are weighed separately.

- Risk to Expected Reductions in Harvesting Costs

Reductions in harvesting cost alone are expected to bring significant economic benefit to the fishery, with fleet consolidation being a major the source of the savings. This consolidation would occur as less efficient vessels transfer quota to vessels that are more efficient and exit the fishery. As more vessels exit, overall harvesting costs in the fishery are reduced as fixed costs and capitalization decrease, and the proportion of efficient vessels in the fleet increases.

Assuming that market conditions for zone-restricted QS/QP remain competitive, and transaction costs not too high, then consolidation and associated cost savings would still be expected within the regional landings zones. The geographic pattern of consolidation would ultimately depend on the configuration of the zones. The degree of consolidation and cost savings could vary between zones and could be higher or lower overall than it would be in the absence of the zone structure, depending on economic conditions within the zones.

Vessel efficiency could also be impacted. Vessel efficiency is a function of the vessel's harvesting capacity and its cost structure. Harvesting capacity would not be expected to differ over the long run under this option, yet a vessel's cost structure might vary because it depends in part on port infrastructure. Zones that contained only high cost ports would thus be expected to hamper cost savings of the vessels within that zone and reduce the overall efficiency gains in the program.

[151] GAO. 2004. Individual Fishing Quotas: Methods for Community Protection and New Entry Require Periodic Evaluation. GAO-04-277.

Bycatch is expected to be a major contributor to harvesting costs in the IFQ program. As described in Appendix C, there are regional differences in the distribution and abundance of overfished species. If a regional zone locked vessels into fishing in one of the known high bycatch areas, the cost of harvesting a given volume of target species would be higher in this zone because of the overfished species QP costs. Yet, this would be true only to the extent that higher bycatch rates could not be avoided within the zone, or if the cost of travel to harvest in lower bycatch rate areas was high. If the zones were large enough to provide multiple fishing and landings locations, high bycatch areas could likely be avoided. Over the long term, we would expect harvesters to try to reduce their bycatch rates by changing fishing locations and strategies. The incentives produced by individual accountability, together with improved at-sea data collection, should push harvesters to identify and avoid bycatch hotspots at a much finer scale than is possible under the status quo management structure. At the same time, if the only available bycatch avoidance strategy available were farther travel to fishing ground, then the increased travel distance would be a forced inefficiency and an undesirable outcome of the program.

- Risk to Potential Increased Access to Target Stocks

Increased access to target stocks is expected to occur under the IFQ program as regulatory discards are eliminated, and individual accountability creates incentives to reduce overall bycatch rates in the fishery. The regional landings zones program could potentially lower target species access compared to having no landings requirements in place if the zones somehow hampered improvement in bycatch rates.

This incentive to avoid bycatch might lead to coast-wide differences in target strategies and, in turn, regional differences in the amount of bycatch needed to access a given volume of target species. If zone restrictions prevented QS/QP from flowing to those areas where target stocks could be accessed for the least amount of bycatcH QP, then bycatch rates would not decrease to what they could have in the absence of the landings restriction. Yet, as mentioned above, this would only be true to the extent that the bycatch avoidance techniques used to achieve the lower bycatch rate would not be effective everywhere. As long as bycatch rates can be lowered through improved fishing techniques, the amount of target stock QP accessible per QP of bycatch would be expected to even out among zones over the long run.

Increased access to target stocks would also depend on demand for the increased volume of raw fish product. Therefore, differential market conditions for raw fish product between zones could also be a factor in how large the increase in landings will be under a zone-restricted IFQ program. For example, assume Zone 1 received zone-restricted QS/QP for a species that had little or no market for the raw fish product within the zone. With no zone restrictions in place, the QS/QP for this locally unmarketable species would flow to regions where demand for the species did exist. With zone restrictions in place, this transfer could only occur with zone-free QS/QP. With no market for the fish, the value of Zone 1 QS/QP would be zero. However, given that the assignment of QS to zones would be based on recent conditions in the zones, such situations should not be common. Significant landings of a species would not have been made in the zone if there were no market for the fish. Moreover, even if such market disconnections did occur, they might only be a problem over the short term. Over the long term, if enough demand existed for the raw fish product, processors or buyers would enter the zone to capture the profits.

Landing Patterns and Implications for Potential Zone-Restricted QS Portfolios

Vessels in the nonwhiting groundfish trawl fleet show a high degree of port fidelity, thus most permit owners receiving a quota allocation based on their trawl permit landings history would likely have their zone-restricted QS/QP assigned to a single zone. Yet, those that visited multiple ports during the zone assignment window period could have their zone-restricted QS assigned to several zones.

We examined permit ownership and landings patterns associated with those permits during 2004 to 2006 to get a sense of how many recipients would have their zone-restricted QS assigned to multiple zones.[152] As shown in Table A-113, 59.5 percent of permit owners hold LEPs with landings history in only one port group, nearly 25.6 percent hold permits with landings history in two or more port groups, and 14.9 percent hold permits with no landings history at all. Considering just the permits with landings during 2004 to 2006, nearly 70 percent hold permits with history in a single port, 12.6 percent in two ports, 10.7 percent in three ports, and 6.8 percent in four or more ports. Given that zones would likely be designed to cover multiple ports, it would be expected that more than 80 percent of quota recipients would receive zone-restricted QS for a single zone.

Quota recipients with history in multiple port groups could have very small portions of their zone-restricted QS assigned to a certain zone. Table A-114 shows that permit owners with landing history in multiple ports tend to make the majority of their landings into a single port group. Those with landings history in three or more port groups made, on average, less than 10 percent of their landings into the third port group. Those with landings history in four or more port groups show even smaller percentages. Some of these small numbers might not reflect regular business practices and could be artifacts of one-time business transactions or the transfer of permits between vessels. If so, then the regional zone landings provision could force additional transactions on quota recipients as they attempt to divest themselves of quota assigned to unwanted zones.

If the processing business received initial allocation of quota based on processing history, they would also potentially receive zone-restricted QS for multiple zones. Almost two-thirds of the QS would go to processors that have processing history in more than one port group. However, processing history is more likely to reflect recent business practices than vessel landings history. In other words, if the zone assignment window period reflects recent conditions in the fishery, then the zone-restricted QS received by processors should tend to match the location of their processing operations. Nonetheless, depending on the zone assignment window period, processors could still receive zone-restricted QS quota for a zone where they no longer, or no longer wish to, do business.

[152] The port groups used in this analysis are based on the PacFIN W-O-C port groupings (e.g., Eureka Area, San Francisco Area, Coos Bay Area; see *www.psmfc.org/pacfin*) except that Washington's north coast (e.g., Neah Bay) and Puget Sound ports were combined into a single port group based on the WDFW proposal's indication that those ports would likely be covered by a single zone.

Table A-115. Profile of limited entry trawl permit owners' nonwhiting groundfish landings history, 2004 to 2006, including count of port groups where landings were made. Ports consisting of less than 1 percent of a permit owner's landings were excluded.

	# of Port Groups with Landings					
	0	***1***	***2***	***3***	***4+***	**Total**
Count of Permit Owners	18	72	13	11	7	121

A-9 COMMUNITY FISHING ASSOCIATIONS (OPTION – NOT PREFERRED)

❖ Provisions and Options

The Council did not include in Amendment 20 any special provisions for formal CFAs but did commit to the consideration of such provisions as part of a trailing amendment.

❖ Rationale and Policy Issues

In the summer and fall of 2005, the Council gave extensive consideration to provisions to address the concerns of communities (see also "Consideration of Communities" on page A-38). In response to the trawl rationalization analysis in the preliminary draft EIS, as well as to public comment, the Council recognized a continuing concern regarding community stability and vulnerability associated with the implementation of the trawl individual quota program. In November 2008, the Council selected a final preferred alternative on the essential elements for a trawl rationalization program, but left three issues for trailing actions: establishing accumulation limits, defining eligibility to own, and an AMP. Part of the latter two actions included consideration of special community-based entities. As a starting point, the Council considered utilizing definitions of two types of special geographic entities provided for by the MSA: Fishing Communities and Regional Fishing Associations. The Council looked at both definitions and chose to define another type of entity more suited to the Council and constituencies' needs - CFAs. CFAs may approximate or utilize certain elements from the MSA's Fishing Communities and Regional Fishing Associations, but would not necessarily match either definition precisely. The MSA requires consideration of RFAs, but does not require the councils to adopt RFAs. In March 2009, the Council indicated interested in defining a CFA as an entity that is expressly eligible to own QS and as an entity that may be entitled to special accumulation limits. Council staff were directed to use, as a starting point, the National Oceanic and Atmospheric Administration (NOAA) Memorandum titled Design and Use of LAPPs, and a public comment letter from The Nature Conservancy. CFAs may be defined as a special class of entities eligible to hold IFQ, or could be an association of QS holders. Through the definition process, CFAs could be given special considerations or privileges, such as higher control caps, waivers of other program requirements, or priority consideration for Adaptive Management QPs. In return for such special privileges, the Council might require CFA goals, objectives, and performance measures that further the Groundfish FMP goals and objectives.

In April, the Council made and then withdrew a motion to further define CFAs and goals related to aiding vulnerable communities. There was little consensus on which communities were vulnerable, how to define vulnerability, and what analysis could be completed before the final preferred option would be selected in June 2009. The Council opted to defer the CFA decision-making to a trailing amendment.

A-10 ADAPTIVE RESPONSE AND FOLLOW-ON ACTIONS

Ad Hoc Response

After program implementation, the Council will continue to monitor the trawl rationalization program and make modifications as necessary. There will be a comprehensive program review after five years; however, adjustments may be made prior to that time. In Section A-3 (Adaptive Management) of the program, QS are set aside specifically to be available to support adaptive response. While this set-aside and the objectives and criteria for its use have been labeled the "AMP," the Council's adaptive response to program performance would extend beyond the objectives specifically identified for using the Section A-3 adaptive management set-aside. The Council will monitor the program and adaptively respond as necessary to address MSA requirements, MSA national standards, groundfish FMP goals and objectives, and goals and objectives for trawl rationalization. In particular, the Council has identified that it may modify the following program elements as part of the biennial specifications process:

- The percent used for the carry-over provisions (Section A-2.2.2.b)
- The vessel unused QP limits (Section A-2.2.3.e)

Through the process of developing the biennial management regulations, the Council may also recommend regulatory modifications to specific elements of the trawl rationalization program identified in Appendix D of this document. Modification to these elements would be made as needed to address the requirements, standards, goals, and objectives that apply to the groundfish plan and trawl rationalization. Any regulatory adjustments requiring a change to the related FMP language (Appendix G) would have to comply with the standard processes for amending the FMP.

Modification and termination of the program are options at any time (after required process and opportunity for public comment); under such circumstances, no compensation would be due to QS holders or others making investment decisions based on the trawl rationalization program.

Comprehensive Program Review

Section A-2.3.4 covers the Council comprehensive review process. The first review will occur five years after implementation with subsequent reviews every four years. In addition to evaluating performance of the program, during the first review process consideration will be given to the use of an auction or other non-history-based methods for redistributing QS that may become available after the initial allocation. Need for a use-or-lose provision may also by a significant topic for consideration.

First Biennial Management Cycle Actions

As part of the process of developing the biennial specifications for the first year in which this program is implemented, the Council will have to specify an allocation between the shoreside nonwhiting and whiting fisheries for all species within the scope of the IFQ program for which such allocations were not established as part of Amendment 21 (including and allocation of whiting bycatch in the nonwhiting fishery and whiting taken in the shoreside whiting fishery). Completion of the allocation decision is a onetime action and will not have to be repeated in subsequent management cycles. As part of every biennial cycle, a determination will have to be made on the need for bimonthly cumulative limits or other catch controls for species not covered within the scope of the IFQ program.

Planned Follow-on Amendments and Rulemakings

As identified in Section A-9, it is the Council intent to consider whether or not there should be special provisions for CFAs. Additionally, during the first two years of the program the Council will be working on an approach for using the QS set-aside for adaptive management (as discussed above and in Section A-3).

A-11 PROVISIONS REJECTED FROM FURTHER CONSIDERATION

During the process of developing the IFQ program, a number of provisions were considered but rejected without further development. When such provisions fall within the scope of sections of the program, they are discussed above in the related sections. For example, allocation to crewmembers was rejected early on, but that option and the reason for its rejection are covered in the section on eligible groups (Section A-2.1.1). In this section, we will cover some rejected provisions that do not fall within the scope of sections of the IFQ program. All such provisions are documented in the administrative record of the Council's deliberations. During the end of the Council deliberations, two potential provisions not covered elsewhere in this document were the topic of discussion and comment:

1. Sideboards or other measures to prevent spillover
2. Owner on Board Requirement

Sideboard and Measures to Prevent Spillover

A rationalized trawl fishery may have an effect on other west coast fisheries through the transfer of effort and capital into other fisheries (spillover). Most of the other nongroundfish fisheries are already under LE programs. Shrimp is an exception.[153] There are generally three additional fisheries in which LE trawl vessels participate: the Dungeness crab fishery, the pink shrimp and prawn trawl fisheries, and the sablefish tier fishery. Because the current bimonthly management structure of the groundfish trawl fishery provides ample opportunity for vessels to participate in other west coast fisheries, both the GMT and the TIQC advised the Council that they did not believe that nontrawl participants in these other fisheries will be impacted to any noticeable degree by a move to manage the groundfish trawl fishery with IFQs. The possibility that consolidation in the groundfish trawl fleet could result in surplus vessels and that these vessels might acquire latent permits for these other fisheries was discussed. However, since the LE systems for these other fisheries are state-managed, it was thought best that the latent permit issue be addressed outside the Council process.

Owner-on-Board Requirements

An owner-on-board requirement was discussed at various times during the process of developing the IFQ program. The topic often came up in the context of concern over absentee ownership of QS ("sharecropping") and the potential need for a "use-or-lose" provision to ensure that QS were not acquired by groups that would like to see harvest reduced to levels lower than those determined appropriate through the processes provided by the MSA. Overall, an owner-on-board requirement would be intended to provide control over resource access to those most closely involved with harvesting operations. By doing so, it would be hoped that the links between the fishery and fishing communities would be maintained and that communities would benefit from QS ownership by their citizens. Additionally, it was thought that by maintaining QS in the hands of active fishermen it would be more available for purchase by those wishing to enter the fisheries as harvesters. Without an owner-on-board requirement, the concern is that QS might be acquired by investors, and it could be more expensive for fishers to acquire the shares.

The owner-on-board provision was rejected because of at least three concerns. First is the practicality of such a provision in a multispecies fishery. Because of the variation in the mix of catch that may be taken on any particular trip, it is expected that there will be substantial QP trading during the year in

[153] Participation in the shrimp fishery is cyclic and more dependent on biomass and the strength of the market. As compared to the situation under cumulative landing limits, an IFQ program is not likely to have a substantial effect on participation in the shrimp fishery.

order for vessels to match the mix of species in the catch with the mix of species held in the vessel account. Developing an owner-on-board rule that accommodated the need to transfer quota between vessels was intractable. Second, if such a rule could be developed, it would add substantially to tracking costs. Under the current design, QP would be transferred to a vessel account, and no distinction would be made between the sources of the QP. Provisions were intentionally designed to make it unnecessary to track QP back to the owner of the QS and to make it unnecessary to split a single trip up and count it against various QP accounts. This approach was taken to reduce administrative costs. An owner-on-board program would require tracking QP to QS owners and splitting the catch taken on a single trip among various QP accounts, instead of just the vessel account. The third reason for not adopting an owner-on-board requirement was concern about the nature of vessel operations in the trawl fishery as compared to other fisheries in which owner-on-board provisions have been implemented. Compared to other coastal fisheries, the trawl fishery is believed to involve many more multi-vessel companies with hired operators. Therefore, it was thought that the owner-on-board provision might change the character of the fishery rather than preserve it. At the same time, it was recognized that under an IFQ program it is highly likely that the character of the fishery will change and that provisions such as that considered here will determine the direction of change. After evaluating this issue, on balance, the Council believed that an owner-on-board provision would be excessively cumbersome in a multispecies fishery, relative to the benefits that it might bring. Provisions such as the owner-on-board provision and use-or-lose requirement could potentially be reconsidered during review of the IFQ program performance.

An Introduction to Harvest Cooperatives and the Pacific Whiting Cooperative Alternative

A cooperative is used to describe a collective arrangement among a like-minded group of individuals. Cooperatives are entities that are controlled by the people who use them. They differ from other business entities because they are member-owned and operate for the benefit of members. The general activity of cooperatives being considered under the Council's rationalization program is the harvest of fish, so these types of cooperatives are best described as "harvest cooperatives" and a harvest cooperative can be defined as an entity which acts to coordinate the harvest of its members.

Harvest cooperatives are organizations made up of vessels that work together to harvest a fishery resource. We can categorize this broad definition into two different possible models. One may be made up of vessels that negotiate catch-sharing arrangements among themselves without agency involvement. The Pacific Whiting Conservation Co-op is an example of this type of cooperative—a voluntary association of catcher-processors that have negotiated catch sharing arrangements among themselves without agency and Council involvement. This cooperative depends on an allocation of whiting to the sector and a barrier to entry by other catcher-processors that are not part of the arrangement.

The second model is created by vessels with catch history assignments (a percentage of allowable catch) that each vessel brings to the cooperative organization. The collective catch history then comprises the pool of catch available to that cooperative. This catch history can be leased to another vessel in the same cooperative through a private agreement without needing agency involvement, and the motivations and outcomes from doing so may be similar to those motivations and outcomes that exist when transferring quota pounds in an Individual Fishing Quota (IFQ) program (the reader is referred to Appendices A and E for a further elaboration on such incentives and outcomes). The administration and enforcement of harvest activities among member vessels is primarily done through the cooperative organizations and through private contracts governing the operation of those organizations. The regulatory activities of the agency are generally limited to reviewing and approving or disapproving cooperative contracts, monitoring for sector or co-op catch levels, and closing when a sector or co-op reaches their allocation. The mothership and shorebased cooperative proposals are examples of this type of cooperative. Each catcher vessel permit would have a percentage of the allowable catch based on their catch history and those catcher vessels would form cooperative arrangements with other catcher vessels. The cooperative organization would coordinate harvest activities of its member vessels and these activities would include leasing of shares between member vessels without agency involvement.

The primary difference between the two models is the assignment of catch history. In cooperative programs with a relatively diverse set of harvesters, catch history assignments may be necessary in order to solve allocation disputes that may arise between vessels over catch sharing. In cooperative programs with harvesters that are less diverse, catch history assignments may not be necessary because vessels have similar historic participation in the fishery and similar historic catch levels, and find it relatively easy to reach catch sharing arrangements.

In some cooperative programs, catch history assigned to each vessel is linked to a processing entity. This linkage provision can trace its roots to the American Fisheries Act (AFA) which rationalized the Bering Sea Pollock fishery. The AFA cooperatives were designed to "ensure that both harvesters and processors benefited from rationalization" (Stevens and Gorton 1999 as cited in Matulich 2000), and one outcome was to establish a partial link between catcher vessels and shoreside processors. Catcher vessels (CVs) and mothership (MS) processors are not linked in the Pollock fishery. Binding a vessel to a processor creates a system that takes on many characteristics of a vertically integrated firm. Harvesters cannot operate without a simultaneous action on the part of a processor and vice versa. With a harvester-processor linkage provision, harvesting entities and processing entities must negotiate with one another, and both are in a similarly powerful negotiating position. Neither the processing entity nor the harvesting

entity can operate independent of the other, and therefore the goals and operations of both entities become more aligned, partly out of necessity. This type of mutual dependence places both entities in a relatively strong negotiation stance resulting in the sharing of profits that accrue as a result of harvesting and processing activity. Furthermore, a processor linkage provision takes on some of the characteristics of a limited access privilege because those linkages are somewhat defensible and are somewhat transferable (at least in the model envisioned for Pacific whiting cooperatives). Processors with an established linkage have catch available to them from linked catcher vessels and other processors cannot take that catch in the current year.[1] When combined with processor limited entry and the fact that processors can transfer their permits and/or associated linkages to another processor, this tool tends to decrease the amount of competition that exists among processors for catch, making it possible for the processing sector to rationalize itself to a certain degree. This participation in processing activity leads to the generation of greater profits.

Although harvesters and processors have been linked in other harvest cooperative programs, that linkage can be broken. Two options are analyzed in the existing cooperative alternatives for breaking or switching a linkage. Under one option, harvesters can break the linkage by electing to fish in a noncooperative fishery that is designed as a derby fishery. Harvesters in this noncooperative fishery compete with one another for the catch allotted to the non co-op, and the non co-op is closed when the allowable non co-op catch is attained. The reason for including a noncooperative portion of the fishery is to make the linkages to processors that may exist in cooperative systems voluntary. Harvesters may elect to not participate in a cooperative and deliver to any processor as long as the harvester remains in the non co-op fishery. Structuring the non co-op as an Olympic fishery is intentional. This manner of fishing has proven to be less beneficial to participants in a fishery economically, thereby providing an incentive for harvesters to remain in a cooperative and maintain the existing processor linkage This also increases the chances that processors can benefit from rationalization.

Another option assessed for switching processors is similar to one that occurs in the shoreside Pollock fishery, where vessels in a cooperative can switch processors by delivering the majority of their catch to a different processor the previous year. The method envisioned for doing this would be fishing the unlinked portion of catch history of other vessels in a cooperative through a lease agreement and delivering the majority of one's catch to another processor in that way. If that vessel delivers the majority of its catch to another processor through that mechanism, then a new linkage is formed the following year without ever participating in the noncooperative fishery. If cooperatives must be formed around processors, this would mean that the vessel would need to join a new cooperative when it switches processors. Requiring that a catcher vessel also switch cooperatives may make it somewhat difficult to switch processors by using this tool because it essentially relies on other catcher vessels agreeing to let that catcher vessel (and its associated catch history) leave the co-op. In the existing alternatives for whiting cooperatives, this processor-switching tool may be combined with an option that does not require co-ops to be formed around processors, and if this is the case, the outcome is one where the effect of a processor tie is substantially reduced, if not eliminated. If a single cooperative is formed for a sector, vessels can fish the catch history and associated linkages of other vessels in that cooperative and effectively switch processors simply by leasing another's catch history. Overall, this approach for switching processors would tend to decrease the amount of time harvesters spend in the noncooperative fishery, but could result in a much different relationship between catcher vessels and processors with catcher vessels assuming greater leverage in negotiations over profits and other matters.

The final tool intended to acknowledge the interest of motherships is a "declaration" procedure. This tool

[1] Provisions exist for breaking the linkage in subsequent years. The decision to break the linkage ultimately rests with the catcher vessel, meaning the processor cannot defend the linked catch history from other processors over the longer term. This condition violates one of the principal definitions of a property right and is one principal reason why the processor linkage is not a resource access privilege.

was ultimately adopted as the Council's FPA and is intended to provide for some certainty to the mothership on a short-term basis without raising some of the legal complexities that were raised by National Oceanic and Atmospheric Administration (NOAA) General Counsel (GC) over the linkage provision. The declaration process is described as a process requiring that, if a catcher vessel elects to participate in a cooperative, it must declare a mothership to which it will deliver in the coming season. The catcher vessel is then obligated to deliver to that mothership for that coming season, but can freely declare a different mothership in the subsequent season. This procedure avoids some of the penalty mechanisms that exist in a linkage provision if a catcher vessel switches motherships, but provides for some relative short-term certainty to assist the mothership with developing business plans for that coming year.

One tool proposed in the Pacific whiting cooperative alternatives that does not exist in the Bering Sea Pollock fishery is the "mutual agreement exception." In cases where a processor elects to not participate in the fishery, this tool allows processors and catcher vessels the ability to enter into a mutual agreement that allows a catcher vessel to deliver to another processor without permanently breaking the existing processor linkage. Upon the original processor's return to the fishery, the original linkage is reestablished. If such a mutual agreement exception did not exist and a processor did not participate in a fishery in a given year, it is possible that processor would permanently lose its linked catcher vessels. In the case of a declaration procedure, the mutual agreement exception also allows the catcher vessel and mothership to enter into an agreement that would allow the catcher vessel to deliver to a different mothership in that current year.

This mutual agreement exception mostly applies to a cooperative structure with a processor linkage (which is not part of the Council's FPA). This provision allows the processing sector the ability to increase or decrease the number of active processors in the fishery so that the amount of processing capital present in any one year is appropriate to the available harvest. If this provision did not exist, it is more likely that the amount of processing capital in the fishery would remain relatively constant even as the allowable catch varies, leading to years where excess processing capital exists in the fishery and cost inefficiencies are present. This would tend to occur because processors would risk losing their linked catcher vessels if they did not participate in the fishery, even if the allowable catch level was relatively low and may not justify the presence and activity of all qualifying processors in that year. This provision does not have quite the same effect in a cooperative system with a declaration procedure. Since a catcher vessel can freely declare different motherships from year to year, the mothership does not have the same risk of permanently losing catcher vessels if it elects not to participate in the fishery in a given year. Under a linkage provision, catcher vessels are penalized for switching motherships, making it difficult for a mothership that has left the fishery to regain deliveries from catcher vessels if it elects to return (unless there is a mutual agreement). Under a declaration process, it is easier for the processor to reacquire catcher vessels since those vessels can easily elect to move back to that original processor. However, a mutual agreement exception still appears to be a valid tool under a declaration procedure. Should a mothership not be able to participate in the fishery after the declaration procedure has taken place, that mothership has some say over which mothership its catcher vessels elect to deliver to, and this may have some advantages.

History on the Development of the Cooperative Alternative

The development of the noncatcher processor cooperative alternatives began with discussions among participants in the mothership fishery. Beginning in 2004, mothership catcher vessel participants, mothership processor participants, and their technical advisers engaged in over 100 hours of discussion and deliberation to develop a rationalization alternative for Council consideration that was palatable to participants in the mothership sector. The objectives of these deliberations were that the alternative:

- Recognize historical participation in the mothership sector,

- Ensure that rationalization benefits those that have participated in the mothership fishery (both harvesters and processors), and
- Strive to treat everyone fairly so that there are "no big winners and no big losers" (Paine 2007 personal communication).

These discussions began with deliberations over the structure of a possible IFQ-based fishery that could accommodate the existing participants in the mothership sector and bring that fishery successfully into a rationalization program. However, the possibility of developing an agreed upon IFQ-based alternative with "no big winners and no big losers" was quickly abandoned due in large part to the friction created over allocation issues and how much IFQ mothership catcher vessels and mothership processors would receive. Participants in the mothership fishery then turned to their experiences in the Bering Sea Pollock fishery and the cooperatives that were enacted in that fishery through the AFA. The cooperatives developed through that legislation were constructed with the goal that "both processors and harvesters benefit from rationalization" (Stevens and Gordon 1999 as cited in Matulich 2000). Participants in the mothership fishery felt that a harvest cooperative model could be successfully applied to the Pacific whiting fishery (with some notable differences) because the whiting fishery is, in many ways, operationally similar to the Bering Sea Pollock fishery, where cooperatives have been used successfully. Participants in the mothership sector also felt that a harvest cooperative model with processor linkage provisions could successfully accommodate existing participants in the fishery and ensure that all sides benefited from rationalization.

The mothership cooperative alternative developed by participants of the mothership fishery was intended to protect the interests of mothership processors and mothership catcher vessels. This was done by granting catcher vessels harvest privileges and linking those privileges to mothership processors. The proposed alternative was intended to be relatively inclusive, by considering the granting of permits to those that had participated in the mothership portion of the fishery after the separation of the two at-sea sectors (which occurred in 1997) and by considering the granting of catch history to catcher vessels with history since the introduction of limited entry (1994). This initial proposal was supported by the membership of United Catcher Boats (a trade association representing, at the time, 15 active catcher vessels in the fishery) and five of the six mothership entities operating in the fishery.

At the September 2006 Council meeting, representatives of the mothership sector presented their proposal for a harvest cooperative alternative in the mothership portion of the whiting fishery. The Council adopted the mothership sector cooperative proposal for analysis, officially moving the concept of a harvest cooperative alternative forward as one means of rationalizing portions of the limited entry trawl fishery.

In November 2006, the Trawl Individual Quota Committee (TIQC) discussed the newly added mothership cooperative alternative and the possibility of expanding the harvest cooperative model to the shoreside portion of the Pacific whiting fishery. The TIQC recommended modifications to the mothership cooperative alternative, including the consideration of additional harvest privilege qualification criteria, and an option to not have a mothership/catcher vessel linkage provision. Several of these suggested additions and modifications took into account the concerns of those mothership sector participants that did not fully support the original mothership sector proposal. The TIQC also recommended that the Council consider a cooperative alternative for the shoreside portion of the whiting fishery, based largely on the mothership cooperative alternative.

Following this meeting, members of the shoreside whiting industry discussed the structure of a shoreside whiting harvest cooperative, with the intention of developing an industry-preferred alternative. The shoreside whiting industry members consulted with the National Marine Fisheries Service (NMFS), members of the mothership whiting industry, and participants in the Bering Sea Pollock fishery.

At the March 2007 Council meeting, representatives of the shoreside whiting harvesting and processing industry presented a proposal for a shoreside whiting cooperative which included many similarities to the mothership sector alternative, but with differences in processor linkages and processor limited entry. These differences were based, in part, on the possibility that a shoreside processor limited entry program with shoreside processor linkages might not be allowable under the Magnuson-Stevens Fishery Conservation and Management Act (MSA). During Council discussion on the alternative, NOAA GC reaffirmed this. The Council voted to move all harvest cooperative alternatives forward for analysis.

At the November 2007 Council meeting, NOAA GC again confirmed that the processor licensing requirements and linkage elements of the shoreside cooperative alternative went beyond the authority of the MSA. Following this guidance, deliberation reverted to an IFQ-based model for rationalization of the shoreside whiting fishery, due in part to the notion that the lack of processor licensing and linkage provisions in a cooperative-based fishery could mean that processors would not benefit from rationalization. At this meeting, the Council also made several refinements to the options that comprised the mothership cooperative alternative. In particular, the option to not have a mothership linkage provision was discussed and the Council decided to drop that option from analysis because it was believed the lack of such a linkage meant processors would not benefit from rationalization.

At the June 2008 Council meeting, the Council adopted their preliminary preferred alternative, which included harvest cooperatives with processor linkages for the mothership sector and a shoreside whiting cooperative program with processor linkages (pending Congressional approval). This motion came about after much public testimony from the harvesting and processing sectors of the fishery on the potential benefit and drawback of rationalizing the fishery. The motion to adopt a cooperative program in the shoreside fishery appears to have been spurred by the idea that a harvest cooperative system with processor linkages may benefit both harvesters and processors while avoiding the friction created by a harvester and processor allocation issue found within an IFQ program. However, the Council also adopted an alternative that would manage the shoreside whiting fishery with IFQs if Congressional approval of a cooperative program with processor linkages does not occur.

Following the June Council meeting and the adoption of the Council's preliminary preferred alternative, additional analysis was done by Council staff, NMFS, and NOAA GC. As part of this effort, NOAA GC indicated that the processor linkage provisions of the mothership cooperative alternative raised "significant and complex legal issues that call into question whether it complies with antitrust laws, and therefore, whether it could be approved by the agency." Leading up to the November Council meeting, several members of the mothership sector met to discuss this issue and some members felt that a mothership "declaration" option may be a viable alternative to a mothership linkage if the linkage provision could not in fact be approved by NOAA. The declaration option would obligate a catcher vessel to a mothership of its choosing for a year. That declaration could be changed without penalty the following year. The purpose of the declaration option was to provide for some degree of certainty over business planning for the motherships engaged in the fishery. At the November Council meeting, several members of the mothership sector testified to the Council that they in fact supported the declaration option if the linkage provision could not be approved by the agency. The Council voted to establish a cooperative system for the mothership sector with a mothership declaration process rather than a mothership linkage.

Also at the November meeting, several members of the public and some Council members expressed their discomfort with pursuing the shoreside cooperative alternative with processor linkages if doing so would rely upon Congressional approval. Rather than potentially having no rationalization program in the event Congress did not approve such a program, many harvesters and processors in the shoreside whiting fishery agreed to support an IFQ program for that fishery. Many of these same industry participants (both harvesters and processors) reached agreement on how to divide an initial allocation of IFQ to harvesters and processors. This agreement established 80 percent of the initial allocation of IFQ to harvesters and 20

percent to processors. These participants, apparently representing the majority of interests in the shoreside whiting sector, jointly testified to the Council where they indicated their support of the 80/20 initial allocation split. The Council voted to establish an IFQ program for the shoreside whiting fishery with 80 percent of the initial allocation going to harvesters and 20 percent to processors.

Description of Approach for Components Analysis

The cooperative alternatives contain multiple elements and sub-options. This appendix is intended to address each of those elements and options that potentially make up the pieces of a cooperative-based fishery by including rationale and analysis of each of the elements of the alternative. The analysis for each option includes a description of related issues and whether those issues are related in such a way that the selection of one element necessitates the selection of another. This appendix also includes a description of rationale and policy issues that are associated with each of the options and elements of the alternatives. Policy issues may include legal or implementation issues that are associated with each of the elements. Rationale includes the reasons, or basis, for considering each of the elements. Finally, an analysis that describes the effect of each of the options and elements is included.

The analysis in this section draws heavily on several different sources. In addition to economic and social theory, these sources include two National Research Council publications (Sharing the Fish and Drama of the Commons), multiple documents published by the North Pacific Fishery Management Council (NPFMC) and the NMFS Alaska Region relevant to cooperative-based management, and proceedings of the Tenth Biennial Conference of the International Institute of Fisheries Economics and Trade.

B-1 Whiting Sector Management under Co-ops

In the cooperative alternatives, all catcher vessels have a choice of whether to participate in a co-op or opt-out (noncooperative) portion of the fishery. For catcher-processors, no formal co-op fishery would be established but rather a closed class would be established. In this case, a vessel could, at its option, decide not to participate in a co-op with other members of that fishery; however, doing so would mean the sector would default to an IFQ-based fishery with each permit in the sector receiving an equal initial allocation of quota shares.

The existing allocation of whiting between the shoreside whiting, mothership, and catcher-processor sectors remains under this alternative (42 percent, 24 percent, and 34 percent, respectively). Within each sector, this allowable catch is assigned each year to co-ops or to the non co-op portion of the fishery. Co-ops will then be responsible for monitoring and enforcing the catch of the organization and of co-op members, and NMFS will monitor the catch of each sector and in the non co-op fishery, as well as the overall catch by all three sectors. NMFS will make the following closures if limits are reached: close a co-op fishery if co-ops have collectively reached their limit, close the non co-op fishery if it reaches its limit, and/or close the combined co-op and non co-op fishery if that whiting sector reaches its limit.

Provisions may also address the catch of bycatch species (overfished species and nontarget species). The Council is considering whether or not to make bycatch limits applicable to the entire whiting fishery, individual whiting sectors, or to individual cooperatives and to which species bycatch limits will be developed. NMFS may close the whiting fishery, whiting sectors, or cooperatives, if a bycatch limit is reached.

B-1.1 Whiting Management

Under the co-op options for the mothership and shoreside sectors, catcher vessel permits will be endorsed for deliveries to these sectors and amounts of "catch history" (a nondivisible share of the allowable catch)

assigned to each catcher vessel permit based on past harvest in the fishery. Catcher-processor permits will be endorsed for participation in the catcher-processor sector.

The whiting catch history calculation for each mothership-endorsed catcher vessel permit [CV(MS)] and shoreside-endorsed catcher vessel permit [CV(SS)] will be assigned to a pool for the co-op in which the permit will participate or a pool for the mothership or shoreside non co-op fishery, respectively. Co-ops are responsible for monitoring and enforcing the catch limits of co-op members.

NMFS will monitor the catch in the non co-op fishery, the co-op fisheries, and the overall catch of all three sectors. NMFS will close the various segments of the at-sea fisheries when their catch limits are projected to be attained and close the overall at-sea fishery when the overall at-sea whiting allocation has actually been attained.

❖ Rationale and Policy Issues

Establishing a system of cooperatives is intended to rationalize the Pacific whiting fishery. Cooperatives create many of the same effects attributed to other types of rationalization programs, including slower paced fishing practices, consolidation of capital, and greater net economic benefits to participants in the fishery. In order for harvest cooperatives to achieve this outcome, several necessary ingredients need to exist, including a barrier to entry, an allocation of fish,[2] and the establishment of a catch sharing arrangement among cooperative members (either through voluntary or regulatory means). Another ingredient some argue is necessary is access to catch data by the members of the cooperative. This is necessary for self-enforcement, monitoring of the catch of each catcher vessel, and making sure that the agreements that the cooperative members have arrived at can be enforced by the cooperative institution.

Endorsements for the catcher-processor, mothership, and shoreside sectors are intended to stabilize participation in these sectors and act as a barrier to entry to these sectors. A barrier to entry is one necessary ingredient for cooperative formation. In the case of the shoreside and mothership sector alternatives, catch histories are established. Catch histories serve as a harvest privilege which grant the holder of that catch history a defensible resource access privilege so long as they become part of a cooperative. This element is included in the mothership and shoreside alternatives because it is widely believed that participants in those two sectors will not be able to arrive at a resource sharing arrangement on their own. Therefore, in order for cooperatives to be able to form, the resource sharing arrangement must be decided for them through a Council action. If a participant in the shoreside or mothership sector elects to participate in the noncooperative portion of the fishery, that catch history is not a defensible harvest privilege because other noncooperative participants may compete for the catch available in that fishery. The presence of a noncooperative fishery is intended to ensure that cooperative membership is voluntary. In a system with processor linkages, the noncooperative portion of the fishery is intended to act as an incentive to maintain those linkages (assuming that breaking or switching a linkage requires participation in the noncooperative fishery). Voluntary membership of cooperatives is necessary to insure that cooperative members are of a like mind and can operate together successfully. Furthermore, structuring the noncooperative fishery as an Olympic fishery is intended to act as a deterrent to catcher vessels that may be contemplating the departure from a cooperative and/or the breaking of a linkage to a processor. This deterrent is intended to stabilize relations between harvesters and processors and also stabilize cooperative membership and help foster longer term relationships among cooperative members. Cooperatives rely heavily on member relations; therefore, longer term relationships tend to help the operation and success of cooperatives.

[2] Options exist for which species sectors would be responsible for covering with catch history or IFQ. This issue is covered under Appendix A.1. The allocation of non-whiting species to various sectors of the trawl fishery will be established through the inter-sector allocation process.

Catch history designations, when combined with a "golden rule" provision, help solve resource sharing arrangements among participants in a cooperative-managed fishery. This combination solves resource sharing for fishery participants ahead of time and helps ensure that cooperative agreements do not suffer due to negotiations and potential disagreements over catch sharing.

Making cooperatives responsible for the monitoring and enforcing of catch limits of co-op members is intended to accomplish several goals. One rationale for requiring cooperatives to self monitor and enforce is that it reduces the administrative workload on management agencies. In addition to this, self-monitoring and self-enforcement allow cooperatives to engage in other types of self-management that may not be possible (or that may take much longer to implement) through a regulatory process. Self-monitoring and self-enforcement are necessary ingredients for cooperatives to implement fishing restrictions such as bycatch performance standards and area closures. Without self-monitoring and self-enforcement (and access to the data necessary to self-monitor and self-enforce), cooperatives would not be able to verify and enforce management goals of the cooperative and, by extension, may not be able to adequately meet the goals specified by the Council.

Having NMFS close appropriate portions of the fishery is intended to ensure that overall management levels are adhered to. This ensures that catch levels do not exceed acceptable biological catches (ABCs) and optimum yields (OYs) and that other fishery sectors are not impacted by higher-than-intended catch levels in sectors managed by cooperatives.

The consideration of factors in this subsection addresses several aspects of MSA and groundfish Fishery Management Plan (FMP) guidance. Specifically, factors discussed here are related to guidance, goals, and objectives related to conservation, net benefits, harvester and sector health, and small entities and new entrants. These factors are outlined more specifically in the next section, which serves as the analysis of this component.

	Related Category of Goals and Objectives									
Element of Cooperative Alternative	**Conservation**	**Net Benefits**	**Disruption**	**Excessive Shares**	**Fairness and Equity**	**Harvester and Processor Sector Health**	**Labor**	**Communities**	**Small Entities and New Entrants**	**General Public**
Divisibility of catch history and harvest cooperative stability	X	X				X			X	
Resource sharing and the golden rule	X	X				X				
Intra and Inter-cooperative management and responsibility	X	X				X				
Noncooperative fishery	X	X				X				

❖ Interlinked Elements

Golden rule provision. This provision assures catcher vessels in a cooperative that they have access to their catch history, but no more (unless a private arrangement is developed for sharing catch differently). This is necessary in order for resource sharing arrangements to be solved. The lack of such a provision may make it difficult for some cooperatives to form.

❖ Analysis

- Divisibility of Catch History and Harvest Cooperative Stability

Cooperative institutions rely on close-knit relationships for success. Divisible catch history assignments make it more likely that new participants will enter and leave the fishery, possibly making cooperative operations more difficult and less successful, or making participation in the noncooperative fishery more common than if relations were more stable. The reader is referred to Chapter 4 for more discussion of cooperative institutions and relationships in those institutions.

Enhanced cooperative stability may help foster fishery management and conservation for a variety of reasons. If a lack of cooperative stability results in more frequent participation in the noncooperative portion of the fishery (which acts similar to an Olympic fishery), fishery participants may behave in a less "rational" way, resulting in higher bycatch or other impacts that are not beneficial to management. Cooperative stability depends on a relatively stable set of participants, for the reasons described above and in Chapter 4. Since cooperative stability is closely tied to having a nondivisible catch history designation, the creation of such nondivisible catch history helps foster conditions that are consistent with MSA – 303A(c)(1)(C)(ii) MSA – 303A(c)(1)(A) and Amendment 20 Objectives 1 and 3.

In addition to conservation guidelines, the granting of nondivisible catch history to fishery participants appears to achieve net benefit and efficiency guidelines as well as guidelines referring to sector health. A fishery with a cooperative fishery structure that is relatively stable can be assumed to have a limited number of participants engaged in the noncooperative portion of the fishery. If participation in the noncooperative portion of the fishery is limited to a substantial degree, the behavior of participants in that portion of the fishery may continue to resemble the behavior of participants in a rationalized fishery. This is because, with a limited number of participants in the noncooperative fishery, they are not likely to feel as threatened, or in as much competition, with one another. Less participation in the noncooperative portion of the fishery equates to more participation in the cooperative portion of the fishery. The result of high degrees of cooperative membership and low participation in the noncooperative fishery are operations that are "rational" and such rational behavior results in fishing operations that are relatively cost efficient, creating a net economic benefit. Such net economic benefits, and the consideration of such benefits, are consistent with the groundfish FMP Objective 6, groundfish FMP Goal 2, and MSA National Standard 5. Such improvement in the cost efficiency of participants is also consistent with Amendment 20 Objective 2 and groundfish FMP Goal 2.

Nondivisible catch history designations may make it more difficult for new entrants to acquire permits. New entrants would be required to purchase the entire catch history associated with a permit which is likely to be relatively costly. If new entrants cannot acquire the capital necessary to purchase a permit with catch history, then they are constrained in their ability to become the owner/operator of a vessel in a cooperative fishery. However, other means of becoming a new entrant may be available. A cooperative system in a high volume, capital-intensive fishery (like Pacific whiting) may be more conducive to the creation of fishing corporations, where multiple individuals have an ownership stake in fishing and processing operations, rather than a smaller volume, less capital-intensive fishery where independent owner operators are more common. Under a corporation-like structure, new entrants may purchase an

ownership stake in a fishing company that is part of a cooperative-based fishery, work their way up the ranks in the business, and in this way become new entrants into the fishery.

- Resource Sharing and the "Golden Rule"

The amount of catch each vessel/permit in a cooperative can access may be the same as the catch history they bring to the cooperative, or it may be different if agreements are made among cooperative members for leasing catch history. In the absence of a leasing arrangement, the "Golden Rule" applies, where a vessel has access to the catch history associated with that permit even though catch history of vessels in a cooperative are pooled. The Golden Rule provision is intended to resolve resource-sharing arrangements if cooperative members cannot agree to sharing arrangements among themselves. If sharing arrangements are not resolved, participants may have trouble forming cooperative agreements, or (if an agreement is reached), a cooperative may destabilize as members continually deliberate over the sharing of catch. Therefore, allowing each vessel access to its own catch history in the absence of some other mutual arrangement helps foster stability among cooperatives and their members. In the absence of a Golden Rule, certain members could hold out against other cooperative members for a larger catch share than they historically harvested (sometimes referred to as the "last man standing" effect). In the worst-case scenario (where a group of individuals that cannot agree to catch-sharing arrangements), cooperative agreements can break down and members may move to the non co-op fishery.

Nondivisible catch history and the Golden Rule both help ensure the stability of cooperative organizations. This affects the economic status of cooperative participants and the successful management of fishery resources. In the most extreme example of a cooperative structure without catch history assignments, participants might not be able to form or maintain cooperative agreements. In this event, fishing behavior would likely become more competitive, with more participants in the non co-op fishery, and with higher rates of bycatch and less economically efficient fishing practices (for reasons explained above). As a result, the application of the Golden Rule to sectors of the fishery where catch history designations are necessary to form cooperative agreements is consistent with MSA – 303A(c)(1)(A), MSA – 303A(c)(1)(C)(ii), Amendment 20 Objective 1 & 3, MSA - 303A(c)(1)(B), groundfish FMP Goal 2, Amendment 20 Objective 2, and groundfish FMP Goal 2. However, it should be noted that catch history assignments and the Golden Rule provision are not always necessary for the successful operation of a harvest cooperative, as evidenced by the existing catcher-processor cooperative.

- Intra and Inter-Cooperative Management and Responsibility

One likely outcome of having NMFS close cooperatives or sectors when catch limits are projected to be reached (and therefore treat participants in those cooperatives or sectors equally) means that cooperatives will manage individual members and develop procedures that shut down members when they have harvested their allowed catch, mostly out of necessity. This reduces the burden on management agencies, but it also influences the agreements and governing contracts developed among cooperative members, simply because the cooperatives must be responsible for managing their members.

Since the cooperative is held responsible for a given amount of catch, more than the expected amount of catch by one member will reduce the catch available to other members. This fosters the development of rules for managing individual catches, and may include enforcement and penalty provisions that discourage behavior that may result in more catch than expected by a single cooperative member. Furthermore, because this arrangement requires cooperatives to self-monitor and self-manage, cooperatives and their members have a strong reason to require quality catch monitoring onboard vessels so that one vessel is not at a relative advantage over others, and so that trust regarding catch levels is maintained. The lack of quality monitoring will erode trust in members' catch levels, adversely impacting the cooperative.

Inter-cooperative agreements can be established for sharing bycatch or whiting harvest opportunities across cooperatives. Inter-cooperative agreements can be constructed to transfer catch history of whiting if one cooperative finds that it will not catch the rest of its available whiting and another cooperative has an interest in doing so. Inter-cooperative transfers of bycatch can also occur if one cooperative finds it needs more bycatch than another. The result of inter-cooperative bycatch agreements may lead to more "risk sharing" of bycatch species across fishery participants and greater utilization of available whiting. Inter-cooperative agreements can also be used by cooperatives to cover catch deficits if one cooperative has harvested more than its available catch history and another cooperative has catch history available. If an inter-cooperative agreement is formed between two cooperatives, NMFS will monitor the two cooperatives as one and close both cooperatives when the collective catch limit has been reached.

- Noncooperative Fishery

The presence of a noncooperative fishery serves several roles. If a cooperative fishery is complimented with a linkage provision, a noncooperative fishery serves as a way for catcher vessels to switch processors, while creating incentives for them to remain linked to their obligated processor. In order to switch processors, it may be necessary for catcher vessels to participate in the noncooperative fishery, which is expected to be less economically beneficial to participants for the reasons described above. Because of this, there is a strong incentive for catcher vessels to remain in the cooperative fishery, which entails retaining the existing processor linkage. This protects the interests of processors because it provides them with some certainty that catcher vessels and their deliveries will remain linked with their processing operations. This allows processors to engage in behavior that resembles a form of processor sector rationalization, leading to more profitability from processing activities.

Requiring that catcher vessels fish in the noncooperative fishery before switching motherships will mean that catcher vessels will participate in a year (or more) of relatively economically inefficient production in order to do so. Harvesters may still generate revenue in the noncooperative fishery, but it is possible that they may not. In any case, the net revenue generated by participants in the noncooperative fishery is expected to be less than the net revenue generated by the cooperative fisheries.

The fact that the noncooperative portion of the fishery is structured as an Olympic fishery means that noncooperative fishery participants are likely to behave less "rationally" than they would in the cooperative fishery. Theory suggests that participants in the noncooperative fishery would engage in a "race" for available catch. As a result, economic performance would deteriorate, bycatch would increase, and management performance of the fishery would suffer. In order to validate or invalidate this theory, it is useful to examine the operation of catcher vessels and processors in the existing fishery, which operates as a sector-wide noncooperative fishery. In the current fishery, motherships are able to influence the behavior of catcher vessels that deliver to that mothership. It is possible that shoreside processors also influence the behavior of catcher vessels delivering to them, but it may be to a lesser degree. It is not unreasonable to expect this influence to temper the behavior of a catcher vessel in a noncooperative mode and result in greater economic and bycatch performance in the noncooperative fishery than may be expected based on theory.

When considering the operations of catcher vessels and processors in a cooperatively-managed fishery with processor ties, the effect of the processor tie will tend to influence the operations of a catcher vessel even if a catcher vessel is in a noncooperative mode. This is because, during this noncooperative mode, catcher vessels and processors attempt to establish new linkages. In order to establish a new linkage, the noncooperative catcher vessel must deliver the majority of its catch to a new processor in the year it participates in the noncooperative mode. To do this, the catcher vessel will need to coordinate with the new processor and be folded into the processor rotation with other catcher vessels delivering to that processor. This tempers the speed and timing at which that catcher vessel harvests fish, translating into a

more modest amount of effort exerted on the part of the catcher vessel and a more rational pace of fishing than might theoretically be expected in a noncooperative mode.

Differences exist between the mothership and shoreside sectors of the whiting fishery. In general, more coordination occurs between motherships and mothership catcher vessels than between shoreside processors and shoreside processing catcher vessels. In the mothership sector, catcher vessels must follow a mothership operation in order to make routine deliveries to that mothership and to coordinate the transfer of codends (codends are often owned by the mothership, while shoreside processors do not provide codends to harvesters). The mothership tries to optimize the economics of harvesting and processing operations, including measures to help ensure that catcher vessels linked to the mothership do not encounter bycatch problems that can prematurely shut down fishing and processing activity (especially if the catcher vessels linked to that mothership operation are in the same cooperative). By default, the noncooperative catcher vessel will take on many of the same behaviors as the cooperative catcher vessels that deliver to that same mothership because it fishes the same general area and delivers in a rotation with those catcher vessels operating in the cooperative mode, and in this way the "race for fish" behavior expected of that noncooperative vessel will be tempered.

The shoreside sector appears to be slightly different in that harvesters operate more independently of shoreside processors, though some coordination still occurs. While this information is largely anecdotal, several factors support this notion, including the fact that catcher vessels in the shoreside sector fish independently of the shoreside processor (provided that they fish within close enough proximity to make deliveries). Industry members have indicated that successful shoreside catcher vessels can leap another shoreside vessel that is in the same rotation. This means that participants in the noncooperative portion of the mothership fishery may have more measured and paced fishing practices than shoreside catcher vessels in a noncooperative mode. However, catcher vessels in both sectors may have their pace of fishing tempered to some degree by coordination with the processor.

Occurrences of catcher vessel participation in the noncooperative fishery are expected to be relatively infrequent in an appropriately designed cooperative fishery. However, information suggests there may be more occurrences of shoreside vessels participating in a noncooperative portion of the fishery than mothership catcher vessels. Supporting information is illustrated in the following tables. These tables show an ad-hoc vessel identifier and the associated processing company where that vessel delivered from 2004 to 2006. It is apparent that catcher vessels in the shoreside sector deliver to more processing entities than catcher vessels in the mothership sector. This may reflect the motivation catcher vessels in each sector have for switching processors and, by extension, participating in the noncooperative fishery. If this shows motivation for switching processors, then there may be more frequent participation of shoreside whiting vessels in the noncooperative fishery compared to catcher vessels in the mothership portion of the whiting fishery. Therefore, the performance of the shoreside sector would be less than that for the mothership sector, if both are managed with harvest cooperatives. This may be especially true when considering the influence processors have over catcher vessel activity in those sectors, and the effect this influence has on fishing behavior.

The presence of a noncooperative portion of the fishery also serves another important purpose. While a sector of the fishery may be managed with a cooperative structure, it is important that the formation of cooperatives (and the membership of those cooperatives) be voluntary. Voluntary cooperative membership helps to ensure that those forming a cooperative are of a like mind and have similar enough objectives that the cooperative will be successful. In the event that a cooperative member develops goals which are not conducive or agreeable to other cooperative members, that individual can leave the cooperative and fish in the noncooperative mode. This helps to protect the stability and make-up of the cooperative over time and helps ensure that the activities of the cooperative do not become disrupted due to disagreements among members.

B-1.2 Annual Whiting Rollovers

Whiting Rollover Option 1 (Preferred Alternative): There will not be a rollover of unused whiting from one whiting sector to another.

Whiting Rollover Option 2: Each year, rollovers to other sectors may occur if sector participants are surveyed by NMFS and no participants intend to harvest remaining sector allocations in that year. Current provisions for NMFS to reallocate unused sector allocations of whiting (from sectors no longer active in the fishery) to other sectors still active in the fishery will be maintained (see 50CFR660.323(c)—Reapportionments).

❖ Interlinked Elements

Bycatch limits. The interaction of bycatch limit management and a rollover provision may prove controversial if a sector is closed because of attainment of bycatch and has not harvested its full whiting allocation. That sector may plan to petition the Council for an increase in the bycatch limit at a later date, and if so, consideration would need to be given regarding the time at which a rollover of that sector's whiting to another should occur.

❖ Rationale and Policy Issues

A rollover mechanism is intended to facilitate the attainment of the Pacific whiting OY if one or more sector(s) does not intend to harvest the full allocation of Pacific whiting. If a rollover mechanism is not established, harvestable amounts of the whiting OY are likely to be foregone, resulting in less revenue than would otherwise be the case.

The consideration of a rollover mechanism is related to MSA and groundfish FMP guidance that are related to net benefits, harvester and processor sector health, and labor. The rationale for considering this provision is largely economic, because rollover allows greater economic activity than would otherwise occur. This ties into harvester and processor sector health, because it stimulates economic activity and may be expected to facilitate a healthier economic status of harvesters and processors. Labor is affected by the same reasons.

	Related Category of Goals and Objectives									
Element of Cooperative Alternative	**Conservation**	**Net Benefits**	**Disruption**	**Excessive Shares**	**Fairness and Equity**	**Harvester and Processor Sector Health**	**Labor**	**Communities**	**Small Entities and New Entrants**	**General Public**
Roll over		X				X	X			

❖ Analysis

A rollover provision provides a mechanism for the Pacific whiting fishery OY to be fully taken if one or more directed whiting sectors does not intend to harvest their full allocation. Rolling over a sector's allocation to another sector grants access to harvestable surplus that otherwise may be foregone. Under status quo conditions, this action occurs if NMFS determines that one sector does not intend to harvest their full allocation. Upon such a determination, NMFS reapportions the unused amount of whiting to a sector that is still active in the fishery. This action has occurred several times in recent years. In a cooperative program, the rollover of one sector's whiting to another will likely require NMFS to calculate the available catch that is to be allocated to each cooperative in the sector that is the recipient of the rollover. Presumably, this will be done on a pro-rata basis. This is an additional administrative step above that which occurs under status quo.

If bycatch is managed at the sector, a sector may close due to bycatch limit attainment but still have whiting available. In this case, a sector may petition the Council for an increase in the bycatch limit in order to reopen the fishery if doing so is an option. Through the rollover provision, that sector's whiting may be rolled over to another sector before that sector can petition the Council for an inseason increase to the bycatch limit. Therefore, if a rollover mechanism is adopted and a sector is closed because of attainment of a bycatch limit, the possibility of an inseason increase to the bycatch limit may need to be considered before rolling the closed sector's whiting to another sector.

Not having a rollover provision from one sector to another is a change from status quo. Not allowing a rollover may mean that the available harvest is not realized in some years, potentially reducing economic activity. However, having a rollover may allow some entities that participate in more than one sector the opportunity of consolidating operations into a single sector, creating the opportunity of working around the sector divisions that are established in regulation. This has been described as a type of "loophole" that is created when the fisheries are rationalized and a rollover occurs. It may be possible for an entity with catch history in one sector to not fish that catch history, declare that they no longer wish to participate in that sector, and have the catch remaining in that sector roll over to another. In the other sector, that entity could then harvest the fish they did not harvest in the first sector, effectively consolidating operations from more than one sector onto the operations occurring in a single sector.

As discussed above, bycatch management is related to a carryover provision. It is not clear how a carryover provision would work if a sector is closed upon attainment of bycatch but wants to increase its bycatch limit at a later date. If bycatch is managed at the sector level, it is possible that a sector may be shut down upon bycatch limit attainment. However, if a sector intends to lobby for an increase in the bycatch limit, it is not clear when NMFS would roll the unharvested whiting over to another sector. If bycatch limits are set at the fishery-wide level, this concern does not exist.

B-1.3 Bycatch Species Management

Final Preferred Alternative

Under the Council's FPA, the at-sea whiting fishery will be managed under bycatch limits (hard caps) for widow, canary, Pacific Ocean perch (POP), and darkblotched rockfish. The Endangered Species Act (ESA)-listed salmon bycatch management measures—that is, the 11,000 Chinook threshold, 0.05 rate threshold, and triggered 100 fathom closure—will also continue to be in place. The goal of bycatch management is to control the rate and amounts of rockfish and salmon bycatch to ensure each sector is provided an opportunity to harvest its whiting allocation.

The anticipated catch of other species which are incidentally caught in at-sea activity, such as Pacific halibut, will be set aside to accommodate incidental catch in the at-sea fishery. No management measures are associated with these set asides. These set asides are established to accommodate incidental catch amounts in the at-sea fishery so that overall management targets are not exceeded.

Set asides are established instead of bycatch caps for some species because incidental catch volumes are small. The benefit to management from establishing bycatch caps on infrequently encountered species would tend to be small in these cases, but the implications to fishery participants could be large, as doing so may constrain fishery activity.

B-1.3.1 Bycatch Allocation Subdivision

Subdivision Option A (No Subdivision): Do not subdivide bycatch species.

Subdivision Option B (Subdivide by Sector): Subdivide bycatch species allocation among each of the whiting sectors (sector allocations will be determined in the intersector allocation process).

Subdivision Option C (Subdivide by Sector and Co-op/Non Co-op Fisheries): Subdivide bycatch species allocation among each of the whiting sectors, and, within the sectors, subdivide between the co-op fishery and non co-op fishery. (Subdivision for the non co-op fishery does not apply to the catcher-processor co-op program.)

Subdivision Option D (Subdivide by Sector, Co-op/Non Co-op Fisheries, and Among Co-ops): Same as C, but also subdivide bycatch among the co-ops.

Subdivision Option E (Preferred Alternative): Same as Option D but also specify that only those species with hard caps will be subdivided for bycatch management and that bycatch will be allocated to each permit and co-op pro rata in proportion to its whiting allocation. The mothership sector's bycatch allocation will be divided between its co-op and non co-op fishery, based on the allocations made to the permits participating in each portion of the fishery.

B-1.3.2 Bycatch Management

Language for Final Preferred Alternative

All sectors and co-ops will close based on projected attainment of the at-sea whiting fishery bycatch cap for any one species. The mothership co-op fishery, non co-op fishery, and catcher-processor fishery will each be closed based on projected attainment of their individual allocation. Additionally, each co-op will cease fishing when its bycatch allocation is reached.

The Council may also use area closures (seasonal or year-round) to manage overfished stocks in the co-op and non co-op fisheries. The area closures may be the same or different for different species. Area closures may be year-round, seasonal, or triggered automatically by the attainment of certain levels of catch.

Unused bycatch may be rolled over from one sector to another if the sector's full allocation of whiting has been harvested or participants in the sector do not intend to harvest the remaining sector allocation.

*The language from the Council's **final preferred alternative** is based on its selection from the options below with the following modifications:*

- *All segments of the at-sea fishery, except the individual co-ops, would close based on projected attainment of their bycatch caps. The individual co-ops would close based on actual attainment of their bycatch caps or the projected attainment of the fishery or sector bycatch caps, whichever comes first.*
- *The references to "seasonal releases" are eliminated.*

Options and Language Considered

All sectors and co-ops will close as soon as the whiting fishery bycatch cap is reached for one species. The Council may use seasonal releases of allocations and area closures (seasonal or year-round) to manage overfished stocks in the co-op and non co-op fisheries. The seasonal releases and area closures may be the same or different for different species. Area closures may be year-round, seasonal, or triggered automatically by the attainment of certain levels of catch.[3]

For Section B-1.3.1, Subdivision Option A (No Bycatch Subdivision): If bycatch species are not allocated among the sectors, then:

Bycatch Management Option 1: Initially, the Council will not use seasonal releases and a controlled pace may be established if the sectors choose to work together cooperatively, potentially forming an inter-sector/inter-co-op cooperative.

[3] The Council asked for analysis of "seasonal releases" and area management at the sector, individual, and co-op levels (if there is an inter-co-op agreement).

Bycatch Management Option 2: There will be seasonal releases of bycatch allocation. At the outset, it is envisioned that the seasonal approach will be used to manage widow rockfish bycatch. For canary rockfish and darkblotched rockfish, status quo management will be maintained (i.e., no sector allocation and no seasonal apportionment).

A seasonal release bycatch management program will be implemented through regulation.[4]

In practice, seasonal releases protect the next sector entering the fishery. For example, a May 15-June 15 release will be used by the catcher-processors and motherships, but it protects the shoreside fishery; the June 15-September release will be used by shoreside and whatever catcher-processors and motherships are still fishing whiting, and to protect a fall at-sea season after September 15; the final release in September will again be shared by the catcher-processors and motherships, assuming shoreside is done fishing.

For example:

1. Status quo for canary and darkblotched rockfish (i.e., no seasonal or sector allocation).
2. May 1-June 15: 40 percent of widow hard cap released.
3. June 15-August 31: An additional 45 percent of widow hard cap released.
4. September 1-December 31: Final 15 percent of widow hard cap released.
5. Once a seasonal release of widow rockfish is reached, the whiting fishery is closed to all three sectors for that period. The fishery reopens to all three sectors upon release of the next seasonal release of widow rockfish.
6. Unused amounts from one seasonal release rollover into subsequent release periods.

(Note: percentages are for illustration purposes only, actual release percentages will be developed through the Council process).

For Section B-1.3.1, Subdivision Options B, C, D, and E (Bycatch Subdivision among Trawl Sectors):

Rollover Option 1: If each sector has its own allocation of bycatch, unused bycatch may be rolled over from one sector to another if the sector's full allocation of whiting has been harvested or participants in the sector do not intend to harvest the remaining sector allocation.

Rollover Option 2: Rollovers are not allowed.

For Section B-1.3.1, Subdivision Options C, D, and E (Bycatch Subdivision among the Co-op and Non co-op Fisheries)[5]: A sector's bycatch allocation will be divided between the co-op and non co-op fishery of the sector, in proportion to the whiting allocated to each fishery. The co-op fishery will close based on attainment of its allocation.

Option 1: For the non co-op fishery, there will be a bycatch buffer. When only the buffer remains, the fishery would close temporarily while a determination is made as to a possible reopening. If the fishery is reopened, it will close based on attainment of its allocation. The buffer amounts considered will be:

Sub-option i: 20 percent
Sub-option ii: 10 percent
Sub-option iii: 5 percent

---

[4] For reference, a similar program is used to manage halibut bycatch in NPFMC-managed flatfish and Pacific cod fisheries, see 50CFR679.21(d).

[5] In the Council's final action, the following provision was eliminated from this location and worked into Section B.1.3.1 and the opening paragraph of this section.

For Section B-1.3.1, Subdivision Option D and E (Bycatch Subdivision among Co-ops): Bycatch will be allocated to each co-op pro rata in proportion to its whiting allocation. Each co-op will cease fishing when its bycatch allocation is reached.

Option 2: For the non co-op fishery, there will not be a buffer. The fishery will close based on projected attainment of its allocation.

In the Council's final action, the following provision was eliminated from this location and worked into Section B.1.3.1 and the opening paragraph of this section.

For Section B-1.3.1, Subdivision Option D and E (Bycatch Subdivision among Co-ops):

> *Bycatch will be allocated to each co-op pro rata in proportion to its whiting allocation. Each co-op will cease fishing when its bycatch allocation is reached.*

Rollover. See previous.

❖ Rationale and Policy Issues

Bycatch limits in a cooperative program are put in place as a catch management tool in order to prevent exceedance of ABCs and OYs, and also to prevent harm to other fishery sectors that may be impacted by higher than expected catch amounts of bycatch species. The appropriate level of bycatch management is a trade-off between the appropriate level of individual accountability, and the appropriate level of risk sharing across fishery participants. For stocks with low OYs and highly variable and uncertain catch events, the risk posed to fishery participants and their fellow cooperative members may be quite high if bycatch is managed at the cooperative level and there is a potential for relatively few tows to catch the full bycatch limit of that cooperative. However, the spreading of bycatch management across a relatively wide enough number of participants may mean that those participants cannot agree on bycatch management conditions and successfully manage that bycatch collectively. Therefore, the appropriate balance is a mix of risk spreading and individual accountability.

A seasonal release of bycatch acts similarly to a sector-specific allocation to each of the whiting sectors, but with more flexibility, and with less risk to individual harvesters. If a common bycatch limit is specified and a bycatch limit is reached (and the fishery is closed) all three sectors can again prosecute the fishery after the subsequent release. This seasonal release acts like a sector allocation because each fishery operates at different times of the year. Depending on how bycatch is released, it may play more into the hands of some sectors during specific times of the year and less into the hands of another sector during that same time period.

Area management of bycatch is intended to minimize the encounters of bycatch species through a regulatory mechanism which would close areas where bycatch is relatively high. Closing areas where bycatch is relatively high is intended to reduce the risk of encounters of overfished species.

A bycatch rollover gives other sectors access to bycatch that may not be necessary to the first sector. This provides increased certainty to the sectors receiving the bycatch that they will not be closed due to attainment of a bycatch limit and increases the chance that the whiting OY will be attained.

A noncooperative fishery bycatch buffer is intended to serve as a risk-mitigating factor that protects cooperative fishery participants from the actions of noncooperative fishery participants. It is intended to increase the certainty that the noncooperative portion of the fishery will stay within its assigned catch and not inadvertently impact other cooperatives or other fishery sectors.

Management of bycatch in a cooperative fishery meets conservation goals because it restricts the harvest of a nontarget species and provides some assurance that management targets will not be exceeded. This

helps rebuild overfished species, promotes conservation and management, and reduces bycatch (compared to no bycatch management). As a result, bycatch management in a cooperative program is consistent with MSA-303A(c)(1)(A), MSA-303A(c)(1)(c)(ii), and Amendment 20 Objectives 1 and 3.

The type of bycatch management can have an effect on the operations of a sector, the economic status and operation of that sector, and the net benefits associated with engaging in fishing operations. In particular, if bycatch is managed across the three whiting sectors, it is possible that a race for fish would ensue because of the common bycatch limit (often described as a "race for bycatch"). Such behavior is contrary to goals of capacity reduction and efficiency. However, it is not necessarily the case that a common bycatch limit would lead to such behavior, although it is possible. A common bycatch limit has the effect of spreading the risk of unexpected bycatch events across a wider number of participants, thus relating bycatch management to equity concerns contained in the MSA.

❖ Analysis

- Bycatch Management and Bycatch Subdivision

As shown above, bycatch limits can be imposed in several ways, including a common bycatch limit for the entire directed whiting fishery, a specific limit for each sector. a specific limit for each sector where each sector's limit is divided between the cooperatives and the noncooperative portion of the sector, and a limit applied to each cooperative and to the noncooperative portion of the fishery.

Bycatch limits in the whiting fishery introduce several types of risk. As noted above, bycatch limits (and the successful management thereof) require that harvesters agree to management conditions. As bycatch limits are spread across more participants, the possibility that those participants can agree decreases. In the worst case scenario, harvesters will not be able to agree to bycatch management terms. Because attainment of a bycatch limit means closure of the fishery, sector, or cooperative (depending on the level of management), harvesters may fear preemption of their target opportunities if a bycatch limit is attained. If they cannot successfully agree to bycatch management conditions, they are therefore liable to begin engaging in Olympic-style behavior, potentially eroding the gains typically attributed to rationalization. Such behavior may result in faster-paced harvest activity, more capital used in the fishery, and lower quality products, among others.

Bycatch limit management at a smaller, cooperative scale may mean that harvesters are more likely to agree to bycatch management terms. However, it also increases individual risk and makes it less likely that a large and unexpected catch event can be absorbed by the collective. This may lead to a bycatch-induced closure that would be limited to the cooperative (rather than the entire fishery) but the impact on the individual harvester would be greater than if bycatch management were spread across a wider collective because it would be more likely to eliminate the future harvest opportunities for that individual.

One factor that may mitigate the risk to individual harvesters if bycatch is managed at the cooperative level is the presence of an intercooperative agreement to manage bycatch. An intercooperative agreement can allow individual cooperatives to develop relationships between one another for successfully managing bycatch species and sharing the amount of bycatch between them, thus spreading the risk across a wider array of participants. Since intercooperative agreements rely on each cooperative agreeing to enter into that relationship, the development of such relationships is likely to rely heavily on each individual cooperative having a successful management plan for their own cooperative members. This provides greater certainty to the other cooperative that management is likely to be successful and, therefore, mutually beneficial.

The following table (also found in Chapter 4 of the Environmental Impact Statement [EIS]) illustrates the type and level of risk associated with each level of bycatch management starting with the lowest level (IFQs) and ending at the highest level (fishery wide bycatch limits). This table illustrates two forms of risk faced by harvesters when dealing with bycatch species, particularly for overfished rockfish where relatively large and unexpected tows can occur. It shows that if bycatch is managed at a small level, the implication of an unexpected catch event spilling over and affecting other harvesters is relatively small compared to a case where bycatch is managed at a relatively large level. Inversely, if bycatch is managed at a low level, the burden faced by individuals from an unexpected catch event is large relative to a case where bycatch is managed at a larger level.

Level of Bycatch Management	**Collective Risk** **(risk of a race for bycatch)**	**Individual Risk** **(risk posed to individuals from catch uncertainty and individual accountability)**
IFQ	Low	High
Co-op level	Med-Low	Med-High[6]
Sector Level	Med-High	Med-Low
Fishery Level	High	Low

- Seasonal Releases and Area Management

Seasonal releases of bycatch can have a similar effect on sector-specific allocations of bycatch. The difference, however, is in the amount of risk spread across fishery participants. In a seasonal release strategy, risk is spread across a wider number of participants, while in a sector-specific allocation, risk is spread across fewer participants.

[6] If inter-cooperative agreements are formed for managing bycatch across co-ops, a co-op level allocation of bycatch species may have a low level of risk posed by individual accountability and catch uncertainty, while also having a low level of risk that a race for bycatch could develop. This is because a co-op level allocation of bycatch forces the cooperative to internalize bycatch management and this would be evident in the cooperative agreement signed by harvesters in that cooperative. Such internalization of bycatch management in the co-ops would tend to foster the development of high levels of individual accountability for bycatch by members. Allowing inter-cooperative agreements to form would allow cooperatives to spread the risk of catch uncertainty across cooperatives (thus reducing individual risk) if those cooperatives can agree to terms.

Seasonal releases are one method of protecting one sector from another (since the sectors operate at different times) and minimizing the risk of bycatch in one sector affecting opportunities in another sector. If the amount of bycatch allocated to each season is well structured, such releases may allow successful prosecution of whiting activity while ensuring that the sector that starts later in the year is not pre-empted by the attainment of a bycatch limit from sectors operating earlier in the year. However, a seasonal release tool will almost certainly have an allocative effect. Depending on how the seasonal release is structured, it may benefit some sectors more than others. For example, if a substantial portion of widow rockfish is released in May and then released again in September, the shoreside sector may be at a relative disadvantage. This is because the at-sea sectors could benefit from the first release before the shoreside sector opens, and would then benefit from the September release when the shoreside sector begins losing access to the whiting resource. The following figure illustrates the average catch of widow rockfish by month and sector in 2006 and 2007.

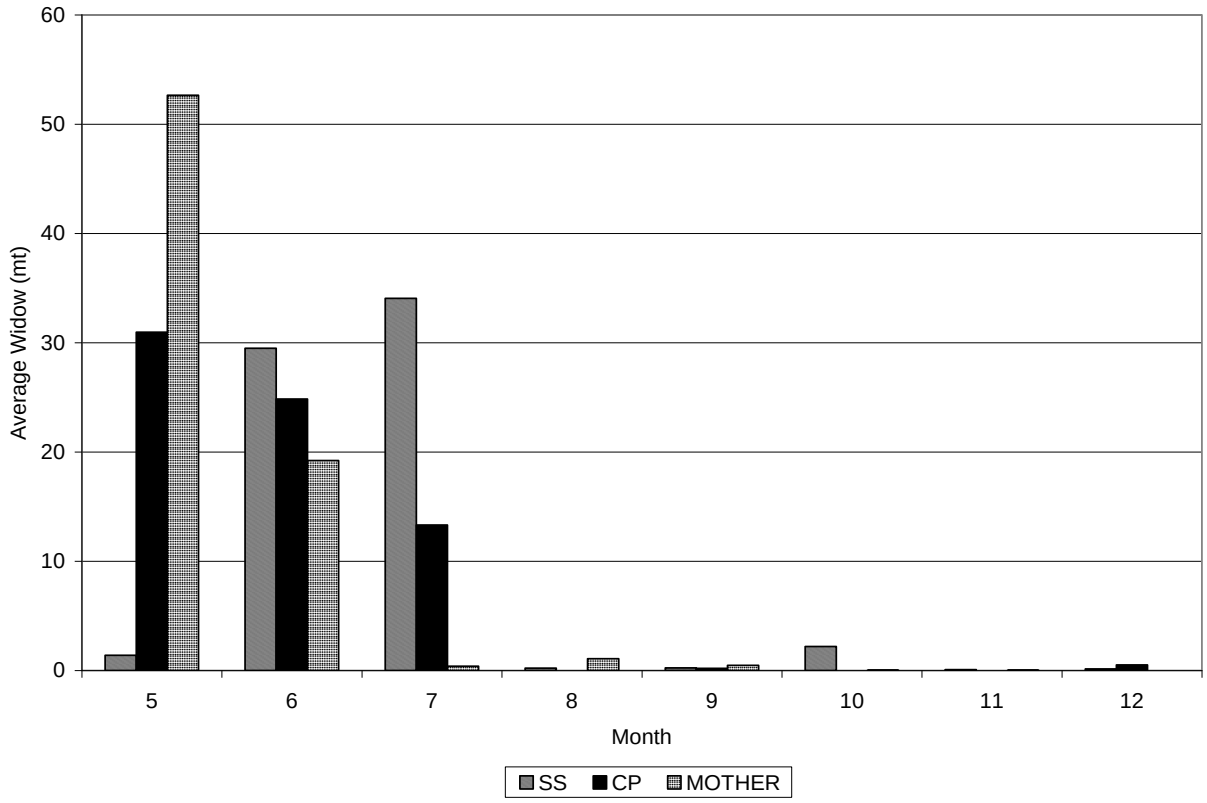

Figure B-1. Average monthly catch of widow rockfish by month and sector (2006 and 2007).

Seasonal releases of bycatch may make it more difficult for harvesters to change the timing of their fishing activity. If, for example, 50 percent of the widow rockfish is allocated between May and June based on past fishing practices, that allocation may preserve fishing opportunity based on past practice. If one sector wants to spend more time fishing in the fall months, however, that widow allocation may make it difficult for harvesters to fish later in the year (because there would presumably be less widow later in the year than would otherwise be the case). In contrast, if each sector or cooperative has its own bycatch limit, harvesters can time their activity for when they find it most appropriate, and use the allocated bycatch during that time. In this case, changing harvest timing may be relatively simple compared to having seasonal releases of bycatch.

One benefit of the seasonal release strategy is that (assuming it is applied to a fishery-wide bycatch limit), the seasonal release strategy will continue to minimize the risks faced by individuals (as would be the

case under a fishery level bycatch allocation) while preserving fishing opportunity throughout various times of the year. For example, if a fishery-wide bycatch limit is used and harvesters cannot agree to a bycatch management plan, then a seasonal release strategy would continue to protect the shoreside whiting sector from the at-sea sectors (which start earlier). In addition, harvesters who encounter large and unexpected catch events would face a relatively low burden for doing so because the covering of that catch event would be spread out across the multiple participants in the fishery instead of being concentrated on that one harvester or that one harvester's cooperative.

Area management is a tool that can be described as one used to reduce the risk of unexpected tows of bycatch species. It may be reasonable to expect that a successful bycatch management plan from a cooperative would include provisions for area management. Therefore, establishing area management through regulation and implementation by the agency would be used to reduce risk if bycatch limits are set at the fishery level, or to mitigate the risk that a harvester in the noncooperative portion of the fishery will unexpectedly encounter a large amount of a bycatch species. Area management may be necessary if bycatch is managed at the fishery level because individual cooperatives would not be internalizing management of their own bycatch and would still be sharing some of the burden with other cooperatives. If cooperatives are internalizing the management of their own bycatch, bycatch management provisions in the cooperative agreements are likely to be relatively more robust. As cooperatives become less responsible for their own bycatch, it is not unreasonable to expect that the cooperative agreements, and the bycatch management plans contained therein, would be less robust, possibly making the implementation of area management restrictions through regulation more necessary.

- Bycatch Buffers

Bycatch buffers can be used to protect co-op fishery participants from unexpectedly large bycatch events in the non co-op fishery. If buffers do not exist and a noncooperative fishery exceeds the amount of bycatch allocated to it, then that overage would need to come from other fishery participants. If bycatch is managed at the co-op and non co-op level with aggregate limits on each sector, then an overage in a non co-op fishery can restrict opportunities for co-ops in that same sector. If the non co-op fishery has a buffer, then that buffer would hedge against the possibility of a bycatch overage restricting the fishing opportunities for co-op fishery participants.

The appropriate buffer size is likely to vary by species. Empirical evidence from the fishery under status quo conditions provides one example of catch uncertainty and the magnitude of buffers that may be necessary for a non co-op fishery. In other words, a non co-op fishery may act similarly to the existing fishery. Based on evidence from past recent years, canary rockfish and darkblotched rockfish appear to be subject to less variability or less potential for "disaster tows." However, in one of the last four years, a large tow of canary rockfish occurred which jeopardized the continued operations of all three whiting sectors. In this event, there is not likely to be a buffer large enough to matter. However, ignoring that particular event, other data suggests that canary rockfish encounters are less variable and therefore less likely to need a large buffer. Darkblotched rockfish appear to exhibit a similar pattern with less variable catch events. Widow rockfish is different from these two species because there is substantial variability in catch events. Some tows encounter relatively little, while others may encounter several dozen metric tons (mt). In the case of widow rockfish, a large buffer on the non co-op fishery may be necessary to minimize the risk to the co-op fisheries posed by the presence of a non co-op fishery. In any event, there does not appear to be a "one size fits all" buffer and, therefore, if buffers are used, a range of available buffer sizes to be used on a case by case basis may be the best approach.

- Species Covered

The set of species for which vessels in the fishery will be accountable for is a subset of all groundfish in the Council's FMP. The rationale for including a subset of species, rather than all species, is that many species are infrequently caught in the whiting fishery and holding vessels accountable for those species may be unnecessarily constraining to harvest activity through a variety of mechanisms. One possibility is that harvesters in the at-sea fishery encounter conditions similar to the thin market conditions described in Chapter 4 of the EIS. Another possibility is simply that the uncertainty of possible catch events of these infrequently encountered species induces fishing behavior that resembles hording to hedge against the risk of that happening. Yet another possibility is that fishing behavior occurs similarly to what happened in the 2007 whiting fishery, where the avoidance of one species resulted in an increase in the catch of another bycatch species. Played enough times, the sector inadvertently reaches the limit of one species and is shut down prior to attaining the whiting allocation. While such stringent management may be appropriate for some species (like overfished stocks and species of which the whiting fishery takes a substantial amount), it is not necessary for all species. The outcome of holding the fishery accountable for species of which it does not catch noteworthy amounts is one where the economic implications to the fishery can be quite large, but the benefit to management or conservation is small to negligible. Therefore, rather than holding vessels accountable for infrequently encountered species, a portion of the allowable harvest is simply set aside to accommodate incidental catch volumes for those infrequently encountered species.

Table B-3 shows the incidental harvest of several species in the at-sea fishery over a handful of years. It is most informative to examine these species relative to the size of the OY or allocation. Species which are not shown in the table are caught in even smaller volumes, so were excluded.

Table B-3. Incidental harvest of selected groundfish species, 2003-07 (mt).

At Sea Sector Catch by Year and Species (mt)						
	Year					
Species	2003	2004	2005	2006	2007	OY/Allocation
Spiny dogfish	269	615	355	61	155	
Widow rockfish	14	21	80	142	146	368
Yellowtail rockfish	36	47	112	110	79	4,548
Slope rockfish (N)		24	51	8	32	1,160
Sablefish	17	29	15	2	3	2,651
Darkblotched rockfish	4	7	11	11	12	330
Shortspine thornyhead	16	5	7	1	3	1,634
Shelf rockfish (N)		5	7	4	2	958
Arrowtooth flounder	4	3	4	3	3	5,800
Pacific ocean perch	6	1	2	3	4	150
Lingcod	1	1	3	3	6	5,558
Canary rockfish	1	5	1	1	2	44
Pacific halibut	3	1	2	1	1	
Other flatfish		2	3	-	-	4,884
Longnose skate		0	1	0	1	

Table B-4 shows another perspective. When the at-sea sector catch is viewed as the average catch of the 2008 OY over the 2004 to 2006 time period, widow rockfish, canary rockfish, darkblotched rockfish, slope rockfish, and POP are the most frequently encountered incidental species. However, there is a substantial overlap in the catch of these last three species. In general, limiting the catch of one of these last three species will tend to indirectly constrain the catch of the other species as they are found in similar areas (the continental slope). Arguably two of the last three species most important for direct coverage are darkblotched and POP, as they are currently undergoing rebuilding. Another worthwhile perspective is to view whether those incidental species are caught in substantial amounts in the nontrawl

sectors. This means that the portion of catch attributed to the at-sea sector may be more important if that species is important to nontrawl sectors.

Table B-4. Average portion of OY caught by at-sea activity.

Species	OY/Allocation	Average Portion of 2008 OY (2004 to 2006)	Substantially Caught in Non-trawl Sectors
Widow rockfish	368	21.89%	No
Canary rockfish	44	4.85%	Yes
Darkblotched rockfish	330	2.77%	No
Slope rockfish (N)	1,160	2.48%	No
Pacific ocean perch	150	2.20%	No
Yellowtail rockfish	4,548	1.69%	No
Sablefish	2,651	0.50%	NA
Shelf rockfish (N)	958	0.47%	Yes
Shortspine thornyhead	1,634	0.38%	No
Arrowtooth flounder	5,800	0.06%	No
Lingcod	5,558	0.05%	Yes
Other flatfish	4,884	0.03%	No
Longnose skate			No
Pacific halibut			Yes
Spiny dogfish			Yes

In summary, several species appear to have a higher degree of priority for direct coverage in the at-sea sectors than the others. This prioritization appears to be (in addition to whiting):

1. Widow rockfish
2. Canary rockfish
3. Darkblotched/Slope rockfish/POP

Selecting one of these last three species may indirectly control the catch of the other two. Covering additional species may lead to adverse economic impacts as discussed above.

B-1.4 At-sea Observers/Monitoring

❖ Provisions and Options

Shoreside Whiting Fishery: Observer coverage for the combined shoreside sector managed with IFQs is described at A-2.3.1.

At-sea Whiting Fishery: 100 percent observer coverage aboard mothership and catcher-processors will continue. Observers would be required in addition to or as a replacement for video monitoring. For some coverage, cameras may be used in place of observers (feasibility to be determined).

Added as part of the Final Preferred Alternative: It is the Council's intent to provide NMFS flexibility sufficient to design and implement a tracking and monitoring program that will achieve the goals and objectives of the trawl rationalization program.

The Council has fleshed out extensive provisions for tracking, monitoring, and enforcement for trawl sector management under the IFQ alternative and this alternative. See Section A-2.3.1 for a description of the provision and options pertaining to discard, at-sea catch monitoring, shoreside landings monitoring, catch tracking mechanisms, cost control mechanisms, program performance measures, and cost recovery. This discussion is also repeated below.

As part of the FPA, the Council indicated its intention to provide NMFS flexibility sufficient to design and implement a tracking and monitoring program that will achieve the goals and objectives of the trawl rationalization program.

❖ Interlinked Elements

Self-monitoring and self-enforcement of cooperative members by the cooperative organization is related to the type of observers/monitoring in place for the fishery and access to information reported by the observation/monitoring system. In addition to having access to catch information from the observation/monitoring system, self-monitoring and self-enforcement relies on relatively robust monitoring systems. The lack of a robust monitoring system may make it problematic to self-enforce if cooperative members can successfully question the accuracy of the data and avoid enforcement penalties that may be brought by the cooperative organization. Furthermore, the lack of robust data may decrease the confidence that individual cooperative members have in the actions of other members, and this can begin to compromise the success of the cooperative agreement. In addition to the need to support self-enforcement, management of the fishery throughout the year (such as cooperative-imposed area restrictions to minimize bycatch) can be compromised if monitoring of the fishery is not relatively robust, largely for the same reasons that enforcement is compromised. A cooperative manager could, for example, suggest area closures be put in place mid-season, but if catch data is questionable, then the ability for that cooperative manager to implement management measures may be compromised.

The interlinked elements are all the tracking and monitoring elements discussed above as well as all elements that affect the costs of management, enforcement, data collection, and analysis. These elements include permits, endorsements, IFQ and co-op allocation and transfer rules, adaptive management rules, excessive share monitoring, gear switching regulations, and regional and area management and allocation rules.

❖ Rationale and Policy Issues

At-sea monitoring is necessary to support a rationalization program that manages total catch (retained catch and discards), because it documents events at sea which may not be documented by fish tickets alone (such as discard events). If at-sea monitoring was not in place in a rationalized fishery that was intended to manage total catch, then individual harvesters would have a large incentive to misreport catches of constraining species. If such misreporting were to occur, the total mortality attributed to fishing activity would not be known, thus compromising the ability to successfully manage fisheries within ABCs and OYs. Furthermore, such misreporting may tend to economically benefit those that misreport (if they are not caught and fined), but if such misreporting is eventually accounted for, it may affect all fishery participants equally.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
At-sea Observers/Monitoring	X	X			X	X				

❖ Analysis

NMFS presented the preliminary estimates below at the November 2009 Council Meeting. (See November 2009 Briefing Book: Agenda Items G.8.B Supplemental NMFS Presentations Lockhart and Freese). NMFS will refine these projections during the regulatory process that converts the Council's preferred alternative into regulation. NMFS will also seek recommendations from the industry on how to lower program costs. NMFS will consult with the states to discuss state needs and how to integrate the elements of this program with existing state programs. Note that there are state budget concerns of upholding existing programs not to mention expanding these programs given the current state of the economy. State resources may need increasing to establish the electronic fish ticket and logbook programs or to hire personnel for port sampling, enforcement, and other purposes.

Below are tables that show the existing tracking and monitoring system, current tracking and monitoring costs by sector, and what the costs of additional observers, and plant monitors. In addition to these costs, also listed are other state, Federal, and Council costs. Total cost projections are then compared with alternative revenue estimates.

Status Quo Tracking and Monitoring Systems (see Table B-5): Vessel monitoring systems (VMS) are employed by all vessels except motherships. Paper logbooks are employed by all harvest sectors. Logbooks are mandatory for shoreside vessels but voluntary for the at-sea motherships and catcher-processors. PSMFC combines the state fish tickets and logbooks into a single database. This database is funded federally; states contribute personnel and other resources. Shoreside whiting trawlers are monitored with cameras. The industry pays for the cameras, while NMFS pays for review and analysis of the resulting video. Observer coverage in the nonwhiting fishery is about 25 percent, which is funded by NMFS while the at-sea motherships and catcher-processors use hired observers from a private company. Shoreside whiting plants also pay a private company for compliance monitors. The equipment, training, and data collection and analysis associated with these observers and monitors are paid for by NMFS. Electronic fish tickets are now used in the shoreside whiting fishery.

Table B-5. Status quo observer coverage and monitoring for all sectors.

Status Quo	Shorebased Nonwhiting Trawl	Shorebased Whiting Trawl	At-Sea Mothership Trawl	At-Sea Mothership Processor	At-Sea Catcher-Processor
VMS	X	X	X		X
Logbooks	X	X	X	X	X
Cameras		X			
Observers	25% WCOP		0	2	2
Compliance Monitors		100%			
Fish Tickets	X	X			
Electronic Fish Tickets		X			

The Council's preferred alternative would:

- Increase the observer coverage to 100 percent in the shorebased nonwhiting trawl fleet.
- Replace the cameras used in shore-based whiting trawl sector with 100 percent observer coverage.
- Expand the whiting compliance monitor program to 100 percent coverage of the shore-based nonwhiting trawl program.
- Institute 100 percent observer coverage to the at-sea mothership trawl fleet.

In comparison to status quo management, rationalization will need increases in NOAA Fisheries' Northwest Region, NOAA GC, Northwest Fisheries Science Center, and the Northwest/Southwest Offices of Law Enforcement staff. State fisheries management and enforcement staff will also need to be increased. Additional equipment, training, and information technology resources (hardware and software) will also be needed by both state and Federal agencies. The Council will also incur additional costs in the early years of the program.

Examples of anticipated additions to state and federal staff levels due to rationalization are listed below.

- Staff for cost recovery, permitting, quota tracking and appeals processes.
- Staff and contracting for performance monitoring including mandatory economic data collection.
- Observers, debriefers, and port samplers.
- Law enforcement officers, technicians, equipment, and training.
- Lawyers, policy analysts, and regulation writers to adopt Federal and state regulations in support of the Program and address enforcement issues.
- IT resources (FTEs, hardware, and software) to support electronic reporting (logbooks, fish tickets, observers, compliance monitoring, etc.).
- State and Federal outreach.

Based on the preferred alternative, NMFS has developed the following preliminary estimates of potential costs.

Implementation Costs (one-time costs to develop the tracking and monitoring programs)

State management and enforcement	$300,000 to $500,000 per state
NMFS management and enforcement	$2.1 million
NMFS (NWFSC) Observer Program and Economics Data Collection Programs	$3.150 million
Total:	**Approximately $6.5 million**

Annual Costs (state, Council, and Federal costs associated with running the Program when fully implemented)

State management and enforcement	$750,000 to $1.5 million per state
NMFS management and enforcement	$1.7 million
NMFS (NWFSC) Observer Program and Economics Data Collection Programs	$3.15 million
Total:	**Approximately $8 million**

Direct Observer and Monitoring Costs (daily costs associated with hiring observers and plant monitors)

Shoreside nonhake trawl fishery	$3.5 million
Mothership Processors	$243,000
Mothership Catcher Vessels	$253,000 to $362,000
Catcher-Processor	$415,000
Shoreplant Compliance Monitors non hake	$950,000
Shoreplant Compliance Monitors hake	$300,000
Total:	**Approximately $5.7 million**

Total Annual Costs and Direct Observer and Monitoring $14 million

These costs are preliminary and it is important to note that the direct observer and monitoring costs are very dependent on operational decisions by industry (both fishing vessels and processors) to reduce costs. In addition, it is impossible to predict how much consolidation will occur, especially in the initial years of program implementation. Because of this, this analysis makes broad assumptions about industry behavior to frame the range of costs. At one extreme, annual observer costs could rise to $18 million if a 100-vessel fleet needed observers 365 days a year, at a cost of $500 per day. The industry could reduce costs by imposing voluntary limits on the number of vessels that can be at-sea at any one time or agreeing to share observer coverage between multiple vessels. These and other costs could decline as the number of participating vessels decline as the fleet consolidates because of the program. A quantitative analysis (Lian et al. 2008) indicates an expectation that after rationalization there will be a fleet of 50-60 vessels of a size of 60-70 feet. If this were to happen, one would expect the costs to be significantly lower and approximately one half of the estimated costs for the current fleet.

Table B-6 below shows harvest, revenue, and price dimensions of the fishery. The 2007 fishery earned $57 million in ex-vessel revenues with the nonwhiting groundfish components earning $28 million and the whiting components earning $30 million. Between 2004 and 2007, there were rising whiting and fuel prices. In 2008, these fisheries earned about $90 million in ex-vessel revenues mainly based on the size of the whiting quota and continued high prices for whiting. The total estimated annual cost of the Trawl Rationalization Program, including the direct observer and monitoring costs, is estimated to be $14 million. These costs can be addressed by a combination of industry fees, congressional appropriations, or state/Federal reprogramming of existing resources. Additionally, as has been stated, these cost estimates can be reduced via industry adoption of operational changes to lower cost tracking and monitoring alternatives.

Table B-6. Economic comparison of 2004 and 2007 revenues.

Economic Comparison		2004	2007
Harvests Metric Tons			
Total Non-Tribal Whiting		191,793	180,056
Total Nonwhiting Groundfish		17,238	22,253
Total Groundfish including Whiting Tons		209,031	202,309
Ex-vessel Revenues Million $			
Total Non-Tribal Whiting		$26.1	$29.7
Total Nonwhiting Groundfish		$16.2	$27.2
Total Groundfish including Whiting Tons		$42.3	$56.9
Ex-Vessel Prices			
Ex-Vessel Price Whiting		0.046	0.075
Ex-Vessel Price All flatfish	$/lb	0.425	0.43
Ex-Vessel Price Thornyhead Compl.	$/lb	0.609	0.627
H&G Whiting Export Price	$/lb	0.55	0.75
Marine Diesel Fuel Costs Newport, Oregon, June	$/gal	1.65	2.5

Regardless of how these costs are addressed, it is likely that the industry will be paying the maximum recovery fee of 3 percent. (NMFS will discuss fee collection processes with the Council and industry when it undertakes cost-recovery rule-making.) All industry borne compliance costs would be expected to reduce the value of QS prices by corresponding amounts. For those having to buy into the fishery, higher compliance costs would be expected to reduce what they have to pay for QS.

However, for perspective, according to the Council's SSC review of the Lian Analysis (see http://www.pcouncil.org/bb/2008/ 0608/F6d_SUP_SSC_0608.pdf). (Note that this analysis included an estimate of $350 per day observer costs.)

> The TIQAT (Trawl Individual Quota Analytical Team) used a fleet consolidation model to estimate the size and profitability of the groundfish trawl fleet that may result from the TIQ program....
>
> A standard econometric methodology was used to estimate the economic efficiency of individual trawl vessels based on vessel cost and earnings data collected for 2003 and 2004 by the Northwest Fisheries Science Center (NWFSC). Results from the analysis, based on 2004 costs and harvests, indicated considerable consolidation, with the fleet being reduced to 40-60 vessels and with cost savings in the range of $18-22 million. The cost savings would arise from a shift in fleet composition to vessels with lower costs, which were estimated to fall in the 50-60 foot size range, and a reduction in fixed costs due to the operation of a smaller fleet.

Catch monitoring is a necessary tool for cooperative function. In order to hold the overall fishery, each sector of the fishery, and each cooperative to a catch limit, catch monitoring must be in place to verify catch relative to that catch limit. Furthermore, catch monitoring must be applied in a manner that is substantially equal to all cooperative participants harvesting fish. Equal application of catch monitoring to all participants in a fishery is arguably necessary because it puts all participants on equal footing, and this equality is necessary for self-management of the fishery by the cooperative members and their governing contracts. If catch monitoring was not applied equally (or not trusted), cooperative members may "second guess" the reported catch of other cooperative members, or feel that other cooperative members are at a relative advantage in some fashion. This second guessing among cooperative participants would tend to result in a destabilization of a cooperative because of an erosion of trust among cooperative members. If substantial second guessing, or questioning, of other participants' catch reporting comes into play, it may break down the strength of the cooperative and the contract.

One necessary component to a catch monitoring program in a cooperative-based fishery is that cooperative members must have access to their own and others' catch data. This is necessary in order for the cooperatives to self manage and enforce the catch quantities of the cooperatives and the cooperative members. It is also necessary so that cooperatives can develop responsive management tools, such as voluntary area management closures, to reduce bycatch. Without access to catch information, it may prove quite difficult for cooperative members to self manage and enforce the actions of cooperative members.

The following paragraphs excerpted from Appendix A, Section 2.3.1 speak to catch monitoring, catch tracking, landings monitoring, and cost control.

Catch Monitoring: Under status quo, mothership processing vessels and catcher-processors currently carry two observers. This monitoring requirement would remain for these vessels under trawl rationalization. However, a new requirement would be the placement of observers, possibly supplemented by cameras, on catcher vessels that deliver to motherships. (Note that for the 2009-10 Groundfish Harvest Specifications and Management Measures, the Council is proposing video monitoring for these vessels.) Cameras are currently employed as an electronic monitoring system (EMS) in the shoreside whiting fishery as a monitoring tool. The EMS employed under the EFP for Pacific whiting allows shoreside vessels to dump unsorted catch directly below deck and would allow unsorted catch to be landed, providing that an EMS is used on all fishing trips to verify retention of catch at sea. The EMS is an effective tool for accurately monitoring catch retention and identifying the time and location of discard events. Catch monitors are already employed in the shorebased whiting fishery. The

addition of observers and EMS monitoring measures for catcher vessels that deliver to motherships is to assure that all fish, including discards, are delivered to the mothership. See also discussion under Program Costs.

Catch Tracking: Other than the declaration reports and the processor production reports, these catch tracking mechanisms are largely the conversion of existing state paper-based systems. Converting to electronic reporting is seen as aid for improved accuracy of reported data and better quota monitoring at the individual vessel, co-op, and sector level. Declaration reports and processor production reports are seen as tools that improve ability to enforce regulations. One of the issues facing the implementation of these reporting systems is how best to adapt the existing state paper-based systems to the needs of the Trawl Rationalization Program.

Landings Monitoring: For shoreside nonwhiting trips, there is a proposed requirement for 100 percent observer coverage on vessels and for shoreside whiting trips, observers in addition to or as a replacement for video monitoring. Note that the Council's preferred alternative is for the Shoreside Whiting and Nonwhiting Fisheries to be managed under an IFQ system and as a single combined sector. However, if Congress provides the needed legislation, the shoreside whiting fishery may be managed as a co-op with processor linkages rather than with IFQs. In addition to 100 percent observer coverage, there is also being proposed a 100 percent shoreside monitoring as the sorting, weighing, and reporting of any ITQ or IBQ species must be monitored by a catch monitor.

Cost Control: All trawl sectors (shorebased nonwhiting, shorebased whiting, mothership catcher vessels and processors, and catcher-processors) would require certification or licenses that show they meet the monitoring requirements. In order to reduce costs, landing hours could be restricted.

Many of the other requirements will be similar to those currently specified as part of the 2008 Pacific Whiting Shoreside Fishery Maximized Retention and Monitoring Exemption Program (see http://www.pcouncil.org/bb/2008/0308/F1a_SUP_ATT2.pdf). This program outlines the reporting requirements, equipment needs, vessel and plant responsibilities including relationships with plant monitors, notification and declaration procedures, and the requirement of a NMFS monitoring plan. For ITQ and co-op fisheries, these elements would have to be expanded to include existing observer requirements, including safety requirements as well as the responsibilities of the crew to assist the observer in the weighing and sorting of catch and responsibilities of the captain to assure that vessel operations do not hinder observer efforts. For ITQ vessels, there is likely to be a need to purchase appropriate scales to meet these requirements. The actual design of these reports are under development and will most likely be more fully analyzed for public comment under the rulemaking process which converts the Council's preferred alternative into regulation. This process includes addressing reporting issues under the Paperwork Reduction Act process and under the Regulatory Flexibility Act (regulatory reporting burden on small businesses).

With respect to a catcher-processor voluntary co-op, it is not clear that the sector as it currently operates is a limited access privilege program (LAPP), as the management alternatives developed by the Council do not include a special permit or endorsement. In the MSA, the term "limited access privilege":

> (A) means a Federal permit, issued as part of a limited access system under Section 303A to harvest a quantity of fish expressed by a unit or units representing a portion of the total allowable catch of the fishery that may be received or held for exclusive use by a person; and
> (B) includes an individual fishing quota; but
> (C) does not include community development quotas as described in Section 305(i).

However, under the tracking and monitoring provisions, vessels are to be certified and, under the catcher-processor provisions, there are fallback ITQ processes in case the voluntary co-op breaks up. It is not clear if these requirements can be deemed a limited access privilege. In addition, NMFS is in the process

of developing formal LAPP guidance which may affect this determination (see http://www.nmfs.noaa.gov/sfa/PartnershipsCommunications/lapp/LAPPguidance.htm).

B-1.5 Mandatory Data Collection (Option)

Mandatory Provisions: The Council and NMFS shall have the authority to implement a data collection program for cost, revenue, ownership, and employment data. Compliance with which will be mandatory for members of the west coast groundfish industry harvesting or processing fish under the Council's authority. Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA.

A mandatory data collection program shall be developed and implemented as part of the groundfish trawl rationalization program and continued through the life of the program. Cost, revenue, ownership, employment and other information will be collected on a periodic basis (based on scientific requirements) to provide the information necessary to study the impacts of the program, including achievement of goals and objectives associated with the rationalization program. This data may also be used to analyze the economic and social impacts of future FMP amendments on industry, regions, and localities. The program will include targeted and random audits as necessary to verify and validate data submissions. Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA. Additional funding (as compared to status quo) will be needed to support the collection of these data. The data collected would include data needed to meet MSA requirements (including antirust).

The development of the program shall include: A comprehensive discussion of the enforcement of such a program, including discussion of the type of enforcement actions that will be taken if inaccuracies are found in mandatory data submissions. The intent of this action will be to ensure that accurate data are collected without being overly burdensome on industry in the event of unintended errors.

Voluntary Provisions: A voluntary data collection program will be used to collect information needed to assess spillover impacts on nontrawl fisheries.

Central Registry: Information on transaction prices will be included in a central registry of whiting endorsed permit and processor permit owners. Such information will also be included for sales and lessees.

Government Costs: Data will be collected and maintained on the monitoring, administration, and enforcement costs related to governance of the rationalization program.

❖ Interlinked Elements

There do not appear to be any elements substantially interlinked with data collection.

❖ Rationale and Policy Issues

The goal of the Council's rationalization alternatives involves several economic components. One stated goal of the program is to:

> *Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.*

The Council has also enumerated several objectives and constraints for the program that involve economic components and monitoring of the program.

The MSA (as amended through January 2007) also places importance on social and economic outcomes resulting with a rationalization program. Section 303A.(c)(1)(C) states that any LAPP to harvest fish submitted by a Council or approved by the Secretary under this section shall promote social and economic benefits.

The MSA also contains a monitoring requirement to determine whether a LAPP is meeting its goals. Sec. 303A.(c)(1)(G) states that any LAPP shall:

> *include provisions for the regular monitoring and review by the Council and the Secretary of the operations of the program, including determining progress in meeting the goals of the program and this Act, and any necessary modification of the program to meet those goals, with a formal review 5 years after the implementation of the program and thereafter to coincide with scheduled Council review of the relevant fishery management plan (but no less frequent than once every 7 years).*

In order to meet the monitoring requirements for the economic goals, improved and expanded economic data would be needed for the trawl IFQ fishery. One of the current trawl rationalization alternatives provides for a mandatory economic data collection provision. Regardless of whether the economic data collection is mandatory or voluntary, the types of data necessary to monitor the effects of the program are the same. However, the choice of mandatory or voluntary data collection will likely have a large effect on the Council's and the NMFS' ability to consistently and systematically collect the necessary data.

Despite the NWFSC's recent progress in voluntary economic data collection, economic analysis of the limited entry trawl fishery has historically been severely constrained by a lack of economic data. Incomplete cost-earnings data on vessels and processors has been a particular problem. While Pacific Fishery Information Network (PacFIN) provides data on most, but not all, earnings sources for limited entry trawlers, little data on the cost of operating harvesting vessels has been available. Data on the costs and earnings of processing plants has not been available to NMFS or Council economists. This lack of economic data has hampered attempts to measure economic performance, build regional economic input-output models, assess overcapacity, and build models which predict economic behavior.

The first attempt to collect economic data from limited entry trawl vessel owners occurred in 1999 and 2000. This mail survey utilized a lengthy questionnaire asking for considerable fishery-specific information, but obtained a response rate well below 20 percent. Because of the low response rate and nonrespondent bias, data collected through this survey was of limited value. A processor survey conducted at about the same time obtained an even lower response rate.

A second voluntary economic survey of limited entry vessel owners was conducted in 2005-2007. In order to obtain higher response rates, this second survey utilized a much shorter questionnaire and collected data through in-person interviews. This survey obtained a fairly high response rate of over 70 percent, but at the cost of considerably less data collection from each respondent due to the shorter questionnaire. While this second survey provides much data of value for assessing industry economic performance and regional economic impacts, the ability to evaluate the contribution of individual fisheries (such as groundfish) to vessel economic performance is limited by the reduced questionnaire length. Collecting data through in-person interviews helped to substantially increase the response rate, but at considerably increased survey cost.

Mandatory economic data collection offers the advantages of reduced nonresponse bias, the ability to collect more detailed fishery-specific data, and reduced survey fielding costs. These advantages would apply to data collection from both the harvesting sector and the processing sector.

The collection of such data is related to several aspects of MSA and groundfish FMP guidance on rationalization. These include the categories of net benefits, fairness and equity, and harvester and processor sector health. To a large degree these broad categories are addressed by data collection because such data collection allows for the measurement of these categories. The measurement of these categories may help inform future decisions on the part of the Council.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Data Collection		X			X	X				

❖ Analysis

The effect of a data collection program includes the effects of increased ability to monitor and measure the economic performance of the industry, as described in the rationale above. Other effects include the burden on agencies involved in the data collection and analysis, and the burden on industry members in the form of time spent reporting data.

The NWFSC has gone through two voluntary survey efforts. The first effort resulted in a relatively low response rate which minimized the ability to use the survey. The second effort used face to face interviews and resulted in a response rate of over 70 percent. This relatively high response rate has resulted in several pieces of analysis utilized in the rationalization process and may prove useful for other means as well. While this survey has largely been considered to be successful, the face to face interview technique is estimated to have cost somewhere on the order of $700 to $800 per interview. This cost does not include the time and cost of developing the survey and analyzing the data. Given that the trawl fishery is over 100 vessels, the field cost of conducting a voluntary survey using a face to face technique could be on the order of $100,000 to the agency each year it is conducted.

On the other hand, a mandatory survey may be able to avoid the need for face to face interviews. Face to face interviews were used in the voluntary survey for several means including returning a favorable response rate. If a survey is mandatory, a face to face technique may not be necessary. However, differences may exist between a mandatory and a voluntary survey which can make the burden on the industry greater for a mandatory survey than a voluntary survey.

Factors affecting the response rate of a voluntary survey include the length of the survey and the difficulty of the questions. If a survey is viewed as being overly lengthy and/or requests information that is not readily available and that may take time to uncover, the response rate is likely to suffer. The response rate from a mandatory survey may not suffer in the same fashion. Therefore, it is reasonable to expect that a voluntary survey may (at least at times) be simpler and shorter than a mandatory survey simply to

get a favorable response rate. If this is the case, a mandatory survey may impose a larger burden on industry than a voluntary survey. In the worst case scenario (one where the survey is highly burdensome), industry members may at times respond with a "protest response" or information that is of poor quality. This can affect the ability to use the survey responses even if the response rate is high.

The collection of economic data relates to several aspects of policy guidance from the MSA, the Groundfish FMP, and Amendment 20 goals and objectives. If better data collection leads to more informed decisions relating to net benefits and efficiency, then data collection is related to MSA-National Standard 5, MSA – 303A(c)(1)(B), Amendment 20 Objectives 2 and 6, and potentially others. In particular, Amendment 20 Objective 6 (Promote measurable economic benefits) is related to data collection because data collection allows economic benefits to be measured. Many benefits may not be able to be measured without the acquisition of additional economic data. If additional data collection helps in the development of policies, then such data collection may also relate to policy guidance on sector health including Amendment 20 Objectives 2 and 6, Groundfish FMP Goal 2, and Groundfish FMP Objectives 7 and 15. Finally, data collection is directly related to several aspects of policy guidance that relate to program performance monitoring and modification. MSA – 303A(c)(1)(G) calls for a regular review and monitoring of the program for progress in meeting goals.

B-1.6 Adaptive Management (Option)

Option 1 (Preferred Alternative): There will not be a set-aside for adaptive management with respect to the whiting co-op programs.

Option 2: During the biennial specifications process, up to 10 percent of the available aggregate harvest pounds for the co-op program (including harvest potentially available both to co-ops and the non co-op fisheries) will be set aside for use in an adaptive management program that could create incentives for developing gear efficiencies, or community development or to compensate for unforeseen outcomes from implementing the trawl rationalization program. Examples of unforeseen outcomes include, but are not limited to, unexpected geographic shifts in the distribution of catch or landings, unexpected effects on certain segments of the industry (e.g., processors), or an unexpected barrier to new entry into the fishery. This provision will apply to the overall trawl sector (whiting and nonwhiting) but the allocation set aside from each trawl sector would be specific to that sector.

❖ Interlinked Elements

There do not appear to be other cooperative components substantially interlinked with the adaptive management provision. However, if adaptive management is used to facilitate new entry into a cooperatively-managed fishery, it is likely that such new entry will mean greater participation in the noncooperative fishery, as those new entrants may not immediately become cooperative members. This new entry may cause some disruption to the particular sectors in which it occurs.

❖ Rationale and Policy Issues

The adaptive management provision is intended to serve several different goals and objectives. The Council identified the goals and objectives for the adaptive management program as: community stability, processor stability, conservation, unintended/unforeseen consequences of the TIQ program, and to facilitate new entrants (both processors and harvesters). The Council's preferred alternative also specified that the adaptive management program would be used for harvests of shoreside nonwhiting species; therefore, the adaptive management program does not apply to the whiting fishery. However, prior to voting to apply the adaptive management program only to nonwhiting species, the Council considered applying the program to Pacific whiting and to harvest cooperatives. This section addresses the potential

effects of applying the adaptive management program to harvest cooperatives. This analysis assumes that the adaptive management program is mostly based on addressing unforeseen/unintended consequences but also addresses several factors that an adaptive management program could be used to address in a harvest cooperative.

The consideration of an adaptive management provision is related to multiple categories of guidance related to the MSA and the groundfish FMP that are related to rationalization. Ultimately, the degree to which adaptive management is related to these categories of guidance depends on how the program is used. Several potential uses include conservation, assisting new entrants, and assisting disadvantaged communities. These potential uses are arguably related to issues of fairness and equity.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Adaptive Management	X				X			X	X	

❖ Analysis

As noted above, an adaptive management provision can be used to achieve multiple objectives. The outcome of the provision depends on the objective and manner in which the provision is used to achieve these objective(s). In order to facilitate analysis, we assume that the adaptive management provision is used for several different outcomes in the whiting fishery, including salmon bycatch reduction; overfished species bycatch reduction; community protection; and facilitation of new entry into the fishery, where new entry is defined as the establishment of new vessel owner-operators.

The use of adaptive management to facilitate salmon bycatch reduction may benefit harvesters who have a demonstrated ability to reduce bycatch, or harvesters who plan to experiment with new gear designs to reduce salmon bycatch. If the latter approach is used, the testing of new gears may eventually be followed up by a regulatory amendment requiring whiting harvesters to use a different gear type that has demonstrated success in reducing salmon bycatch. It should be noted that the Council has given no indication that this is the process that would be followed. However, assuming this is the process that would be followed is useful to illustrate the possible effects of this provision.

If the adaptive management provision is used to encourage the development of new gears, it is likely that any benefit to harvesters from experimenting with new gears would be short-term. As the success of experimental gears is determined, the need to direct adaptive management to those harvesters would lessen because the next logical action would either be a regulation designed to implement those gears, or a determination that the gear is not successful. In either case, it may not be necessary to continue directing adaptive management quota toward those harvesters after a particular goal has been achieved, thus freeing up the quota for another use. However, the original recipients of that adaptive management quota would have future opportunities to receive adaptive management quota by attempting to achieve other, future objectives specified by the Council.

If adaptive management quota is used to reward those with a demonstrated ability to reduce salmon bycatch, then the quota may be allocated on a longer-term basis, depending on the long-term success of harvesters in reducing salmon bycatch. If harvesters demonstrate a continued ability to reduce salmon bycatch more than others, then they may continue to receive adaptive management quota. However, this also depends on the way the measures used to achieve the objectives are specified. For example, if the adaptive management quota is distributed to the top five harvesters (in terms of salmon bycatch reduction), then harvesters could receive the quota on a long-term basis. However, if the objectives set a benchmark for reducing salmon bycatch to a specified rate, then more and more harvesters may begin meeting that benchmark, thus reducing the amount of adaptive management quota available to each harvester meeting the benchmark.

Using adaptive management for overfished species bycatch reduction may work in the same way. Again, the specific effects depend on the objectives of the program and the manner in which they are achieved. The effects may be short- or long-term. If the program objectives are to allow harvesters to benefit over the long-term from adaptive management, harvesters who alter fishing practices in order to achieve overfished species bycatch reduction may receive adaptive management quota over the long-term. However, if adaptive management quota is used to encourage the development of new gears, which are then put into regulation if successful, then recipients are likely to receive that quota only for as long as it takes to determine whether a new gear design is successful.

The use of adaptive management quota for community protection will almost certainly have positive effects for recipient communities. However, it may have differing effects for fishery participants, processors, and fishing-dependent businesses. For example, since the at-sea fishery does not make routine deliveries to shoreside processors and does not make routine stops into port, except perhaps cities in the Puget Sound region, it is not clear how the adaptive management provision could be used for community protection for the at-sea fishery. In the shoreside whiting fishery, activity is more closely aligned with a geographic place. Using adaptive management quota in the shoreside whiting fishery could be used to direct landings of whiting to certain ports, thus spurring fishing-related activity in a distinct area. It is unclear how the specific mechanisms would work in order to achieve this outcome, but one method could tie adaptive management to vessels that home-port in specific locations, thus increasing the chances that whiting would be landed in those ports.

The use of adaptive management to facilitate new entry (in the form of new owner-operators) may achieve that very outcome. This could be accomplished by allocating the adaptive management shares to entities that desire to enter the fishery. However, there is some question about how this would work, since catch history assignments made to CV(MS) permits are not divisible and not separable from the permit. Thus, a new entrant to the fishery would still need to acquire a CV(MS) permit with catch history to remain in the fishery. Adaptive management quota may make it easier for a new entrant to acquire the CV(MS) permit since that new entrant would have access to the catch associated with the CV(MS) permit, as well as to the catch attributed to him/her from the adaptive management provision. This would tend to increase revenues (both gross and net) to the new entrant, increasing the ability of that new entrant to purchase the new permit.

Although the adaptive management provision could be constructed in a manner that facilitates new owner-operators, cooperatives rely on close-knit and long-term relationships for success. This means that some barriers to new entry are necessary in order to maintain stable relationships between harvesters in a cooperative. As discussed in Chapter 4, collective institutions (like cooperatives) often develop complex relationships and/or function in complex systems effectively. The ability to work within these complex systems requires that participants be stable and that entry and exit be limited, in order for relationships to develop and for knowledge to be shared across participants. Fostering the entry of new owner-operators into a cooperative system may inject uncertainty and instability into cooperative relationships. This instability, in the worst case scenario, may jeopardize the success of cooperatives. Therefore, while an

adaptive management program could be used to assist new entrants, a relatively large number of new entrants could compromise the operation of harvest cooperatives which rely on relationships among participants who are familiar with one another.

B-1.7 Length Endorsement

Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained; however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e., length endorsements will not change when a trawl endorsed permit is transferred to a smaller vessel).

❖ Rationale and Policy Issues

The modification of the vessel length endorsement is intended to serve a couple of different purposes. The rationale for not removing the length endorsement entirely is that many vessel owners have made substantial investments in their vessels, and the vessel size is governed by the length endorsement on the associated permit. Since there is a limited number of permits of any given size category, this means that the fishery must be comprised of a certain number of vessels of lengths specified by the various LE trawl permits. This creates a somewhat artificial value for vessels that may fall under a relatively inefficient size category as the regulations ensure that a certain number of vessels of inefficient size must remain in the fishery. There is some belief that eliminating the length endorsement from the permit would make some vessels that are in a relatively inefficient length category less valuable over time as more efficient vessels are sought, enter the fishery, and replace those relatively inefficient vessels. Retaining the length endorsement puts a cap on the number of efficient vessels that can enter the fishery and makes the less efficient vessels more valuable than they otherwise may be.

One reason for not requiring that the length endorsement be reduced in size, should it be transferred to a vessel of a smaller size, is that the need for capital reduction in the fishery is achieved through a reduction in fleet size rather than a reduction in the length of vessels in the fishery. In other words, the requirement that the permit length endorsement decline if it is transferred to a smaller vessel acts as a capacity reduction measure. That particular capacity reduction measure is no longer necessary in a rationalized fishery because capacity is reduced through fleet consolidation. Therefore, to require that the permit length endorsement decline if the permit is transferred to a smaller vessel is no longer appropriate.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Length Endorsement		X			X					

❖ Analysis

The retention/modification of the length endorsement provision appears to do very little to the potential efficiency gains of catcher vessels in the fishery or to fleet consolidation. By extension, it appears to do very little in terms of retaining asset values for vessels that may be in a relatively inefficient size category. In the nonwhiting fishery, some degree of fleet consolidation is expected which will lead to a case where enough permits in the "efficient" size category will remain to accommodate many, if not all, of the remaining vessels in the fishery. While these same estimates do not exist for the whiting portion of the fishery, some fleet consolidation is to be expected in that fishery. Since the efficient size category for whiting vessels is not known, it is difficult to predict whether enough permits of the efficient size will be available in the whiting fisheries to accommodate the entire fleet after it is consolidated. However, the fact that excess permits will be in the fishery – combined with the fact that catch history or IFQ will be instated – means that permits will likely have very little value. If insufficient numbers of permits exist which are in the efficient size category for the whiting fisheries, several permits could be combined at relatively little cost to create a larger permit which may be in a more efficient category for the whiting fishery.

The following figure illustrates the existing count of limited entry trawl permits by size category. From this figure it is apparent that nearly 80 permits exist which fall under the efficient size category for the nonwhiting fishery as identified by Lian, Weninger, and Singh (2009). When compared to the expected amount of fleet consolidation, it appears that there will be sufficient permits in the efficient category to handle the number of boats in the nonwhiting fishery. This means that, contrary to some arguments made for retaining the endorsement, retaining the length endorsement is likely to do very little in terms of retaining the asset value of permits or associated vessels. However, as the number of permits in the efficient category is still somewhat limited, there may still be some small effect of retaining that endorsement. Furthermore, if the efficient vessel size changes over time through technological change, retaining the length endorsement would limit the ability for the fleet to adapt to that new, more efficient size, but only if the more efficient size is larger. This is because the modification of the length endorsement provision (which does not make the length endorsement decline if it is placed on a smaller vessel) means that the length endorsement is effectively changed to mean that vessels can be equal to or less than the length specified by the permit.

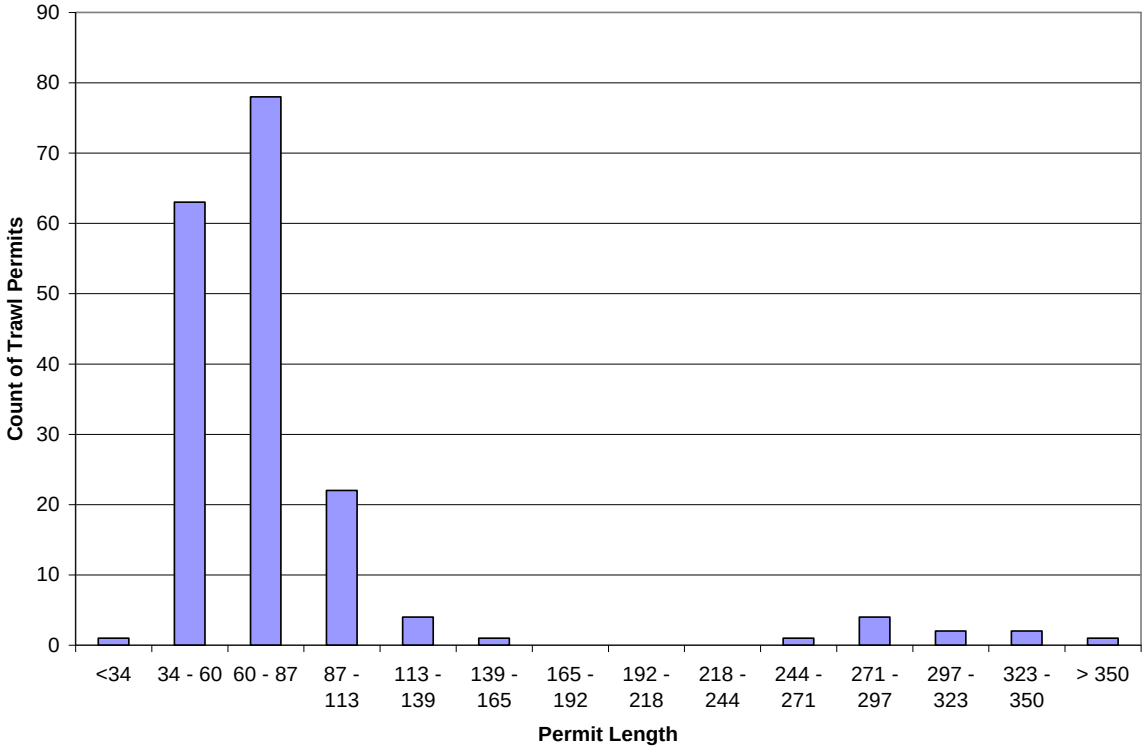

Figure B-2. Count of limited entry trawl permits by size category.

B-2 Whiting Mothership Sector Co-Op Program

Overview. Qualified permits will be endorsed for mothership co-op participation. Each year the holders of those permits will choose whether their vessels will fish in the co-op fishery, in which individual co-ops will direct harvest, or fish in a non co-op fishery that will be managed by NMFS as an Olympic-style fishery.

Certain elements of the whiting cooperative program have the effect of obligating catcher vessel deliveries to a specific mothership. The Council's Final Preferred Alternative specifies a "declaration" process for catcher vessels wherein those catcher vessels desiring to participate in a cooperative would declare a mothership to which they will deliver to in the coming year. LE permits will be issued for motherships and required for a mothership to receive whiting from catcher vessels.

The preferred alternative for the mothership sector cooperative program can be described as a LAPP that allocates portions of the mothership sector allowable catch level to catcher vessel permits licensed to participation in the mothership sector. Participants in the mothership sector only have defensible access to their assigned catch if they join a cooperative. If a permit fails to join a cooperative, the share of catch attributed to that permit is placed in the noncooperative fishery (a common quota fishery where participants are likely to fish competitively). Permits that join a cooperative have access to their own catch history through the "golden rule" provision, but can share catch with other vessels in that cooperative voluntarily. Furthermore, cooperatives in the mothership sector may form inter-cooperative agreements and voluntarily share allowable catch across cooperatives. The catch history associated with each permit cannot be separated from the trawl permit, nor can the catch history be made divisible. This lack of divisibility in catch history is intended to stabilize membership in the fishery, thereby stabilizing relationships within the cooperative institutions that are formed.

Under the preferred alternative, motherships in the sector will receive limited entry permits designed to restrict the number of participating motherships. Catcher vessel permit holders in a cooperative must enter into a declaration procedure, where they declare that their catch will be delivered to a particular mothership in the upcoming year. The purpose of the declaration procedure is to help provide some business planning certainty to the mothership within the current year. If a catcher vessel desires to deliver to a different mothership in a subsequent year, the catcher vessel can simply declare that intention without penalty. This declaration can be broken within the year through "mutual agreement" on the part of both the mothership permit holder and catcher vessel permit holder.

The qualifying criteria for motherships and mothership catcher vessels differ. In the case of motherships, the qualifying criteria are based on participation in the fishery from 1997 through 2003. This is a time period that reflects the separation of the two at-sea sectors (1997) and the control date for the rationalization program (2003). The qualifying criteria for catcher vessels encompass 1994 through 2003, a time period reflecting limited entry for catcher vessels and the control date.

Catcher vessel permit ownership is allowed to grow under the preferred alternative. The ownership limit for catch history is specified at 20 percent, which is higher than the largest amount estimated to be initially allocated to catcher vessel entities. Consolidation among catcher vessels is also provided in this alternative through the usage limit, set at 30 percent of the mothership sector allocation. This provides opportunities for cost efficiencies to be realized through fleet consolidation while assuring at least four (4) catcher vessels in the fishery, though the number is likely to be higher.

The size of the catcher vessel accumulation limits simultaneously takes into account the mothership accumulation limits. Since motherships and catcher vessels are both dependent on the fishery, accumulation limits for both catcher vessels and motherships were set while taking into account the balance of power between catcher vessels and motherships and the relationships that may be established and changed through fleet consolidation. In taking these factors into account, the mothership limit was set at 45 percent, assuring at least three (3) motherships in the fishery.

B-2.1 Participation in the Mothership Sector

a. Catcher Vessels

Vessels with CV(MS)-endorsed permits may participate in either the co-op or non co-op portion of the mothership fishery. They will choose annually which fishery they will participate in for the coming year. Additionally, any groundfish LE trawl permitted vessels may participate in the co-op portion of the fishery if they join a co-op (as described in Section B-2.3.3).[7] No other catcher vessels may participate in the mothership fishery.

Option: A vessel may not engage in the processing of whiting during any year in which a CV(MS)-endorsed permit is registered for use with the vessel.

b. Processors

Only motherships with a mothership LE permit may receive deliveries from catcher vessels participating in the co-op or non co-op portions of the mothership sector whiting fishery. (Note: motherships may acquire such permits by transfer; see Section B-2.2.2.)

[7] When such permits participate in a co-op, the co-op will not be allocated any additional fish based on participation by such a vessel.

c. Vessels Excluded[8]

Motherships also operating as a catcher-processor may not operate as a mothership:

Option 1 (Preferred Alternative): During a year in which it also participates as a catcher-processor.
Option 2: During a month in which it also participates as a catcher-processor.
Option 3: At the same time it is participating as a catcher-processor.

❖ Interlinked Elements

CV catch history. Catcher vessel license limitation and catch history designations are both necessary for rationalizing the harvesting side of the mothership fishery. Without these provisions, other catcher vessels could enter the fishery and compete with existing catcher vessels. Such competition runs counter to the ingredients necessary for rationalization. The issuance of catch history to catcher vessels must be implemented alongside a license limitation program in order for the amount of catch available to each cooperative to be calculated and to ensure that members of that cooperative do not compete with other vessels for that catch.

Processor linkage. Processor license limitation and processor linkages work in concert to help ensure that processors will achieve some benefit from rationalization. Processor license limitations and linkages restrict other processors from entering the fishery and reduce competition between existing processors for deliveries from catcher vessels.

Processor declaration. Processor license limitation and processor declarations help provide some stability to processors from rationalization. A declaration process helps a processor develop business plans to accommodate expected catch volume in the coming year.

❖ Rationale and Policy Issues

- Mothership Sector Licensing

    - ♦ *Catcher Vessels*

Limiting participation of catcher vessels in the mothership sector is one component necessary for the rationalization of a fishery managed with harvest cooperatives. Limitation means that only those participants with appropriate licensing may harvest fish in the sector, creating a barrier to entry which is necessary for rationalization – and associated effects – to occur. If other vessels were able to harvest fish in the sector, this would introduce competition that would tend to eliminate the rational type of behavior expected from setting up a cooperative-based fishery. Furthermore, allowing other vessels to harvest fish in the sector would lead to more fishing capital than necessary, eroding the potential economic gains induced through fleet consolidation and associated cost savings. However, if other licensed trawl vessels are allowed to join cooperatives, and therefore be subject to legally-binding agreements which would manage the participation of those vessels, this would give participants in the mothership sector additional tools for harvesting the catch available to them while also managing the participation of those non-CV(MS) endorsed vessels through the cooperative contract.

Restricting a vessel from engaging in mothership opportunities if it has been registered to a CV(MS) permit during the year is intended to maintain the distinctions between motherships and catcher vessels

[8] A vessel that has been under foreign registry after the date of the AFA and that has participated in fisheries in the territorial waters or exclusive economic zones of other countries will not be eligible to participate as a mothership in the mothership sector of the Pacific whiting fishery, as per Section 12102(c)(6) of the AFA.

and also prevent opportunities for participants in the mothership sector from engaging in catcher-processor activity.

♦ *Motherships*

The rationale for the two possibilities for licensing motherships (one would license motherships and one would not) is described in this section. The rationale against establishing a mothership limited entry program is that under status quo, vessels are not required to have a permit to operate as a mothership and there is no limit on the number of vessels that can participate as a mothership. Under these unrestricted conditions, the entire mothership sector allocation is often not harvested completely, so limiting the number of motherships would limit the ability to realize the full economic potential of the mothership sector harvest. Furthermore, establishing a mothership limited entry provision would limit the number of motherships that catcher vessels can deliver to.

A mothership limited entry program is intended to stabilize participation of motherships in the mothership sector. This is an important component of a fishery managed with cooperatives, especially if the fishery includes processor linkages. Linkages require relationships between catcher vessels and motherships and will affect the behavior of catcher vessels and the operation of the cooperatives. Allowing unfettered participation in the mothership sector would cause instability in mothership participation, affecting the entire fishery. Furthermore, it would negatively affect existing motherships. Because of the competition that could occur between motherships if a limited entry mothership program were not implemented, existing mothership processors might not benefit from rationalization.

Restricting catcher-processors from also engaging in mothership activity is intended to protect existing mothership processors in the sector and help ensure that they benefit from rationalization in addition to catcher vessels. Catcher-processor vessels may have the ability to attract catcher vessels from other motherships due to their relatively greater efficiency and the ability to pay higher prices for raw fish deliveries as a result.

License limitation for mothership catcher vessels and mothership processors arguably is intended to help achieve net benefits and efficiency guidance contained in the MSA and Groundfish FMP and to foster a healthy catcher vessel and mothership sector. Furthermore, license limitation of catcher vessels is a necessary ingredient for rationalization through a harvest cooperative structure. The result of such successful rationalization tends to achieve such things as bycatch reduction, thereby relating to conservation goals found within the MSA and Groundfish FMP. Considering the allowance of catcher-processors to also operate as a mothership addresses several aspects of policy guidance on rationalization from the MSA, the Groundfish FMP, and Amendment 20 goals and objectives. In particular, allowing catcher-processors to operate as motherships would arguably increase the efficiency of the program and would contribute toward achieving the greatest benefit to the nation, thus meeting MSA Standard 5, Groundfish FMP Objective 6, and Groundfish FMP Objective 2. However, allowing catcher-processors to operate as motherships may cause disruption in mothership sector participation, which is contrary to Groundfish FMP Objective 14. Allowing catcher-processors to operate as motherships is also related to policy guidance referring to sector health - Groundfish FMP Goal 2 in particular.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Catcher vessel license limitation	X	X				X				
Mothership license limitation		X				X				
Catcher-processors operating as a mothership		X	X			X				

❖ Analysis

- Catcher Vessel Participation in the Mothership Sector

Catcher vessels participating in the mothership sector must be a limited entry trawl vessel. Only those vessels that have a CV(MS) endorsement are able to fish in either the co-op or in the non co-op portion of the fishery. Vessels with a limited entry groundfish trawl permit may participate in a co-op and harvest the catch available to that co-op, but those vessels that do not have a CV(MS) endorsement cannot participate in the non co-op fishery. These participation requirements effectively limit participation in the sector, but mechanisms exist that allow capital in the fishery to change and adapt to varying conditions by allowing non-CV(MS) vessels into a cooperative Allowing any limited entry trawl vessel to participate in a co-op allows the cooperatives the flexibility to determine the amount and type of capital appropriate for harvesting the fish available to the cooperative. This also provides a greater certainty that the harvest available to the cooperative will be realized. If a situation occurs where CV(MS)-endorsed vessels in a cooperative all travel to the Bering Sea to participate in the Pollock fishery and cannot leave the Bering Sea without foregoing Pollock catch, that mothership whiting cooperative can use other licensed trawl vessels on the west coast that are members of that cooperative to harvest their allowable catch, thus providing a mechanism to cooperative members for harvesting the cooperative catch while not foregoing other harvest opportunities. For those motherships that may be relying on harvest from mothership whiting cooperatives, allowing licensed trawl vessels without a CV(MS) permit to harvest cooperative fish provides a greater certainty that the catch in that cooperative will be realized and the motherships will be able to expect delivery activity from the catch attributed to those cooperatives.

- Mothership Processor Limited Entry

Establishing a mothership limited entry program stabilizes participation of motherships in the mothership sector. In addition to stabilizing the capital involved in the processing of whiting, a mothership limited entry program will tend to stabilize the relations between motherships and catcher vessels. This is because it restricts the ability for different mothership participants to enter into the fishery. As described previously, and in Chapter 4, cooperatives rely heavily on close knit relationships between participants. While mothership entities are not members of a cooperative, the relationships established between motherships and catcher vessels will almost certainly have an effect on the prosecution of the fishery and influence cooperatives, especially in a fishery where processor/catcher vessel linkages are established. By extension, the relationships between motherships and catcher vessels will tend to influence the relationships present in a cooperative. It may be reasonable to expect that more stable relations between

individual catcher vessels and individual motherships will affect the stability of relationships that exist among catcher vessels in a cooperative.

The stability in mothership participation created through a mothership limited entry program may lead to longer term and more stable relationships between catcher vessels and motherships compared to a case where there is no limited entry for motherships. If mothership participation is not limited, new motherships may enter into the fishery. If catcher vessels are allowed to freely deliver to any mothership, this would lead to increased competition between motherships for catch from catcher vessels. This is likely to play into the catcher vessels favor because it is likely that catcher vessels would receive higher prices as a result of bidding among motherships for catcher vessels. However, if switching motherships requires that a catcher vessel fish in the noncooperative fishery, having new motherships enter into the fishery may make it more likely that catcher vessels will move into the noncooperative portion of the fishery in greater numbers, or on a more frequent basis. Increased participation in the noncooperative portion of the fishery may decrease the management performance of the fishery because of increased probability of bycatch events or other matters. This may occur because this noncooperative portion of the fishery is a competitive, derby fishery and behavior in that type of a fishery may be less rational.

If new motherships were allowed to enter into the fishery, the effect on existing motherships would tend to be adverse. New motherships would likely reduce the number of catcher vessels (and therefore catch) delivering to the average mothership, which would lead to reduced revenue being generated by each mothership operation. Limiting the number of motherships would work in the opposite direction with more catcher vessels delivering to the average mothership. When combined with processor linkages, processor limited entry may also allow processors to rationalize, similar to what may occur among the catcher vessel portion of the fishery.

● Catcher-processors Operating as a Mothership

Allowing catcher-processors to operate as a mothership effectively means that rationalization will allow consolidation to occur across the catcher-processor and mothership sectors rather than remaining within each of two sectors. Over time, theory would suggest that (if catcher-processors are allowed to operate as a mothership) the differentiation of catcher-processors and motherships would no longer exist. Instead, the fishery may be made up of several vessels which do a combination of catcher-processor and mothership activity in order to reach a more efficient point of production.

Several factors indicate that some entities will be in a relatively better position than others to capitalize upon this breakdown in sector divisions that occurs by allowing catcher-processors to operate as a mothership. These include institutional factors affecting the make-up of operations in each sector, institutional factors influencing participation in both activities, and the marginal amount of revenue generated by catcher-processor activity and mothership activity. These are outlined briefly below with additional explanation following.

<u>Institutional factors</u>

- Through the catcher-processor cooperative governing contract, catcher-processors have a defensible harvest privilege that may allow them to be flexible and accommodating to mothership catcher vessels without giving up access to fish in the catcher-processor sector. Catcher-processors that operate in Bering Sea Aleutian Islands (BSAI) Pollock also have a defensible harvest privilege that allows them to be flexible because they do not risk losing BSAI Pollock opportunities based on their activities in the whiting fishery.
- Mothership vessels may not be able to be as flexible and accommodating to catcher vessels because they do not have a defensible access to catcher vessel catch (especially if a long-term linkage does not exist). Furthermore, motherships in the BSAI Pollock fishery do not have

linkages to catcher vessels, meaning motherships compete to a certain extent with other mothership vessels for deliveries. This may at times mean a mothership can lose potential Pollock deliveries if they accommodate a whiting catcher vessel rather than a Pollock catcher vessel.[9]

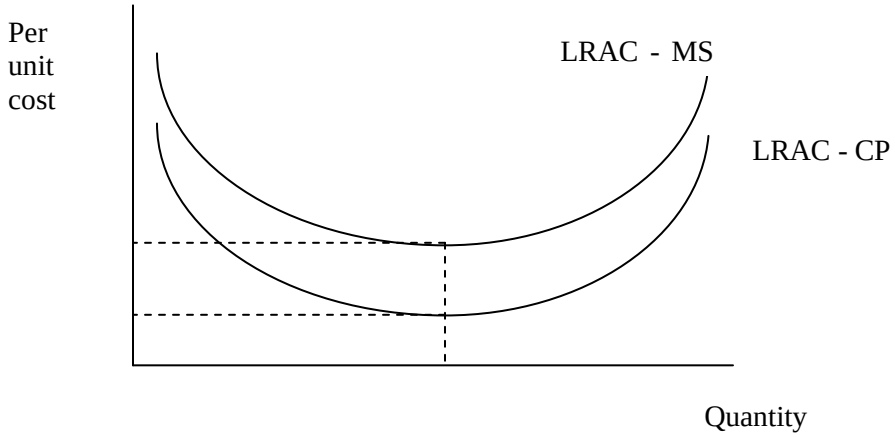
- Mothership vessels could participate in catcher-processor activity (if they acquire the necessary license), but flagging requirements make several mothership vessels unable to participate in the harvesting of fish. This means that only three existing motherships would be able to engage in catcher-processor activities, but all catcher-processors would be able to engage in mothership activities (subject to appropriate licensing).

Cumulative and marginal revenue

- A vessel that engages in both catcher-processor and mothership activity may be able to take a smaller profit margin in the mothership sector than a vessel that operates exclusively as a mothership vessel and still generate cumulatively more revenue. This means that a catcher-processor could pay catcher vessels higher prices (and attract catcher vessels from other motherships) and still be more profitable than a mothership which processes the same volume through mothership activity exclusively.

♦ *Catcher-processors Operating as a Mothership, the Potential Attainment of Cost Minimization, and the Effect on Efficiency*

Allowing catcher-processors to operate as a mothership is a change from status quo, and breaks down some of the barriers created through the division of the mothership and catcher-processor sectors (created in 1997). This allows both motherships and catcher-processors to access greater volumes of whiting, but only if consolidation occurs and some motherships and/or catcher-processors leave the fishery. Assuming both motherships and catcher-processors have a limited entry program restricting access, then theory would suggest that some catcher-processors are likely to acquire mothership permits and some motherships acquire catcher-processor permits, resulting in consolidation in both sectors.

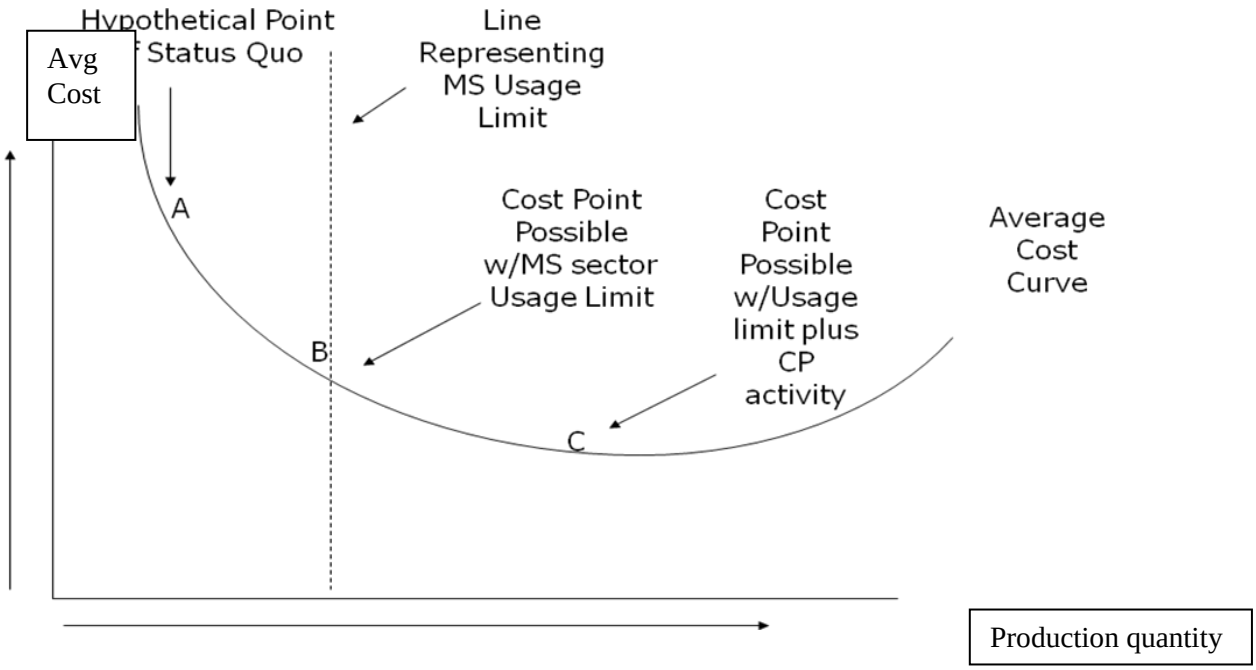


Assuming motherships can engage in catcher-processor activity and vice versa, then the least efficient motherships will theoretically drop out of the fishery as catcher-processors move into the mothership sector, and the least efficient catcher-processors will theoretically drop out of the fishery as motherships move into the catcher-processor sector. Vessels that remain would participate in both sectors of the fishery simultaneously (if allowed), and the outcome would be an improvement in the economic efficiency of the fishery. However, because of flagging requirements restricting the ability of some motherships to harvest fish, just three existing motherships would be able to operate as catcher-processors, meaning that several others would be restricted from operating as catcher-processors even if they were the more efficient vessels. Catcher-processors would not be restricted from operating as motherships (so long as they hold a mothership permit). This means that several existing motherships would not be able to capitalize on this breakdown in sector divisions, and would be more likely to be consolidated out of the fishery even if they are more efficient.

♦ *Catcher-Processor and Mothership Cost Structure Comparison*

The cost structure associated with catcher-processing activity is generally acknowledged to be different than that cost structure associated with mothership activity. While a catcher-processor and a mothership platform may be made up of entirely the same capital, a mothership operation must pay for fish deliveries

[9] Anecdotal information indicates that a substantial amount of vertical integration exists in the mothership portion of the Pollock fishery. Therefore, competition for catcher vessels among motherships in that fishery may not be widespread.



from catcher vessels, while a catcher-processor operation does not. A mothership operation uses more capital than a catcher-processor operation because of the involvement of catcher vessels. This additional capital arguably makes mothership operations more costly than catcher-processor operations (assuming a catcher-processor vessel and a mothership vessel are made up of the same capital). The higher cost associated with mothership operations may come in the form of purchasing fish from catcher vessels, or if the mothership and catcher vessel are vertically integrated, higher operational costs from operating both a catcher vessel and a mothership. The following figure illustrates, conceptually, the difference between a mothership operation's cost structure and a catcher-processor's cost structure. Both operations could theoretically have the same minimum cost point of production quantity, where the same production quantity is their minimum cost level, but the cost of producing at that minimum point is less for a catcher-processor operation than a mothership operation.

The next figure illustrates yet another conceptual view of how allowing catcher-processors to engage in mothership operations can impact a vessel's cost structure.[10] Assuming the existing average cost of mothership activity in the mothership sector is at point A, motherships can theoretically decrease average costs by engaging in fleet consolidation and increasing production per vessel. This can be done up to a point representing the MS usage limit, or point B. Allowing a catcher-processor to engage in mothership activity allows that vessel to spread even more production quantity across that same platform, providing opportunities for that vessel to achieve point C. The concept here is two-fold. This concept allows catcher-processors to engage in mothership activity, providing an opportunity for that platform to increase production and decrease average costs, meaning an increase in efficiency. It also allows a vessel that engages in both sectors to not be held to production quantities defined by the MS usage limit. It is only held to a production quantity defined by the usage limit while it is participating within the mothership sector. Vessels that remain in the mothership sector are restricted by regulation from producing quantities above point B, meaning that vessels only engaging in mothership activity do not have opportunities to access as much fish as a vessel producing in both the catcher-processor and mothership sector, therefore their ability to increase efficiency is more limited. This is particularly important when considering that some mothership vessels do not have the opportunity to engage in catcher-processor activity because of flagging requirements. This means that those entities which can only participate as a mothership do not have the opportunity to decrease average costs like entities that can participate in both sectors for at least

[10] This figure illustrates a single average cost curve for both mothership activity and catcher-processor activity. While both of these activities would be better represented by different cost curves, one is presented in the interest of easily communicating the concept.

two reasons: one being that they cannot engage in catcher-processor activity, and another being that their production is limited by the mothership sector usage limit.

When a catcher-processor operates as a mothership, it may have the same variable cost per unit of production as a mothership that only operates as a mothership. However, a vessel which has engaged in catcher-processor activity may have covered costs and generated revenue through that, meaning that participation in the mothership sector would simply be an additive benefit above the revenue generated through catcher-processor activity. This is not unlike the concept identified by Pinkerton and Edwards (2009), where they found that initial recipients of quota share pay high rates to lease quota above the amounts that they own, simply because the leased quota is an additive amount of revenue which is above that revenue generated through their own quota. In this case, catcher-processors may be in a similar situation where the catcher-processor cooperative governing contract acts similarly to the initial allocation described in Pinkerton and Edwards (2009) and participation in the mothership sector is similar to the leasing of quota also described in that research. Catcher-processors in this example have generated revenue and covered costs through catcher-processor activity and view mothership activity as an added benefit, or "icing on the cake." In a cumulative sense, catcher-processors also operating as a mothership generate cumulatively more revenue than a pure mothership operation producing the same quantity even if the marginal cost of engaging in mothership sector activity is the same.

The fact that mothership activity by a catcher-processor may be viewed as an added benefit brings up a second point. Following the concept outlined in the research done by Pinkerton and Edwards (2009), catcher-processors engaging in mothership activity may tend to bid up the price of engaging in mothership activity if more than one catcher-processor participates in the mothership sector. This would take the form of paying catcher vessels higher prices for deliveries as those catcher-processors compete among one another for deliveries from catcher vessels. Meanwhile, motherships that only engage in mothership activity are likely to find it difficult to follow suit and pay those higher prices for deliveries because they have an overall higher cost structure. This is because they generate their income from mothership activity alone, which has a smaller profit margin than catcher-processor activity, and cannot afford to follow the higher prices that are created as the catcher-processors compete among themselves for deliveries from mothership catcher vessels. Over time, the mothership operations become out-competed by those catcher-processors that also engage in mothership operations, unless those motherships decide to become a catcher-processor and take on the same business model. However, it is

important to point out again that several motherships would be prohibited from taking this action due to flagging requirements.

♦ *Institutional Factors and Catcher-Processors Operating as a Mothership*

The ability for a catcher-processor/mothership vessel to acquire deliveries from mothership catcher vessels is related to the time at which a catcher-processor can engage in mothership activities. Since a catcher-processor vessel has a defensible harvest privilege in its participation in the catcher-processor sector (either in the form of an IFQ, or as part of the cooperative agreement), it can elect to harvest its share of the catcher-processor allocation at a time of its choosing without fear that another catcher-processor will take its catch. This is different from a mothership operation, which is not granted a defensible resource access privilege, but may be granted a linkage to a vessel with a harvest privilege in a cooperative program that can be broken over the long-term. This structure takes on some of the characteristics of a limited access privilege in the short-term, but means the mothership linkage is not ultimately defensible because it can be broken and moved to another processing vessel. This same concept holds true for the declaration process.

While motherships with processor linkages or a declaration have more stable and predictable production volumes than motherships without linkages, they must negotiate arrangements with catcher vessels in order to accept deliveries from those vessels. Such negotiations will undoubtedly take into account the timing of opportunities in Bering Sea Pollock and the shoreside whiting sector. At times, the objectives of the two vessel types may be at odds. If an agreement is not reached, a mothership can lose that catcher vessel, if not in the current year, then in the subsequent year. This is different from the catcher-processor sector, where a catcher-processor does not risk losing catch privileges if it participates in other fisheries or sectors. A catcher-processor's catch privileges are protected by a cooperative contract. This allows catcher-processors to better accommodate the harvest timing of mothership catcher vessels, because they do not risk losing their catcher-processor opportunity. This flexibility may make a catcher-processor/mothership operation more attractive than a pure mothership operation that is constrained by its participation in other fisheries, especially since not participating in those other fisheries may mean foregoing deliveries from catcher vessels. For example, motherships that participate in the BSAI Pollock fishery do not have processor linkages, so that mothership must balance Pollock catcher vessels with whiting catcher vessels. Should there be a time when those fisheries are in competition for timing, the mothership may risk losing catcher vessels in one of those fisheries. This catcher-processor timing advantage is true regardless of whether catcher-processors can operate as a mothership simultaneously, or cannot operate in the same month, though the timing advantage is certainly larger if a catcher-processor can operate as a mothership simultaneously.

♦ *Motherships Operating as a Catcher-Processor*

One way in which a mothership could more easily attain a cost minimization strategy, and attain a cost minimization structure that is comparable to a catcher-processor, would be to acquire a catcher-processor endorsed permit and also operate as a catcher-processor. In this way, the mothership would take on the (arguably more efficient) operation of a catcher-processor model for a portion of that vessel's production. If the cost efficiency that vessel can attain is greater than the cost of the catcher-processor permit, that vessel would find participation in the catcher-processor sector profitable. However, a mothership also operating as a catcher-processor raises a question about how that participant may impact the existing catcher-processor cooperative. Depending on the catcher-processor cooperative agreement, a mothership that acquires a catcher-processor permit and participates in the catcher-processor sector may introduce some aspect of "new entry" that causes instability in that voluntary cooperative. However, it is important to note that this instability is no different than that caused by any other new participant that acquires a

catcher-processor permit. Another possible model is the lease of a catcher-processor permit by a mothership capable of engaging in catcher-processor activity. This could occur if a catcher-processor company does not desire to participate in the whiting fishery and instead allows a mothership operation to fill their role in the catcher-processor sector. This may prove less disruptive to the existing catcher-processor cooperative because, presumably, the cooperative agreement would still apply to the entity leasing a catcher-processor permit from an entity that has signed the cooperative agreement. However, only three existing motherships would be allowed to engage in catcher-processor activities because of flagging requirements. Other existing mothership operations cannot engage in the harvest of Pacific whiting.[11] This is contrary to the catcher-processor vessels that exist in the fishery – all of which could potentially engage in mothership activity.

- *Entities Qualifying for Catcher-processor and Mothership Permits*

The qualification rules for receiving a catcher-processor endorsed permit and a mothership permit result in one entity receiving both a catcher-processor permit and a mothership permit. Other entities involved in the catcher-processor or mothership sectors would receive a mothership permit or a catcher-processor permit, but no other entity would receive both. This means that other entities that may desire to participate in the other sector would face a barrier to entry in the form of the cost of a permit.

- *Effect on Efficiency from Allowing Catcher-processors to Engage in Mothership Activity*

While the information above indicates that allowing catcher-processors to operate as a mothership may tend to benefit vessels capable of engaging in catcher-processor activity at the expense of some pure mothership vessels, net benefits and the efficiency of a rationalization program are expected to be greater if catcher-processors are allowed to engage in mothership activity. This increase in net benefit and efficiency is a result of breaking down the barriers between the two sectors that will tend to eliminate less efficient vessels in favor of the more efficient vessels and result in consolidation overall. Unfortunately no empirical information is readily available with which to estimate the relative effect on net benefits and efficiency.

B-2.2 Permits/Endorsement Qualification and Characteristics

B-2.2.1 Catcher Vessel Mothership Whiting Endorsement (CV(MS) Whiting Endorsement)

a. Endorsement Qualification and History Assignment

Permits with a qualifying history will be designated as CV(MS) permits through the addition of an endorsement to their LE groundfish permit. At the time of endorsement qualification, each permit will also be assigned a catch history that will determine the share of the mothership whiting allocation associated with that permit.

Qualifying for a CV(MS) Whiting Endorsement. An LE permit will qualify for a CV(MS) whiting endorsement if it has a total of more than 500 mt of whiting deliveries to motherships from:
Qualification Option 1 (Preferred Alternative): 1994 through 2003
Qualification Option 2: 1997 through 2003

[11] Since 1995, eleven vessels have engaged in mothership activity. Six vessels have participated between the years of 1997 and 2004.

Catch History Assignment (Identification of Endorsement Related Catch History). The following are options for the initial calculation to be used in determining NMFS distribution to co-op and non co-op fishery pools. A CV(MS) whiting endorsement calculated catch history will be based on whiting history during the related permits.

Catch History Assignment Option 1: The initial catch history calculation for CV(MS) whiting endorsements will be based on whiting history of the permit for 1997 through 2003, dropping one year.
Catch History Assignment Option 2 (Preferred Alternative): The initial catch history calculation for CV(MS) whiting endorsements will be based on whiting history of the permit for 1994 through 2003, dropping two years.[12]

A permit's history for each year will be measured as a share of the fleet history for that year (i.e., "relative pounds" will be used). The Council also considered but rejected using a straight sum of pounds in the allocation formula ("absolute pounds").

(Note: the Council considered but rejected a requirement that permit qualifying in both the shoreside and mothership co-op programs would have to drop the years from their allocation calculation.)

For the purpose of the endorsement and initial calculation, catch history associated with the permit includes that of permits that were combined to generate the current permit.

b. Whiting Endorsement Transferability and Endorsement Severability

Transfer Option 1 (Preferred Alternative): The CV(MS) whiting endorsement (together with the associated catch history) may not be severed from the groundfish LE trawl permit.
Transfer Option 2: The CV(MS) whiting endorsement (together with the associated catch history) may be severed from the groundfish LE trawl permit and transferred to a different LE trawl permit. Catch history associated with the whiting endorsement may not be subdivided.

Added as part of the Preferred Alternative: CV(MS) permits may be transferred two times during the fishing year, provided the second transfer is back to the original catcher vessel (i.e., only one transfer per year to a different catcher vessel).

c. Accumulation Limit

CV(MS) Permit Ownership: No individual or entity may own CV(MS) permits for which the allocation totals greater than the following percentage of the total mothership sector whiting allocation:

Option 1: 10 percent,
Option 2: 15 percent,
Option 3: 25 percent,
Option 4: the amount of the largest current owner (no grandfather clause), or
Option 5 (Preferred Alternative): 20 percent**.**

Added as part of Preferred Alternative:

Catcher Vessel Usage Limit: No vessel may catch more than 30 percent of the mothership sector's whiting allocation.

[12] February 2010: The word "worst" was removed in line with the Council's April 2009 action specifying that the permit owner would be allowed to select the years dropped from the calculation.

d. Combination

CV(MS) Permit Combination to Achieve a Larger Size Endorsement. When a CV(MS)-endorsed permit is combined with another permit, the resulting permit will be CV(MS) endorsed, except when the CV(MS) permit is combined with a CP permit, in which case the CV(MS) endorsement will not survive on the resulting permit.[13]

❖ Interlinked Elements

Permit length endorsement. If the permit length endorsement is eliminated, bullet D above is irrelevant.

The definition of "largest current owner" should be better defined. If "current" is interpreted to mean the date immediately before rationalization goes into effect, there will likely be a race to accumulate permits prior to the implementation of the rationalization program.

❖ Rationale and Policy Issues

- Qualifying Years Formula

Two options exist for years making up the catch history formula. One option includes the time period between the separation of the at-sea sectors (1997) and the control date (2003), while the other includes the time between the establishment of limited entry (1994) and the control date. Both options require at least 500 mt of deliveries to motherships in order to ensure that the permit has substantially participated in the fishery.

- Catch History Formula

Two options exist for years making up the catch history formula. One option is intended to reflect participation during the years between the time the at-sea sectors were separated and the control date. This time period is intended to be more reflective of existing mothership fishery participation patterns while taking into account the control date. The second option (1994 to 2003) is intended to reflect participation in the mothership sector between the time of limited entry and the control date. This option reflects participation by catcher vessels delivering to processing vessels after limited entry. Going back to 1994 is arguably reasonable because catcher vessels that delivered to processing vessels prior to 1997 still operated in mothership activity, and the separation of the at-sea sectors in 1997 affected mothership vessels and catcher-processors, not catcher vessels necessarily.

Dropping the worst year, or worst two years, is intended to excuse a poor year or two a vessel may have had for a variety of issues including the possibility that a vessel may have broken down within the catch history calculation period.

[13] Specifically, a CV(MS)-endorsed permit that is combined with an LE trawl permit that is not CV(MS)-endorsed or one that is CV(SS)-endorsed will be reissued with the CV(MS) endorsement. If the other permit is CV(SS)-endorsed, the CV(SS) endorsement will also be maintained on the resulting permit. However, CV(MS) and CV(SS) catch histories will be maintained separately on the resulting permit and be specific to participation in the sectors for which the catch histories were originally determined. If a CV(MS) permit is combined with a CP permit, the CV(MS) endorsement and history will not be reissued on the combined permit. The size endorsement resulting from permit combinations will be determined based on the existing permit combination formula.

A variety of other dates were considered but dropped. These other options included the year 2004 as the end year for the qualifying period, and 1998 as the start year for the qualifying period. The year 2004 was dropped because it was after the control date, while the year 1998 was dropped because the at-sea sectors were separated in 1997, not 1998. Further explanation of other catch history formulas and supporting rationale can be found in Appendix A, Section 2.1.3.a.

The Council also considered whether to use "relative pounds" (i.e., an entity's catch history for a particular year measured as its share [percent] of the total catch for that year) or "absolute pounds" (i.e., an entity's catch history for a particular year measured as the total pounds for the year). The Council chose to use relative pounds because it was consistent with how landings history was measured for the IFQ program, it puts a heavier emphasis on more recent landings (consistent with the MSA) and the Council felt it was likely to better reflect the distribution of capitol in that fishery.

- Endorsement Transferability and Endorsement Severability

The rationale for not allowing endorsements to be severed from the limited entry trawl permit is that it stabilizes the membership of harvesters in the mothership sector and this helps foster better relationships among cooperative members.

Allowing endorsements to be severed from the permit is a mechanism which allows for more fluid transfer of access to the mothership sector while retaining a limitation on participation. If an existing bottom trawl vessel were to desire to participate in the mothership fishery, that vessel could participate by purchasing a CV(MS) endorsement, and this may be less costly than having to purchase the entire CV(MS)-endorsed permit.

- Accumulation Limits

Limits on the accumulation of catch history are intended to prevent excessive control by any single entity. A range from 10 percent to 25 percent analyzes the effect of requiring a minimum of 10 to 4 entities controlling harvest privileges in the fishery. Establishing an accumulation limit that is equal to the amount of the largest current owner is intended to recognize existing ownership and participation in the fishery, but not allow an entity to acquire more. In order to implement an accumulation limit that is equal to the amount of the largest current owner, the term "current" will need to be defined, presumably as a particular date.

The consideration of appropriate accumulation limits for catcher vessels is done while simultaneously considering accumulation limits for motherships. These accumulation limits are considered simultaneously in order to help balance the number of motherships with the number of catcher vessels. This balance is arguably important in a cooperative-based mothership fishery because the relationships that exist between motherships and catcher vessels can impact what occurs in a cooperative. Arguably, an appropriate balance entails establishing catcher vessel accumulation limits that result in more than one catcher vessel per mothership, and enough motherships in the fishery that catcher vessels have alternative markets.

As part of the preferred alternative the Council added a "usage limit" which restricts the amount of fish any catcher vessel can catch. This is different from a vessel limit specified as part of the IFQ program. Where a vessel limit restricts the amount of quota pounds that can be registered to a vessel, a usage limit restricts the amount of fish a vessel can catch. This differentiation is necessary since a cooperative program does not include provisions for tracking the trading of catch history among vessels during the course of a season. The reason for having a usage limit is to place a limit on the amount of consolidation that can occur in the harvesting portion of the fishery. This limit on consolidation is important in

maintaining a balance between motherships and catcher vessels. Mothership operators have indicated that they need at least two catcher vessels to make a mothership operation work. Alternatively, catcher vessel operators have indicated that some fleet consolidation may be necessary – at least in some years – to achieve desired levels of efficiency. The Council considered the appropriate size of the usage limit and specified their desire to allow some growth while maintaining a balance between catcher vessels and motherships. The adopted limit is slightly higher than the percent of catch of some catcher vessels in recent years, meaning it allows for some growth of the largest operators, even though the initial allocation of catch history will be far less than this number.

- CV(MS) Permit Combination to Achieve a Larger Size Endorsement

In cases where permits are combined to achieve a larger size endorsement, the permit will be CV(MS)-endorsed (except if a permit is combined with a CV[SS] permit, in which case it will have both endorsements). This is intended to ensure that a permit cannot become dually endorsed and be able to participate in another sector. This restriction is intended to act as a capacity control measure.

The consideration of permit qualification years and catch history years is related to disruption and fairness and equity goals found within the MSA and groundfish FMP because it grants permits and catch history to certain entities based on historic participation in the fishery. Endorsement transferability is related to disruption, fairness and equity, and harvester and sector health, while accumulation limits are related to excessive share guidance found with the MSA and groundfish FMP.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Qualifying years formula			X		X					
Catch history formula			X		X	X				
Endorsement transferability and severability			X		X	X				
Accumulation limits				X						

❖ Analysis

- Endorsement Qualification and History Assignment

The issuance of permits with CV(MS) endorsements is necessary to limit access to the mothership sector. A limitation on participation in the mothership sector is necessary for a cooperative-based fishery to rationalize itself. Otherwise new participants may enter the fishery and introduce an element of competition which is intended to be eliminated through rationalization. This was described in more detail under Section B.2.1. Catch history assignments are a resource access privilege. The collective catch history of a cooperative determines the pool available to that cooperative, while the collective catch history of participants in the noncooperative fishery determines the pool available to that fishery. Catch history assignments help solve resource sharing problems among cooperative members, thus helping to stabilize relations among participants in cooperatives. This effect was described previously under Section B.1.1.

- Qualification for a CV(MS) Endorsement and Catch History

In order to receive a CV(MS) endorsement, vessels must have a total of more than 500 mt of whiting deliveries to motherships from either 1994 through 2003, or 1997 through 2003. Applying a 500 mt filter excludes two permits that participated in the fishery. One participated in 1994, while the other participated in 1995. Of those permits that harvested more than 500 mt, only one permit is affected by the choice of qualification formulas. The inclusion of this permit and associated catch history into the initial allocation does not appear to substantially affect the total amount of catch history available to the other permits because the amount of quota allocated to this permit is small. However, these other permits are affected by the years upon which catch history calculations are made.

Table B-7. Permit level participation in the mothership whiting fishery and the effect of qualification years (only includes permits that meet the minimum metric ton threshold for CV(MS) endorsement qualification).

	AD-HOC	Qualification Years Considered for Receiving a Mothership CV Endorsement

- Effect of Catch History Calculation Formulas

The effect of the catch history calculation formulas is shown in the figures below. The difference between the catch history formulas is slight for most permits, though some permits see differences of several percentage points. When compared to catch during the recent periods (the period after the control date), some permits receive catch shares that differ very little, while others receive catch shares that are several percentage points different (Figure B-3 and Figure B-4).

Amendment 15 created mothership and shoreside whiting sector catcher vessel endorsements, which vessels are required to have in order to participate in each of the designated sectors. Amendment 15 endorsements are required in addition to limited entry trawl permits. There are a total of 30 catcher vessels with Amendment 15 endorsements for the mothership sector and 25 of these have limited entry trawl permits. Of the 25 permits currently associated with an Amendment 15 mothership-endorsed catcher vessels, 24 would receive an initial mothership sector catch history allocation. The total allocation for these 24 permits would be 90.18 percent. There are six other permits that will receive an initial allocation that are not currently associated with Amendment 15 mothership-endorsed catcher vessels. These permits will receive the remaining 9.82 percent of the allocation. Three of the permits are assigned to vessels that, under Amendment 15, are qualified to participate in the shoreside whiting fishery. The remaining three permits are associated with vessels that are not qualified to participate in either the shoreside or mothership whiting fisheries. With the implementation of trawl rationalization, the Amendment 15 vessel endorsement system will sunset.

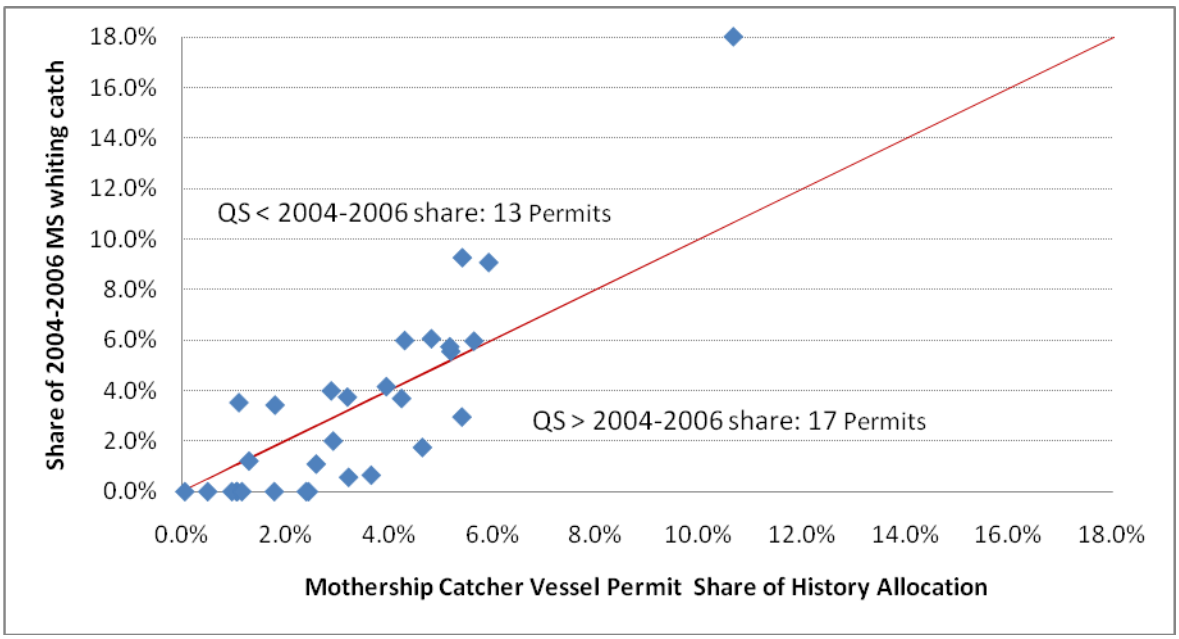

Figure B-3. Initial mothership sector allocation shares to catcher vessel permits in comparison to 2004-2006 average share of harvest for the each permits.

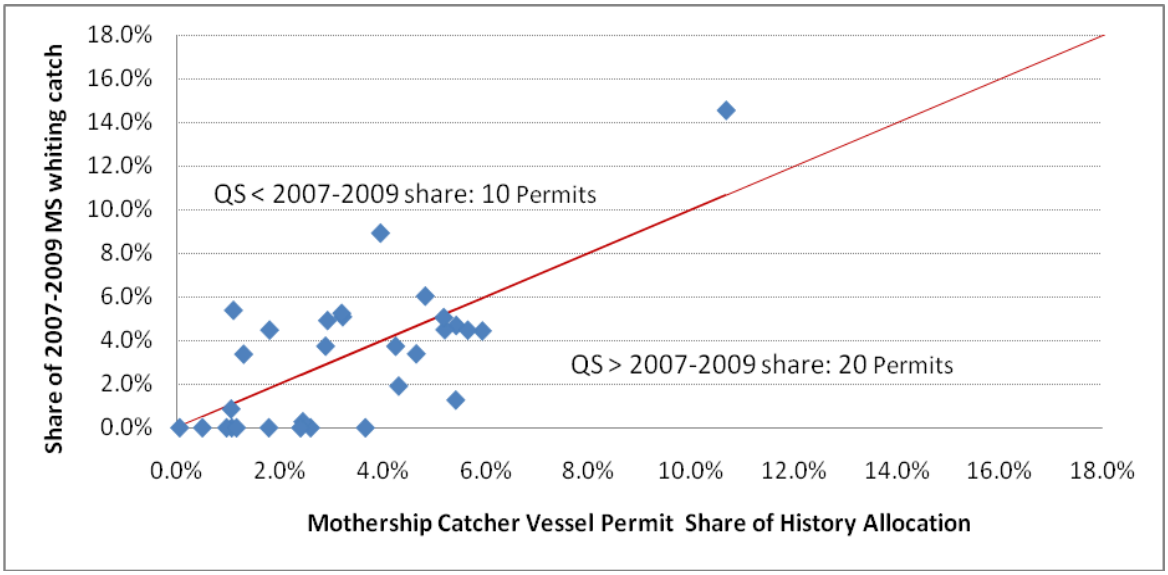

Figure B-4. Initial mothership sector allocation shares to catcher vessel permits in comparison to 2007-2009 average share of harvest for the each permits.

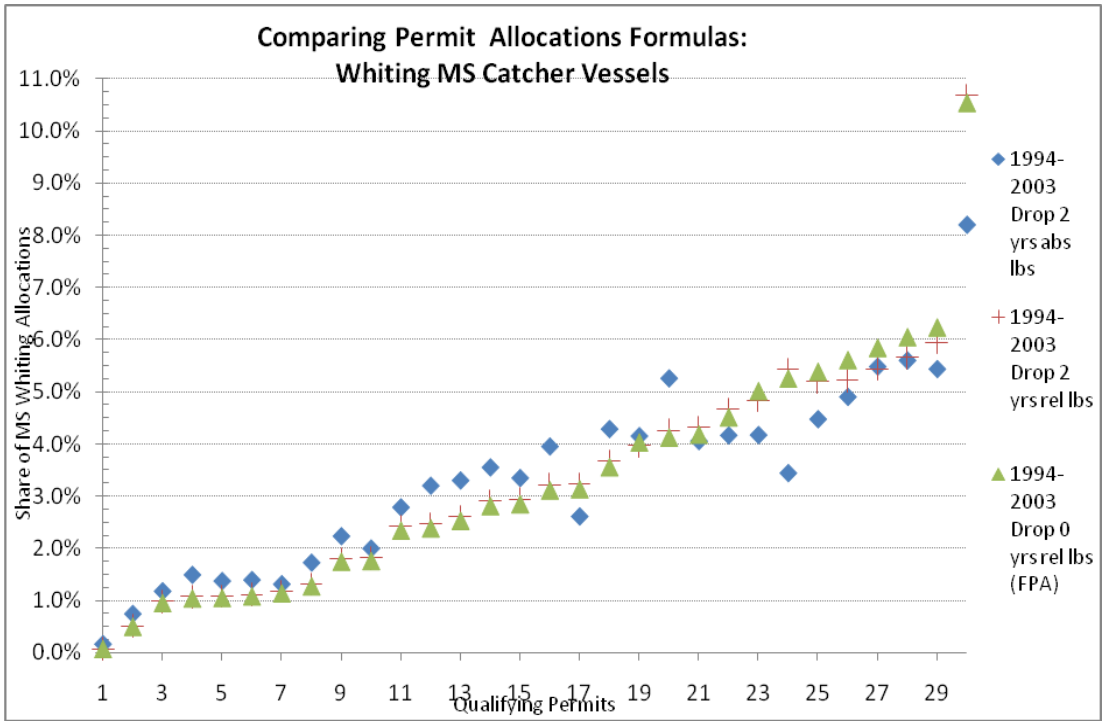

Figure B-5. Catch history distributions to permits by relative versus absolute history calculation formula.

When catch history distributions are estimated at the business entity level, the effect is somewhat different than when examined at the permit level. Some entities receive catch histories that are several percentage points different than their recent catch shares regardless of the allocation formula, though all entities are below the accumulation limits.

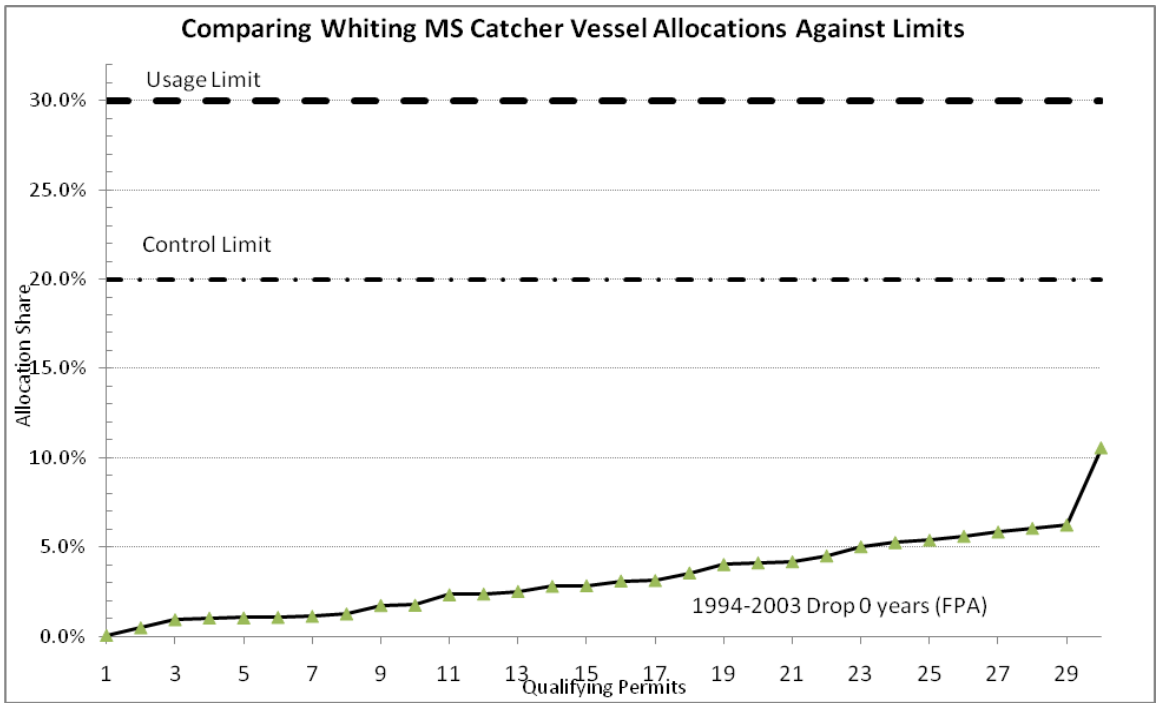

Figure B-6. Catch history distributions and accumulation limits to entities.

The trade-offs between use of relative pounds and absolute pounds are discussed for the IFQ Program in Section A-2.1.3.a of Appendix A. Those that are relevant to the allocation of catch history to mothership catcher vessels are summarized here. One impact of using a relative history (annual shares) to calculate an allocation is to weigh each year's catch. For example, a pound of whiting caught in the mothership sector in 1998 would give a permit about half as much credit toward an allocation as a pound caught in 2003 (Table B-8).

Table B-8. (Rows Excerpted from table in Appendix A Section A-2.1.3.a). Illustration of relative lb "weights" (sector catch in year 2003 divided by annual catch): 1994 to 2004.

Stocks or Stock Complex	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004
Pacific Whiting											
Shoreside Whiting	0.70	0.68	0.60	0.59	0.58	0.61	0.60	0.70	1.12	1.00	0.55
At-Sea Whiting (MS)	0.45	0.29	0.56	0.53	0.54	0.55	0.63	0.73	0.98	1.00	1.08
At-Sea Whiting (CP)	0.48	0.67	0.63	0.58	0.59	0.61	0.71	0.70	1.13	1.00	0.56

On the one hand, relative history may be considered more fair and equitable because it weighs each vessel's performance each year based on how it did in its competition with the rest of the fleet given the opportunities present that year (its relative effort level). On the other hand, the amount and distribution of private and community capital involved in the fishery may be more related to total harvests than the proportion of harvest each year. It should also be noted that under a relative weighting scheme, as compared to a straight summing scheme, catch histories that diverge from the pattern exhibited by the entire fleet tend to be rewarded when determining an initial allocation.

The relative pounds (annual share) measure of history puts a heavier emphasis on more recent landing history because landings of whiting have declined during the 1994-2003 allocation period. This may be consistent with MSA language that encourages consideration of current harvests when making an initial allocation. Increasing the emphasis on more recent years through the mechanism of relative weighting could better reflect the distribution of capital and labor in the fishery, depending on how long the capital

persists in a particular use after the investment is made. The MSA also encourages consideration of historic harvests. In a situation where the harvest in recent years has diminished, as is the situation here, recent year harvest could be less of a driver of the current distributions of capital than older history. Because capital is generally a long-lived asset, harvests during years of higher production may drive the current distribution of capital in the fishery more than years of lower harvest, even if those higher years of harvest were in the more distant past.

Alignment of the initial allocation to existing patterns of investment and participation in the fishery reduces disruption to labor, capital, the fishing sector, and communities. Reduced disruption implies greater net benefits because there will be less need for transactions to bring the distribution of capital and labor into line with the distribution of QS.

For the mothership catcher vessel allocation, a choice to use relative pounds (annual shares) will benefit those expected to receive the largest amount of the initial allocation (those with the most catch history) while a choice to use a straight summing of the pounds (absolute pounds) will tend to benefit those that would receive a lesser initial allocation. This pattern of effect on initial allocation is likely a result of a harvest pattern whereby those receiving more have a greater catch history from having participated more consistently over a larger number of years (including significant participation in more recent years) while those receiving less tend to have stronger participation in earlier years relative to their participation in more recent years.

- Endorsement Transferability and Endorsement Severability

Making the CV(MS) endorsement transferable makes the endorsement, or the permit to which it is tied, take on value that is reflected by the amount of revenue that could be generated from CV(MS) activity. Transferability means that the market will be able to determine the participants in the fishery as the more efficient operators purchase those permits and less efficient operators drop out. Transferability also helps ensure that there are harvesters engaged in the fishery over the long run. If, for example, the owner of a permit is deceased, allowing the estate to transfer that permit to another owner will ensure that participation in the fishery remains. If permits could not be transferred, participation in the fishery may eventually disappear.

While a restriction on endorsement severability is intended to maintain stability in the participation of catcher vessels in the sector, it is not immediately clear that restricting the endorsement from being severed from the permit would make participation in the fishery more stable. To the extent that holding endorsements and permits together creates "stickiness" in the market and makes it more difficult for those permits to be transferred, then restricting endorsement severability may make participation more stable.

❖ Accumulation Limits

The ownership limits of 10 to 25 percent could allow for a minimum of 10 to 4 entities to control the mothership sector allocation of Pacific whiting (though it seems unlikely that these minimums would be realized as doing so would mean entities would need to consolidate up to the limit). Under some catch history calculations, one permit may be restricted by the 10 percent ownership limit. Other ownership limits do not appear to be restrictive.

One expected effect of rationalization is fleet consolidation. This is expected to occur because doing so reduces the cost of engaging in fishing opportunity. The usage limit restricts the degree to which fleet consolidation can occur, while the ownership limit restricts the amount of consolidation that can occur among owners of catcher vessel permits. Past information is useful for illustrating the annual catch capability that harvesters in the mothership sector have, and this information is useful for illustrating one potential effect of possible usage limits.

Since 1995, several vessels have caught more than 4,600 mt of whiting in the mothership sector. When compared to the metric tonnage that would be restricted by a 10 percent usage limit under a US whiting OY of 269,545, the catch of some of these vessels would exceed that accumulation limit. It is reasonable to expect that the average catch of mothership catcher vessels would increase as a result of rationalization due to the associated fleet consolidation. A usage limit of 15 to 30 percent does not appear to be as restrictive.

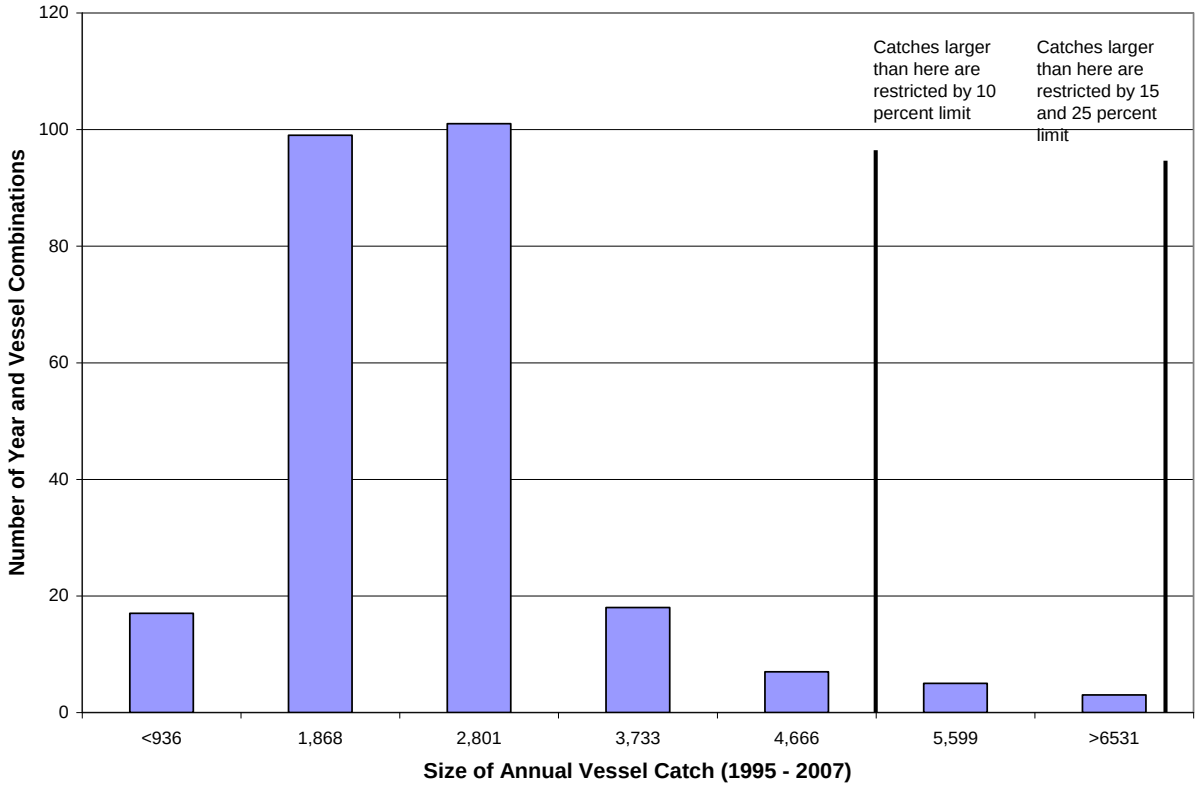

Figure B-7. Frequency of annual vessel catches by metric tonnage category (1995 through 2007).

The information shown above can be complimented with information showing the tonnage associated with the various accumulation limits and two possible whiting OYs. These OYs reflect a range of future whiting OYs based on ranges specified in the recent past. This information shows that in years where the whiting OY is relatively large, most accumulation limits are larger than the annual size of catch by vessels over the past several years. When the OY is relatively small, a 10 percent ownership limit may restrict some entities and a 10 percent usage limit may restrict some vessels.

When viewed in the context of consolidation among the entire fishery (rather than the effect on individual entities and/or vessels), the effect of accumulation limits is different. It is difficult to determine the degree to which rationalization will affect accumulation of catch history at the entity level and the number of entities that will control that catch history. However, the ownership limits of 10, 15, and 25 percent would result in a minimum of 10, 7, and 4 entities owning the catcher vessel catch history in the mothership sector. The usage limit of 30 percent would result in a minimum of four catcher vessels in the mothership sector, though it seems unlikely that any of these minimums would actually be realized.

Table B-9. Mothership catcher vessel accumulation limits and associated metric tonnage based on two hypothetical whiting OYs.

Hypothetical mothership Sector Allocation (mt)	Associated US Whiting OY (mt)	Accumulation Limit and Associated Metric Tonnage			
		10%	15%	25%	30%
63,120	300,000	6,312	9,468	15,780	18,936
34,320	170,000	3,432	5,148	8,580	10,296

B-2.2.2 Mothership Processor Permit

a. Qualifying Entities

Option 1 (Preferred Alternative): The owners of qualifying motherships will be issued MS permits. In the case of bareboat charters, the charterer of the bareboat will be issued the permit.
Option 2: The owners of qualifying motherships will be issued MS permits.

b. Qualification Requirements

A qualifying mothership is one which processed at least 1,000 mt of whiting in each of any two years from 1997 through 2003.

c. Transferability

1. MS permits will be transferable.
2. MS permits may be transferred to a vessel of any size (there will be no size endorsements associated with the permit).
3. **Option 1 (Preferred Alternative):** MS permits may not be transferred to a vessel engaged in the harvest of whiting in the year of the transfer.
   Option 2: MS permits may be transferred to a vessel engaged in the harvest of whiting in the year of the transfer.
4. Limit on the Frequency of Transfers:
   Option 1: MS permits may not be transferred during the fishing year.
   Option 2: MS permits may only be transferred one time during the fishing year.
   Option 3 (Preferred Alternative): MS permits may be transferred two times during the fishing year, provided that the second transfer is back to the original mothership.

d. Usage Limit

No individual or entity owning an MS permit(s) may process more than the following percentage of the total mothership sector whiting allocation:

Option 1: 20 percent,
Option 2: 30 percent,
Option 3: 40 percent,
Option 4 (Preferred Alternative): 45 percent, or
Option 5: 50 percent.

❖ Interlinked Elements

There do not appear to be any components that are substantially interlinked with the mothership permit provisions. However, the sub-options may have a wide ranging array of effects depending upon which sub-option is chosen. The reader is referred to the subsequent options for a more in-depth discussion of these effects.

❖ Rationale and Policy Issues

- Owner of the Vessel or Bareboat Charterer

Eligible entities may include the bareboat charterer of a mothership or the owner of the mothership. The rationale for granting permits to the bareboat charterer is that the chartering entity has engaged in effort and operation of the vessel that has generated historical participation. Therefore, if a permit is to be granted to historical participants, it is the bareboat charterer that has participated in the fishery and that participation should be recognized. Furthermore, granting a permit to the bareboat charterer does not necessarily mean that the charterer will seek out another mothership vessel, so granting a permit to the charterer does not imply the owner of the vessel will be adversely affected.

The rationale for granting the permit to the owner of the vessel is that the owner of the vessel has made an investment in that vessel, and that investment should be recognized and protected by granting a permit to the owner. Granting such a permit to the owner increases the likelihood of that vessel remaining in the fishery and/or protecting the investment of the vessel owner.

- Processing of 1,000 metric tons between 1997 and 2003

Minimum processing requirements are intended to recognize those participants that have substantially participated as a mothership in the Pacific whiting fishery. Using the years 1997 to 2003 is intended to reflect the time period between the date the catcher-processor sector and the mothership sector were separated in regulation (1997) and to be consistent with the control date (2003).

- Transferability

The ability to transfer to a vessel engaged in the harvest of whiting is covered in previous sections documenting the effect of allowing a catcher-processor to operate as a mothership.

The ability to transfer a mothership permit to another mothership may be necessary if, for example, a mothership vessel breaks down. It may also allow mothership vessels to take advantage of unexpected opportunities in other fisheries (such as BSAI Pollock). Allowing a mothership to transfer its permit to another mothership in such a case would provide a way for one mothership to fill the role of the original mothership.

A restriction on the number of transfers ensures that participation in the mothership processing portion of the fishery remains limited. This helps maintain stable relations between motherships and catcher vessels. In a fishery managed with processor linkages, stable relations between processors and catcher vessels translate into more stable operation of cooperatives.

- Usage Limit

A usage limit protects against excessive consolidation of operations among mothership entities. The range of usage limits of 20 to 50 percent examines the effect of allowing a minimum of two to five entities to process the entire mothership sector whiting allocation in a season.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Owner of the vessel or bareboat charterer			X		X					
Minimum processing requirements					X	X				
Transferability		X				X				
Usage limit				X						

❖ Analysis

- Qualifying Entities

Two options exist for identifying a qualifying entity. One grants the permit to the "bareboat charterer," while the other grants the permit to the owner of the mothership vessel. The decision of which entity to allocate the permit to is, to a large degree, a distributional decision. However, there are some implications associated with this decision, described below.

As described previously, a cooperative program relies heavily on relationships between participants in a cooperative. Relationships between motherships and catcher vessels will likely affect relationships among catcher vessels in a cooperative. The charterer of a mothership vessel operates the mothership, and in this capacity has established relations with catcher vessels. Maintaining this relationship helps make the transition to a cooperative-based fishery more seamless, while disrupting the relationship may make the transition to a cooperative fishery (especially one where linkages are established based on past delivery patterns) more difficult. Therefore, granting a permit to the bareboat charterer of a mothership should help make the transition to a cooperative-based fishery easier than it would be if the permit were granted to the owner of the mothership. Granting a permit to the mothership owner means a different entity could operate that mothership and could have different objectives or relationships with catcher vessels than the previous mothership operator.

On the other hand, granting a permit to the mothership owner makes it more likely that the owner will continue to see his/her investments (in the form of the mothership) participate in the whiting fishery. If the owner is not granted the permit, the charterer could move the permit to another mothership vessel, and the mothership owner could find his/her mothership investment less active, or inactive, in the fishery.

This could lead to a loss of revenue and a devaluation of the mothership as an asset. The likelihood of this outcome is unknown.

- Qualification Requirements

The requirement that a mothership must have processed at least 1,000 mt in each of any two years between 1997 and 2003 means that six motherships, owned by five different entities, would qualify. The following table shows the participation of vessels and entities that have taken deliveries from catcher vessels from the years 1995 to 2007. This indicates that five of those vessels would not receive a mothership permit. Two of these vessels may be better described as catcher-processors that have taken deliveries from catcher vessels in the past, two other vessels are no longer present on the west coast, and the remaining vessel only participated in a single year, after the control date. Based on the information shown below, the qualification requirement eliminates one mothership that only participated in a single year after the control date. Other vessels that have received deliveries from catcher vessels have either left the west coast or are better defined as catcher-processors, meaning the qualification formula does not affect their activities.

Table B-10. Historic participation and mothership qualification.

Company	Vessel Name	Qualify/Does Not Qualify	Year												
			95	96	97	98	99	00	01	02	03	04	05	06	07

- Transferability

Making an asset transferable allows it to take on value. A transferable mothership permit acts as a capital asset to the permit holder. The value of the permit is theoretically equivalent to the net present value of a future stream of profits associated with engaging in activities allowed by that permit. Unfortunately, no data is available with which to calculate the potential value of a transferable permit. Furthermore, the amount of value a processor permit can generate depends on whether processor linkages exist, and to what degree. Greater processor linkages will tend to make the transferable permit more valuable, as they provide more certainty over future deliveries and grant processors more leverage in negotiations with catcher vessels over profit sharing.

Wide-spread transferability of mothership permits can affect the relations between catcher vessels and motherships, with repercussions to a fishery managed with harvest cooperatives if processor linkages exist. As stated previously, harvest cooperatives rely heavily on long-term, stable relationships among catcher vessels. In a cooperative-based fishery with processor linkages, catcher vessels must negotiate

arrangements with processors. When negotiating arrangements with other catcher vessels in a cooperative, each catcher vessel implicitly brings the interests and arrangements made with the processing entity to the cooperative. In order for the arrangements made with the processing entity to work, it is important that the cooperative agreements allow for those arrangements between the catcher vessel and the processor. If mothership permits are transferred frequently, this can lead to a change in arrangements between processors and catcher vessels, and may change or disrupt the relationships and agreements made among catcher vessels in a cooperative. Therefore, fewer transfers of mothership permits during a fishing year will help stabilize relations between processors and catcher vessels, leading to more stable operations among cooperative members if processor linkages exist.

An annual declaration provision (one year obligation) acts similarly to the linkage case described above. While the declaration can be easily switched in the next year by the catcher vessel, within a particular year the declaration acts like a linkage provision: the declaration means that the interest of the mothership is indirectly brought to the cooperative by the catcher vessel and frequent transfers of mothership permits may cause changes in the relationships between catcher vessels and motherships, thus affecting the cooperative.

Allowing a permit to be transferred to a vessel of any size allows capital in the mothership portion of the fishery to be determined by market conditions, rather than by regulation. This makes it more likely that capital in a rationalized fishery will attain a level that is near, or at, a cost efficient condition (so long as processor ties exist in the program). This is different than an Olympic fishery, where excess capital is more likely to exist. However, if limited entry is put in place but processor linkages are not established, competition would occur among processors for catcher vessel deliveries and this may inhibit the ability of processors to effectively match capital to production volume due to a variety of reasons. One reason is because processors will not be able to plan for delivery volumes as effectively because they will have relatively uncertain expectations about those delivery volumes in any given year.

Allowing a permit to be transferred to a vessel engaged in whiting harvest is covered under the section describing the effect of allowing catcher-processors to also operate as motherships. While it is theoretically possible for a catcher vessel to acquire a mothership permit and engage in mothership activities, the most likely type of vessel that would engage in harvesting and mothership activities (if allowed) is a catcher-processor, because of the amount of capital required to process and handle deliveries of Pacific whiting.

- Transfer Restrictions

Restricting mothership permits from being transferred during the fishing year helps foster stability in relationships between motherships and catcher vessels, and, by extension, the cooperatives. This is especially true if arrangements have been made between motherships and catcher vessels prior to the start of the fishing period. If a mothership permit is transferred during the fishing period to another entity, there is no certainty that the arrangements initially made between the mothership and catcher vessel would remain in place. If those arrangements are not maintained, that can cause instability in the plans of the catcher vessel and the new owner of the mothership permit, especially if linkages between the mothership and the catcher vessel are established, and those linkages follow the permit when it is transferred. By extension, allowing mothership permits to be transferred twice during a fishing year would cause greater instability than a single transfer during a year.

If a mothership experiences a breakdown or other similar event, the ability to transfer permits would allow for another mothership to take its place.

- Usage Limit on Motherships

A usage limit affects the amount of consolidation that can occur in the mothership processing portion of the whiting fishery. Consolidation can affect ex-vessel price negotiations and/or revenue sharing. The fewer mothership processors, the more leverage each mothership processor has in negotiating over ex-vessel prices or profit sharing arrangements. In addition, consolidation can improve the efficiency of the mothership processing sector. If greater quantities per mothership vessel result in greater cost efficiencies, then consolidation may result in a more efficient use of capital resources and greater net benefits to society. Consolidation also depends on fluctuations in the whiting OY. During a low OY year, it may be appropriate to allow fewer motherships to process whiting compared to a year when the whiting OY is relatively high.

Assuming the entire mothership whiting allocation is attained, then the five options for usage limits of 20, 30, 40, 45, and 50 percent could result in a minimum of 5 to 2 mothership vessels processing in the year, respectively. Unfortunately, no data is available with which to estimate the cost efficiencies associated with this number of vessels, nor is data available with which to estimate the potential leverage over ex-vessel prices and profit sharing arrangements that may be associated with these numbers of vessels.

The following information, which uses a reasonable high and low bound for mothership sector allocations of whiting based on the range of Pacific Whiting OYs specified in recent years, may help determine the appropriate usage limit. Historical fishery information was reviewed in an attempt to establish a potential amount of daily mothership capacity (estimated at 450 mt), and this was used to establish an estimate of season length based on a) a possible number of motherships, and b) two possible mothership sector allocation tonnages. For reference purposes, the mothership fishery predominately operates over a month and a half. From this information, it appears that a single mothership may mean the season could last nearly five months long in years where the whiting OY is large, though this seems unlikely given that catcher vessels may not be able to access whiting during the fall months. With two motherships, the season may last just over two months during years when the whiting OY is large. With three motherships, the season may last just over a month if all motherships operated at daily capacity. This is similar to status quo, though the season length under status quo occurs with four to five mothership vessels, suggesting that every mothership is not operating at capacity. If this is true, then establishing an accumulation limit restricting the minimum number of motherships to three may still result in/allow for some consolidation among motherships.

If consolidation limits are set at a level that allows for a single mothership, it is likely that more than one mothership would continue to participate. This is because it is unlikely that a single mothership would have the capacity to handle that volume within the seasonal time constraints. However, it is possible that those motherships operating could be owned by a single company depending on whether the limit applies to the mothership platform or to the mothership company. Therefore, an accumulation limit that restricts the amount of mothership consolidation but does not restrict the number of companies operating those motherships may result in a single entity engaging more than a single mothership.

Table B-11. Potential mothership sector season length based on number of motherships and two hypothetical mothership sector allocation amounts.

Hypothetical Mothership Sector Allocation (Mt)	Associated US Whiting OY	Season Length With 1 Mothership (In Days)	Season Length With 2 Motherships (In Days)	Season Length With 3 Motherships (In Days)
63,120	300,000	140	70	47
34,320	170,000	76	38	25

Even if aggregate consolidation occurs among motherships, individual mothership entities may be restricted by the accumulation limits. Past information shows the amount of volume handled by mothership processing entities/companies, and shows the potential constraint on mothership processing activity from each of the usage limits depending on the mothership whiting allocation. Though not readily apparent from this information, a usage limit of 50 percent may restrict the amount of processing of some motherships in some years. This is especially true in years when the whiting OY may be relatively low.

Table B-12. Range of mothership usage limits in mt based on two hypothetical mothership sector allocation amounts - compared to historic mothership company usage amounts.

Hypothetical Mothership Sector Allocation (Mt)	Associated US Whiting OY (Mt)	Usage Limit and Associated Metric Tonnage				Historic Mothership Activity	
		20%	30%	40%	50%	Max Mothership Company % (1997 - 2006)	Average Mothership Company Mt (1997 - 2006)
63,120	300,000	12,624	18,936	25,248	31,560	36%	9,764
34,320	170,000	6,864	10,296	13,728	17,160		

B-2.3 Co-op Formation and Operation Rules.

B-2.3.1 Who and Number of Co-ops

Co-ops will be formed among CV(MS) permit owners.

Co-op Formation Option 1 (Multiple Co-ops): Multiple co-ops would be organized around motherships. Permit owners choosing to participate in the co-op fishery must form a separate co-op based on the mothership where the CV(MS) permit holders delivered the majority of their most recent year's catch.

Co-op Formation Option 2: Multiple co-ops are not required. Catcher vessels may organize a single co-op or multiple co-ops but are obligated to deliver to the processors as proscribed in B-2.4.

Co-op Formation Option 3 (Preferred Alternative): Co-ops are not required but may be voluntarily formed among CV(MS) permit owners. The number of co-ops will be indirectly limited by the limit on the number of vessels able to form a co-op (see Section 2.3.3-b).

B-2.3.2 When

Each year at a date prior to the start of the fishery, mothership and CV(MS) permit holders planning to participate in the mothership sector must register with NMFS. At that time CV(MS) permit holders must identify which co-op they will participate in or if they plan to participate in the non co-op fishery.

B-2.3.3 Co-op Agreement Standards

a. Submissions to NMFS and the Council

Co-op permit and agreement. Federal co-op permits will be issued for co-op agreements approved by NMFS. Signed copies of the cooperative contracts must be filed with the Council and NMFS and available for public review before the co-op is authorized to engage in fishing activities (DURING COUNCIL DISCUSSION THIS WAS FLAGGED BY NOAA GC AS A POTENTIAL LEGAL

PROBLEM.) Any material changes or amendments to the contract must be filed annually with the Council and NMFS by a date certain.

Letter to Department of Justice. Co-ops must also file with the Council and NMFS a copy of a letter from the co-op requesting a business review letter on the fishery cooperative from the Department of Justice and any response to such request.

b. Number of Participants in Each Co-op (Including Inter-co-ops)

Option 1: Two or more permits may form a co-op for harvesters, but participation must conform to the requirements of Section B-2.3.1.
Option 2 (Preferred Alternative): CV permits may join together in separate harvester co-ops. A minimum of 20 percent of the CV(MS) permit holders are required to form a co-op.[14]

For both options, co-ops may form co-ops with other co-ops. Within one of the whiting sectors, these co-ops may be formed to manage directed catch and/or bycatch.

c. Catch History Distributions among Permits

Co-op agreements must stipulate that catch allocations to members of the co-op be based on their catch history calculation distribution to the co-op by NMFS.

d. Participation by NonCV (MS) Endorsed Permits

Through temporary arrangements, a co-op allocation may be harvested by any catcher vessel holding a valid limited entry trawl permit which has joined the co-op (including one that does not have a CV[MS] endorsement).[15]

e. Other Required Co-op Agreement Provisions:

1) A list of all vessels and permit holders participating in the co-op and their share of allocated catch which must match the amount distributed to individual permit holders by NMFS.
2) Signature by all permit holder owners participating in the co-op.
3) A plan to adequately monitor catch and bycatch.
4) Adequate enforcement and penalty provisions to ensure that catch and bycatch overages do not occur.
5) Measures designed to reduce bycatch of overfished species.
6) Obligation to manage inseason transfers of catch history.
7) A requirement that at least a majority of the members are required to dissolve a co-op, (DURING COUNCIL DISCUSSION, THIS WAS FLAGGED BY NOAA GC AS A POTENTIAL LEGAL PROBLEM.).
8) An obligation to produce an annual report to the Council and NMFS by a date certain documenting the co-op's catch and bycatch data and inseason transfers (the report is to be available for review by the public).
9) Identification of a co-op manager who will

[14] The minimum threshold number of participants required to form a co-op balances the potential advantages for multiple co-ops while limiting implementation and management costs and administrative requirements for managing this sector.

[15] As a member of the co-op, such a vessel would be subject to paragraph B-2.4 and the indicated processor obligations.

a. serve as the contact person with NMFS, the Council and other co-ops,
b. be responsible for the annual distribution of catch and bycatch,
c. oversee transfers,
d. prepare annual reports, and
e. be authorized to receive or respond to any legal process against the co-op.

10) Provisions that prohibit co-op membership by permit holders that have incurred legal sanctions that prevent it from fishing groundfish in the Pacific Fishery Management region.

11) A provision that requires new owners to comply with membership restrictions in the co-op agreements.

f. Additional Provisions for Inter-co-op Agreements

1) In the case of two or more cooperatives entering into an inter-cooperative agreement, the inter-co-op agreement must incorporate and honor the provisions of the individual co-op agreements unless all such agreements (or modifications thereof) are resubmitted for approval.

2) The requirements of paragraph a through e apply to the inter-co-op agreement, except that for the purpose of subparagraph e.7, the members of the inter-co-ops are the co-ops and not the participants in each co-op.

B-2.3.4 Annual Allocation Transferability

a. The annual allocations received by a co-op based on catch history of the whiting endorsements held by its members may be transferred among co-op members and from one co-op to another so long as obligations to processors are met (as per Section B-2.4). Additionally, in order to transfer annual allocation from one co-op to another, there must be a NMFS-approved inter-co-op agreement.

b. Allocations may not be transferred from the mothership sector to another sector.

❖ Interlinked Elements

A requirement that cooperatives are/are not required to form around the motherships to which they deliver is related to ongoing processor ties and movement between processors. If a catcher vessel can switch processors simply by switching the processor to which they deliver the majority of their catch, then not requiring cooperatives to be formed around motherships may erode the benefits motherships can realize from an ongoing processor tie. If a single cooperative is formed for the mothership sector, then a catcher vessel with linkages to processor B can lease catch history from a catcher vessel linked to processor A. Through that simple voluntary lease agreement, the catcher vessel could switch processors because it will have delivered the majority of its catch to another processor in that year. Compared to a requirement that catcher vessels fish in the noncooperative portion of the fishery in order to change processors, this simple switching arrangement provides little disincentive to catcher vessels considering switching processors and may reduce the benefits processors see from rationalization. It is important to note that this interlinkage is not applicable to the mothership declaration provision adopted as part of the Council's final preferred alternative.

❖ Rationale and Policy Issues

- Who Can Form Co-ops

Cooperatives are intended to coordinate members' harvest. Allowing entities that are not harvesters to join a cooperative may affect the performance of those cooperatives. This may mean a different manner of harvesting than if just left up to harvesters. In order to optimize the harvesting performance (both bycatch and economic) of those cooperatives, it is important that those cooperatives be formed by those engaged in harvesting.

Alternatively, requiring cooperatives to form around motherships helps ensure that cooperatives are formed by a like-minded group of individuals, and protects the interests of the mothership by allowing more certainty about who is providing deliveries. This helps motherships facilitate delivery coordination and timing, allowing the mothership to optimize business operations.

Allowing harvesters to form cooperatives that are not necessarily associated with a particular mothership allows harvesters to determine the most appropriate composition of the cooperatives and ensures that they are comprised of like-minded individuals, which is important to their success. Since cooperatives are voluntary and rely on agreed-upon standards by members, having like-minded members increases the potential for cooperative success and long-term cohesion. This helps ensure optimal performance of the cooperative and of the fishery as a whole.

- When

Requiring harvesters to state their intention to participate in a cooperative or in the noncooperative portion of the fishery by a particular date facilitates the administration of the cooperative program on the part of the agency.

- Cooperative Agreement Standards

Requiring standards for cooperative agreements (and requiring that they be filed with and reviewed by NMFS) assures that goals and objectives specified by the Council are being met through a legally binding agreement by cooperative members. Requiring these agreements be filed with NMFS assures that a review process exists to verify that the Council's goals and objectives are likely to be met by the agreement.

Requiring that cooperatives develop a report that is made publicly available aids in the transparency of the cooperative program and allows the Council and NMFS to verify the success of management tools used by the cooperative. If those tools are specified as part of a cooperative agreement, the production of annual reports allows the public and NMFS to determine whether the tools described in that cooperative agreement are likely to be successful in meeting the cooperative's intentions. This helps inform future approval/disapproval decisions on the part of NMFS reviewers and whether particular elements of the cooperative agreement are likely to meet the goals specified by the Council.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Who can form co-ops	X	X	X			X				
Number of co-ops	X	X	X			X				
When co-ops must be formed										
Cooperative agreement standards	X	X	X	X	X	X	X	X	X	X

❖ Analysis

- Who Can Form Co-ops and Number of Co-ops

Two general options exist for co-op formation. One option requires that co-ops form around the mothership processor to which they deliver. The second option allows a single cooperative to form among all catcher vessels in the sector, but participants in that single cooperative may deliver to several different motherships.

One intention of establishing the multiple co-op requirement was the idea that if multiple co-ops were required, they would more likely be made up of like-minded individuals. The other rationale was that operational timing between the mothership and associated catcher vessels would be improved if multiple co-ops were required.

In regards to the first rationale, theory would indicate that requiring multiple co-ops to be formed may actually restrict the ability for like-minded individuals to co-op with one another. This is because harvesters may have more in common with other harvesters that deliver to another mothership, but those harvesters may have formed a relationship with different motherships for business reasons. Contrary to theory, the logistical operations of the mothership sector will likely lead to a set of catcher vessels that deliver to a mothership to be fairly similar in their goals and objectives and in their relationships with that mothership. Such similarities would tend to lead to those catcher vessels belonging to the same cooperative. This is because cooperatives are formed among parties that can agree to a set of terms. If those parties are similarly minded, it is much more likely they will form cooperatives and agree to terms. The reason similarly minded catcher vessels are likely to have the same mothership in common is because of the relative degree of coordination that occurs among motherships and catcher vessels. In order for the entire mothership operation to be successful, that coordination activity must be successful and be reasonably agreed-upon by both catcher vessels and motherships. Furthermore, agreed-upon delivery timing and delivery rotation is related to coordination of harvest activity among catcher vessels. If catcher vessels delivering to the same mothership also belong to the same cooperative, those catcher vessels can engage in catch history leasing agreements that align with the coordination that occurs with the mothership.

However, allowing catcher vessels to form a broader cooperative that stretches across multiple mothership operations may further enhance the ability of catcher vessels to optimize their operations. A broad cooperative that includes vessels linked to multiple motherships would allow catcher vessels delivering to various motherships to coordinate harvest activity across a wider number of participants. Enhanced flexibility in harvest activity coordination may lead to more desirable results. However, this enhanced flexibility could also be achieved through an inter-cooperative agreement.

In addition to the above factors, not requiring that cooperatives form around motherships may make it more difficult for the mothership to engage in coordination with catcher vessels and this may reduce the ability for motherships to successfully plan business activities for the year. If cooperatives are formed around motherships, those motherships know which entities and catcher vessels they should expect deliveries from during the year, and they know which entities and catcher vessels to coordinate with over operational issues. If catcher vessels form a single cooperative that stretches across the entire mothership sector, motherships may not know which catcher vessels are delivering to them. This is because of the private lease agreements that exist as part of the cooperative and the ability that gives catcher vessels to have another vessel(s) fish their catch and deliver to their obligated processor. This type of uncertainty may make it difficult for the mothership to plan and coordinate delivery activity with catcher vessels. In addition, this makes the processor tie obligations (and the catcher vessels which have those obligations at any given time) less visible. This may reduce the ability for motherships to negotiate with catcher vessels over delivery timing and prices, because they may not know who is planning to fish those obligated deliveries. The result may be a reduction in the benefits motherships may otherwise expect to see from rationalization.

- Co-op and Non Co-op Fishery Declaration

Filing the intention to fish in the co-op or non co-op portion of the fishery is likely to be a necessary rule for administration and implementation of a cooperative-based fishery. In addition, requiring that harvesters state their intention to fish in the cooperative or noncooperative portion of the fishery for that entire season means that cooperative membership will be more stable. Stability in membership during a year increases the incentives for harvesters in a cooperative to work with one another to resolve any potential issues. If harvesters could leave cooperatives or enter cooperatives as the season progresses, substantial administrative workload could result in order to track and modify membership, track appropriate catch histories, and attribute ongoing catch to appropriate cooperatives. In addition, if membership of cooperatives can change throughout the year, there is far less incentive for cooperative members to jointly resolve any unforeseen and problematic issues.

- Cooperative Agreement Standards

In general, requiring that cooperative agreements meet certain standards increases the chances that cooperatives will operate in a manner that achieves objectives stated by the Council. For example, requiring that cooperatives have a bycatch management plan which includes monitoring and penalty provisions means that harvesters in that cooperative will be striving to reduce bycatch. This behavior is consistent with objectives specified by the Council and found in the MSA. In addition, requiring that cooperative agreements be validated by NMFS ensures that those standards are being met.

B-2.4 Processor Ties

Permits will be obligated to deliver:

Option 1: all (the preferred alternative does not include an ongoing obligation but does include a one year obligation)
Option 2: 90 percent[16]
Option 3: 75 percent
Option 4: 50 percent

of their catch (the permits' "obligated deliveries") to certain motherships, as specified in the following sections. Catch that is not so obligated may be delivered to any mothership with an MS permit.

B-2.4.1 Formation and Modification of Processor Tie Obligations

Option for One Year Obligations (Preferred Alternative). There will not be a processor tie that carries from one year to the next. CV(MS) permits participating in a cooperative will be obligated to a single MS permit for an entire year but may change to a different MS permit through a preseason declaration of intent.

Between September 1 and December 31 of the year prior to implementation and every year thereafter, each CV(MS) permit is required to contact NMFS and indicate whether the CV(MS) permit will be participating in the co-op or non co-op fishery in the following year. If participating in the co-op fishery, then the CV(MS) permit must also provide the name of the MS permit that the CV(MS) permit will be linked to in the following year (i.e., annual catcher vessel, mothership linkage that may be changed each year without requirement to go into the non co-op fishery). Once established, the catcher vessel, mothership linkage shall remain in place until changed by the CV(MS) permit. By September 1 of the year prior to implementation and every year thereafter, if the CV permit would be participating in the co-op fishery in the following year, then the CV permit must notify the MS permit that the CV permit QP will be linked in the following year.[17]

Option for Ongoing Obligations. In the first year of the program, the CV(MS) permit owner's choice

---

[16] 90 percent was the Council's preliminary preferred alternative, along with a year-to-year processor tie obligations (Section B-2.4.1). *NOTE: During discussion of processor linkage provisions at the Council's June 2008 meeting, the Council members expressed that by selecting a 90 percent linkage option as part of their preliminary preferred alternative it was their intent to provide a means for vessels to move between motherships without entering into the non-co-op fishery. In order to achieve this intent, additional modifications will be required. Specifically, in the last paragraph of the following section, the sentence*

> *"*Thereafter, each year, CV(MS) permit owners choosing to participate in a co-op will deliver their obligated catch to the same mothership to which they were obligated in the previous year."

would need to be changed to read:

> *"*Thereafter, each year, CV(MS) permit owners choosing to participate in a co-op will deliver their obligated catch to the mothership to which they delivered the majority of their catch in the previous year."

[17] February 2010: The last sentence of this paragraph was part of the November 2008 Council motion and was inadvertently omitted from previous drafts of the Council's final preferred alternative. At its April 2010 meeting, the provision was modified to specify September 1st as the notification date. Previously, the date was July 1st.

will be between delivering in the non co-op fishery and making deliveries as part of a co-op. If the permit chooses to participate in a co-op, its obligated deliveries must go to the licensed mothership to which the permit delivered the majority of its whiting catch in:
Option 1: The most recent year that it fished before the program was implemented
Option 2: From 1997 through 2004
Option 3: From 1994 through 2003
Option 4: If the permit chooses to participate in a co-op, its obligated deliveries must go to the licensed mothership to which the permit made a majority of its whiting deliveries in 2009.

If a mothership does not qualify for an MS permit in the first year of the program,[18] the catcher vessel which delivered to that mothership in the previous year may deliver its obligated catch to the qualified mothership to which it last delivered the majority of its catch. If none of the motherships to which the permit would be obligated qualify for an MS permit, the permit may participate in the co-op and deliver to a licensed mothership of its choosing. Alternatively, the permit may choose to participate in the non co-op fishery.

Thereafter, each year, CV(MS) permit owners choosing to participate in a co-op will deliver their obligated catch to the same mothership to which they were obligated in the previous year. However, if the CV(MS) permit owners chose to participate in the non co-op fishery in the previous year, or did not participate in the mothership whiting fishery, they are released from their obligation to a particular mothership and may deliver to any mothership with an MS permit.

Mothership Permit Transfer (applied to both Obligation Options). If a mothership transfers its MS permit to a different mothership or different owner, the CV(MS) permit obligation remains in place and transfers with the MS permit to the replacement mothership unless the obligation is changed by mutual agreement or participation in the non co-op fishery.

B-2.4.2 Flexibility in Meeting Processor Tie Obligations

a. Temporary Transfer of the Annual Allocation within the Co-op or from One Co-op to Another

Temporary Transfer with One Year Obligation (Preferred Alternative). When CV(MS) permit owners transfer co-op allocations from one co-op member to another within the co-op or from one co-op to another within an inter-co-op, such allocations must be delivered to the mothership to which the allocation is obligated through the preseason declaration, unless released by mutual agreement.

Temporary Transfer with Ongoing Obligation. When CV(MS) permit owners transfer co-op allocations from one co-op member to another within the co-op or from one co-op to another within an inter-co-op, **and the allocation that is transferred is part of the obligated deliveries**, such allocations must be delivered to the mothership to which the allocation is obligated, unless released by mutual agreement.

[18] If a mothership that does not qualify for a permit acquires such a permit (i.e., arranges for the transfer of a permit) by the time co-ops are established for the first year of the program, would it be the Council's intent that the catcher vessel obligation to that mothership remain in place?

b. Mutual Agreement Exception

By mutual agreement of the CV(MS) permit owner and mothership to which the permit is obligated, and on a year-to-year basis, a permit may deliver its obligated deliveries to a licensed mothership other than that to which it is obligated.

The following applies only if there is an ongoing obligation to processors (which is not part of the Preferred Alternative): Such an agreement will not change the permit's future-year obligation to the mothership (i.e., the permit will still need to participate in the non co-op fishery for one year in order to move its obligated deliveries from one mothership to another).

B-2.4.3 Mothership Processor Withdrawal

Mothership Withdrawal with One Year Obligation (Preferred Alternative). If a mothership withdraws subsequent to quota assignment, then the CV(MS) permit that it is obligated to is free to participate in the co-op or non co-op fishery. The MS permit shall notify NMFS and linked CV(MS) permits of its withdrawal, and CV(MS) permits shall notify NMFS of their intent to participate in the co-op or non co-op fishery thereafter. If continuing in a co-op fishery, then the CV(MS) permit shall provide NMFS with the name of the new MS permit to which it will be obligated for that season.

Mothership Withdrawal with an Ongoing Obligation. If a mothership does not participate in the fishery and does not transfer its permit to another mothership, or does not agree to transfer delivery to another mothership, the CV(MS) permit holders obligated to that mothership may:

Option 1: participate in the non co-op fishery.
Option 2: join a different co-op and deliver their obligation to a different mothership; or the entire co-op which delivered to that mothership may deliver its obligated catch to a different mothership. The permits will not be required to participate in the non co-op fishery in order to shift from one mothership to another.

SubOption 2a: If the mothership returns within two years, any permit with an obligation to that mothership prior to its departure will have the obligation reinstated, unless the permit has participated for one year in the non co-op fishery. After two years, the permit's obligation will become linked to the mothership to which it most recently delivered its obligated catch.

SubOption 2b: The permit will become obligated to the mothership that it delivers its obligated catch to subsequent to the withdrawal of the mothership to which it was previously obligated.

❖ Interlinked Elements

Processor limited entry. See earlier section on processor licensing.

Processor ties are associated with the mutual agreement exception and whether a catcher vessel must fish in the noncooperative fishery in order to switch motherships, or whether a vessel can fish the unlinked portion of catch history of other vessels in his cooperative and establish a new linkage without ever going into the noncooperative fishery. While each of these elements can technically work together, there may be a substantial cumulative effect that occurs through the combined selection of a number of these sub-options.

Elements Interlinked with Long Term Obligations (not part of the preferred alternative)

Ongoing processor ties (not part of the preferred alternative) and the ability for catcher vessels to move processors by delivering the majority of their catch to a different processor in a given year is substantially related to the decision of whether to require cooperatives to be formed around motherships or whether a

single cooperative could form which delivers to multiple motherships. If a single cooperative is allowed and a catcher vessel can switch motherships by delivering the majority of their catch to a different mothership in a given year, then catcher vessels could simply lease catch history (and the associated linkages) between one another regardless of the processor those catch histories are tied to. Through a simple voluntary lease agreement with catcher vessel B (who is connected to another processor), catcher vessel A could switch processors because it will have delivered the majority of its catch to another processor by leasing catcher vessel B's catch history. If cooperatives are required to be formed around motherships to which they deliver, but can still switch processors by delivering the majority of their catch to a different processor, then movement is relatively more difficult (though still easier than if a vessel is required to fish in the noncooperative fishery). This movement would require a catcher vessel desiring to switch processors to fish the unlinked portion of other vessel's catch history in that cooperative and deliver to a different processor. If that catcher vessel does so, it would need to leave the original cooperative in order to join the new cooperative linked to that new processor and effectively reduce the pool of catch available to that original cooperative. This means that catcher vessels in the original cooperative may be against the idea of a catcher vessel switching motherships because it would involve a departure from the cooperative and a reduction in the pool of catch available to that cooperative. Therefore, other catcher vessels in a cooperative may be reluctant to allow a single catcher vessel to fish their unlinked catch history in order to switch motherships and this may make it more difficult for processor switching to occur.

Mothership withdrawal and the mutual agreement exception are inter-related. The selection of sub-option 2b for mothership withdrawal may affect the good faith negotiations over a possible mutual agreement exception. This could be avoided through the selection of sub-option 2a for mothership withdrawal.

Mutual agreement and the ability for processors to switch motherships by fishing the unlinked portion of other catcher vessels are inter-related and may directly conflict with one another. A mutual agreement allows a catcher vessel to deliver all of its catch to a different processor during the year a mutual agreement is in effect. However, if catcher vessels can switch processors by fishing the unlinked portion of other vessels' catch histories, then language regarding the establishment of a mothership linkage would state:

> Thereafter, each year, CV(MS) permit owners choosing to participate in a co-op will deliver their obligated catch to the mothership to which they delivered the majority of their catch in the previous year.

For more detail, the reader is referred to B-2.4 above. This language is in direct conflict with the intention of a mutual agreement exception. A mutual agreement would allow another vessel to deliver the majority of its catch to another processor, but the quoted language shown above would imply that doing so would result in the permanent switching of processor linkages. This result would be in conflict with the intention of a mutual agreement exception. In order to resolve this issue, Council staff is interpreting the intention to be the following:

> If a mutual agreement is established between a catcher vessel and a mothership, that linkage is not permanently broken regardless of the mothership(s) which the catcher vessel delivers to during the year(s) the mutual agreement exception is in place. Those linkages may be broken, however, if the catcher vessel participates in the non co-op fishery. This provision effectively supersedes the language above describing the rules for switching motherships by delivering the majority of one's catch in a given year to another mothership.

Mothership withdrawal and the subsequent treatment of processor linkages if the processor return is related to the ability for catcher vessels to switch processors by fishing the unlinked portion of catch history of other catcher vessels. If the language shown above is used for determining the processors to

which a catcher vessel is linked to, then this could be in direct conflict with some of the processor withdrawal and return provisions. Council staff is interpreting the interlinkage of these two provisions as the following:

> If a mothership withdraws from the fishery, and Option 2a is chosen for the mothership withdrawal topic, then the linkages will be re-established with the original mothership if that mothership returns within two years. Other sub-options would result in a permanent switching of processor linkages. This provision effectively supersedes the language above describing the rules for switching motherships by delivering the majority of one's catch in a given year to another mothership.

If a provision to allow mutual agreement exceptions is selected, these mutual agreements may need to be filed with NMFS prior to a date certain. This may be necessary in order to adequately monitor the fishery.

❖ Rationale and Policy Issues

- Processor Ties (Ongoing Obligations)

Processor ties help to ensure that processors benefit from rationalization in addition to harvesters. Processor ties increase the certainty that processors have over deliveries from catcher vessels and helps ensure that both processors and harvesters have negotiation power when deliberating over profit sharing arrangements.

- Processor Declaration (Annual Obligations)

Annual declarations are intended to help motherships develop business plans for the coming season. The declaration procedure allows a mothership to develop expectations of catch volume that the mothership will handle during the upcoming season. From this expectation, the mothership company can find markets, purchase adequate supplies (such as packaging), and hire labor that is appropriate for the upcoming fishery.

The Council and several advisory bodies spent a noteworthy amount of time deliberating over whether to have processor ties and in what form. The Council heard substantial amounts of testimony and considered analysis which indicated that rationalization would tend to benefit harvesters, but without a provision to specifically address the interest of the processors, opportunities existed to shift the balance of power in the industry toward the harvesters' favor at the expense of processors. A processor tie was viewed as one mechanism which may work at striking a balance between the harvester and the processor when a fishery moves to rationalization.

During deliberation and consideration over processor ties, NOAA GC indicated that the ongoing processor tie provision raised some issues that may make it difficult for NOAA Fisheries to approve of such a provision. The Council and its advisory bodies considered the appropriateness of other types of tools that may provide an opportunity for motherships to benefit from rationalization, or at least minimize some potentially adverse impacts on motherships that may occur as a result of rationalization. During public testimony over this matter, the Council heard that the lack of any type of tie in the BSAI Pollock fishery nearly led to the bankruptcy of one mothership company involved in that fishery after the fishery was rationalized. The reason for this near bankruptcy was the sudden departure of several catcher vessels from that mothership company after that company had made plans and purchased supplies for that upcoming year. The mothership company was unable to attract deliveries from other catcher vessels and thus was unable to cover the up-front costs that had been assumed by that company prior to the start of the year. Following this testimony, the Council considered an alternative to an ongoing obligation that would

come in the form of an annual declaration. This declaration would act in a manner that would tend to avoid the scenario that occurred in the BSAI mothership Pollock fishery by providing both the mothership and the catcher vessel several months of advance time with which to develop business plans. The Council adopted this annual declaration provision as its preferred alternative.

- Formation and Modification of Processor Tie Obligations

The years considered for the formation of the ongoing processor tie reflects periods intended to match with catch history assignments and also to reflect recent relationships that exist in the fishery prior to rationalization. Maintaining recent relationships is intended to make the transition to a rationalized fishery easier, while aligning linkages to catch history calculation years is intended to match processor participation and receipt of linkages to the catch history that catcher vessels receive.

Making mothership permits transferable while maintaining the ongoing obligations that exist during that transfer is intended to help ensure that processors have a means of benefiting from rationalization and that the purchaser or seller of a mothership permit has a reasonable expectation of having catcher vessel deliveries associated with that permit.

Making the mothership permits transferable while maintaining the annual obligation does very little except in the year during the period of the annual obligation. If a declaration is made to a mothership permit and that permit is transferred prior to the season starting or during the season, that obligation remains and this allows the owner of the MS permit the ability to engage in a short-term arrangement with another mothership company. This arrangement may be beneficial to the original MS permit owner because the transfer occurs with the obligations in place, allowing the original MS permit owner the ability to capitalize on the benefit that comes from those obligations.

- Flexibility in Meeting Processor Ties

Requiring that ties remain in effect even if catch histories are leased to another catcher vessel in a cooperative, or to another cooperative through an inter-co-op agreement, helps to maintain the relative degree of certainty motherships have over whiting deliveries in the current year. If catcher vessels could avoid ties by temporarily leasing catch history to another vessel, the relative certainty that ties are intended to provide to processors would not be meaningful because the ability to avoid processor obligations would be relatively easy.

The mutual agreement exception is a tool intended to allow mothership participation to vary appropriately according to the size of the whiting OY while also allowing catcher vessels to temporarily fish for a different mothership vessel without having to go into the noncooperative fishery. Motherships with a mutual agreement exception option are not liable to find it necessary to participate in the fishery during years when the whiting OY is low, and potentially lose money as a result, just to maintain the existing linkages with catcher vessels. Inversely, catcher vessels with a mutual agreement option can deliver to another mothership temporarily while still being part of a cooperative and realizing the benefits of cooperative membership.

- Mothership Withdrawal

There are two options for dealing with the withdrawal of a mothership from the fishery. One option would require that the catcher vessel fish in the noncooperative fishery in order to deliver to another mothership. The other option explores different ways of leaving the catcher vessel relatively harmless from such a withdrawal.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Processor ties			X		X	X				
Formation and modification of processor ties	X		X		X	X				
Flexibility in meeting processor ties		X	X		X	X				
Mothership withdrawal		X	X			X				

❖ Analysis

- Ongoing Processor Ties

Ongoing processor ties act differently than an initial allocation of quota shares. Where an initial allocation of quota shares to processors can directly reduce the quota share that may otherwise be allocated to harvesters (or to some other potential group), a processor tie provision does not impact the amount of catch history, or quota share, a harvester may receive. Furthermore, an ongoing processor linkage takes on some of the characteristics of a defensible resource access privilege (like quota shares), but with less "defensibility" on the part of the processor. This is because catcher vessels can switch motherships and break that tie.

Through a processor tie, mothership processors become a more interested party in the harvesting activities of a linked catcher vessel. This linkage provides the processor more certainty over delivery volumes and more leverage in negotiations with catcher vessels over delivery timing and profit sharing compared to a case where no tie or no initial allocation of quota shares exists. The arrangements created between the catcher vessel and the linked processor may influence the manner in which the catcher vessel prosecutes fishery resources, and because of this influence, the creation of processor linkages means that processors have some indirect bearing on the operations of members of a harvest cooperative. However, because that linkage can be broken by the actions of the catcher vessel, such a linkage does not appear to resemble the conditions of a property right (like a quota share does) where assets must be defensible from the actions of others. In other words, the mothership processor cannot "defend" and maintain the linkage if a catcher vessel wishes to switch mothership processors.

Processor ties in a cooperative program may serve several different purposes. One goal of the AFA was to construct a rationalization system that benefited both harvesters and processors, and the ongoing processor tie provision that exists in the shoreside portion of the Pollock fishery appears to have been one means of achieving that goal. The cooperative structure possible under the mothership alternative resembles those created for the shoreside sector of the Pollock fishery under the AFA. Establishing a processor tie makes the harvester and processor both strong entities in the negotiation over profits and the likely outcome is one where profits are shared between both the harvester and processor. In addition, a processor linkage creates a relationship between a harvesting and processing operation that takes on the characteristics of a vertically integrated firm where the harvester and processor work in concert toward a

similar goal. However, as the degree of the processor tie diminishes, it is reasonable to expect the amount of profit sharing to move more toward the harvester's favor because the harvester has more influence over negotiations and can "shop around" for the highest price for the un-tied catch history.

In addition to profit sharing, processor ties influence stability in the relationships between harvesters and processors. It may also affect the willingness of a catcher vessel to remain in a co-op if a catcher vessel and a mothership are at odds, and this may influence the manner in which the fishery is prosecuted. This issue is addressed in more detail in a following sub-section.

The effect of processor ties, and the appropriate degree of processor ties, should be considered along with the degree of vertical integration that exists in a sector. Relatively high degrees of vertical integration may reduce the need for processor ties since a processor that owns a catcher vessel effectively buys fish from itself and can direct the harvest activity of that catcher vessel. In the mothership sector, available information indicates that five trawl permits are "owned" by mothership processing companies and these five permits catch approximately 25 percent of the sector's catch in any year. Anecdotal information indicates that partial ownership of other permits and vessels exist, making vertical integration even larger.

- Annual Declaration

An annual declaration provision, or annual obligation, provides for some business planning certainty for the mothership. The business planning certainty comes from knowing which catcher vessels a mothership will receive deliveries from. Because each catcher vessel receives an annual "catch history," the mothership knows the quantity of fish that it can expect to receive during the course of the upcoming fishing season. With this knowledge, the mothership company can find markets for the processed product and purchase supplies and hire labor that is appropriate for the upcoming season. Making an effective match between supplies and delivery volumes provides for an opportunity for that mothership company to minimize costs.

The declaration provision is likely to lead to the development of relations between catcher vessels and processors that is similar to an ongoing linkage provision; however, these relations may not be as strong. Because the declaration can be broken easily by the catcher vessel, the relations between the processor and catcher vessel are likely to be fairly cohesive within a given year, but those relations may not hold through time.

- Effect of Ongoing Processor Ties on Profit Sharing

If properly constructed, processor ties are likely to result in profits being shared between harvesters and processors. This appears to have been one objective of the AFA and the cooperative structure formed through that legislation. The mothership and shoreside whiting cooperative alternatives resemble AFA cooperatives. One of the most notable differences between processor ties and an initial allocation of shares to processors is the fact that issuing ties results in an outcome between harvesters and processors that begins to resemble the operation of a vertically integrated firm. This is because both the harvester and processor are bound to one another and cannot operate independently, at least in one year. The processing entity cannot process fish without an action on the part of the harvester, and the harvester cannot sell fish without an action on the part of the processor. Furthermore, the harvesting entity cannot move to another processor, and the processor cannot acquire harvest from a vessel that is linked to another processor. This construct leads to two powerful entities involved in negotiation over profits generated by the collective harvest and processing activity, and this type of mutual negotiation power may result in profits being shared between both harvesters and processors. However, over the long term, the harvester can fish in the non co-op fishery and break the tie, thus potentially leaving the initial processor or mothership with no guaranteed catch. This ability on the part of the harvester to un-link themselves

from a mothership by participating in the non co-op fishery provides some long-term flexibility and also provides some negotiation power over motherships simply through the threat of breaking the linkage.

Establishing a partial tie between a harvester and a mothership or processor can alter the relationship that results in profit sharing by playing toward the hands of the harvesters. If shares are allocated to harvesters and processors in an IFQ program, both harvesters and processors can attempt to reach an agreement, but if one is not made, then both the processor and harvester can walk away and fish their quota share independently. In a cooperative system with a processor tie, the processor and harvester cannot walk away from negotiations unless the harvester participates in the non co-op fishery. If that tie is only partial, then the harvester can fish the un-tied portion of the allowable catch and deliver to any processor or mothership. However, both the harvester and the processor are still linked to one another through the tied portion of the catch. Such a situation with a partial mothership tie is likely to shift the balance of power into the harvester's favor, and that balance of power will increase as the percent of linked catch history decreases. The harvester gains power by being able to "shop around" with the un-tied portion of the catch history and to leverage higher prices from mothership processors. Motherships are likely to bid among one another for the un-tied catch history, resulting in higher prices paid to harvesters and eroding profits motherships might otherwise realize if all catch history is linked. Inversely harvesters are likely to realize greater profits and operational flexibility if less catch history is linked to a mothership.

- Effect of Annual Declaration on Profit Sharing

An annual declaration provision does not make it difficult for the catcher vessel to move motherships from year to year. Because of this, the mothership tends to have much smaller amounts of leverage over price negotiations and profit sharing compared to an ongoing processor tie. However, the fact that the declaration must be made several months in advance of the upcoming season is likely to do a couple of things. Since the declaration is made prior to the setting of the Pacific whiting allowable catch level and also well in advance of what may be known about the Pacific whiting market that year, the declaration is likely to result in a profit sharing arrangement of some type rather than an agreement over actual ex-vessel prices. This agreement is likely to be in favor of catcher vessels, as they can shop around for the most beneficial arrangement with relative ease prior to the start of the season.

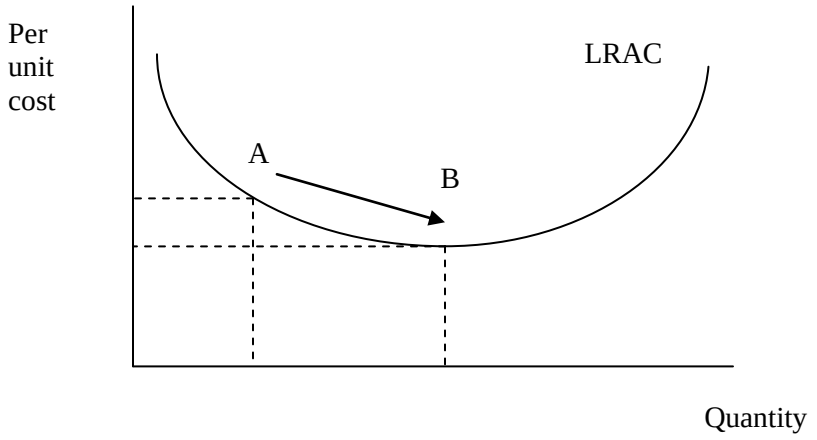
Degree of Mothership Linkage	Benefit to Catcher Vessel	Benefit to Mothership	Effect on Mothership/Catcher vessel relationship
100%	Smallest profit negotiation scenario to catcher vessel	Greatest certainty over deliveries and price negotiation	Most stable relations between mothership and catcher vessel
90%	Moderately low profit negotiation	Moderately high	Moderately high stability in relations
75%	Moderately high profit negotiation	Moderately low	Moderately low stability in relations
50%	High profit negotiation scenario to catcher vessel	Lowest certainty over deliveries and price negotiation	Lowest stability over mothership and catcher vessel relations
Annual Declaration	Highest profit negotiation scenario to catcher vessel	Greatest certainty over delivery volumes in current year. Low profit negotiation	Relationships may not last over long term, but may be cohesive in a given year

- Effect of Ongoing Processor Ties on Cooperative and Fishery Stability

Stability in the relationship between the catcher vessel and mothership has an economic effect through increased levels of business planning. Establishing a full processor tie creates a relationship that resembles a vertically integrated firm, and operations between the harvester and processor become more aligned as a result. However, reducing the degree of processor tie may stabilize cooperative membership and make it less likely that a catcher vessel will fish in the non co-op fishery in order to break the tie with a mothership. If a catcher vessel is at odds with a mothership, but needs to fish in the non co-op fishery in order to break that tie, the catcher vessel may continue to remain in the co-op if that catcher vessel can deliver part of his catch to someone else. Since the non co-op fishery is inherently less stable than the co-op fishery (because of competition among noncooperative participants), increasing the chances that a catcher vessel will remain within a cooperative may result in more rational fishing practices among participants in a fishery.

On the other hand, if a catcher vessel is engaged in a noncooperative mode, but is intending to establish a linkage with a new mothership, that mothership and catcher vessel will have established relations even though that catcher vessel is in the noncooperative mode. This will undoubtedly affect the behavior of a catcher vessel in that non co-op fishery and may temper some of the irrational behavior theoretically expected of participants in the noncooperative fishery. This is simply because that catcher vessel will need to take into account the needs of the to-be-linked mothership, and that mothership will effectively pace the operations of the catcher vessel to some degree by folding that vessel into its delivery rotation.

Therefore, a cooperative fishery with processor linkages helps ensure that processors benefit from rationalization by giving processors some negotiation power. Furthermore, processor linkages affect the operations of catcher vessels in a cooperative based fishery because negotiations between catcher vessels and processors will include such topics as delivery timing. These linkages also affect the behavior of participants in the noncooperative fishery if those catcher vessels are attempting to establish new relations with processors, and these participants are likely to fish in a more paced manner than simple theory would suggest.



- Effect of Annual Declarations on Cooperative and Fishery Stability

An annual declaration provision may make the relations between motherships and catcher vessels less long term, but it may increase the stability of a cooperative and the fishery as a whole. Since changing the declaration does not require participation in the noncooperative mode, it is reasonable to expect that less participation will occur in the noncooperative fishery under a system with an annual declaration compared to a system with an ongoing tie.

Degree of Linkage	Effect on Profits and Stability
Full processor linkage	Profits likely to be shared between harvesters and mothership processors. Stability exists between the harvester and mothership leading to paced harvest timing. Increases the probability that a catcher vessel will fish in the non co-op fishery to break a processor linkage if the catcher vessel and mothership are at odds.
Partial processor linkage	Profits may be shared, but more heavily weighted toward the harvester than in the case of a full linkage. Reduces the probability that a catcher vessel will fish in the non co-op fishery if they are at odds with a mothership because that catcher vessel can deliver some catch to someone else.
Annual Declaration	Profit sharing arrangements likely to result, but will most likely favor harvesters. Lowest probability of a catcher vessel participating in the noncooperative fishery.

- Processor Ties and the Potential for Rationalization of the Processing Sector

The issuance of harvest privileges grants fishery participants, and their invested capital, the potential to reach the minimum point on the long run average cost (LRAC) curve. Long run average cost is defined as the total cost in the long run divided by output. As shown in the diagram below, a potential cost structure for capital in a fishery prior to rationalization is to the left of the lowest point on the long run average cost curve (depicted as point A). This is because of overcapitalization in the fishery. With the implementation of rationalization, excess capital drops out of the fishery and remaining capital is able to increase production, tending toward the point of cost minimization (point B). Production beyond the minimum point is possible, but is in the realm of "diseconomies to scale" where increasing production begins to increase cost.

Generally speaking, the ability for participants in a rationalized fishery to move toward the minimum point on their LRAC curve is one principal factor determining the reduction of capacity in an over-capitalized fishery. Participants in a rationalized fishery can acquire shares of the allowable catch (either through IFQ transfers or through sharing of catch history) and match production volume to capital capacity. This is possible because those privileges are defensible from others and this eliminates the aspect of competition in the fishery that was originally responsible for build up of excess capital. The tendency is for the amount of capital in a fishery to decrease in order for capital to move toward a point of cost minimization, reflected as the minimum point on the LRAC curve. This is done by reducing the amount of capital in the fishery so that the remaining capital experiences an increase in production. The

amount of capital remaining in the fishery after it is rationalized is partially determined by the tendency toward the point where cost is minimized in the fishery.

The combination of processor ties, transferable mothership limited entry permits, and a mutual agreement exception allows cost efficiencies to be created in the processing portion of the fishery. The effect of these three elements works at reducing the amount of competition among processors for deliveries from catcher vessels and allows processing capital to vary appropriately with variations in the Pacific whiting OY. In a highly competitive structure with no linkages, processing entities would have incentives to participate in the fishery up to a point where economic profits for processing entities approach zero (processors would continue to enter as long as profits can be generated from doing so). The result would be more processing capital than necessary for the fishery. This is cost inefficient. The establishment of a linkage provision with mothership limited entry and a mutual agreement exception makes it possible for processing capital to vary according to conditions in the fishery and tend toward a more cost efficient level. This occurs for a handful of reasons:

- Due to processor limited entry, processors are not concerned that a new processor may enter into the fishery and compete with them for deliveries;
- Processors have more certainty over delivered catch levels through the linkage provision;
- Processors can stack more than one mothership permit, and associated linkages, onto a single mothership, thus allowing consolidation to occur while retaining some certainty over the volume of catcher vessel deliveries; and
- Processors can agree to allow catcher vessels to deliver to other processors through the mutual agreement thereby allowing processor B to take deliveries from processor A's linked catcher vessels without processor A permanently losing those linked catcher vessels and their future deliveries.

This structure starts to resemble the conditions often necessary to confer a defensible and transferable limited access privilege, though it does not meet these requirements fully because the processor linkage can be broken by the catcher vessel. Nevertheless, these similarities facilitate the development of a more cost efficient level of participation among processors in a fishery because it reduces competition among processors for catcher vessel deliveries. This makes it possible for motherships to reduce costs through consolidation (if necessary) and better business planning. Implied in this concept is that linkages exist between the mothership permit and the catcher vessel permit, rather than the physical mothership vessel and catcher vessel.

An annual declaration provision allows for some of these same cost minimization strategies to occur among motherships; however, the situation may be more tenuous than compared to an ongoing obligation. The elements described above also exist for an annual declaration provision, such as allowing transfers of mothership permits to occur with the declared catcher vessels remaining obligated to that permit creating conditions where motherships can stack mothership permits with their catcher vessel obligations and reduce costs. However, since the obligation can be broken easily by the catcher vessel by simply declaring a different mothership in the next year, the mothership company that transfers a mothership permit (and associated catcher vessel obligations) to another mothership will need to carefully consider whether doing so will increase the chances of catcher vessels declaring a different mothership in the next year. If this risk seems evident, motherships may be less willing to engage in the types of behavior that may lead to rationalization of the mothership sector as described above.

● Switching Motherships under an Ongoing Obligation

This section does not apply to the Council's preferred alternative.

Different ways exist for allowing catcher vessels to switch motherships with an ongoing processor tie, or obligation. One option would be to require that catcher vessels participate in the noncooperative portion of the fishery for one year. Another option is related to the unlinked portion of a catcher vessels catch history. This second option would give catcher vessels the ability to switch processors without participating in the noncooperative fishery. Catcher vessels could fish the unlinked catch history of other vessels in a cooperative. If that unlinked catch history resembles the majority of catch of that vessel, and it is delivered to another processor, that catcher vessel is linked to that new processor the following year, effectively switching processors without participating in the noncooperative portion of the fishery. The effect of this provision is that less participation in the noncooperative portion of the fishery may occur. This can have an impact on the success of bycatch management since the noncooperative fishery is a derby fishery and harvesters in such a mode may be less likely to fish cleanly. However, the logistics of a mothership sector operation may mean that the potential for a catcher vessel in a noncooperative fishery to race for fish (and therefore not fish cleanly) is minimized if that catcher vessel is attempting to establish a new linkage with a mothership. This concept was discussed in the above subsection. A catcher vessel in the noncooperative fishery attempting to establish a new linkage with a mothership would still need to operate alongside other catcher vessels that may be in a cooperative fishery but delivering to that mothership. In doing so, that noncooperative fishery catcher vessel would be subject to delivery rotations and would need to travel with that mothership and the cooperative fishery catcher vessels as that mothership operation moves. Furthermore, a catcher vessel attempting to establish a new linkage with a mothership will undoubtedly take into account the needs of the mothership even while that catcher vessel is in a noncooperative fishery mode where they are competing with other catcher vessels for catch. These conditions would tend to pace the fishing effort of the catcher vessel to some degree and result in less "irrational" behavior than may be theoretically expected.

Switching Motherships under an ongoing tie and the requirement to have multiple cooperatives are substantially related. If catcher vessels can switch processors by delivering the majority of their catch to another processor rather than fishing in the noncooperative fishery, then the decision of whether to require multiple cooperatives around motherships can have a substantial effect. If a cooperative can be formed around multiple processors, and catcher vessels can switch processors by simply delivering the majority of their catch to another processor in a year, then the effect of a processor tie may be substantially reduced. Under this scenario, a catcher vessel could enter into a lease agreement with another catcher vessel that is linked to another mothership. If deliveries from that catcher vessel to that other mothership constitute the majority of that vessel's catch, then the catcher vessel (and associated catch history) would be linked to that new mothership in the following year. This provides little disincentive to a catcher vessel considering the possibility of switching motherships and substantially reduces the effect of a processor tie. The outcome is one where catcher vessels have substantially more leverage in negotiations over prices and other matters. Some processor leverage could be established if cooperatives are required to form around the mothership to which they are tied and even more processor leverage could be established if catcher vessels must fish in a noncooperative fishery to switch processors.

- Summarization of the Effect of Processor Ties on Mothership and Catcher Vessel Relations and Profit Sharing

In summary, a cooperative system with ongoing processor ties should theoretically result in two powerful entities negotiating over profits in the fishery. The outcome is likely to be one where the operation of the mothership and the catcher vessel resemble the operation of a vertically integrated firm, and profits are shared between the harvester and processor. Furthermore, when combined with processor limited entry and a mutual agreement exception, linkages decrease the amount of competition among processors and make it possible for the processing sector to rationalize itself and to match the amount of processing capital in the fishery to the whiting OY.

If an ongoing processor tie is established and that tie is less than 100 percent, harvesters are likely to experience greater negotiation power over mothership processors when negotiating over profits compared to a case where ties are 100 percent. As the tie provisions decrease from 100 percent, negotiation power on the part of harvesters is likely to increase.

If harvesters are able to switch processors without participating in the noncooperative portion of the fishery, processor switching may be more likely, reducing the certainty that processors have over future deliveries, increasing the negotiation power that catcher vessels have over profit sharing arrangements, and therefore skewing profits more toward the harvester's favor. However, not requiring that catcher vessels participate in the noncooperative fishery in order to switch processors is likely to lead to fewer occurrences of vessels in the non co-op fishery. While theory would suggest that minimal participation in the noncooperative fishery will improve the performance of the fishery, the effect of processor linkages may carry into the noncooperative fishery and influence catcher vessel behavior in that fishery. The likely result is a more measured pace of fishing among noncooperative fishery participants than theory would suggest. However, it is still likely that the noncooperative fishery will have a lower degree of economic bycatch, and general fishery management performance compared to the cooperative fishery.

If catcher vessels switch processors without participating in the noncooperative fishery as described above, and single cooperatives can span multiple motherships, then the effect of the processor tie may be minimal. Through simple leasing of catch histories, catcher vessels can move processors by "delivering the majority of their catch" to another processor in a year through that lease agreement. The result is one where the processor tie may be largely ineffective in helping processors benefit from rationalization, but on the other hand, is likely to result in greater economic benefits and flexibility to harvesters.

An annual declaration provision works differently than an ongoing processor tie. The declaration provision allows the mothership entity to develop business plans for the upcoming year, but because switching motherships simply requires the catcher vessel to declare a different mothership in a subsequent year, the mothership entity has far less negotiation power over profits compared to a case where there is a full and ongoing processor tie. Since switching motherships is relatively easy under a declaration provision, participation in the noncooperative portion of the fishery is expected to be less than a fishery with ongoing processor tie provisions where the way to break those ties is through participation in the noncooperative fishery. This means that fishery performance may be greater under a fishery with declarations than a fishery with ongoing ties.

Method of Switching Motherships	Effect on Catcher Vessel	Effect on Mothership
Requirement to fish in non co-op fishery	Results in less negotiation power over prices and other aspects of mothership/CV relationship	Provides motherships relative certainty over future deliveries and some leverage over negotiations with CVs
Can switch motherships by fishing unlinked catch history of other co-op participants	Increases CV negotiation power over prices and other aspects of mothership/CV relationship	Reduces certainty over deliveries and minimizes leverage over negotiations with CVs
Can switch motherships by leasing a catcher vessel's catch history that is linked to another mothership	Increases CV negotiation power over prices and other aspects of mothership/CV relationship to a greater degree than above method	Minimizes the potentially beneficial outcome processors may realize from processor ties
Annual Declaration	High CV negotiation power over profits and other aspects of mothership/CV relationship	Allows for business planning on the part of the mothership. Provides little leverage in negotiation over profits and other matters

- Formation and Modification of Ongoing Processor Ties

This section does not apply to the Council's preferred alternative.

Each option for tie formation creates a relationship between a catcher vessel and a mothership based on patterns that exist prior to the implementation of a rationalization program. Implementing a system that maintains past relationships between harvesters and motherships may ease the transition from status quo management to a rationalized fishery. However, each of these options may result in some implications that, although short-term, may have mixed effects.

Option 1 has potential benefits in that it maintains the most recent relationships between motherships and catcher vessels, and therefore the transition from status quo management to a rationalized fishery may be made easier, at least theoretically. However, Option 1 may inadvertently result in a race for catch history among motherships in the year immediately prior to the implementation of the rationalization program. This could mean that harvesters receive higher prices for their fish that year, but it also may end up stimulating race for fish conditions in the mothership sector above those which already exist. Furthermore, those vessels that are less active in the fishery, but stand to gain catch history due to historic participation in the fishery, will find it necessary to participate in the fishery prior to rationalization in order to establish a processor linkage. Such participation by participants relatively unfamiliar with the fishery may make bycatch management in the fishery in the year prior to rationalization problematic. However, a failure for these participants to make a delivery to a mothership prior to rationalization may mean that participation in the noncooperative portion of the fishery is necessary for these vessels to establish a linkage with a mothership and participate in a cooperative. Option 4 is likely to result in the same outcome, except that the competitive behavior described above would tend to occur in 2009.

Potential ways of avoiding such a scenario are to allow vessels that do not fish in the year prior to rationalization, or in 1999, to establish a linkage with a mothership through a mutual agreement at the start of the program. A second method is to allow vessels that do not fish in the year prior to rationalization to join a cooperative and to deliver to a mothership of its choosing in the first year of the rationalization program. The processor linkage would be established in the second year of the program based on the mothership to which that vessel delivered the majority of its catch in the first year of rationalization. This type of situation would avoid the race for fish potential in years prior to rationalization as well as avoid the relatively high rate of participation in the fishery by unfamiliar

operators in years prior to implementation. The outcome may be more successful management of bycatch in years prior to implementation of a rationalization program.

Options 2 and 3 implement a program that maintains historic relations between motherships and catcher vessels; however, these historic delivery patterns will be several years removed by the time a rationalization program goes into effect. If the rationalization program goes into effect in 2011, for example, Option 2 would be 7 years removed, while catch patterns under Option 3 would be 8 years removed. These options may not result in the possibility of race for history conditions like under Option 1, but the relationships established under Options 2 and 3 may not be the same as those that exist immediately prior to the implementation of a rationalization program, potentially making the transition to rationalized fishery conditions somewhat difficult.

- Mothership Permit Transfers

Maintaining the ongoing tie between catcher vessels and motherships during the transfer of a mothership permit provides additional certainty to the purchaser of the mothership permit and increases the certainty a potential buyer has regarding the expected returns associated with that permit. Under an annual declaration procedure, this relative certainty over future returns associated with the permit does not exist as the obligation can be easily moved to another mothership by the catcher vessel. However, if that transfer occurs during the period of the declaration, then that new permit owner has some relative certainty in the current year.

Maintaining the obligation during the permit transfer also provides a mechanism for mothership entities to trade linked catch history among one another, and if permits are stacked on more than one mothership, to allow for a form of rationalization in the processing portion of the fishery.

As stated previously, constructing a cooperative-based system with processor ties implicitly makes mothership interests part of the harvesting activity. This implicit interest becomes evident because of the relationships that exist between the owner or operator of the catcher vessel and the owner or operator of the mothership. When a new owner acquires a mothership permit, that owner's interests will influence the relations between the catcher vessel and mothership. If interests and objectives are similar to the old owner of the mothership permit, then the transition from the old mothership permit owner to the new mothership permit owner – and the effect that transition has on linked catcher vessels – may be relatively seamless. However, if the new owner of the mothership permit has substantially different interests and objectives than the old owner of the mothership permit, then the sale of a mothership permit may cause some adverse effects on catcher vessels linked to that permit and make the transition to the new owner somewhat difficult. Since linkages make processing interests implicit in the behavior of cooperative members, a difficult transition could adversely affect the operation of a cooperative. However, under a declaration procedure, the effect of that interest is likely to be short-term, as the catcher vessel can easily switch motherships in the subsequent year.

- Flexibility in Meeting Processor Tie Obligations

If CV(MS) permit owners transfer catch privileges to another participant in the same co-op or one co-op establishes an inter-cooperative agreement with another cooperative to transfer catch, then the original processor tie obligation still remains. Requiring that the original tie be adhered to retains the mothership's expected deliveries and allows processors to realize other benefits from rationalization described previously, while also allowing harvesters the flexibility to share and transfer catch history in order to maximize harvest potential and net revenues.

♦ *Mutual Agreement Exception*

By mutual agreement, the processor tie can be broken temporarily. If both the CV(MS) permit owner and the mothership agree, then the catcher vessel may deliver its catch to another mothership. This mutual agreement exception is temporary and allows catcher vessels to deliver to another mothership if a case arises where the original mothership does not elect to participate in the fishery. The fact that the mutual agreement exception is temporary means that the future expectation of catch being received by the first mothership can still be reasonably expected if that mothership returns to the fishery, if that fishery has an ongoing obligation rather than a declaration. If a declaration exists, the mutual agreement exception allows the catcher vessel to deliver to another mothership should the declared mothership not participate in the fishery. That catcher vessel can simply switch to another mothership the next year, meaning the mutual agreement exception has no long-term effect if a processor declaration procedure is established.

This mutual agreement exception allows capital in the processing portion of the fishery to be more in line with the available harvest in the fishery. In a fishery with ongoing obligations, this is due to the fact that processors with linkages to catcher vessels do not fear losing those catcher vessels in subsequent years if they can temporarily release them to another mothership through that mutual agreement. This means that the ongoing processor linkage is somewhat "defensible" even if the mothership does not participate in the fishery. The presence of this defensibility means the mothership is at a minimized risk of losing linked catcher vessels and can elect to not participate in the fishery during years where the available harvest of whiting is low. Instead, some motherships may allow another mothership to take the deliveries of their linked catcher vessels. In effect, this allows the amount of capital in the processing side of the fishery to become more aligned with the available harvest, and this results in the minimization of processing costs (relative to the available harvest) and enhanced efficiency. If such a mutual agreement does not exist, it would be more likely that all motherships would be engaged in the fishery each year, at times leading to excess processing capacity and cost inefficiencies. Inversely, if motherships did not participate in the fishery and a mutual agreement provision does not exist, catcher vessels linked to that mothership may be required to fish in the noncooperative fishery, though not necessarily (the reader is referred to the next section on processor withdrawal for further discussion of this topic).

In a fishery with a declaration procedure, the mutual agreement exception also allows for a form of processor sector rationalization. While the obligations are short-term, the processing entity may find that participation in the fishery cannot be justified after the declarations have been made. This could be for a variety of reasons, including the possibility that after the declarations are made, the Pacific whiting stock assessment results in a relatively low allowable harvest level. In a case where less processing capital is necessary, the mutual agreement exception provides the processor with some say over where the catcher vessel delivers its fish. This could prove to be more beneficial to that processor than compared to a case where the processor has no say in where the catcher vessel goes.

In the event that a processor withdrawal would otherwise require catcher vessels to fish in the noncooperative fishery to deliver to another mothership, then the mutual agreement exceptions allow catcher vessels to continue operating in cooperatives if a mothership does not wish to participate in the fishery. This would tend to maintain the benefits catcher vessels have from rationalization of the fishery.

● Mothership Processor Withdrawal

A mothership's withdrawal from the fishery without a permit transfer or without a mutual agreement exception can affect catcher vessels with catch history that is linked with that mothership's permit. Several options exist for catcher vessels in this situation. One option would require that the catcher vessel participate in the noncooperative fishery. The second option would allow the catcher vessel to join another cooperative and deliver to another mothership. Two sub-options to the second option exist in the event the original mothership returns, but these sub-options only apply to a fishery with ongoing

obligations. One option states that if the original mothership returns within two years, the original linkages (if the fishery has ongoing obligations) would be reestablished, while the other option states that the catcher vessel will be linked to a new mothership (if ongoing obligations are in place) and will not be affected if the original mothership returns. If the fishery includes a declaration procedure rather than an ongoing obligation, then the effect on the linkage when the processor returns does not apply.

The effect of these provisions impact catcher vessels linked to the withdrawn mothership in several ways depending on the option. If the catcher vessel is forced to participate in the noncooperative fishery, then the mothership withdrawal from the fishery effectively penalizes the catcher vessel because that vessel must fish in a competitive fishery. On the other end of the spectrum is the option which would allow the catcher vessel to stay within the cooperative fishery and deliver to a mothership of its choosing. This leaves the catcher vessel harmless, but it may mean that a catcher vessel is not as liable to engage in a mutual agreement if a mothership does not wish to participate in the fishery, but is seeking out a mutual agreement with a catcher vessel. If, for example, a mothership does not plan to participate in the whiting fishery and seeks out a mutual agreement with a catcher vessel, that catcher vessel may be more inclined to refuse any agreement. If that mothership then withdraws from the fishery anyway, that catcher vessel would then be free to deliver to any mothership and be released from the linkages to the prior mothership. In the middle of the spectrum (but only if an ongoing processor obligation is included) is one which would allow the catcher vessel to continue participating in the cooperative fishery if a mothership withdraws, but require that the original linkage be established if a mothership returns. This may make it more likely that both catcher vessels and motherships would seek out mutual agreements in good faith because they would both expect to be re-linked in the future if a mothership withdraws from the fishery. However, this option would not penalize the catcher vessel if the mothership withdraws from the fishery. Therefore, Option 2a for mothership withdrawal may help maintain good faith in relationships between catcher vessels and motherships (and good faith in dialogue over mutual agreement exceptions) while avoiding any penalizing impacts on catcher vessels in the event a mothership withdraws from the fishery.

B-2.5 NMFS Role

B-2.5.1 Permit and Endorsement Issuance

NMFS will issue all necessary permits and endorsements under the rules specified under this program. Appeals processes will be provided as appropriate and necessary.

B-2.5.2 Fishery Registration and Co-op Approval

NMFS will announce a deadline before which all co-op agreements must be received for the coming year. NMFS will review and approve or reject co-op agreements based on standards provided here and other standards which it deems necessary to achieve the policy intent of the Council's actions.

B-2.5.3 Annual Allocation to Co-ops and the Non Co-op Fishery

a. Co-op Allocation

Each year NMFS will determine the percent of the mothership sector's harvest allocation to be given to each co-op based on the catch history calculation of CV(MS) permits registered to participate in the co-op that year. NMFS does not allocate to the individual permit holder, but rather allocates an aggregate amount of harvest tonnage annually to the co-op, based on the catch histories associated with the members of the co-ops.

b. Non Co-op Allocation

Each year NMFS will determine the distribution to be given to the non co-op fishery based on the catch history calculation of permit holders registered to participate in that fishery.

c. Adaptive Management Allocation *(not part of preferred alternative)*

In determining the amounts available for co-ops and the non co-op fishery, subtractions will be made, as necessary, for the adaptive management set aside described in Section B-1.6.

B-2.5.4 Fishery Management and Co-op Monitoring

a. NMFS will track all permit and endorsement transfers (if endorsement transfers are allowed) and the invocation of mutual agreement exceptions. Permit and endorsement transfers will not be valid until registered and acknowledged by NMFS.
b. NMFS will monitor catch and close segments of the fishery as necessary to ensure catch limits are not exceeded for:
    1. the whiting mothership co-op fishery,
    2. the whiting mothership non co-op fishery, or
    3. the mothership whiting sector as a whole,
c. NMFS will not necessarily monitor but will investigate and enforce as it deems necessary the permit and co-op obligations to processors.
d. NMFS will not necessarily monitor or enforce (except as it deems necessary):
    1. an individual permit's progress towards its catch allocations (permit level catch control will be at the co-op level and enforced through execution of the private contract),
    2. a co-op's progress toward its catch allocation,[19] or
    3. actual performance on the co-op agreement (the parties to the contract will resolve through private contract and remedies any deviation from provisions such as that requiring that a vessel have the opportunity to harvest the catch allocated to the co-op based on that vessel's permit, Section B-2.3.3.c).
e. NMFS will monitor other program provisions as needed. In some situations, there may need to be a declaration procedure for determination where a permit is delivering its obligated catch, for example, if a mothership withdraws without transferring its permit or reaching a mutual agreement for the transfer of obligated deliveries to a different mothership.
f. ***Not part of preferred alternative:*** NMFS will administer the adaptive management program, allocating the set aside for that program as needed based on the adaptive management goals, objectives and adjustment measures recommended by the Council.

❖ Rationale, Policy Issues, and Analysis

The current Pacific whiting fisheries are managed at the sector and fleet level. Managers monitor fleet harvests attempting to time their closure announcement with either the full harvest of the sector allocation of OY or the attainment of a common bycatch limit (beginning in 2009, bycatch limits are managed at the sector level). The level of management specified in the mothership sector cooperative alternative would require that the agency monitor catches at a lower, cooperative level, and take action when a cooperative, or inter-cooperative, is projected to reach its allocation. Furthermore, season timing is expected to change under rationalization and agencies will need to modify resources to monitor the fisheries over different time periods than what occurs under status quo.

[19] This assumes that there is an inter-co-op agreement in place that covers the entire co-op fishery. If such an agreement is not in place covering both catch and bycatch, NMFS may need to monitor catch by each individual co-op (but not by the individual vessels in the co-op).

The implementation of a cooperative system for the mothership sector will require that agencies develop resources necessary for reviewing cooperative agreements, developing infrastructure and programming necessary for estimating the collective catch history of various cooperatives, estimating the amount of catch each cooperative is available to catch each year, and debiting the appropriate amount of catch from the various cooperative pools as the fishery progresses.

The role of NMFS as specified in the options assures that the agency remains in a relatively strong position over the management of fishery resources and assures that the objectives of the Council are being met by participants in a cooperative-based fishery.

In order to administer the program effectively, it is necessary to establish a date by which cooperative agreements must be submitted and participants must state their intention to fish in a cooperative or in the noncooperative portion of the fishery. Establishing a date by which such filings must be made allows the agency the time necessary to review and approve/disapprove cooperative agreements prior to the start of the fishery and set up the appropriate systems for tracking catch and managing the fishery.

B-3 Whiting Shoreside Sector Co-Op Program

The cooperative alternative for the shoreside whiting fishery is identical, in many respects, to the mothership sector alternative which was analyzed in the previous section. Therefore, analyses of many elements of the shoreside whiting alternative are not repeated here. However, some differences do exist between the shoreside whiting alternative and the mothership whiting alternative, most notably in the processor licensing and linkage provisions. The principal differences between the shoreside whiting cooperative proposal and the mothership proposal include:

- Shoreside processor licenses expire after two years.
- Shoreside processor linkages may link a catcher vessel to more than one processor.
- Any shoreside processor may receive deliveries from vessels in the noncooperative fishery during the first two years of the program.
- The number of years a catcher vessel must participate in the noncooperative fishery in order to break a processor linkage may be one to five years.

The effects of a shoreside whiting cooperative alternative may differ from the effects of a mothership whiting cooperative alternative, particularly when considering the behavior of catcher vessels in a noncooperative fishery. This is due, in large part, to the characteristics and logistical differences that exist in the shoreside and mothership sectors of the whiting fishery. Much of this difference was illustrated in previous sections at the start of this document, so these effects are mentioned only briefly here:

- Participation in a noncooperative portion of the fishery may be more frequent in a shoreside cooperative program than a mothership cooperative program. This appears to be the case because of the apparent frequency at which shoreside catcher vessels tend to switch processors under status quo conditions. If this frequency underlies motivation for switching processors under a cooperative fishery, the result may mean more frequent participation of shoreside catcher vessels in a noncooperative fishery. This can have implications for economic performance of the sector as a whole and for management concerns if behavior in such a fishery is less “rational” and leads to higher bycatch than in the cooperative side of the fishery.

- The relations that exist between mothership catcher vessels and mothership processors may temper the behavior that catcher vessels in the noncooperative portion of the fishery have in that

sector. This may mean greater economic and bycatch performance in the mothership noncooperative fishery than pure theory would indicate. It is possible that such a tempering effect exists in the shoreside fishery as well, but information indicates that it may not exist to the same degree in the shoreside whiting sector, if at all.

- When the above factors are combined with a requirement that a shoreside catcher vessel may need to participate in the noncooperative fishery for more than one year in order to switch processors, the economic and bycatch performance of the shoreside fishery as a whole is likely to be less than the performance of the mothership fishery operating under a similar cooperative structure.

Before considering the particular elements of the shoreside whiting cooperative program that differ from the mothership cooperative program, it is important to point out several factors that are related to the decision of whether to manage the shoreside sector with cooperatives. These include:

- Shoreside processor licensing and linkages do not appear to be authorized under MSA. This differs from the mothership sector because a legal opinion has identified mothership operations as fishing whereas shoreside processing is not defined as fishing.
- The selection of harvest cooperatives as a tool for rationalizing the shoreside whiting fishery necessitates the selection of four distinct trawl sectors as opposed to three trawl sectors (which would be possible if the shoreside whiting and nonwhiting sectors were both managed with IFQs).

B-3.1 Participation in the Shoreside Whiting Sector

a. Catcher Vessels

Vessels with CV(SS)-endorsed permits may participate in either the co-op or non co-op portion of the shoreside fishery. They will choose annually which portion of the fishery they will participate in for the coming year. Additionally, any groundfish LE trawl permitted vessels may participate in the co-op portion of the fishery if they join a co-op (as described in Section B-3.3.3).[20] No other catcher vessels may participate in the shoreside whiting sector.

[20] When such permits participate in a co-op, the co-op will not be allocated any additional fish based on participation by such a vessel.

b. Processors

Any processor may receive fish from vessels participating in the shoreside non co-op fishery. In the first two years, only co-op qualified shoreside processors[21] that have declared their intent to participate may receive deliveries from catcher vessels in a shoreside co-op (Section B-3.3). Thereafter, any shoreside processor may receive deliveries from co-ops.

c. Catcher Vessels and Processors in the Nonwhiting Fishery

This program does not affect vessels or processors receiving whiting taken incidentally in the nonwhiting fishery.

B-3.2 Permits/Endorsement Qualification and Characteristics

B-3.2.1 Catcher Vessel Shoreside Whiting Endorsement (CV(SS) Endorsement)

a. Endorsement Qualification and History Assignment

Permits with a qualifying history will be designated as CV(SS) permits through the addition of a CV(SS) endorsement to their LE groundfish permit. At the time of endorsement qualification, each permit will also be assigned a catch history that will determine the share of the shoreside whiting allocation associated with that permit.

Qualifying for a CV(SS) Endorsement. An LE permit will qualify for a CV(SS) endorsement if it has a total of more than 500 mt of whiting deliveries to shoreside processors from 1997 through 2003.

Catch History Assignment. An initial calculation will be used to determine NMFS's distribution to co-op and non co-op fishery pools. A CV(SS) permit calculated landings history will be based on whiting history during the related permit's best 6 out of 7 years from 1997 through 2003. (Note: for vessels qualifying in both the shoreside and mothership co-op programs, the same year must be dropped.)

For the purpose of the endorsement and initial calculation, landing history associated with the permit includes that of permits that were combined to generate the current permit.

c. Accumulation Limits

CV(SS) Permit Ownership. No individual or entity may own CV(SS) permits for which the allocation totals greater than 15 percent of the total whiting shoreside allocation.

---

[21] **A shoreside processor** is an operation, working on U.S. soil, that takes landings of trawl-caught groundfish that has not been processed at-sea or previously processed shoreside, and that thereafter subjects those groundfish to shoreside processing. Entities that received fish that have not undergone at-sea processing or shoreside processing (as defined in this paragraph) and sell that fish directly to consumers shall not be considered a processor for purposes of the shoreside co-op program.
"Shoreside processing" is defined as any activity that takes place shoreside; and that involves:
a) cutting groundfish into smaller portions; or
b) freezing, cooking, smoking, drying groundfish; or
c) packaging that groundfish for resale into 100 pound units or smaller for sale or distribution into a wholesale or retail market.

Catch history formula			X		X	X		X		
Accumulation limits				X	X	X		X		

❖ Analysis

A total of 54 permits have reported deliveries of shoreside whiting during the 1997 to 2003 period. Of these, 45 permits have made landings larger than the 500 mt minimum for qualification of a CV(SS) permit. When examined on a year to year basis, the number of permits in the fishery is much smaller. During this period, a range of 38 to 29 permits participated in the fishery in any given year. Of the 54 permits that reported deliveries between 1997 and 2003, only 15 reported deliveries of shoreside whiting in each of the 7 years. On average, the 54 permits reporting deliveries were active 4 out of the 7 years.

Table B-13. Summary statistics on shoreside whiting permit participation from 1997-2003.

Total number of permits reporting SS whiting deliveries (1997 – 2003)	Total number of permits delivering at least 500 metric tons (1997 – 2003)	Number of permits active in the fishery in any given year (1997 – 2003)	Number of permits active in all 7 years	Average number of years each permit was active in the fishery
54	45	29 to 38	15	4

The number of active permits in the fishery over the time period appears to be affected by the variations that existed in the Pacific whiting OY and the Pacific whiting market during that time period. During 2002 and 2003, the fewest number of permits were active in the fishery compared to the previous years, and this was a time of relatively low whiting OYs and poor market conditions.

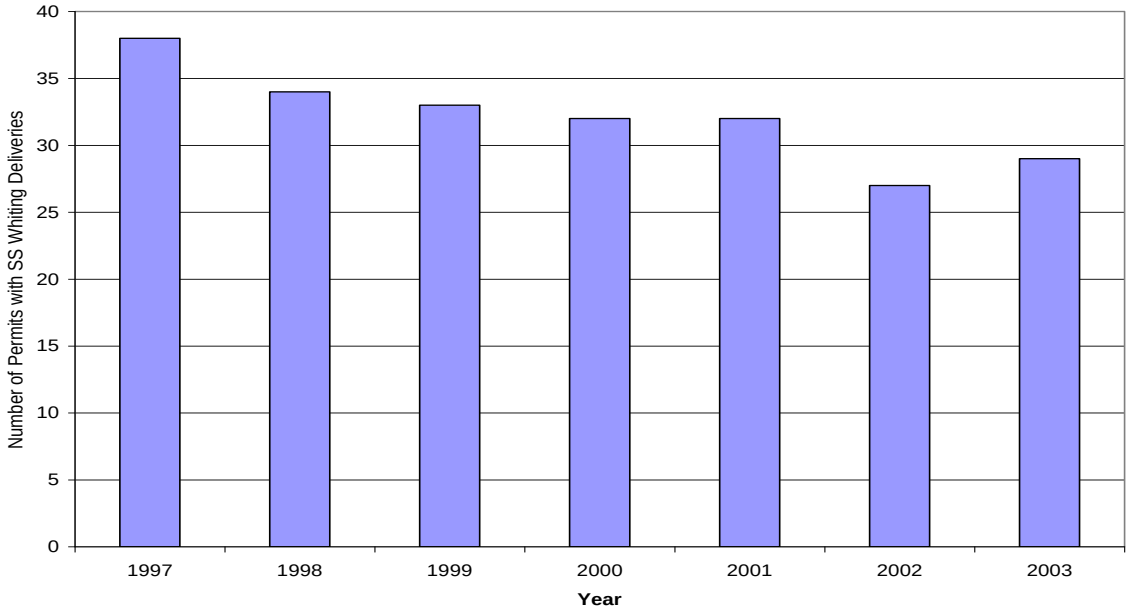

Figure B-8. Number of permits reporting shoreside whiting deliveries by year.

The following table is a more detailed set of information indicating the years particular permits have participated in the fishery and whether or not those permits qualify under the year and minimum metric tonnage criteria. This information includes data through the year 2006. From this data, it is apparent that several permits recently entered the fishery (in 2006) that would not qualify and this is most likely due to the improvement in market conditions for Pacific whiting.

Table B-14. Participation of limited entry trawl permits in the shoreside whiting fishery by year and qualification criteria.

	63	x	x	x	x						

The effect of the catch history formula is relatively inclusive of past participants in the fishery. The majority of permits reporting directed landings of Pacific whiting qualify to receive catch history designations. The assignment of catch history to permits ranges from just under 6 percent of the shoreside allocation to approximately 0.1 percent of the shoreside whiting allocation. When examined on a business entity level, the high to low distribution is more pronounced with the largest entity receiving over 12 percent of the shoreside whiting allocation. This indicates that the accumulation limit may not be restrictive if compared to existing ownership, but when considering the possibility of fleet consolidation (making it likely that fewer entities will hold permits) the accumulation limits may become restrictive to some entities.

When examined next to the catch shares that have occurred over the 2004 to 2006 time period, the catch history assignments deviate substantially (in some cases) from the percent of catch generated by some permits during this period. This can be explained by the recent increase in interest in the whiting fishery, driven in large degree by improvements in market conditions, but also because several permits have not participated in the fishery in recent years.

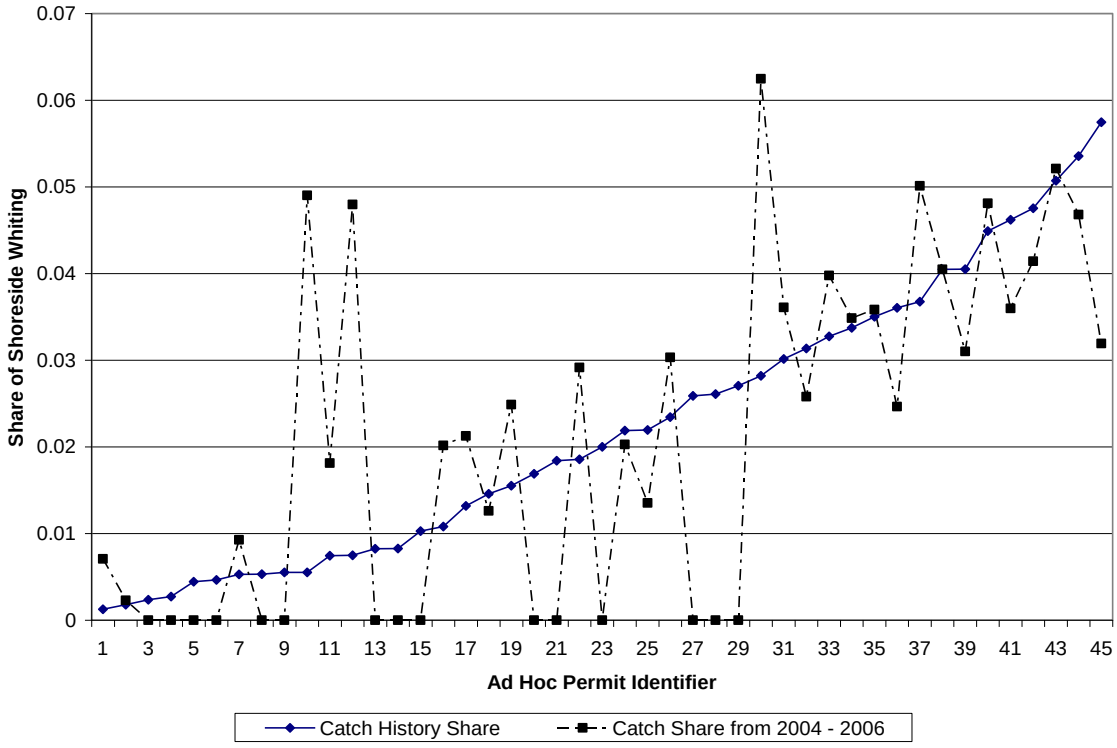

Figure B-9. Share of shoreside whiting allocated to permits.

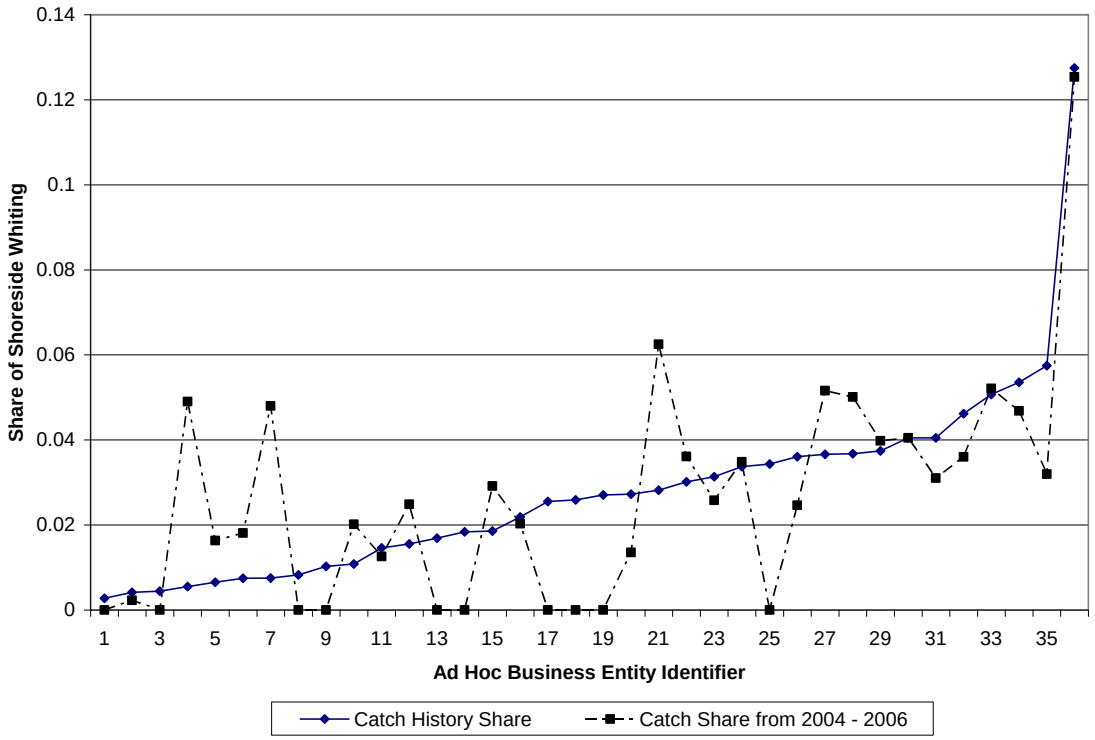

Figure B-10. Share of shoreside whiting allocated to business entities.

B-3.2.2 Shoreside Co-op Eligible Processor Permit

a. Activities Requiring this Permit

Only processing entities with a shoreside co-op processor permit (SSP) are eligible to receive whiting fish from whiting cooperatives in the first two years of the program. Thereafter, any processing corporation could be eligible to receive whiting from participants in a whiting cooperative, subject to the other provisions of this plan. Processors without SSPs may receive whiting from participants in the non co-op fishery and whiting harvested incidentally in the nonwhiting fishery at any time, including within the first two years of the program.

b. Qualification Requirements

An initial co-op-qualified shoreside processing entity is one that processed at least 1,000 mt of whiting in each of any two years from 1998 through 2003.

d. Duration of this Section

Since SSP permits are only in effect for the first two years of the program, this section is also in effect only for the first two years of the program.

❖ Rationale and Policy Issues

The justification for processor licensing is so that the interests of processors are protected when the fishery moves to rationalization. Such licensing would restrict the ability for new processor participants

to come into the fishery and compete with existing processors which may tend to result in excess processing capacity. Limiting this competition would tend to protect the interests of existing processors for several reasons including: A) volume per processor would not risk being diminished due to new processors entering the fishery, and B) fewer numbers of processors would tend to enhance processor leverage during negotiations over ex-vessel prices and other matters.

The licensing restrictions described here, which are only in effect for two years, were originally meant to serve the role of a transition period for processors with the idea that processors would have ample time to adapt and change business plans to work with the newly rationalized fishery. The original intention of the two year time limit established as part of the licensing program was based on the notion that such a provision may be able to be implemented under the authority of the MSA; however, it appears that is not the case.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Shoreside co-op processor permit			X			X		X		

❖ Analysis

The effect of processor licensing would be relatively inclusive of those processors that have participated in the fishery on a relatively steady basis, but would exclude many processors that have not participated in more recent years, or have recently entered into the fishery. In total, 18 companies have participated in whiting activity, with three non-qualifying companies participating in 2006. Under the qualification criteria, eight processing companies would receive licenses to process shoreside whiting. Those companies not qualifying would have their participation in the fishery restricted, disrupting operations that exist under current conditions. Information regarding participation and qualification by processing entities is illustrated in the table below.

Table B-15. Shoreside whiting processing company participation by year and qualification criteria.

Qualification Filter	Ad Hoc Processor ID	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	2006

	R					x								

In general, instituting processor licensing and linkages allows the processing sector to rationalize itself to some degree and generate higher levels of revenue than would be the case without such provisions. This topic was discussed in more detail in previous sections describing the effect of this provision on mothership processors. When processor licensing requirements are only in effect for two years, the ability for processors to realize some gains as a result of rationalization will begin to erode at the end of that two year window, and that erosion should occur gradually over time. After those licensing provisions expire, processor engagement in the fishery will almost certainly change. Competition among processors should be expected to increase over time as new companies enter the fishery, the amount of capital processing Pacific whiting may increase if new processors enter into the processing sector, and catcher vessels may assume greater leverage in negotiations with processors over prices and other matters as a result of that competition among processors. The result is likely to be one where processors assume less revenue from processing activity over time compared to a case where processor licenses are in effect over the long-term. As a result, the expiration of processor licenses is likely to mean that processors will not benefit as greatly from rationalization of the fishery compared to a case where processor licenses exist over the long-term.

The way in which processor ties are constructed will have secondary impacts on communities where whiting deliveries and processing take place. Depending on the way in which the ties are established, community engagement in the fishery could change as delivery patterns are altered to meet processor obligations.

B-3.4 Processor Ties

B-3.4.1 Initial Formation of Ties

During the first two years of co-op formation, permit owners that join a co-op shall be required to deliver their whiting catches to the co-op qualified processors that were the basis of their landing history during the following period on a pro rata basis:

Years Option 1: 2001
Years Option 2: 2000
Years Option 3: 2000-2003

Determination of the processor(s) to which a permit owner is obligated will take into account any of the processor's(s') successors in interest. (Note: Several permits would not be tied to processors under the above options. It is unclear how ties would be established for those permits.)

Processor Successor in Interest. In determining the processor to whom a permit owner that participates in a co-op is required to deliver in the first two years of the program, a processor's successor in interest will be taken into account. If a processor's assets were purchased and the landing history expressly identified as an asset in the purchase agreement, then any permit owner obligation based on those landings will accrue to the processor making the purchase. For landings history associated with a defunct or non-qualifying processor, that portion of a permit's allocation will be linked to the permit's initially-assigned landing history on a pro rata basis.

B-3.4.2 Duration and Modification of Processor Ties (Options 1 and 2)

A permit's obligation to a processor will remain in place from one year to the next unless modified through the following process.

Option 1: Once a CV(SS) permit has participated in the non co-op fishery for [***Options: 1 to 5 consecutive years***], it is released from its delivery obligations to the processor(s) that were the basis of its history, and may join any of the various co-ops, or join with other permit holders who have also been released from delivery obligations to form a new co-op, and deliver to any shoreside processor in the subsequent years after the SSPs have expired.

Option 2: Any CV(SS) permit participating in a co-op is linked indefinitely to the processor they are delivering to under the initial linkage requirements. The permit can sever that linkage by participating in the non co-op fishery for a period of [***Options: 1 to 5 years***]. After completing their non co-op obligation, the permit is then free to reenter the co-op system and deliver to a processor of their choosing. Once the permit reenters the co-op system and elects to deliver their fish to a processor, a new linkage is then established with that processor. Should the permit later choose to break that new linkage, the non co-op participation requirements again apply.

Should a permit elect to enter the non co-op fishery within the first two years of this program, that permit must participate in the non co-op fishery for a minimum of [***Options: 2 to 5 years***], regardless of other non co-op participation requirements applying elsewhere in this document. Once the permit meets that obligation and later elects to enter a co-op, all provisions of co-op participation, including the processor linkage provisions, apply.

❖ Interlinked Elements

The possibility that a catcher vessel could be linked to more than one processor potentially creates complexities in bycatch management and in breaking and establishing new linkages with processors.

If a catcher vessel is linked to more than one processor and the fishery is closed upon attainment of a bycatch limit, there may be conflict over whether a permit's obligations to various processors have been met. At this time it is unclear whether a processor could seek compensation from a harvester if a harvester is tied to more than one processor, but fails to deliver the specified proportion of deliveries to all obligated processors. Even if a processor could not seek such compensation, being tied to multiple processors may still create unintended consequences. If processors believe there is likely to be a premature closure of the fishery because of the attainment of a bycatch limit, those processors may fight over the timing of deliveries from that catcher vessel, resulting in a variety of effects outlined in more detail in the analysis section of this element.

Modifying and breaking processor ties are related to the possibility of a catcher vessel being linked to more than one processor. If a catcher vessel desires to break a tie with one of its linked processors, that catcher vessel would need to undergo the same action as if it wanted to break ties with all linked processors by fishing in the noncooperative fishery. Furthermore, when a new tie is established, that catcher vessel will only be tied to a single processor. This means that if a catcher vessel wants to break a tie with a single processor, it would need to fish in the noncooperative fishery and the participation of that catcher vessel in the noncooperative fishery would put all processor ties connected to that vessel at risk. Therefore, the relationships between one processor and that catcher vessel may indirectly affect the ties that exist between that catcher vessel and other processors.

❖ Rationale and Policy Issues

The rationale for establishing processor ties is largely the same as that rationale found in the parallel section on the mothership alternative. The years for establishing processor ties in the shoreside sector are different from those years used in the mothership sector. The rationale for shoreside sector ties are based on the idea that the processors and harvesters engaged during each of the possible time periods for establishing linkages are the processors that have been most engaged in the fishery and/or elected to knowingly participate during years when conditions were poor. During the possible time periods for establishing ties, the market for whiting was depressed and the whiting OY was low. Initial ties based on patterns during this period recognize the participation of processors that have consistently participated in the fishery, especially during times of relatively little economic benefit from participating in the fishery.

- Successor in Interest

The rationale for recognizing a successor in interest is that the purchase of assets by a processing entity may have included in the purchase price the historical involvement of that original processing entity in the fishery. If the buyer and the seller believe such historic participation may lead to the receipt of quota, a license, or processor linkages, that historic participation is likely to influence the sales price of those assets. In order to get a return on the investment made in those assets, it is therefore necessary for the successor in interest to be the recipient of the processor tie. Furthermore, recognizing a successor in interest of the processing assets would result in the recognition of the current owner of those assets, and this is consistent with the concept of granting quota share or catch history to the current owner of a limited entry trawl permit.

● Duration and Modification of Processor Ties

The rationale behind the requirement to participate in the noncooperative fishery in order to break processor ties is largely the same as that rationale provided in the analysis of the mothership cooperative alternative. However, the shoreside whiting alternative includes a possible range of years (one to five) in which a vessel would need to participate in the noncooperative fishery in order to break the processor linkage. Furthermore, if the vessel elects to break processor ties in the first two years of the program, that vessel would need to participate in the noncooperative fishery for a minimum of two years. These years are intended to provide a range of possible disincentives to vessels for breaking ties. Requiring that vessels participate in the noncooperative fishery for one year has the lowest relative disincentive (although that disincentive may be relatively large), while requiring that vessels participate for five years provides the highest degree of disincentive to a vessel that is considering breaking a tie with a processor.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Processor ties			X			X		X		
Initial Formation of Ties			X			X		X		
Duration and Modification of Processor Ties			X			X		X		

❖ Analysis

● Initial Formation of Ties

The options for processor linkages result in a varying degree of linked catch history percentages to each qualifying processing entity. This information is shown in the figure below. Using the years 2000 to 2003 assures that all of the qualifying processors receive some linked catch history. Using 2000 or 2001 results in one qualifying processor not having linked catch history.

The way in which processor ties are established would tend to impact participants in the fishery and where deliveries are made, thus affecting communities. Establishing ties based on a historic period may disrupt relationships that exist in current conditions, if harvesters and processors have an existing relationship that is broken through the establishment of a tie during a period when a different relationship existed.

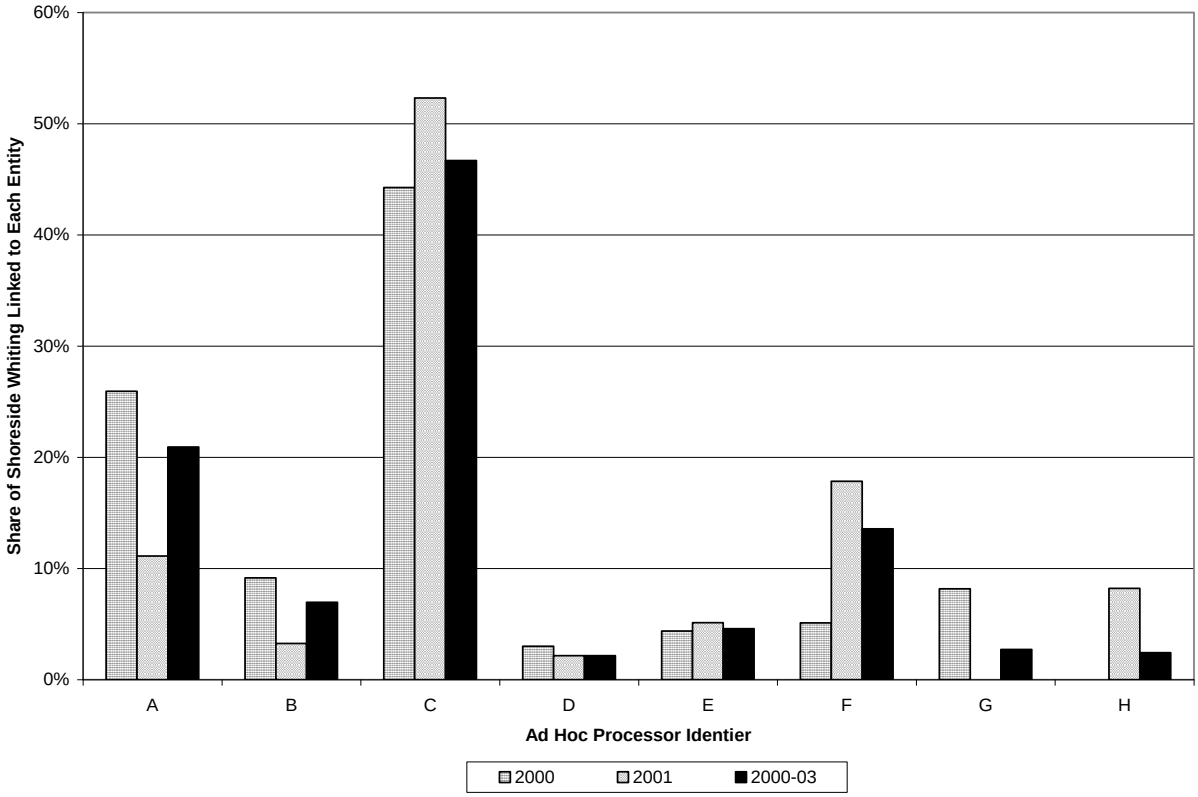

Figure B-11. Share of linked shoreside whiting catch history by processing entity and linkage formula.

The number of catcher vessels linked to each processing entity is shown in the following figure. Based on this information, the number of catcher vessels linked to each processing entity varies widely depending on the formula used for establishing initial linkages. In addition, catcher vessels can be linked to more than one processing entity if the 2000 to 2003 processor linkage formula is used. Using the other two linkage formulas means that those catcher vessels that have linkages established appear only to be linked to one processing entity. However, multiple permits that receive catch histories would not be linked to processors through application of the 2000 or 2001 processor tie formula. As illustrated previously, 45 permits would receive shoreside whiting catch histories, yet according to information shown below, three permits would not be linked through the 2000 to 2003 formula, 15 permits would not be linked through the 2000 formula, and 16 would not be linked through the 2001 formula.

The effect of choosing these years for establishing linkages means that linkages may be created for permits and processors that have had relationships prior to the implementation of a rationalization program. However, the years used for these linkage formulas may be more than 10 years old by the time rationalization is implemented, and if catcher vessels and processors have not had relations since that time, reestablishing them through a linkage provision may introduce disruption to the fishery. This can have significant implications for a fishery managed with cooperatives, as cooperatives rely heavily on relationships to operate successfully. Even though processors are not cooperative members (unless they own a permit which is part of a cooperative) the relationships between catcher vessels and processors may affect the way in which catcher vessels prosecute fishing activity.

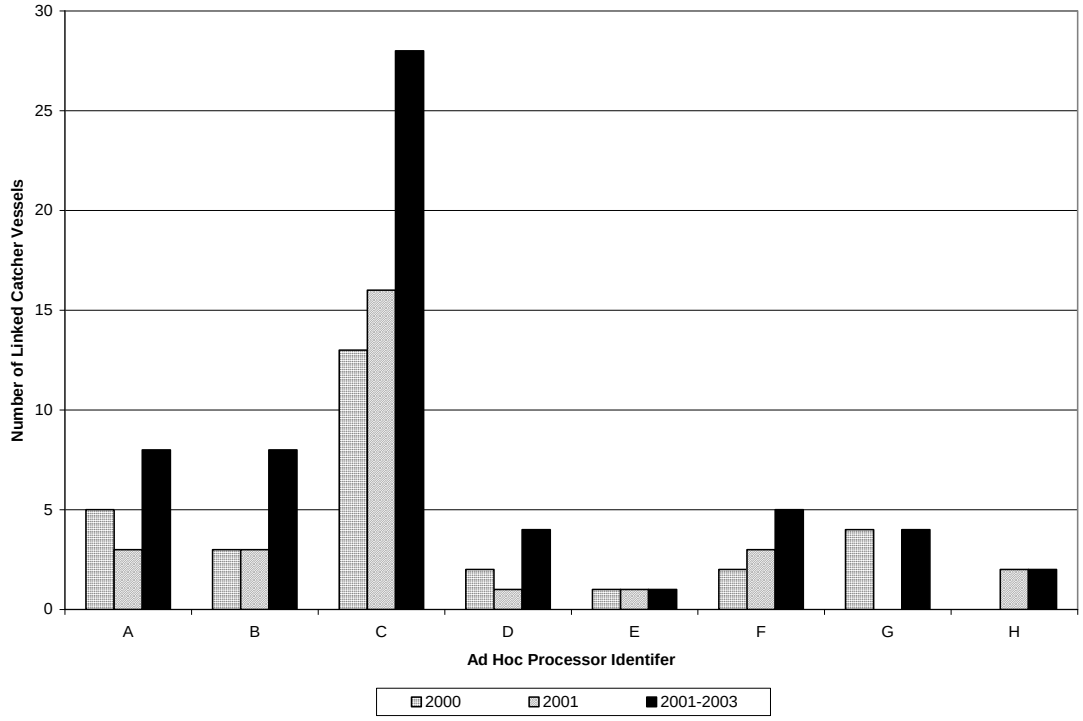

Figure B-12. Number of linked catcher vessels by processing entity and linkage formula.

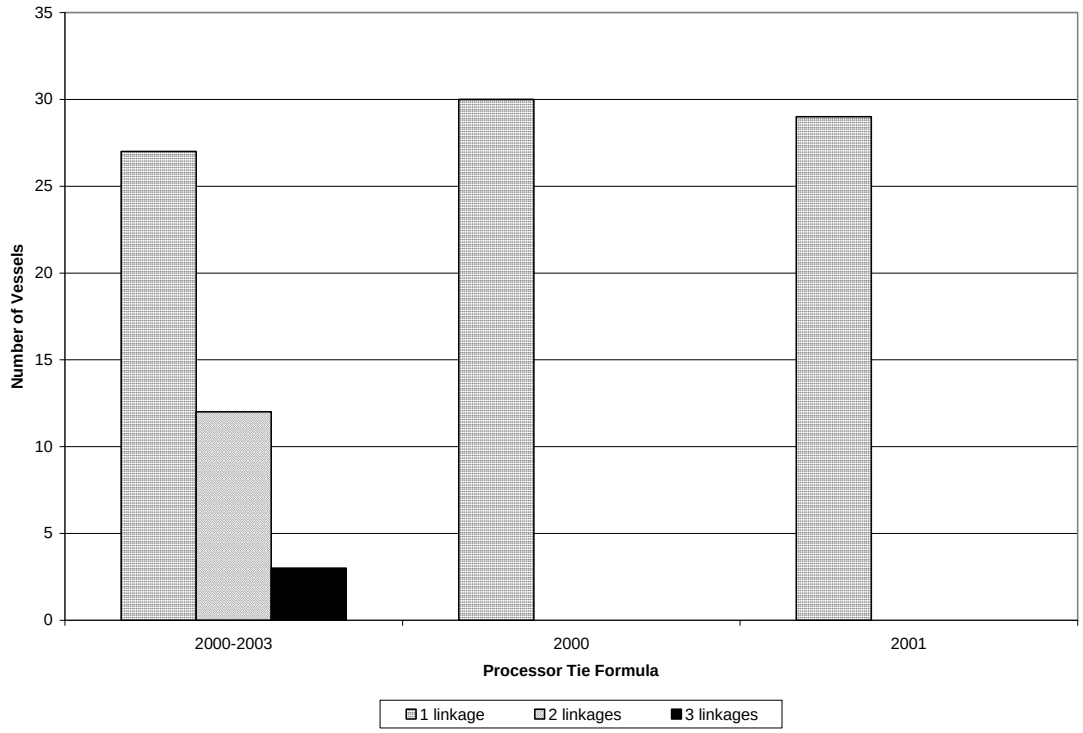

Figure B-13. Count of vessels by number of processing linkages and processor linkage establishment formula.

♦ *Potential Implications of Having a Catcher Vessel Tied to Multiple Processors*

The possibility of having a catcher vessel tied to more than one processor means that the activities of one processor can put all processors tied to that catcher vessel at risk if that catcher vessel wants to abandon a tie with only one of those processors. In order to break a processor tie, a catcher vessel would need to participate in the noncooperative fishery, and when the catcher vessel rejoins the cooperative fishery, that catcher vessel will be tied to one processor. When that catcher vessel engages in the noncooperative fishery, it could elect to permanently abandon ties with all of its tied processors and develop a tie with a completely different processor. In addition to this concept, establishing ties between a catcher vessel and more than one processor could mean that processors tied to that catcher vessel will try to influence delivery patterns in a way that benefits them. In the worst case scenario, processors may desire to have their deliveries during a particular time window, and if the catcher vessel is pressured to a great enough degree by those processors, that catcher vessel may elect to engage in a type of race, or excessive effort, to accommodate and appease the multiple processors that are seeking deliveries during a specific time window. When compared to a case where a single processor is tied to a catcher vessel, the pressure that catcher vessel has to meet the desired timing of a single processor may be less than the pressure a catcher vessel has in meeting the desired timing of multiple processors.

In addition to the above examples, having catcher vessels tied to more than one processor raises several questions about what would happen in the event that a fishery is closed based on attainment of a bycatch limit before the sector allocation is reached. Closing on the attainment of a bycatch limit will mean that catcher vessels have not harvested their full quota for the year and this means that the deliveries various processors may have expected during the year would not be achieved. If a catcher vessel is linked to more than one processor, but delivers catch to only one processor prior to the closure of the fishery, other linked processors may not feel that their obligated deliveries have been received. This raises some questions about whether those processors would pursue some financial compensation from that catcher vessel since it will have delivered all of its catch to one processor even if it was scheduled to deliver to multiple processors later in the season. Even if this type of compensation cannot be sought, the fear of not catching quota or of receiving obligated deliveries may induce a race for fish spurred by the processors as well as the catcher vessel in order to catch their whiting quota before the fishery is closed. This is likely to have negative implications to the performance of the fishery.

● Duration and Modification of Processor Ties

The general rationale for allowing vessels to break processor ties by participating in the noncooperative fishery is that it makes the processor ties voluntary to some degree while providing a strong incentive to keep processor ties intact. It is acknowledged that participation in the noncooperative fishery is less economically beneficial (and may indeed be costly) to those engaged in that mode. Furthermore, because of the structure of the fishery, participants in a noncooperative mode may fish less carefully and this may result in higher rates of bycatch. Because of reasons explained in the introductory portions of this document, the potential for this type of behavior to occur may be higher for a noncooperative fishery vessel in the shoreside sector than a noncooperative fishery vessel in the mothership sector. This means that the requirement that vessels in the shoreside sector participate in a noncooperative fishery to break a processor tie is likely to result in diminished economic and bycatch performance compared to a vessel in a cooperative fishery. The result of requiring that vessels participate in the noncooperative fishery for several years in order to break a tie is likely to be one of much greater participation in that mode in any given year, resulting in lower economic benefits and diminished bycatch performance. This outcome would tend to be exacerbated as the required number of years of noncooperative fishery participation in order to break a processor tie is increased.

- *Implications of Multiple Years of Noncooperative Participation in Breaking a Processor Tie*

In addition to the above factors, the ability for catcher vessels to realistically break a processor tie may be necessary for the successful operation of a fishery managed with cooperatives. As mentioned previously, harvest cooperatives are formed by harvesters and it is important to maintain this distinction in order for the fishery to operate successfully. It is ultimately the harvesters that eliminate the race for fish currently responsible for much overcapitalization and inefficiency, and it is ultimately the harvesters that achieve other benefits such as bycatch reduction.

Processor ties help ensure that processors benefit from rationalization, but the establishment of such ties implicitly make the processing entity an involved party in the fishing practices of the linked catcher vessel. This is because processor ties result in a type of mutual dependence on the part of the harvester and the processor, and the outcome is one where the activities of the harvester and processor take on the characteristics of a vertically integrated firm. Through these characteristics of vertical integration, the processor tie makes the processor an influential party in the harvesting activities of a catcher vessel. If a relationship between the catcher vessel and a processor become strained, this can have a negative effect on the fishing practices of the catcher vessel, and this can mean less economic efficiency and less improvement in other management goals. It is because of this potential that the catcher vessel be able to break the tie. Being able to realistically break the tie and form a new tie with another processor allows catcher vessels and processors the ability to find other processors and catcher vessels with goals and similarities that make for the efficient operation of both the catcher vessel and the processor. Being able to establish ties between processors and catcher vessels that are similarly minded makes for a more efficient operation for both parties.

While processor ties provide a disincentive to vessels that are considering switching processors (and therefore help ensure that processors benefit from rationalization), switching processors must be a realistic possibility to those catcher vessels. This is necessary to ensure good faith and balanced relations between catcher vessels and processors and operating in good faith may be important to the overall economic health and performance of participants in the fishery. Good faith relations may be affected if a processor knows that a catcher vessel cannot realistically break the tie. This can result in increasing demands placed on a catcher vessel in the form of delivery timing, profit sharing, and other matters that may be at odds with other goals of that catcher vessel. If a catcher vessel is required to participate in the noncooperative fishery for more than one year, it is likely that the ability to switch processors will become increasingly unrealistic, and at some point, switching processors may not be a realistic possibility at all, especially if participation in the noncooperative fishery results in a loss of revenue.

B-3.6 Exclude Processor Ties and Processor Licensing (Option)

Option: Exclude from the above all references to processor ties and processor licensing. This option includes the following changes to Section B-3:

Section B-3.1.b. Processors. Delete "non co-op" from the first sentence and delete the remainder of the section. This section constrains processor participation in the first two years of the program.
Section B-3.2.2. Shoreside Co-op Eligible Processing Permit. Delete the entire section.
Section B-3.3.4 Annual Allocation transferability. Delete the last sentence (refers to the handling of permit obligations to processors when allocations are transferred).
Section B-3.4. Processor Ties. Delete the entire section.
Section B-3.5.2.b. Delete the entire paragraph (addresses preseason registration of processors with shoreside processing permits).
Section B-3.5.3.a. Delete the last sentence (refers to the NMFS need to make determinations on permit

links to processors).
Section B-3.5.3.c. Delete "and co-op obligations to processors."

❖ Rationale and Policy Issues

Dropping processor linkages from the cooperative program is intended to serve as an analysis of a cooperative based fishery that can be implemented under the authority of the MSA. Based on input from NOAA GC, the processor licensing and linkage provisions specified in earlier portions of this alternative are outside the existing authority of the MSA.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Exclude Processor Ties and Licensing			X		X	X				

❖ Analysis

Processor licensing and linkages are tools intended to protect the interests of processors that exist in the fishery. The lack of processor licensing and linkages would therefore be expected to have an opposite effect where processor interests are not protected. The expected outcome would be one where new processors may enter the fishery and processors would compete with one another for catch from catcher vessels. Processors would theoretically enter into the fishery as long as profits can be generated from doing so. The result may be one where there is more processing capital in the fishery than is necessary to process the available harvest. However, establishing a cooperative-based management program without processor ties is expected to result in efficiencies at the catcher vessel level from slower paced harvest activity and fleet consolidation, among other factors described earlier in this section and in Chapter 4. Furthermore, the lack of processor ties would tend to result in more processor competition than a case with processor ties and harvesters can use that competition to their advantage when negotiating over ex-vessel prices and other matters. The result is one where harvesters see benefits from increased cost efficiency and also from enhanced negotiation power over ex-vessel prices.

One additional outcome of not having a processor linkage provision is that the noncooperative fishery may not exist. While catcher vessels could still elect to participate in the noncooperative portion of the fishery, it is highly unlikely they would do so because catcher vessels would not need to break any processor linkages and because participation in the noncooperative fishery is expected to be relatively inefficient. The lack of participation in the noncooperative fishery may improve some management goals of the fishery related to management performance, bycatch performance, and economic efficiency.

B-4 Co-ops for Catcher-Processors

Catch by the catcher-processor sector will be controlled primarily by closing the fishery when a constraining allocation is reached.[22] As under status quo, vessels may form co-ops to achieve benefits that result from a slower-paced, more controlled harvest. The main recommendations are the creation of a limited number of catcher-processor endorsements, the requirement that a catcher-processor co-op qualify for a Federal co-op permit, and the specification in regulation of the amounts that will be available for harvest by the voluntary co-op. A new entrant will have to acquire a permit with a catcher-processor endorsement in order to enter the fishery.

B-4.1 Participation in the Catcher-Processor Sector and Endorsement Qualification.

Catcher-Processor Endorsement. The class of catcher-processor endorsed permits (catcher-processor permits) will be limited by an endorsement placed on an LE permit. LE permits registered to qualified catcher-processor vessels will be endorsed as catcher-processor permits. A qualified permit is one that harvested and processed in the catcher-processor sector of the Pacific whiting fishery sometime from 1997 through 2003. Only catcher-processor vessels with a catcher-processor endorsed limited entry permit will be allowed to catch and process whiting at-sea as part of the CP sector. Limited entry permits with catcher-processor endorsements will continue to be transferable.

Participation as Mothership (Preferred Alternative). A catcher-processor cannot operate as a mothership during the same year it participates in the CP fishery.

Catcher-processor Permit Combination to Achieve a Larger Size Endorsement. A catcher-processor permit that is combined with an LE trawl permit that is not catcher-processor endorsed will result in a single catcher-processor permit with a larger size endorsement (a CV[MS] or CV[SS] endorsement on one of the permits being combined will not be reissued on the resulting permit. ***The reference to the CV[SS] endorsement is not relevant under the preferred alternative.***) The resulting size endorsement will be determined based on the existing permit combination formula.

CP Permit Transfers to Smaller Vessels. Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained; however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e., length endorsements will not change when a trawl endorsed permit is transferred to a smaller vessel). **(Added as part of preferred alternative.)**

Number of Transfers per Year. CP permits may be transferred two times during the fishing year, provided that the second transfer is back to the original CP (i.e., only one transfer per year to a different CP). **(Added as part of preferred alternative.)**

B-4.2 Co-op Formation and Operation Rules

Annual registration. As under status quo, the co-op(s) will be formed among holders of permits for catcher-processors. Participation in the co-op will be at the discretion of those permit holders. If eligible participants choose to form a co-op, the catcher-processor sector will be managed as a private voluntary cooperative and governed by a private contract that specifies, among other things, allocation of whiting among CP permits, catch/bycatch management, and enforcement and compliance provisions. The co-op will submit an application to NMFS for a Federal co-op permit. NMFS will not establish an allocation of

[22] All references to catcher-processors in this section references to vessels operating in the catcher-processor sector. Vessels under 75' which catch and process at-sea as part of the shoreside sector are not covered here.

catch or catch history among permits unless the sector fails to organize itself under a single co-op agreement that qualifies for a Federal co-op permit. **Added as part of the preferred alternative:** If the co-op system fails, it will be replaced by an IFQ program and the initial issuance of IFQ will be divided equally among all CP endorsed permits (see B-4.3.2, Option 2).

Annual Reporting Requirements. The catcher-processor cooperative will submit an annual report to the Council at their November meeting. The report will contain information about the current year's catcher-processor fishery, including the catcher-processor sector's annual allocation of Pacific whiting; the catcher-processor cooperative's actual retained and discarded catch of Pacific whiting, salmon, rockfish, groundfish, and other species on a vessel-by-vessel basis; a description of the method used by the catcher-processor cooperative to monitor performance of cooperative vessels that participated in the catcher-processor sector of the fishery; and a description of any actions taken by the catcher-processor cooperative in response to any vessels that exceed their allowed catch and bycatch. The report will also identify plans for the next year's catcher-processor fishery, including the companies participating in the cooperative, the harvest agreement, and catch monitoring and reporting requirements.

B-4.3 NMFS Role

B-4.3.1 Permit and Endorsement Issuance

NMFS will issue all necessary permits and endorsements under the rules specified under this program. Appeals processes will be provided as appropriate and necessary.

B-4.3.2 Annual Allocation

Option 1: There will be no government-directed subdivision of the catcher-processor sector quota among participants.
Option 2: Harvest amounts for the co-op will be specified in regulation. If the co-op breaks up, IFQ will be issued and divided equally among the 10 permits.

However, up to 10 percent of the allocation to the catcher-processor may be set aside as necessary for the adaptive management set aside described in Section B-1.6. **(This paragraph is not part of the preferred alternative.)**

The catcher-processor sector allocation may be divided among eligible catcher-processor vessels (i.e., those catcher-processor vessels for which a CP permit is held) according to an agreed catcher-processor cooperative harvest schedule as specified by private contract.

B-4.3.3 Fishery and Co-op Monitoring

a. NMFS will track all permit transfers. Permit transfers will not be valid until registered and acknowledged by NMFS.
b. NMFS will monitor catch and close the catcher-processor sector fishery as necessary to ensure catch limits are not exceeded.
c. NMFS will administer the adaptive management program, allocating the set aside for that program as needed based on the adaptive management goals, objectives and adjustment measures recommended by the Council. **(Paragraph c is not part of the preferred alternative.)**

❖ Rationale and Policy Issues

The catcher-processor sector currently operates as a rationalized fishery through the formation of the voluntary cooperative. This cooperative is managed by a governing contract which spells out such things as catch sharing arrangements among members of the cooperative. The result of this contract has meant that the effects attributed to a rationalization program have already occurred in the catcher-processor sector and therefore there is little reason to change the way that sector is managed.

In the event the catcher-processor cooperative breaks apart, the issuance of quota shares to permits in the catcher-processor fishery is intended to ensure that the fishery continues to operate as a rationalized fishery. Granting each permit 10 percent of the quota share is intended to result in a distribution of fishing opportunity that is highly similar to the catch sharing agreement that exists in the existing cooperative contract.

During the Council's consideration of rationalization of the catcher-processor sector, the Council discussed the issue of whether the preferred alternative for the catcher-processor sector was a limited access privilege program. During the Council's debate over the preliminary preferred alternative in June of 2008, the Council explicitly voted down a motion that would have made the catcher-processor a limited access privilege. During the November 2008 final action, the Council adopted measures that were highly similar to the preliminary preferred alternative adopted in June of 2008. Following this motion, NOAA Fisheries indicated its preliminary intent to treat both the mothership and catcher-processor portions of the fishery as a limited access privilege program effectively meaning that both sectors may be charged for cost recovery in order to implement the program. At its April 2010 meeting, the Council revised its final preferred alternative such that a permit would be required for the catcher-processor co-op and it would be clear that the system was a LAPP. The method for determination of the appropriate fees for cost recovery for the catcher-processor sector LAPP was left for a later action.

Element of Cooperative Alternative	Conservation	Net Benefits	Disruption	Excessive Shares	Fairness and Equity	Harvester and Processor Sector Health	Labor	Communities	Small Entities and New Entrants	General Public
Participation and Endorsement Qualification			X		X	X			X	
Co-op formation and operation rules			X			X				

❖ Analysis

The existing alternative for cooperative management in the catcher-processor sector is essentially the continuation of the No Action alternative for this sector, with the added provision that the sector would be managed with IFQs if the voluntary cooperative falls apart. Amendment 15 established sector specific limited entry for that sector and an allocation of whiting for the sector already exists. These two tools make it possible for a sector to establish and sustain a voluntary cooperative if they can agree to catch sharing arrangements. The one factor that may put the voluntary cooperative at risk is the management of

bycatch in a common fashion across the three sectors. This can put the voluntary cooperative at risk because members of that cooperative do not have control over catch of vessels outside that cooperative and catch from those vessels outside the cooperative can affect opportunities in the catcher-processor sector since all three sectors close when that limit is reached.

Beginning in 2009, bycatch limits for the whiting fishery will be applied to specific whiting sectors, which is a departure from the three sector common bycatch limit which has been used since 2004. This change is expected to protect the catcher-processor sector from other sectors which could inadvertently pre-empt opportunities in the catcher-processor sector. As a result, this change enhances the likelihood of the catcher-processor sector maintaining the existing voluntary cooperative.

As indicated in earlier sections of this analysis, cooperatives may need to have resource sharing arrangements solved for them. In cases where participants in the fishery are relatively diverse and have different levels of historic participation and reliance on the fishery, requiring that those participants decide on catch sharing arrangements themselves may prove difficult and problematic. If catch sharing arrangements are reached, they may be unstable and lead to frequent revisions of the cooperative contract and instability in the cooperative. In cases where participants are relatively diverse, solving catch sharing arrangements by issuing catch history and implementing a golden rule provision may be necessary for cooperatives to form and/or help to ensure that cooperatives are sustained. However, this is not necessary in all cases. In instances where participants have similar characteristics and have similar historic participation and reliance on a fishery, solving catch sharing arrangements may be relatively easy. This appears to have been the case in the catcher-processor sector as that sector was able to form the voluntary cooperative and solve catch sharing arrangements without Council intervention. This cooperative has been maintained for 11 years, suggesting that the catch sharing arrangements that were agreed to have not led to much disruption or instability across cooperative members. In spite of this, the break up of the voluntary cooperative is not outside the realm of possibility. Several events could lead to the break up of the cooperative including the transfer of an existing catcher-processor permit to another entity that is not currently part of the cooperative or disputes over catch sharing. In such an instance, one option would automatically grant IFQ to catcher-processor participants in order to ensure that fishery remains "rationalized."

The following sub-parts analyze each of the elements comprising the catcher-processor cooperative alternative.

- Catcher-processor Endorsement

Endorsing permits for participation in the catcher-processor sector is an extension of measures established through Amendment 15. An endorsement establishes a barrier to entry to the catcher-processor sector and provides one of the necessary ingredients for a cooperative to form. The barrier to entry established by the sector endorsement prevents other potential participants from entering into the catcher-processor sector and competing with existing participants for catch. If competition for catch arises, a breakdown in "rational" fishing practices should be expected to occur. This is because it results in the elimination of competition for catch that eliminates the race for fish. The elimination of the incentives that exist in a race for fish reduces effort in the fishery, reduces capital in the fishery, and slows down the pace of harvesting. These effects reduce cost and increase value, resulting in a net improvement in the economics of the fishery.

- Catcher-processor Permit Combination to Achieve a Larger Size Endorsement

If the permit length endorsement is retained, a catcher-processor would need to acquire an additional permit in order to increase vessel size. The alternative for combining permits indicates that, in such an event, the catcher-processor endorsement would remain, but other endorsements would not. This effectively limits the relatively large catcher-processor vessel to the catcher-processor sector. If other sector endorsements remained on that permit, that relatively large catcher-processor vessel could theoretically participate in other sectors. That possibility would not occur under the existing permit combination option.

- Annual Reporting Requirements

An annual reporting requirement enhances transparency of a cooperative-based fishery. Since many of the outcomes and events in a cooperative fishery occur through private agreements and negotiations, the annual reporting requirement provides information on those activities to the public and management agencies. This helps to ensure that those groups are relatively informed about the activities occurring within a cooperative and helps the public and management agencies to understand cooperative management more thoroughly. This can be important if changes to required cooperative standards or regulations are deemed necessary by the Council in order to meet new challenges or management goals.

The requirement that the annual report submit a record of catch by each vessel may violate confidentiality provisions of the MSA.

- NMFS Role

The role of NMFS in administering this cooperative program is effectively no change from status quo. The exception to this is in the event the voluntary cooperative breaks apart and IFQ is issued to catcher-processor permits. Furthermore, if an adaptive management provision is utilized in the catcher-processor sector, the role of NMFS in managing the catcher-processor portion of the fishery may change in order to implement that provision. Since the adaptive management provision and associated specifics on how that provision would work are necessarily general, it is not possible to determine the amount of workload or infrastructure that may be required of NMFS if that adaptive management provision is used.

- Annual Allocation

Two options exist in the existing catcher-processor alternative that pertains to annual allocation. One option would continue to allocate Pacific whiting to the catcher-processor sector with no subdivision of the allocation within that sector. The other option would allocate to the catcher-processor cooperative instead of the sector. In practice, there does not appear to be any difference between the two options because the amount of fish allocated will be the same and the participants that have access to that fish will be the same. Therefore, there is not expected to be any difference in the effects of either option. However, the Council's preferred alternative specifies measures which would be taken if the voluntary cooperative breaks apart.[23]

Under the Council's preferred alternative, the break up of the voluntary cooperative would trigger an automatic issuance of quota shares to catcher-processor participants, creating an IFQ program for that sector. Each participant would receive 10 percent of the catcher-processor quota and this amount is

[23] The term "break apart" in this context is assumed to apply to cases where a single catcher processor permit leaves the cooperative but other permit owners agree to maintain a voluntary cooperative agreement.

intended to be reflective of the catch sharing agreement that currently exists in the voluntary catcher-processor cooperative. The reader is referred to Appendix A for a description of an IFQ program and outcomes from managing a sector using that tool.

C.1 A Comparative Advantage Analysis Illustrating the Potential for Regions to be Made Better or Worse Off by Rationalization of the Non-Whiting Trawl Fishery

Several variables determine the amount of fishing activity occurring in different ports, including access to fishing grounds, port infrastructure, and fish purchasing and processing, among other things. In a rationalized fishery, the incentives created by market-based management and individual accountability may impose additional forces that will alter the decision that vessel operators make regarding the location of fishing activity, the delivery location, and home-port location for a given vessel. Assuming profit is the motivating factor for fishermen engaged in commercial fisheries, the decision framework created by a rationalized fishery will tend to shift the location of fishing and delivery activity.

Under status quo management, vessels are not held individually accountable for the amount of fish they catch, provided their landings are within their cumulative landing limit. In addition, operators cannot choose to grant their cumulative limit to another, potentially more profitable, operator. Under a rationalized fishery, both scenarios change, and fishermen are held individually accountable and can transfer their fishing privilege to another vessel. The aspect of individual accountability will tend to put pressure on operators to fish in areas with lower encounter rates of constraining overfished species. The ability to transfer catch privileges also allows the fleet to consolidate to fewer, but more profitable, vessels as the market directs quota in a more economically efficient manner.

In a rationalization program, more economically efficient vessels are expected to remain in the fishery, while less efficient vessels are expected to drop out of the fishery. Economic efficiency is determined by several variables including the ability of the operator to generate gross revenues and the vessel's cost structure. Cost structure is determined by variable costs such as fuel, fixed costs, "transfer costs," and day-to-day operations. Ports that have a higher degree of fishing support business (agglomeration) tend to make it easier and more efficient for operators to conduct day-to-day activities. This makes the cost of running a fishing business, acquiring parts, and negotiating work relationships lower than in other ports.

Given these arguments, it is reasonable to expect ports with vessels that have a relatively long travel time to fishing grounds, relatively unsuccessful operators, relatively costly vessels, and relatively few support businesses to be at a disadvantage when compared to other regions. In addition, ports that are adjacent to fishing grounds with high constraining overfished species abundance would also tend to be at a disadvantage as the presence of constraining overfished species would encourage operators to move to areas with lower abundance. Given enough disadvantaging (or advantaging) factors in a port, that port may find itself losing (or gaining) trawl groundfish activity after rationalization, absent some mitigation tool that the Council may elect to implement as part of the program.

Information is available to illustrate these relationships and provide information indicating which ports or areas may be at a relative advantage or disadvantage. Available information includes the following:

- Logbook data can be used to show the preferred fishing grounds of trawl vessels categorized by homeport (e.g., we can identify the preferred grounds for Astoria-based trawlers). This information can be combined with west coast groundfish observer program data to show whether preferred fishing grounds of vessels in some ports are in areas with relatively high bycatch rates of constraining overfished species. Those ports with vessels fishing in areas with relatively lower bycatch rates may be at an advantage in a rationalized fishery.

- West coast fishing community profiles provide information about community business and infrastructure. In addition, industry members, extension agents, and extension publications are

sources of this information. Using the theory of agglomeration, those communities with larger amounts of support business and infrastructure may be at an advantage in a rationalized fishery.

- The fleet consolidation model can be used to identify the geographic effects of consolidation based on the most likely vessels to drop out of the fishery and the most likely vessels to stay in the fishery.

- The initial distribution of quota can be used to show which ports will receive more or less quota relative to status quo and relative to the initial distribution made to other ports. This will determine the initial state of harvest privileges on a regional basis, and this initial state may influence the future location of fishing activity.

The output of this analysis illustrates the relative advantage or disadvantage each port has with respect to several variables. These variables include 1) bycatch rates of constraining stocks that are in preferred fishing grounds of various ports, 2) relative economic efficiency of vessels in that port, 3) the relative amount of fishing business and infrastructure that exists in that port, and 4) the initial distribution of quota shares to those ports relative to status quo and relative to the distribution made to other ports.

C.1.1 Geographic Assessment of Constraining Bycatch

In this analysis, bycatch rates in various areas are assessed based on the constraining nature of the bycatch species. An area with a relatively high bycatch rate of a highly constraining species is assessed differently than an area with a moderately constraining overfished species. For example, since canary rockfish is a highly constraining species to fishing opportunity, an area with a relatively high canary bycatch rate will be labeled as a high bycatch area. An area with a relatively high bycatch rate of a less constraining species, like darkblotched, will be labeled as a moderately high bycatch area. This labeling scheme creates three categories for bycatch areas that are A) not a relatively constraining bycatch area, B) a moderately constraining bycatch area, and C) a highly constraining bycatch area.

The effect of these areas on the comparative advantage of a port relies on the integration of the preferred fishing grounds of various ports with those areas. If vessels from a port fish exclusively in a high bycatch area, then that puts that port at a disadvantage, whereas if vessels from a port spend only some of their time fishing in a high bycatch area, then the presence of that high bycatch area may not necessarily influence the comparative advantage of that port. In this analysis, we determine whether a port is at an advantage or disadvantage based on where the majority of the catch has occurred. If greater than 50 percent of a port's catch has occurred in a high bycatch area, then we determine that port to be at a disadvantage.

The following figures illustrate the preferred fishing grounds of non-whiting trawlers based on their port of landing. These figures also identify areas of relatively high bycatch of constraining overfished species. Areas that are highly constraining are indicated by the presence of a shaded box with hash marks. An area with an overfished species that is not typically as constraining is indicated by a shaded box without hash marks. This figure shows one moderately constraining area off Oregon and three highly constraining areas off the west coast.

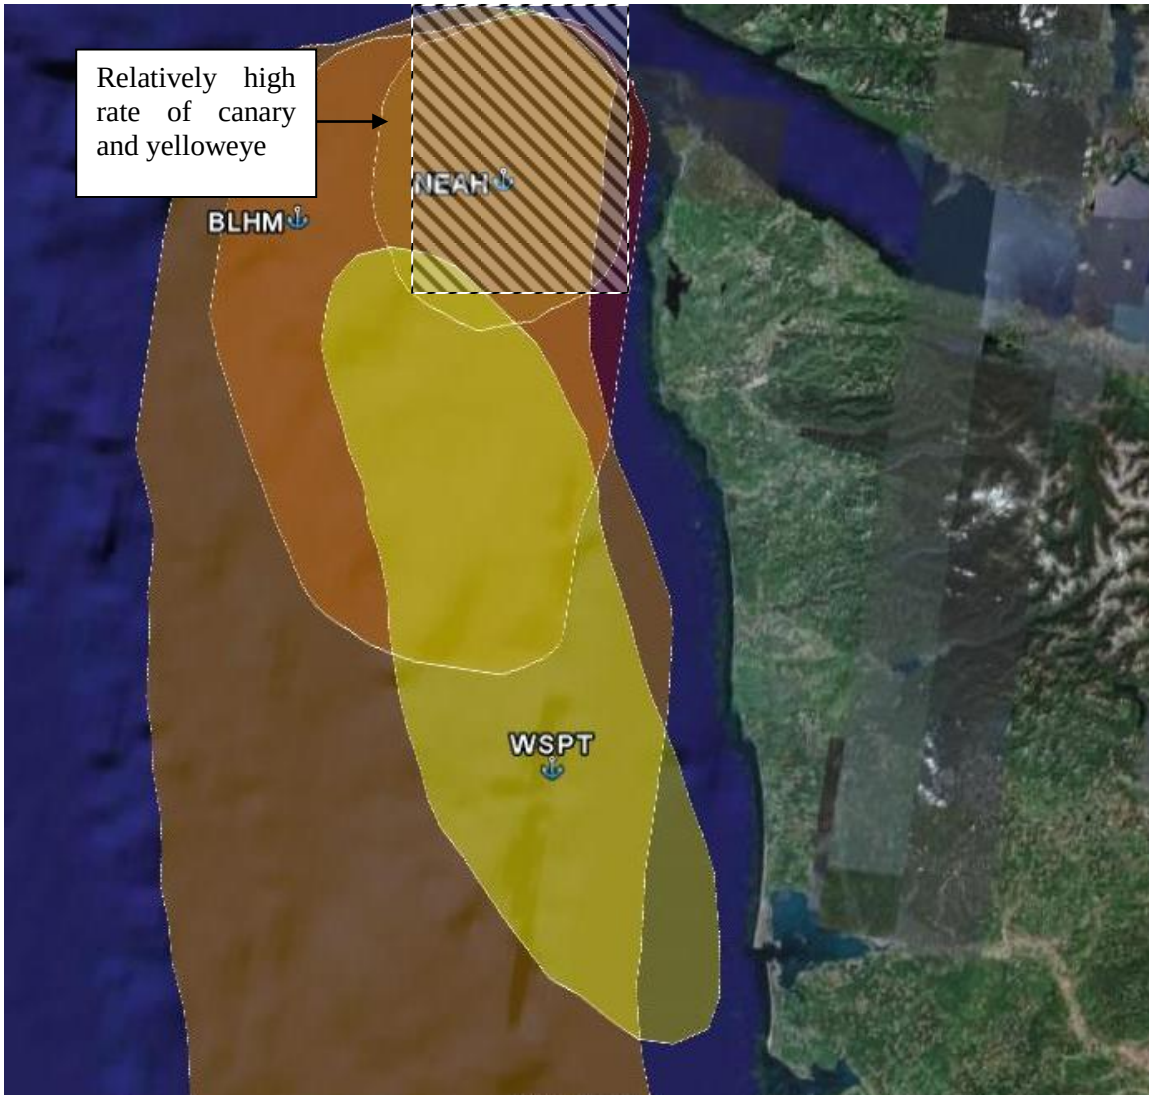

Figure C-1. Preferred fishing grounds of non-whiting trawlers based on their port of landing, Washington.

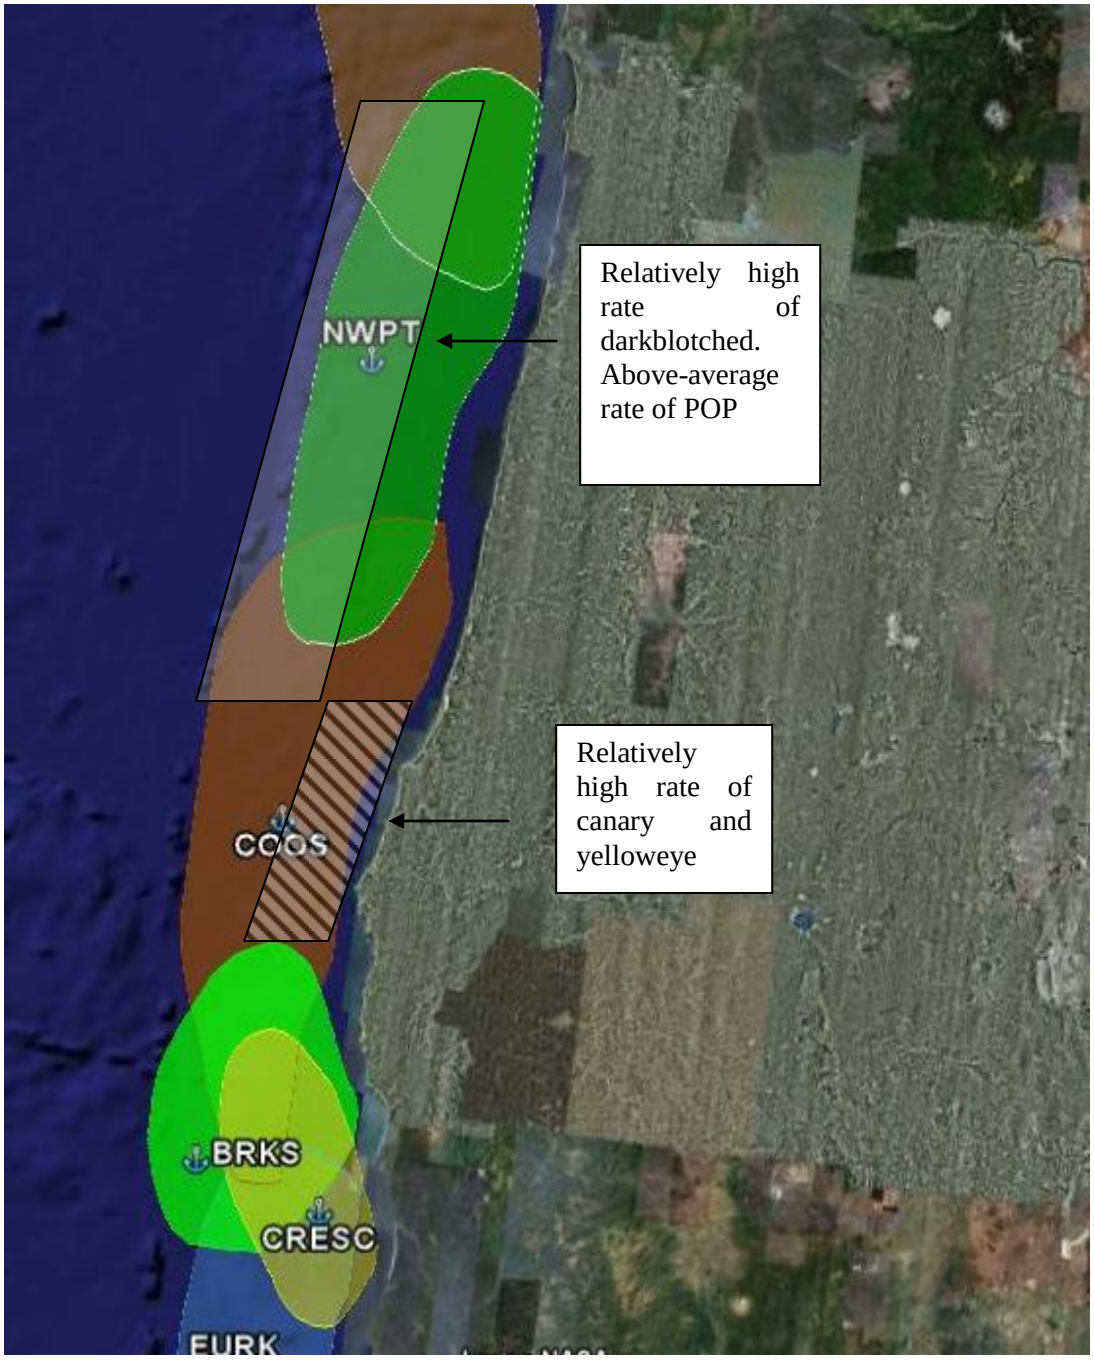

Figure C-2. Preferred fishing grounds of non-whiting trawlers based on their port of landing, Oregon and northern California.

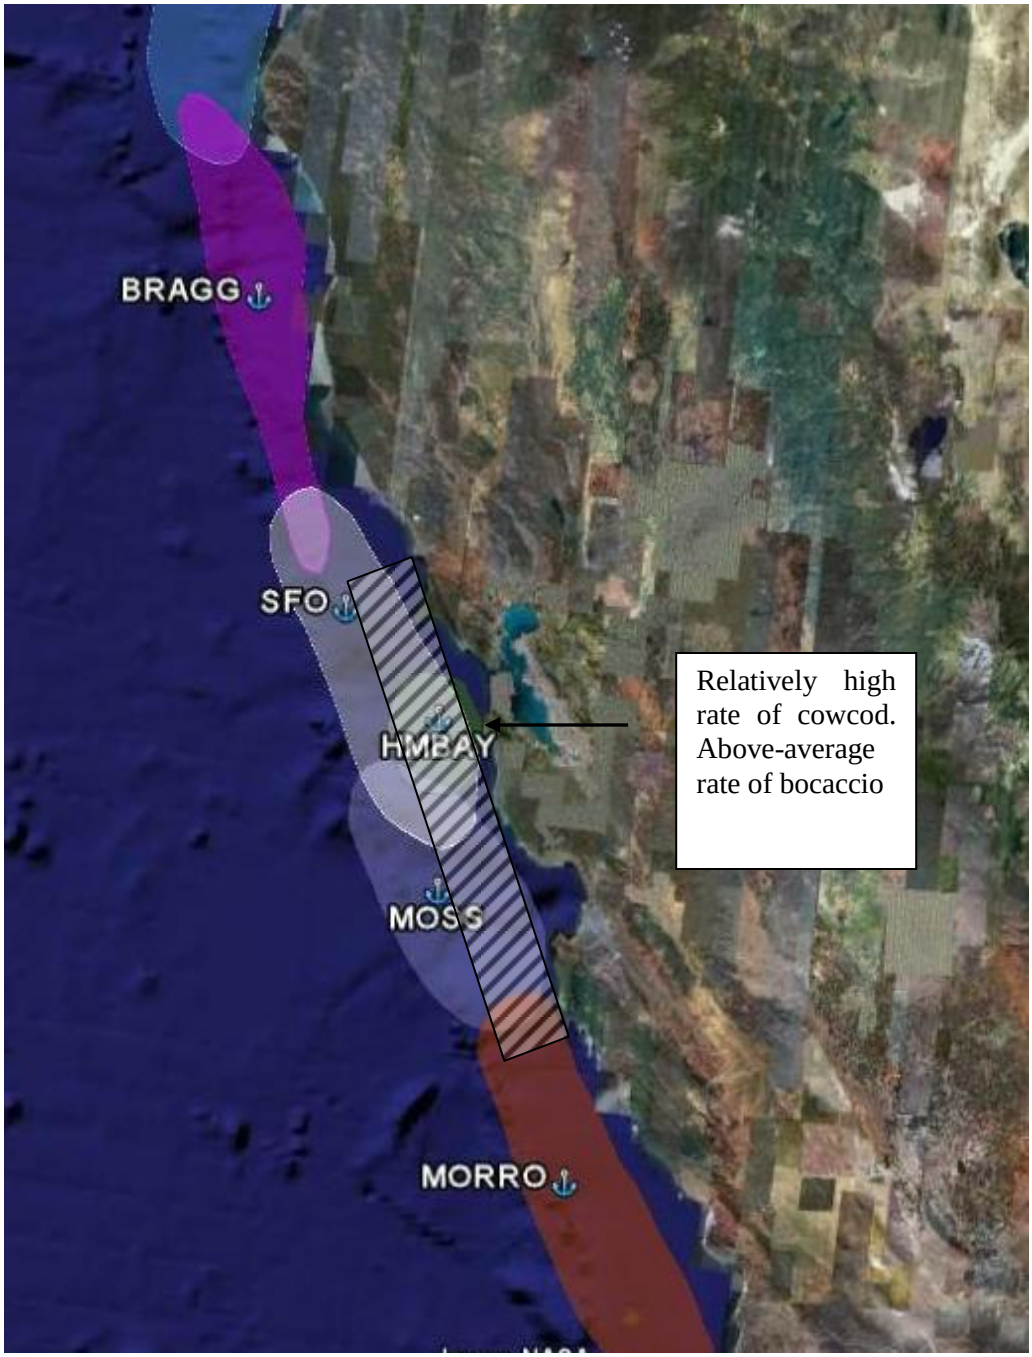

Figure C-3. Preferred fishing grounds of non-whiting trawlers based on their port of landing, central California.

By using logbook data, we assess the percentage of catch that has occurred within several areas of the coast (defined by seaward or shoreward of the RCA, and by latitude). We then trace each vessel's catch to a port of landing based on the port of landing associated with a trawl logbook record. If 50 percent of a port's landings are associated with a high bycatch area, we assign a double negative score for that port because the majority of its catch can be considered "at risk" due to the relative difficulty vessels will have in accessing their target species relative to vessels fishing in other areas. For ports with activity in a moderately high bycatch area, we assign a single negative score. However, it is important to keep in mind that other variables influence the amount of fishing activity that will occur in a port, and the

presence of a high bycatch area can be overcome by other variables such as an efficient fleet or substantial presence of shoreside infrastructure. The following table illustrates the data constructed as a result of this exercise. Areas shaded in grey are moderately high and high bycatch areas. This information shows that Bellingham, Neah Bay, Newport, and Princeton/Half Moon Bay have greater than 50 percent of their non-whiting trawl catch occurring in areas identified as a moderately high or high bycatch area. It is also important to note that the high bycatch area where the Newport fleet fishes is a moderately high bycatch area because it is made up of species that are less constraining to harvest activity (POP and darkblotched) than the other grey shaded areas.

Table C-1. Percent of non-whiting trawl catch by port and area.

Depth	Port	LATITUDE AREA							
		N 47.40	45.35 - 47.40	43.55 - 45.35	42.3 - 43.55	40.10 - 42.3	38.25 - 40.10	36.08 - 38.25	34.25 - 36.08
Sea-Ward Of The RCA	Bellingham/ Blaine	29.8%

	Morro Bay								

Note: Totals may not sum to 100 percent because of confidentiality.

While the above information shows that several ports are engaged in relatively high constraining bycatch areas, other factors will influence the comparative advantage that vessels have in a rationalized fishery. These other factors include the relative efficiency of vessels that deliver to the various ports, the amount of agglomeration in shoreside business and infrastructure that exists in various ports, and the initial state of harvest privileges in each port as determined by the initial distribution of fishing quota.

C.1.2 Assessment of Industry Agglomeration by Port

The concept of agglomeration is used routinely in regional economic literature. When similar businesses are located near one another, the cost of doing business tends to decrease. Agglomeration cost savings come from the clustering of economic activity, that is, an attraction for other firms affected by noncollusive proximity economies once a cluster begins to form (Maki and Lichty 2000). Several sources of agglomeration exist including the folowing:

- Internal agglomeration. Internal sources of agglomeration typically occur as a firm increases in size and is able to specialize and use standardized inputs.
- Localization economies. These types of economies include situations where a business locates near its suppliers.
- Urbanization economies. These economies stem from a diverse labor force found in metropolitan areas, a large number of people, frequency of communication, and research and development in a populated area that may spur new ideas.
- Industry linkages. These linkages create cost savings from such things as transportation. These linkages typically occur in close proximity to one another.
- Public facilities and infrastructure. Government facilities and infrastructure comprise a set of units that can complement clustering of private enterprise.

In this section, we describe a series of factors that lead to an assessment of whether a port has a relatively high or relatively low level of agglomeration that would benefit a trawl sector. The concept that agglomeration results in cost savings can have implications as a trawl fishery is rationalized and quota flows toward the greatest return.

Table C-2. Description of port infrastructure.

Community	Infrastructure
Bellingham/ Blaine	Bellingham is home to 2 processors of trawl groundfish. Bellingham also has access to a large seafood cold storage facility and has a relatively well-developed level of port infrastructure. Bellingham is located on the I-5 corridor, which enhances access to distribution facilities in the Seattle area.
Neah Bay	There are no known processing facilities of trawl groundfish in Neah Bay. Port and harbor facilities are limited, and the location is considered remote and removed from distribution and transportation networks.
Westport	Westport has one known processing facility engaged in trawl groundfish. This facility concentrates primarily on Pacific whiting. Westport is somewhat removed from distribution centers.
Astoria	Astoria has several processing facilities engaged in trawl groundfish. In addition, several support businesses are known to exist in the area, and dock and harbor facilities are fairly well developed. Astoria is fairly removed from distribution centers.
Newport	Newport has several processing facilities engaged in trawl groundfish. In addition, several support businesses are known to exist in the area and dock and harbor facilities are fairly well developed. Newport is fairly removed from distribution centers.
Coos Bay	Coos Bay has several processing facilities engaged in trawl groundfish. In addition, support business and fabrication services are known to exist in the area, and dock and harbor facilities are fairly well developed. Coos Bay is fairly removed from distribution centers.
Brookings	Brookings has no known processing facilities of trawl groundfish. Brookings is fairly removed from distribution networks, but has a well-developed shallow draft port. Infrastructure necessary to service the trawl sector is limited with one icehouse and some small metalworking capabilities.
Crescent City	Available information shows that Crescent City has one processing facility that has engaged in small quantities of trawl groundfish in recent years. Crescent City is fairly removed from distribution centers. Crescent City has one of the principal vessel fabrication companies used by trawlers on the west coast. Crescent City has a number of fish hoists.
Eureka	Eureka has one large processing facility engaged in trawl groundfish. An icehouse exists in the area, as well as a new yard with several hoists. A ship hoist (cradle) exists that can service moderately sized trawl vessels.
Fort Bragg	Fort Bragg has one known processing facility engaged in trawl groundfish. Fort Bragg is relatively close to the distribution centers in San Francisco. An icehouse exists as well as a fuel dock.
Moss Landing	Moss Landing is not known to have any processing facilities engaged in trawl groundfish. Transportation networks are nearby. Limited infrastructure exists to service trawl vessels.
Princeton / Half Moon Bay	Princeton/Half Moon Bay is known to have three processing facilities engaged in trawl groundfish, but limited processing of trawl groundfish occurs. Several fish hoists exist in the area.
San Francisco	San Francisco has several small processing facilities engaged in trawl groundfish. San Francisco has a relatively developed port and harbor infrastructure. San Francisco is one of the primary distribution centers on the west coast.
Morro Bay	Morro Bay has no known processing facilities engaged in trawl groundfish. Morro Bay is relatively removed from distribution facilities. Infrastructure exists in the harbor area to support commercial fishing operations.

C.1.3 Cost Efficiency of Harvesters

The cost efficiency of the local fleet will likely have an impact on how a port fares as a result of rationalization and the consolidation that occurs as a result. Using information from the cost efficiency and fleet consolidation model, we are able to identify the relative efficiency of vessels delivering to various ports. While this information is based on vessels that currently exist in the fishery (and in the longer run, we would expect newer vessels to be constructed that are in the efficient range), the initial state can have long-term impacts. In other words, ports with relatively efficient trawl vessels at the start of a rationalization program may end up better off than ports with relatively inefficient vessels. The following tables show the number of non-whiting trawl vessels delivering to each groundfish trawl port over the 2004 to 2007 period and the weight of catch being delivered by efficient and inefficient vessels.

Table C-3. Number of non-whiting vessels making deliveries by port and efficiency category (2004 to 2007).

Port	Efficient Size	Inefficient Size
Astoria	13	25
Bellingham*	4	7
Brookings	5	8
Charleston (Coos Bay)	13	14
Crescent City	2	10
Eureka	6	21
Fort Bragg*	0*	12
Monterey	1	4
Morro Bay	5	8
Moss Landing	5	16
Neah Bay	3	4
Newport	11	19
Princeton / Half Moon Bay	1	17
San Francisco	5	15
Westport	1	6

* Fort Bragg has four vessels that are very near the efficient size category. It may be reasonable to assume that these vessels will remain in the fishery. Bellingham vessels must travel long distances to reach fishing grounds. While there are several vessels that deliver to Bellingham in the "efficient range," this travel distance suggests these vessels may be more appropriately categorized as "inefficient."
Note: These are not unique records, and they should not be summed.

Table C-4. Weight of non-whiting groundfish landed by port and vessel efficiency category (2004 to 2007).

Port	Efficient Size	Inefficient Size
Astoria	16,310,277	34,106,827
Bellingham Bay	4,596,540	5,876,909
Brookings	2,382,507	3,998,491
Charleston (Coos Bay)	15,820,364	7,013,554
Crescent City	C	2,854,037
Eureka	6,293,634	11,831,280
Fort Bragg		11,474,450
Monterey	C	1,054,166
Morro Bay	383,468	1,403,130
Moss Landing	2,034,403	1,118,074
Neah Bay	515,476	2,921,366
Newport	4,841,903	11,630,108
Princeton / Half Moon Bay	C	1,901,957
San Francisco	591,719	3,963,064
Westport	C	3,032,000

C.1.4 Initial Allocation of Quota Shares

The initial allocation of quota will likely tend to favor some geographic areas more than others, and such geographic differences are likely to extend to the level of fishing activity expected for a given location. Using the initial allocation rules being considered, the following table was developed. This

information shows the amount of quota pounds that would be allocated to each port if existing harvest volumes were maintained. This information is broken into two major fields with one field reflecting an initial allocation rule where the buyback history is allocated equally across recipients. The second field reflects an initial allocation made based purely on catch history. This information shows that clear patterns exist regardless of the initial allocation, and they tend to put a large share of quota into some ports. Using the average across all ports as an indicator of those standing to be successful, all ports shown in the table from Astoria to Moss Landing stand to be successful regardless of the initial allocation. Princeton/Half Moon Bay may be successful depending on the initial allocation rule. It is important to note that the average in this case is the average across all ports, including those that were aggregated into the "other" category in the table below. The "other" category consists of 12 ports. These averages result in 600 to 640 mt being allocated to ports on average under the equal sharing of buyback options, while 1,400 mt is the approximate average for the catch-history-based options.

Table C-5. Quota pounds attributed to west coast ports (assume status quo harvest amounts).

Port	Initial Allocation made with Equal Sharing of Buyback History			Initial Allocation made Based Entirely on Catch History		
	75% Hvstr ES	87.5% Hvstr ES	100% Hvstr ES	100% Hvstr HS	87.5% Hvstr HS	75% Hvstr HS
Astoria	4,497	4,472	5,068	4,248	4,150	4,115
Coos Bay	2,313	2,365	2,648	2,043	1,944	1,876
Newport	1,891	1,949	1,529	1,046	1,003	999
Eureka	1,573	1,594	1,425	1,005	1,000	1,008
Fort Bragg	1,144	1,180	1,357	966	919	873
Bellingham/ Blaine	1,054	991	1,372	1,192	1,197	1,216
San Francisco	754	808	961	744	689	636
Brookings	714	743	724	517	495	477
Moss Landing	695	717	769	611	588	567

Morro Bay	447	414	412	317	340	364
Crescent City	363	355	300	226	238	252
Westport	292	304	355	303	288	275
Monterey	209	203	200	176	180	185
Other	497	502	456	389	383	380

C.1.5 Development of the Assessment Tool

Based on the information described above, we established the following summary of relative comparative advantage. While this information does not allow us to quantify the relative degree of comparative advantage in each port, several patterns seem apparent from this information. In particular, the port of Neah Bay appears as one community that may be at a disadvantage in a rationalized fishery

because of fleet efficiency, the lack of shorebased infrastructure, and the high degree of dependence that vessels in this port have on areas defined as "high bycatch." Inversely, the ports of Astoria and Coos Bay appear to be at a relative advantage compared to other ports. Astoria has the benefit of a relatively large number of efficient vessels, a relatively large presence of shorebased infrastructure, and a low dependence on fishing grounds located in high bycatch areas. Coos Bay also appears to be at a relative advantage because of fleet efficiency and the relatively large amount of shorebased infrastructure. While catch landed in Coos Bay historically has been caught in high bycatch areas, this amount of catch does not constitute the majority. Therefore, it is likely that vessels originating in Coos Bay will adjust fishing practices to avoid bycatch, but the community is not likely to suffer as a result.

Other communities are less certain. Bellingham and Half Moon Bay may experience their vessels bearing a relatively high degree of constraint because of their reliance on fishing grounds in high bycatch areas. The efficiency of vessels in Half Moon Bay is relatively low; while Bellingham has a number of vessels that fall within the efficient range, vessels from that area have a much longer travel distance to and from fishing grounds relative to vessels from other ports. This raises cost for those vessels relative to vessels from other ports, suggesting that these vessels may be more appropriately categorized as inefficient.

The effect on Fort Bragg and Crescent City is also somewhat uncertain. While several scores appear to work in Fort Bragg's favor, this community does not score in the top bracket on any of the determinant variables and may have a fleet consisting of inefficient vessels, though several vessels are close to the efficient range. Crescent City scores in the negative category on several variables and positively in others. The overall effect on Crescent City may depend on the relative importance of the variables. If bycatch dependency is the overall, driving factor, then Crescent City may actually be at an advantage, even though it has a relatively inefficient fleet and a relatively small amount of quota initially allocated to it.

Table C-6. Summary of ports' relative comparative advantage.

Port	Fleet Efficiency Score	Bycatch Dependent Area Score	Shorebased Infrastructure	Initial Allocation of Grndfish	Score
Astoria	+	+	+ +	+ +	+
Bellingham	?	− −	+ +	+	
Brookings	+	+	−	+	
Charleston (Coos Bay)	+	+	+ +	+	+
Crescent City	−	+	+	−	
Eureka	+	+	+	+	+
Fort Bragg	−	+	+	+	
Morro Bay	?	+	−	−	
Moss Landing	−	− −	+	+	
Neah Bay	−	− −	− −	−	−
Newport	+	−	+ +	+	
Princeton/Half Moon Bay	−	− −	+	+	
San Francisco	−	−	+ +	+	
Westport	−	+	+	−	

C.1.6 The Potential for Geographic Shifts in Fishery Patterns

The regional comparative advantage structure will also influence the geographic nature of fish harvesting activities. When the variables described above are combined, the comparative advantage of different regions will influence the level of fishing effort occurring in the fishing grounds of those ports.

Individual accountability in a rationalization program is likely to result in cleaner fishing practices. In particular, the individual accountability associated with constraining overfished species will encourage vessels to modify gears as well as to fish in areas where overfished species are less abundant. In addition, the rationalization program will tend to slow the pace of Olympic style fisheries that exist in the shorebased and mothership sectors of the whiting fishery. Both of these measures will tend to adjust fishing patterns at a geographic level. Cleaner fishing practices are likely to result in some pressure to move away from areas where there are relatively high encounters of constraining species like canary, yelloweye, and cowcod. A rationalized whiting fishery will tend to slow the pace of harvesting, and, given that the whiting stock tends to migrate north over the course of the year, this is likely to result in more midwater trawl effort occurring further to the north than under an Olympic style fishery. These effects may be enhanced or restrained by the economic activity and efficiency of fishing fleets that focus on certain areas. For example, if the fleet originating in a particular port tends to concentrate its effort in an area with a relatively high abundance of overfished stocks, we would expect that fleet to move or for quota shares from that fleet to be sold to other areas of the coast because it would be more profitable to do so[1]. However, if that fleet is relatively efficient, and there are shoreside support businesses and infrastructure in ports adjacent to those grounds that make fishing activity in those areas more attractive, vessels may continue to fish in those areas, even though constraining stocks are relatively more abundant. This is because the economic effectiveness that exists because of an efficient fleet and the presence of shoreside infrastructure can outweigh the effect that a relatively high presence of constraining stocks can have on regional fishing patterns.

Geographic shifts in fishing effort in the non-whiting trawl fishery are assessed by whether a port is at a relative advantage or disadvantage. If a port is at a disadvantage, then it is inferred that their fishing grounds are likely to be trawled less intensively than under status quo. In addition to the port-based comparative advantage structure, areas defined as relatively high bycatch are assumed to have less trawl effort than under status quo. This is true even if a port is at a relative advantage. The rationale is that ports with a relative advantage may gain trawl activity compared to status quo, but vessels fishing out of those ports are still likely to avoid high bycatch areas in order to stay away from constraining stocks and attain higher catch rates of target species. This analysis uses the same information as described in the above section. This information shows that several areas may be trawled less intensively than status quo, including sites off northern Washington, central Oregon, southern Oregon, and Central California.

<u>Areas Likely to be Trawled Less Intensively than Under Status Quo</u>

- Northern Washington
  – shoreward of the RCA
- Northern and North/Central Oregon – seaward of the RCA
- Central Oregon
  – shoreward of the RCA
- Central California
  – shoreward of the RCA

[1] Moving or selling quota to another area of the coast would be more profitable in this case because more target species could be accessed per unit of constraining overfished species in a relatively low bycatch area. For example, if vessels can leverage 100 pounds of target species per pound of canary rockfish in one area, but 500 pounds of target species per pound of canary rockfish in another area, more effort would be expected to occur in the second area in order to maximize harvest potential.

C.2 An Analysis Illustrating the Potential to Reduce the Catch Rate of Overfished Species and the Associated Potential for Increased Target Species Catch and Revenue

The reduction in the bycatch rate of overfished species is envisioned as one of the principal outcomes of a trawl rationalization program. One large implication of reductions in the bycatch rate of overfished species is the ability to access more target species and generate higher levels of revenue than under status quo. Under status quo management, fishing opportunities have been reduced to protect overfished species. In some cases, opportunities to catch species that have historically been large targets of the trawl sector have been eliminated because of their relatively high degree of correlation with overfished species (yellowtail and chilipepper rockfish, for example). In many cases, those species that are not highly correlated with overfished species have also seen target opportunities reduced. For example, the catch of sablefish (one of the primary targets for the trawl sector) has been less than the total trawl allocation by several hundred tons in recent years, and this represents a substantial economic loss in ex-vessel revenue. It is envisioned that a rationalization program will encourage fishermen to operate in a manner that avoids overfished species more effectively than the command and control type of management that exists in the status quo regime. This expected change in behavior is directly related to the individual accountability aspect of a rationalization program and the fact that there are individual rewards (because of access to target species) result from decreases in the bycatch rate. Some changes in the way fishing opportunities are prosecuted to change bycatch rates include changing the location of fishing, changing the gear that is used to prosecute those activities, and changing the time of fishing.

C.2.1 Non-Whiting Fishery Bycatch

Several sources of information can be used to show how the bycatch rate of overfished species can change in a rationalized fishery and the implications of that bycatch rate reduction. This information can be used to modify the NMFS/GMT trawl bycatch model[2] that predicts overfished species catch, target species catch, and ex-vessel revenue given an estimated overfished species bycatch rate and a set of assumed ex-vessel prices. By modifying the bycatch rate, the model can be used to simulate potential changes in harvest outcomes that will occur in a rationalized fishery.

Information that can be used to estimate changes in the bycatch rate of overfished species in a rationalized fishery includes exempted fishing permit (EFP) fisheries have been conducted with requirements that are nearly identical to what would likely be required under a rationalized fishery.

The Washington Arrowtooth Flounder EFP was a project that occurred over four years with requirements nearly identical to what would be expected under a rationalized fishery. In this EFP, vessels carried observers and were given an overall cap on the amount of overfished species. Vessels were also given individual vessel limits on overfished species. Vessels that could avoid overfished species and stay within their limits had access to arrowtooth flounder and petrale sole in excess of the normal two-month limits that were in place and to areas within the trawl Rockfish Conservation Area (RCA). When a vessel reached or exceeded the individual cap, that vessel was no longer allowed to participate in the EFP and was required to fish under normal two-month limits and RCA restrictions while still carrying an EFP observer. In other words, observations were collected while fishing under the EFP and while the vessel was fishing under status quo regulations (the latter serves as the control on

[2] The Trawl Bycatch Model was originally developed by staff at the Northwest Fisheries Science Center for use in setting regulations that manage the non-whiting trawl fishery. This model was reviewed and endorsed by the Scientific and Statistical Committee (SSC) in 2003.

the experiment). In addition to information collected on overfished species and target species catch, information on non-marketable discards was collected during the first year of the program. This information can be used to show order of magnitude estimates regarding the amount of regulatory discard occurring under status quo management and the increased amount of revenue that can be attributed to the fishery via an elimination of regulatory discards.

The information collected when vessels fished outside the EFP is directly comparable to bycatch information collected from the West Coast Groundfish Observer Program in a fishery that is not rationalized, while information collected in the EFP illustrates the bycatch rates that would be expected in a rationalized fishery. While the actual bycatch rates collected in this area cannot be used on a coast wide basis (the EFP occurred off northern Washington, which has different overfished species interactions than other areas of the coast), the percentage difference between EFP-based observations and non-EFP observations using the same observers can be used to show the reduction in bycatch rates that can be expected, and to estimate how coast wide bycatch rates collected through the WCGOP should be modified to reflect bycatch under a rationalized fishery.

The figure below illustrates the recorded canary bycatch rates for vessels participating in the EFP by year. The information below shows the bycatch rate when those vessels were participating in the EFP and the bycatch rate when those vessels were fishing under normal (non-EFP) fishing conditions. As is shown on the figure, in 2001 and 2002, the difference in EFP and non-EFP bycatch rates was substantial, while in 2003 and 2004 the difference was less, though still very noticeable. The explanation for this change is indicated in the figure. In 2003, gear modifications were required of vessels participating in the EFP, and those gears (which had demonstrably lower bycatch rates) were used outside the EFP as well. In 2004, those vessels became more accustomed to using those gears, and only gears that had demonstrated "satisfactory" results were used (which further reduced bycatch rates). In 2003 and 2004, the RCAs were in place during the months when observations were recorded; thus, the bycatch rate for non-EFP observations fell because vessels were no longer fishing in areas with high canary bycatch.

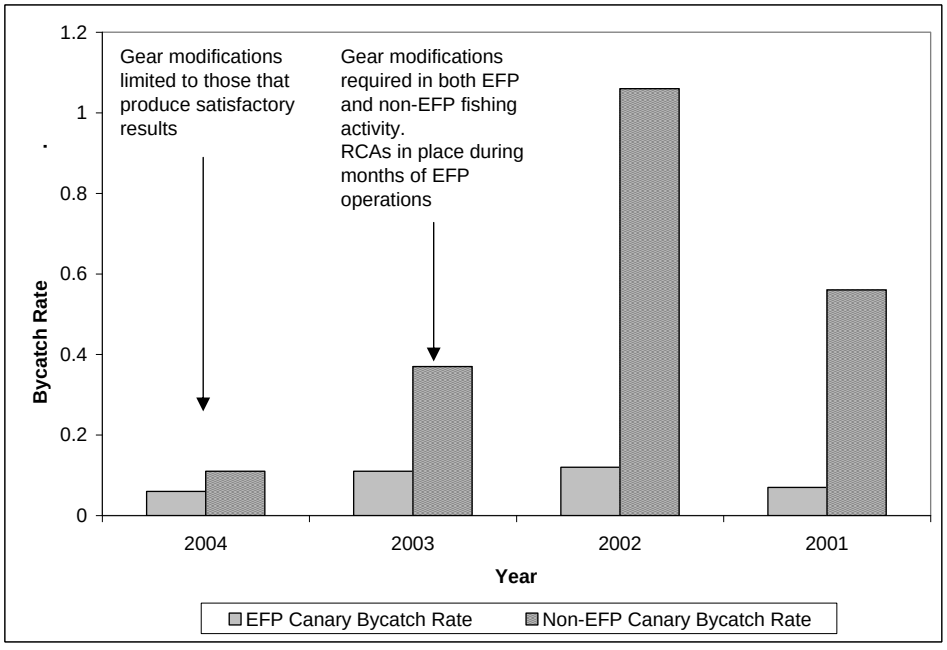

Figure C-4. Observed canary bycatch rates in the Washington arrowtooth EFP.

Table C-7. Summary statistics reflecting differences between EFP and non-EFP fishing activity.

	Canary Rockfish Bycatch Rates by Year and EFP vs. Non-EFP Activity Bycatch rate = (kg Canary / kg target species)*100%			
	2001	**2002**	**2003**	**2004**
Non-EFP Canary Bycatch Rate	0.56%	1.06%	0.37%	0.11%
EFP Canary Bycatch Rate	0.07%	0.12%	0.11%	0.06%
EFP as a % of Non-EFP	13%	11%	30%	55%
P(T<=t)	(insufficient data)	(0.002)	(0.206)	(0.135)

Comments received during the review of proposed methodology questioned whether the bycatch rates in the arrowtooth EFP changed because overfished species were being avoided, or whether they changing because the denominator, or set of target species, was shifting between EFP and non-EFP fishing activity. If the denominator, or set of target species, differs between EFP and non-EFP activity, then the argument was that the results shown above may not be indicative of what could occur under a rationalization program because they could be explained by differences in targeting behavior. To examine this question, bycatch rates were estimated in several additional ways: the first method examined canary bycatch relative to the amount of revenue generated by fishing activity; the second method examined canary bycatch relative to the amount of shelf target species; and the third method examined canary relative to the amount of shelf target revenue. All three additional approaches show substantial differences in the bycatch of canary rockfish in directed EFP activity compared to non-EFP activity. Canary rockfish is examined in this case because it was the most constraining species to target fishing activity during the four years of the EFP (because of the individual accountability measures of the program). Along other portions of the coast, other species such as darkblotched rockfish would likely be more constraining; therefore, substantial reductions in darkblotched would be expected instead.

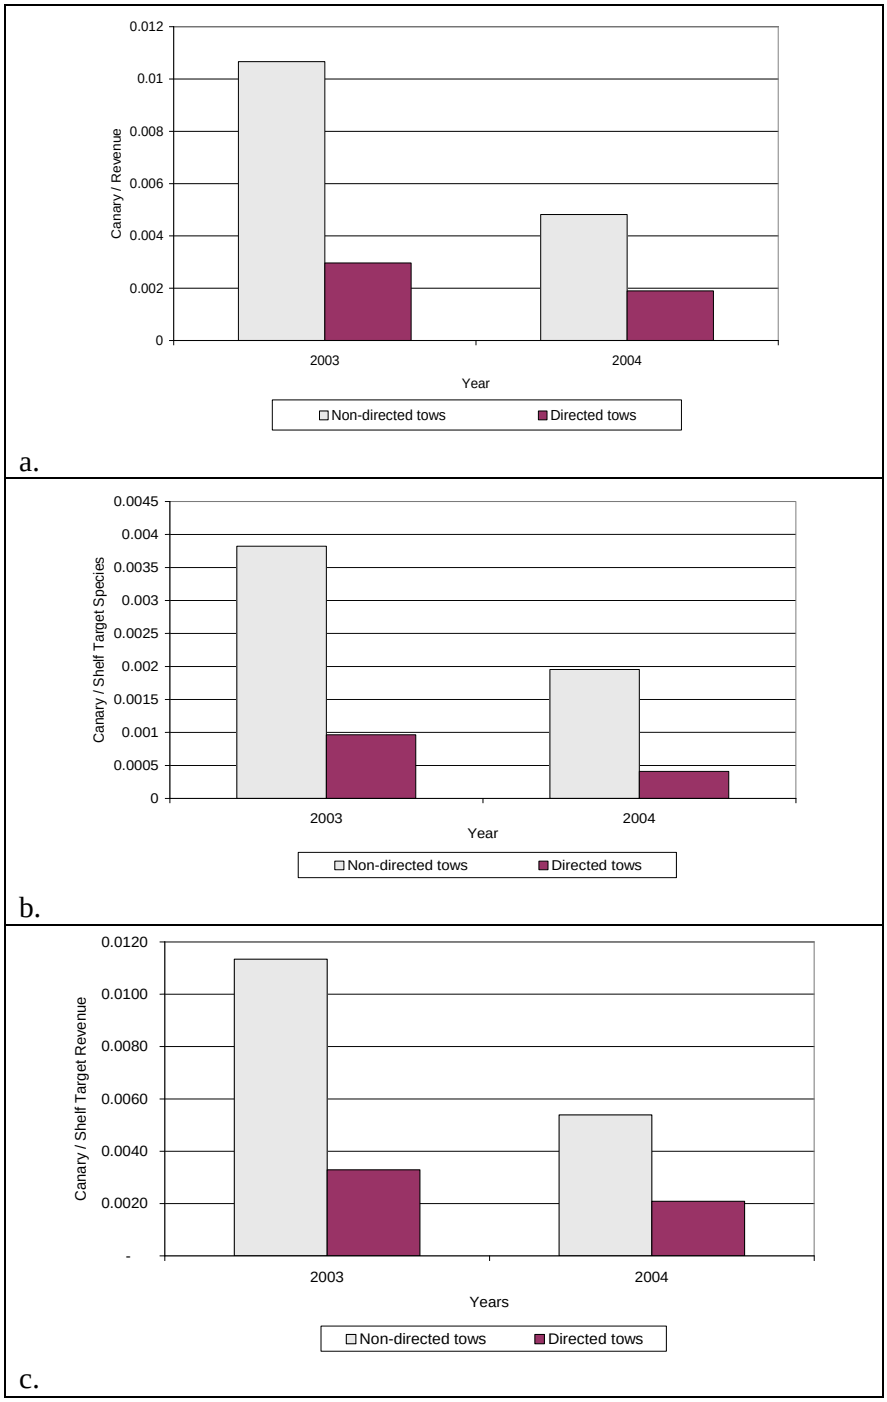

Figure C-5. Rate of canary rockfish encounters where (a) ex-vessel revenue is the denominator, (b) retained pounds of shelf target species is the denominator, (c) ex-vessel revenue of shelf target species is the denominator.

Looking into the data further, we compare canary bycatch rates at the haul level and stratify those hauls based on the dominant target strategy.[3] Target strategy is estimated at a species level and is determined

[3] Although the EFP was designed primarily to test targeting of arrowtooth flounder (and to a lesser extent, petrale sole), there is evidence in the data to suggest that some hauls were directed at different species.

based on the species that makes up the majority of catch in a tow. We establish nine different target species strategies from the project: arrowtooth flounder, Dover sole, petrale sole, "other flatfish," Pacific cod, sablefish, shortspine, arrowtooth and petrale combined, and a mixed target species strategy.[4] Of these, we find that the arrowtooth strategy is the largest category by weight for both directed and non-directed EFP activity, followed by Pacific cod. The third through sixth largest strategies by weight are the mixed stock strategy, the combined arrowtooth and petrale strategy, the Dover sole strategy, and the petrale strategy, respectively. After categorizing the data in this fashion, we compare canary rockfish bycatch rates in directed and non-directed activity. At this point, it is worthwhile to reiterate that canary rockfish is used because that was the constraining bycatch limit species in this EFP, so canary rockfish was the primary species with which fishermen were concerned.

After categorizing data according to a species-specific target strategy, we find insufficient observations to compare directed and non-directed bycatch rates in cases where the haul appears directed at sablefish and shortspine. This is not surprising, however, given that shortspine and sablefish are found along deep areas of the continental shelf and along the continental slope and that the EFP was conducted in areas along the shelf where flatfish are more common. Because there were insufficient observations to compare directed and non-directed tows from these species, we do not include a comparison of bycatch rates for these target strategies.

Finally, bycatch rates for canary rockfish were stratified according to whether they occurred in depths outside the RCA or both inside and outside of the trawl RCA. This separation is intended to isolate the effect of bycatch reduction measures that could be implemented via regulation (implementation of an RCA) from those bycatch reductions that would occur because of fishermen's behavior. We do not show a comparison of directed and non-directed activity within the RCAs because non-directed activity was conducted according to regular management measures, and, therefore, data do not exist on non-directed activity within the RCA. We do, however, compare directed EFP activity that occurred in all areas (both inside and outside the RCA) with non-directed activity outside the RCA. This is intended to provide an order of magnitude estimate that compares the effect on bycatch reduction from fishermen's behavior versus a bycatch reduction as a result of regulation. This comparison is labeled in the following table as "Inside and Outside RCA."

The following table shows the result of the categorizations described above. This table shows canary bycatch rates by directed EFP activity and non-directed activity. Those data are further stratified according to bycatch rates that occurred by target species strategy outside the RCA and a comparison of target species strategies for all areas (directed EFP activity took place within and outside the RCA). These data show that, for all target strategies listed, the bycatch rate of canary rockfish was lower in directed-EFP activity in every case except when petrale sole target tows in directed EFP activity that occurred inside the RCA are included in the comparison. This suggests that fishermen's behavior was more effective at reducing bycatch than regulatory mechanisms in all cases except for when those vessels targeted petrale sole. In the case of petrale sole targeting, fishermen's behavior would tend to reduce the bycatch rate of canary rockfish (as shown in the comparison between directed and non-directed activity outside the RCA), but the implementation of RCAs would result in a lower canary bycatch rate during petrale sole targeting activity than relying on fishermen's behavior alone.

[4] A mixed target strategy is a tow where a dominant species does not appear to be caught in the tow.

Table C-8. Canary bycatch rate in arrowtooth flounder EFP by target strategy and relation to RCA.

Strategy	Non-Directed Bycatch Rate Outside RCA	Directed Bycatch Rate Outside RCA	Directed Inside And Outside The RCA
Mixed Species Strategy	0.011	0.000	0.001
Arrowtooth/ Petrale	0.003	0.002	0.002
Pacific Cod	0.002	0.001	0.001
Dover Sole	0.001	0.000	0.000
Petrale	0.002	0.000	0.003
Arrowtooth	0.002	0.001	0.001

The data used from the Arrowtooth EFP project compare observed bycatch rates that occurred in depths outside (deeper or shallower than) the trawl RCA. Including observations outside the RCA is consistent with the expectation that RCAs will remain in place under a rationalization program and provides a more direct comparison between a rationalized fishery and status quo management (which relies on RCAs). This involves using observations from 2003 to 2004 that occurred outside the RCA. The percentage difference between EFP and non-EFP rates are applied to coast wide bycatch rates estimated from the West Coast Groundfish Observer Program. These modified rates are then used in the NMFS/GMT bycatch model for estimating the change in target species catch and ex-vessel revenue that would be expected in a rationalized fishery given the expected reduction in the encounters of constraining overfished species.

It is important to note the uncertainty associated with using the Arrowtooth EFP data in a manner for predicting coast wide changes in the bycatch rate. While available information clearly shows that changes in the bycatch rate of constraining stocks should be expected to occur under a rationalized fishery, the degree to which the quantitative results can be extended along the entire coast is uncertain. It is likely that other areas of the coast will be constrained by a different set of overfished species than the northern Washington coast (where the EFP was conducted), and it is not entirely clear how bycatch rates will change when another species is the constraining factor on target opportunity. For example, darkblotched rockfish do not tend to aggregate in the same fashion as canary rockfish (Steve Parker, personal communication), and, therefore, a different approach may be necessary in order to avoid darkblotched compared to canary rockfish, which tend to aggregate to a greater degree. Furthermore, bycatch rates in status quo management are representative of status quo fishing opportunity. Using the EFP results to modify bycatch rates collected under the status quo regime may be reasonable to inform bycatch rate associated with species that are currently targeted such as flatfish, sablefish, and thornyheads. The bycatch rate associated with species that are not currently targeted (such as chilipepper and yellowtail rockfish) is not well understood; therefore, the change in the bycatch rate associated with these species that should be expected in a rationalized fishery is also not well understood. In light of these uncertainties, the prediction of coast wide catch and ex-vessel revenue is displayed as a range, and that range should be treated as an order of magnitude.

In addition to the change in target species catch that may occur as a result of changes in bycatch rates, the catch of one target species may be limited by the catch of another target species. This is particularly the case for target species that co-occur with sablefish and petrale sole because these two species are caught at levels near their OY under status quo management. In other words, any increase in co-occurring stocks will mean successful avoidance of sablefish and petrale to some degree, to facilitate increased catch of co-occurring target species. Based on available information, the target species most limited by sablefish and petrale sole are "other flatfish," Dover sole in areas seaward of the RCA, shortspine thornyheads to some degree, and arrowtooth flounder to some degree. To assess the likely change in the co-occurrence of target species catch, we turn to recent patterns of landings and discard

relative to catch limits, permit-specific fish tickets, and the expertise of analysts who have been involved in structuring and proposing fishing opportunity for the limited entry trawl fleet. Based on these data sets and information, it appears that the "other flatfish" category, Dover sole, and thornyheads are limited by the OYs of petrale sole and sablefish, though increases in the catch of those species still occur under a rationalization program. The following table shows a range in the modeling results that is meant to bracket the range of uncertainty and to provide target species catch estimates that fall within a realistic order of magnitude.

Table C-9. Estimated catch of select groundfish in the non-whiting trawl sector by bycatch reduction scenario.

Species	Low Catch	Med Catch	High Catch
Sablefish	2,371	2,371	2,371
Longspine	2,071	2,071	2,071
Shortspine	1,536	1,536	1,536
Dover	11,985	11,985	15,000
Arrowtooth	4,943	4,943	4,943
Petrale	2,223	2,223	2,223
Other Flatfish	2,547	2,547	4,800
Yellowtail	51	51	1,000
Chilipepper	46	2,000	2,000
Pacific cod	723	1,200	1,200
Lingcod	220	670	855
Slope Rockfish	680	1,120	1,120

C.2.2 Pacific Whiting Fishery Bycatch

It is likely that overfished species bycatch rates will also change in the mothership and shorebased sectors of the whiting fishery because those fisheries are operating as an Olympic fishery under status quo management. The whiting fishery operates under sector-wide bycatch limits that can close all sectors of the fishery if reached. Each sector has demonstrated a reduction in bycatch rates since bycatch limits were put in place, however the catcher-processor sector has demonstrated a lower rate of canary rockfish bycatch (the species that was most constraining from 2004 to 2006). From this information, we can infer that changes in the bycatch rates in the mothership and shorebased sectors of the whiting fishery are likely to occur if those sectors of the fishery are rationalized. It is important to note that it is not appropriate to assume the mothership and shorebased sectors of the whiting fishery would have the same bycatch rates as the catcher processor sector.

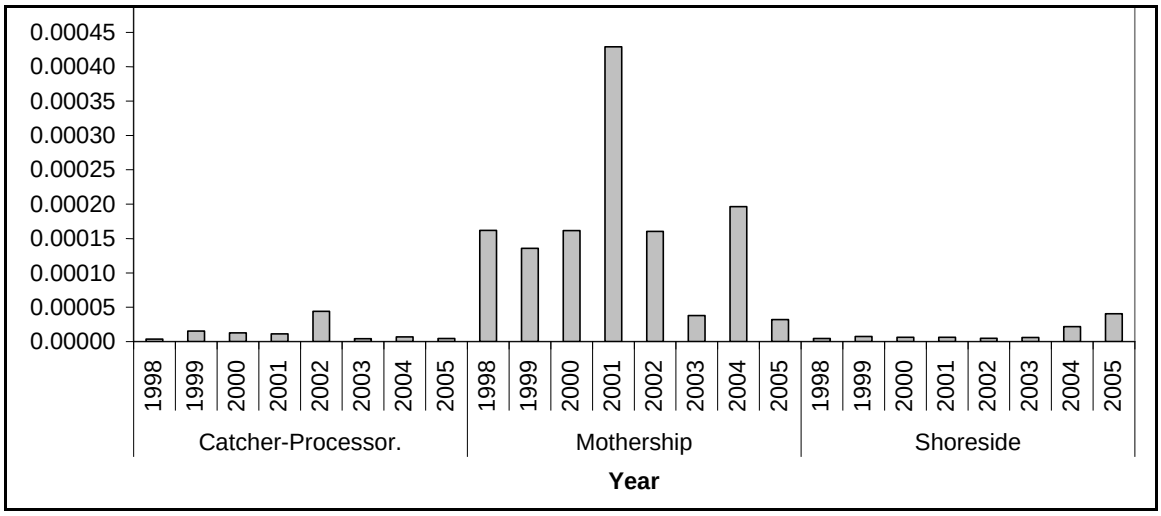

Figure C-6. Canary bycatch rate by year and whiting sector.

While it appears that bycatch rates in the mothership and shorebased sectors of the Pacific whiting fishery may decrease as a result of rationalization, such decreases are not expected to result in the same effect on the fishery as in the non-whiting fishery. Namely, the quantity of Pacific whiting harvested in the fishery has not been historically constrained by overfished species, with the exception of the 2007 season. Therefore, reductions in the bycatch rate of overfished stocks in the shoreside and mothership whiting sectors may not have an overall, aggregate economic impact in and of itself, though it is likely to change the behavior of harvesters in this fishery. Such behavior may have an indirect effect on the economics of the fishery if, for example, the timing of the fishery changes in order to respond to bycatch concerns.

C.3 Allocating Overfished Species on a Bycatch Rate (Proxy Species)

C.3.1 Introduction

This document describes a proposed methodology for allocating overfished species quota to LE trawl permits in the non-whiting sector based on a bycatch rate. This concept was originally proposed by the Groundfish Management Team (GMT) as a mechanism to allocate overfished species in a manner that would allow for the prosecution of current fishing practices given the constraints overfished species place on access to target species.

Empirical evidence from other quota programs throughout the world have shown that initial allocations of IFQ that differ substantially from current or recent fishing practices result in some negative consequences during the initial years of the program (dislocation of fishermen, high discard rates). Over time, these consequences are fixed through the natural trading of quota on the market, but a more refined initial allocation may still be able to avoid such negative consequences in the first place.

Preliminary analysis of initial allocation options has shown that, in general, if allocations of overfished species are made based on landings history, the distribution of overfished species quota would be heavily weighted toward a relatively few number of permits. This is because those were the permits that had previously targeted those species when they were abundant and because, under more recent regulations, catch of overfished species in the shoreside non-whiting fishery has been largely discarded rather than landed. For the near future, overfished species will constrain access to target species, so an

argument can be made for a more refined and equitable distribution of overfished species to allow permits to gain access to target species. While the market is likely to end up making necessary adjustments to the ownership of quota, overfished species quota is likely to be extremely costly because it will constrain access to target species. This means that those permits not receiving enough overfished species quota would essentially be forced to buy into the fishery again at a high cost, or leave the fishery all together. Allocating overfished species based on a bycatch rate is an attempt at making the initial allocation more equitable and avoiding such negative consequences.

C.3.2 General Description

The objective of allocating based on a bycatch rate is to allocate those species in a way that accommodates the current and recent spatial fishing patterns of LE non-whiting trawl vessels, to the extent possible. The bycatch rate of overfished species exhibits clear patterns across depth and latitude, and matching those patterns in the bycatch rate against relevant target fishing patterns can result in allocations that better accommodate recent fishing practices. Several sources of information are available for making allocations in a manner that accommodates these fishing practices:

- Logbooks are required of LE trawl vessels that deliver shoreside. Logbook information shows location, depth, and quantity of species that have been harvested by a particular vessel, among other things.
- The West Coast Groundfish Observer program samples the LE trawl fishery and records depth and location of species caught in observed fisheries.
- Information from these two data sets can be merged to allocate overfished species based on the spatial distribution of catch by LE trawl vessels and the corresponding spatial bycatch rates as estimated from WCGOP data.

During a 2007 meeting of west coast fisheries management agencies, it was revealed that logbook compliance in the shoreside trawl fishery was over 90 percent in recent years for all three west coast states. This information was contrary to the belief that logbook compliance was around 60 to 70 percent in some cases. Based on this information, the GMT recommended using permit-specific logbook information to determine a vessel's spatial and temporal catch history in recent years. In cases where there are no logbook records for a particular permit, then the fleet average would be used.

C.3.3 Data used in Application

The information used in this application includes fish ticket data, logbook data, and overfished species bycatch rates from the observer program. Fish ticket data are used because they are treated as the record of landed catch made by a vessel. Logbook data are used to stratify landed catch recorded on fish tickets into shoreward or seaward of the RCA locations in order to apply an overfished species bycatch rate and to identify the latitudinal area of catch. Observer program data are used for estimating shoreward and seaward bycatch rates of overfished species that are differentiated by latitudinal area. Several different latitudinal areas were considered, including 1) stratifying north and south of 40° 10' North latitude and south of 40° 10' North latitude, and 2) stratifying at 47° 40' North latitude, 43° 55' North latitude, 40° 10' North latitude, and 38° North latitude. The Council's decision resulted in a hybrid of those two options, using latitudinal stratifications at 47° 40' North latitude, 43° 55' North latitude, and 40° 10' North latitude.

Logbook records are used for estimating the location of catch. Location of catch in this case is defined as a latitudinal area, and whether the area was shoreward or seaward of the RCA. These estimates of catch location are developed for those species categorized as "target species" in existing trawl

management. Hypothetical catch location percentages (in terms of seaward and shoreward of the RCA) are shown in the table below.

Table C-10. Hypothetical percentage of target species catch that were caught shoreward and seaward of the RCA (2003 to 2006).

	Shoreward Catch Percentage	Seaward Catch Percentage
Dover	48%	52%
Longspine	5%	95%
Shortspine	12%	88%
Sablefish	11%	89%
Petrale	22%	78%
Other Flatfish	98%	2%
English sole	95%	5%
Splitnose	35%	65%
Pacific cod	88%	12%
Slope Rockfish	3%	97%
Arrowtooth	12%	88%

C.3.4 Model Development and Application

The model for this approach uses fish ticket data during the qualifying period, logbook data from 2003 to 2006, and observer data from 2003 to 2006. Quota shares of target species are first calculated from the fish ticket data, then target species quota shares are split by latitudinal area and by shoreward and seaward amounts based on catch depth recorded in 2003 to 2006 logbook data. This information is then multiplied by the trawl allocation amount of target species in place during the implementation year to get an estimate of implementation year quota pounds that are stratified by latitudinal area, and by seaward and shoreward of the RCA. These depth-stratified quota pounds are then multiplied by West Coast Groundfish Observer Program bycatch rates that are stratified by latitudinal area and by shoreward and seaward of the RCA from 2003 to 2006. The result is then converted to an overfished species quota share by dividing each permit's overfished species calculation by the sum of all non-whiting overfished species calculations.

1. The first step is to estimate each permit's target species quota shares.
2. The second step is to estimate the latitudinal area and depth of target species catch from logbooks for determining what each permit has caught by area from 2003 to 2006.
3. The third step is to stratify each permits' target species quota shares by latitudinal area and shoreward and seaward catch amounts based on each permits' depth stratified catch from step 1.
4. The fourth step is to multiply the depth and area stratified quota shares by the trawl allocation amounts during the initial implementation year to get quota pounds for the initial implementation year.
5. The fifth step is to multiply the corresponding latitudinal area and shoreward and seaward fleet average overfished species bycatch rates by the implementation year quota pounds of target species given to each permit.
6. The final step is to calculate overfished species quota shares by summing together the shoreward and seaward implementation year quota pounds for each permit and dividing that

amount by the total non-whiting trawl sector amount of implementation year quota pounds for those overfished species. This final step calculates the overfished species share.

The following tables illustrate the development and application of the proposed method. The table above (Table C-10) shows the first step in the model. The second step is to stratify each permit's target species quota shares into shoreward and seaward of the RCA portions and then estimate shoreward and seaward implementation year quota pounds. The following table shows an example of splitting quota shares for a hypothetical permit into seaward and shoreward areas.

Table C-11. Derivation of seaward and shoreward quota shares to a hypothetical permit.

Area	Species	Quota Share to Permit X	Shoreward Share	Seaward Share
North of 47 40	Dover	1%	48%	52%
	Longspine	2%	5%	95%
	Shortspine	3%	12%	88%
	Sablefish	3%	11%	89%
	Petrale	1%	22%	78%
	Other Flatfish	1%	98%	2%
	Pacific cod	1%	88%	12%
	English sole	1%	95%	5%
	Splitnose	0%	0%	0%
	Slope Rockfish	4%	3%	97%
	Arrowtooth	3%	12%	88%

The table below shows hypothetical quota shares for a permit that has only caught fish north of 47° 40' N latitude. Target species quota shares are differentiated as seaward and shoreward of the RCA from logbook information, as shown in the table above. The trawl allocation is then multiplied by those shares to derive an implementation year quota poundage of target species for that permit. This amount is shown in the right two columns of the table.

Table C-12. Hypothetical development of seaward and shoreward implementation year target species quota pounds.

Area	Species	Shoreward Share	Seaward Share	Implementation Year Trawl Allocation (mt)	Shoreward Lbs	Seaward Lbs
North of 47 40	Dover	48%	52%	16000	169,315	183,424
	Longspine	5%	95%	2000	4,409	83,776
	Shortspine	12%	88%	1200	9,524	69,842
	Sablefish	11%	89%	2600	15,763	127,537
	Petrale	22%	78%	2500	12,125	42,990
	Other Flatfish	98%	2%	7000	151,237	3,086
	Pacific cod	88%	12%	1000	19,401	2,646
	English sole	95%	5%	14000	293,214	15,432
	Splitnose	0%	0%	460	-	-
	Slope Rockfish	3%	97%	800	1,852	59,877
	Arrowtooth	12%	88%	10000	79,366	582,020

After determining a seaward and shoreward implementation year quota poundage, seaward and shoreward bycatch rates are applied to determine hypothetical darkblotched poundage. That poundage is then divided by the sum of all permits' poundage to derive a quota share of overfished species. The following table illustrates this method by continuing the use of shoreward and seaward implementation year quota pounds. Hypothetical darkblotched bycatch rates are multiplied by this amount in order to determine a darkblotched poundage. That poundage is then divided by a hypothetical fleetwide poundage to derive that permits quota shares of darkblotched rockfish.

Table C-13. Hypothetical derivation of darkblotched quota shares using proposed method.

Area	Species	Shoreward Lbs	Seaward Lbs	Shoreward bycatch rate	Seaward bycatch rate	Shoreward Drkbltchlbs	Seaward Drkbltch lbs	Total	Fleet total	Darkblotched QS
North of 47 40	Dover	169,315	183,424	0.0001	0.02	16.93	3,668.49			
	Longspine	4,409	83,776	0.0001	0.02	0.44	1,675.51			
	Shortspine	9,524	69,842	0.0001	0.02	0.95	1,396.85			
	Sablefish	15,763	127,537	0.0001	0.02	1.58	2,550.75			
	Petrale	12,125	42,990	0.0001	0.02	1.21	859.80			
	Other Flatfish	151,237	3,086	0.0001	0.02	15.12	61.73			
	Pacific cod	19,401	2,646	0.0001	0.02	1.94	52.91

C.4 Allocating Pacific Halibut to LE Trawl Permits in the Non-Whiting Trawl Fishery Based on a Bycatch Rate

C.4.1 Introduction

The catch of Pacific halibut may be regulated by way of individual bycatch quota in the trawl fishery after a rationalization program goes into place. Allocating Pacific halibut to individual trawl permits may prove to be difficult because there are no permit-specific records available with which to make an allocation based on catch history (outside the whiting fishery). This is because regulations prohibit the retention of Pacific halibut with gears other than hook and line gear. An initial allocation can be made to permits if it is done based on a bycatch rate to target species that have been landed and by the area that was fished. This paper describes a method for allocating Pacific halibut based on a proxy, or a bycatch rate.

C.4.2 General Description

Pacific halibut are encountered incidentally in trawl fisheries. Pacific halibut are a prohibited species, meaning their retention is not allowed in fisheries using trawl gear, so there are no permit-specific records of Pacific halibut catch. The incidental catch of Pacific halibut is documented through the West Coast Groundfish Observer Program, which samples the non-whiting trawl fishery. This information is used to estimate the total catch of Pacific halibut in the non-whiting trawl fishery based on an encounter rate to a target species. The approach described here proposes a method that is similar to the approach used for estimating total trawl mortality, but includes additional stratifications based on International North Pacific Fishery Commission (INPFC) area and whether a vessel was fishing seaward or shoreward of the trawl RCA. For practical purposes, seaward and shoreward are identified as being deeper or shallower than 115 fathoms. These additional stratifications are proposed to consider the known spatial abundance and encounter rates of Pacific halibut that exist, as well as the spatial fishing patterns exhibited by fishermen.

C.4.3 Data Used in Application

Several sources of information exist for deriving permit-specific catch histories of Pacific halibut. These sources of information include logbook data, West Coast Groundfish Observer Program data, and fish ticket data. These sources of information can be used similarly to the approach described for allocating overfished species based on a bycatch rate, however the approach described here has several of differences. The first difference is that the approach for allocating Pacific halibut uses two species that have been shown to have positive correlations with Pacific halibut—arrowtooth flounder and petrale sole—while the method for allocating overfished species uses all target species. The second difference is that this approach uses an area stratification that is based on landings of target species that have occurred north of 40° 10’ N latitude, and stratifies that area into two sub-areas. One sub-area is a combination of the Eureka and Columbia INPFC areas, and the other sub-area is the Vancouver INPFC area. These areas were chosen because available observer information shows a clear difference in encounters of Pacific halibut off northern Washington compared to areas to the south, and this INPFC area-based stratification can be readily accommodated with logbook data.

Limited-entry trawl logbook data are used in the same fashion as the approach taken for allocating overfished species, although the number of target species is lower because arrowtooth and petrale sole show positive correlations with Pacific halibut. Depth-based landings are used to distribute the fish ticket landings of individual permits between shoreward and seaward of the trawl RCA. In addition to

using logbooks to determine depth of catch, logbook data are also used to determine latitudinal area of catch.

Table C-14. Hypothetical vessel average depth-based catch proportion of target species that were caught by a vessel fishing in the Vancouver area (2003 to 2006).

Area	Target Species	Average Seaward Catch Percentage	Average Shoreward Catch Percentage
Vancouver INPFC Area	Arrowtooth Flounder	48%	52%
	Petrale Sole	11%	89%

C.4.4 Model Development and Application

The model for this approach uses fish ticket data during the qualifying period. Petrale sole and arrowtooth flounder from these fish ticket records are split into shoreward and seaward amounts based on permit-specific catch depth from logbook data from 2003 to 2006 as shown in the above table, and by the Vancouver INPFC area and the combined Columbia and Eureka INPFC area based on logbook data. Where fish ticket records exist for a particular species, but logbook records do not, the fleet average depth or area distribution for harvests of that species is used. This information is matched against West Coast Groundfish Observer Program data that are stratified shoreward and seaward of the RCA for the years 2003 to 2006 and also stratified between the Vancouver and combined Columbia/Eureka INPFC areas. Quota shares for petrale sole and arrowtooth are then calculated for each permit and applied to the trawl allowable catch during the implementation year of IQs to estimate the implementation year quota pounds. These implementation year quota pounds are stratified by shoreward and seaward amounts and INPFC area, based on catch history. Each of these quota pound estimates are matched up to a corresponding depth and area Pacific halibut bycatch rate, and the result is summed. The result is a poundage estimate for Pacific halibut for each permit. That estimate is then divided by the fleet total to estimate each permit's quota share of Pacific halibut.

The following tables illustrate how the quota shares of arrowtooth and petrale sole are separated into shoreward, seaward, and latitudinal amounts. The table below uses the above table showing depth-based catch from logbooks. The first column of the table shows the species, and the second column of the table shows the quota share that permit would receive of arrowtooth and petrale sole. The third, fourth, and fifth columns then show the source area and depth of catch. In this case, the particular permit only has catch history from the Vancouver area. This hypothetical permit would receive 1 percent of the arrowtooth flounder share, 0.476 percent of which was caught seaward of the trawl RCA in the Vancouver area.

Table C-15. Hypothetical development of area-specific seaward and shoreward quota shares of target species.

Permit XXLE Catch History				
Target Species	Quota Shares to Permit X	Area	Seaward Share	Shoreward Share
Arrowtooth Flounder	1.00%	Vancouver	0.476%	0.524%
		Columbia/Eureka	0.0%	0.0%
Petrale Sole	3.00%	Vancouver	0.317%	2.683%
		Columbia/Eureka	0.0%	0.0%

The next table uses the information from the previous table to estimate the quota pounds a permit would get during the implementation period. This calculation uses the shoreward and seaward delineation of target species shares to estimate a shoreward and seaward quota poundage amount during the implementation year.

Table C-16. Hypothetical development of shoreward and seaward implementation year quota pounds.

Target Species	Area	Seaward Share	Shoreward Share	Implementation Year Trawl Allocation (mt)	Seaward Pounds	Shoreward Pounds
Arrowtooth Flounder	Vancouver	0.476%	0.524%	5,000	52,464	57,767
	Columbia/ Eureka	0%	0%			
Petrale Sole	Vancouver	0.317%	2.683%	16,000	111,744	946,474
	Columbia/ Eureka	0%	0%			

The next table then matches the shoreward and seaward quota pounds with the corresponding bycatch rates of Pacific halibut. That amount is then summed and divided by the fleet total to derive each permits' quota shares of Pacific halibut, shown in the last column.

Table C-17. Derivation of Pacific halibut quota shares.

Target Species	Area	Sea-ward lbs	Shore-ward lbs	Sea-ward Bycth Rate	Shore-ward Bycth Rate	Sea-ward Pacific Halibut LBS	Shore-ward Pacific Halibut LBS	Permit P. halibut Total	Fleet P. halibut Total	P. Halibut Share
Arrowtth Flounder	Vncvr	52,464	57,766	0.001	0.04	52	2,311			
	Colum/ Eureka	0	0	.00005	0	0	0			
Petrale Sole	Vncvr	111,744	946,473	0.001	0.04	112	37,859			
	Colum/ Eureka	0	0	.00005	0	0	0			
								40,334	**1,800,000**	**2.2%**

Acronyms and Abbreviations

Acronym	Definition
Council	Pacific Fishery Management Council
CP	catcher processor
CV(MS)	mothership-endorsed catcher vessel permit
EIS	environmental impact statement
FMP	fishery management plan
IBQ	individual bycatch quota
IFQ	individual fishing quota
MS	mothership
MSA	Magnuson-Stevens Fishery Conservation and Management Act
NMFS	National Marine Fisheries Service
OY	optimum yield
RCA	Rockfish Conservation Area
QP	quota pound
QS	quota share

D.1 Overview of Recommendations by Sector

The Pacific Fishery Management Council's (Council) sector specific recommendations for rationalizing the trawl fishery are provided here and will be finalized and forwarded to the National Marine Fisheries (NMFS) for approval later in 2009. The recommendations were adopted at the Council's November 2008 meeting. In general, the Council recommends the following:

Shoreside Trawl Sector (nonwhiting groundfish species and whiting):

Manage with individual fishing quotas (IFQs).

Provide 90 percent of the initial allocation of nonwhiting IFQ to holders of vessel permits; and

set aside 10 percent of the initial allocation for an adaptive management program that may benefit processors and communities, among others.

Provide 80 percent of the initial allocation of whiting IFQ to holders of vessel permits; and

provide 20 percent of the initial allocation of whiting to processors.

Mothership (MS) Trawl Sector (whiting and groundfish bycatch species):

Manage with a harvester co-op system and limited entry for MS processors.

Require that vessels declare preseason the MS processor for which they will fish in a coming year.

Catcher Processor (CP) Sector (whiting and groundfish bycatch species):

Create a permit endorsement to prevent expansion of the number of participants.

Allocate whiting and bycatch to the existing voluntary co-op.[1]

Provide an IFQ program if the voluntary co-op fails (initially allocate IFQ equally among all permit holders).

The amount of allocation available for these sectors will be determined through the intersector allocation process. IFQ for the shoreside fishery may not be delivered to at-sea processors, nor may quota allocated to the mothership (MS) or CP sectors be delivered shoreside.

The following sections provide a general summary of the program for each sector, followed by a complete description that also identifies trailing actions the Council has been working on in 2009. These actions will be completed prior the time it submits the package to NMFS for approval.[2] *The trailing actions pertain to eligibility to own IFQ, accumulation limits, and adaptive management. Implementation is not expected earlier than 2011.*

D.2 Shoreside Trawl Sector: IFQ Program (Appendix A of the Environmental Impact Statement [EIS])

This section details the IFQ program that the Council is recommending for the shoreside sector of the groundfish fishery. The first part of the section describes major components of the program. Table D-1, which starts on page 5, presents complete details on elements of the recommended IFQ program.

[1] When the Council took final action, NMFS indicated its preliminary intent to license the voluntary co-op. However, this was not part of the Council's final action.

[2] During its March and April 2009 meetings, the Council also clarified a number of its recommendations. These clarifications are reflected in the version of the trawl rationalization recommendation provided here.

D.2.1 Overview of the IFQ Program Elements

Under this program, most status quo management tools would remain in place. The main exceptions are cumulative landing limits for nonwhiting groundfish species and a closure period to control whiting harvest at the start of the year.[3] Other measures, such as Rockfish Conservation Area (RCA) boundaries, may be adjusted as experience is gained with the IFQ program.

An IFQ will grant an entity the privilege to catch a specified portion of the trawl sector's allocation. Within the IFQ program, vessels will be allowed to use a variety of directed groundfish commercial gear (including nontrawl gear) to take the shoreside trawl sector allocation, which will enable "gear switching." IFQs will be created for most species of groundfish under the Groundfish Fishery Management Plan (FMP) (although some will still be managed collectively at the stock complex level, e.g., remaining minor slope rockfish). Some groundfish species rarely caught by trawl gear and dogfish will be excluded from the IFQ program. To ensure that optimum yields (OY) for species not covered by IFQ are not exceeded, catch of those species will be monitored and deductions made from the OY in anticipation of the expected level of shoreside trawl sector catch. For trips targeted on whiting, IFQ will be required only for whiting and the main bycatch species.

Halibut individual bycatch quota (IBQ) will be required to cover the incidental catch[4] of Pacific halibut in the groundfish trawl shoreside fishery. Under an IBQ program, retention would not be allowed.

The following sections describe the major provisions of the IFQ program.

D.2.1.1 Initial Allocation

The program will initially allocate IFQ as quota share (QS) to fishery participants based mainly on their historic involvement in the fishery. Following the initial allocation, transfers (described below) will also allow others to participate in the fishery as quota holders. The initial allocation can be viewed in two segments:

First, in developing its recommendation, the Council considered the groups that should be included in the initial allocation and the proportional split among the groups. The Council recommended that harvesters (those holding limited entry permits for trawl vessels) be given an initial allocation of 90 percent of the nonwhiting QS and 80 percent of the whiting QS. Ten percent of the QS for nonwhiting species would be made available for an adaptive management program and processors would receive 20 percent of the whiting QS.

Second, the Council considered specific allocation formulas to determine the amount of QS each eligible entity will receive. These calculations are based primarily on the delivery history associated with a vessel permit or processing company over a set number of years. For the allocation to permits, the QS associated with the history of permits retired in the buyback program will be distributed equally among the remaining qualified permits (about 44 percent of the QS will be allocated in this fashion). A special calculation is provided for incidentally caught overfished species. For these species, the allocation will be based on the QS recipient's need to cover incidental catch under current fishing practices (as measured by bycatch rates, individual permit logbooks for recent years, and the amount of target species QS that an entity receives). None of the QS for overfished species will be allocated equally among harvesters, with the exception of canary rockfish. A similar approach would be used for the allocation of halibut IBQ.

[3] This closure period is necessary because of Endangered Species Act concerns related to salmon.

[4] At its June meeting, the Council will consider a recommendation by the Groundfish Allocation Committee to interpret previous Council action under Amendment 21 as creating an IBQ program to cover incidental mortality rather than catch.

D.2.1.2 Stock Management Units for IFQs

QS will be issued for the species groups and areas for which there are OYs (management units). However, QS will not be required for some rarely caught species. Catch of these species would be monitored to ensure that they do not exceed any established allocations. There may be further area subdivisions for species for which there is an area specific precautionary harvest policy. There are also provisions that provide for both species group and area subdivision of QS after initial allocation.

D.2.1.3 Annual Issuance, Holding Requirements, and Transfer Rules

In designing the management regime for the IFQ program, the Council is balancing the benefits of flexibility and individual accountability with program costs and the constraints of the very low allowable catch levels of overfished species. Prior to the start of each fishing year, NMFS will issue quota pounds (QP) to entities based on the amount of QS they hold and the shoreside trawl sector allocation. The QP would have to be transferred to a vessel account in order to be used. When a vessel goes fishing under the IFQ program, all catch must be recorded (including discards), and it must be matched by an equal amount of QP from the vessel's QP account. If there is not enough QP to cover the catch from a trip, there is a 30-day grace period during which adequate QP must be transferred into the vessel's account. A vessel's fishing will be limited, and its permit cannot be sold, until the overage is covered. A carryover provision will allow for an overage in one year to be covered by up to 10 percent of the following year's QP; likewise, the provision also will allow QP that were not used in one year to be carried over into the following year, up to 10 percent.

Bycatch reduction and greater efficiency are expected to occur in the groundfish fishery under the IFQ program because of the transferability of QS and QP. Through the transfer of QS/QP (bought and sold or leased through private contract), it is anticipated that those best able to avoid catching overfished species and those who are most efficient will increase the amount of QS/QP registered to them. Those who consistently have high bycatch rates or operate less efficiently might choose to sell their QS and leave the fishery. Generally, anyone eligible to own a U.S.-documented fishing vessel could also acquire QS and QP, and the QS and QP could be acquired in very small increments.[5] These provisions will allow for new entrants into the fishery; for example, a crewmember could slowly purchase amounts of quota. They also allow for ownership of QS by entities that do not otherwise participate in the fishery. *In early 2009, during its trailing actions the Council considered but rejected substantially modifying provisions pertaining to who is eligible to own the QS.*

While transferability is an important component, some provisions limit transferability in order to protect against unintended consequences. For example, there will be accumulation limits on the amount of QS or QP that can be controlled by an entity and accumulation limits on the amount of QP registered to a vessel. The intent of these limits is to prevent excessive control of quota by a participant. *The exact percentages that will be used in these limits will be determined through a trailing action.*

An adaptive management provision will allow the Council to use 10 percent of the trawl allocation to provide incentives, support, or other compensation to offset adverse impacts of the program. This program may benefit communities and processors, among others. *Details will be the subject of a trailing action.*

[5] To be eligible to own QS, the person need not actually own a U.S. documented fishing vessel.

D.2.1.4 Tracking and Monitoring

A tracking and monitoring program is necessary to ensure that all catch (including discards) is documented and matched against QP. At-sea observers would be required on all vessels, as well as shoreside monitoring during all off-loading (100 percent coverage). Cameras may be used to augment the observers and ensure compliance. Compared to status quo monitoring, this will be a significant increase for a large portion of the trawl fleet, particularly nonwhiting shoreside vessels. More accurate estimates of total mortality will benefit stock conservation goals. Discarding will be allowed, though all fish discarded will also have to be covered by QP. There would be 100 percent shoreside monitoring; and there may be limited landing hours to control costs. Additionally, a program for the mandatory submission of economic data is included to facilitate monitoring program performance.

D.2.1.5 Costs and Fee Structure

Program costs are of concern and ongoing Federal administrative costs are discussed in Appendix A and in Appendix H.. Program benefits are expected to exceed costs One of the major sources of costs is associated with industry payments for observers and catch monitors. To help mitigate against these costs, NMFS has announced its intent, subject to available Federal funding, that participants would initially be responsible for 10 percent of the cost of hiring observers and catch monitors. The industry proportion of the costs of hiring observers and catch monitors would be increased every year so that, once the fishery has transitioned to the rationalization program, the industry would be responsible for 100 percent of the cost of hiring the observers and catch monitors by 2014. Fee structures will be proposed to recover program costs from industry, up to the limit of 3 percent of ex-vessel value.

D.2.1.6 Program Monitoring, Review and Future Auction

The Council will conduct a formal review of program performance no later than five years after implementation and every four years thereafter. The result of the evaluation could include dissolution of the program, revocation of all or part of quota shares, or other fundamental changes to the program. At the time of its first review, the Council will also consider the use of an auction or other non-history-based method when distributing quota share that may become available after the initial allocation.

D.3 Detailed Specification of IFQ Program Elements and Options

Table D-1 provides a complete description of the IFQ program.

Table D-1. Full description of the IFQ Program for shoreside trawl deliveries.

	Element	Sub-element	
A. Trawl Sector Management			
A-1.1	Scope for IFQ Management, Including Gear Switching		For trips delivered shoreside, QP will be required to cover catch of all groundfish (including all discards) by limited entry (LE) trawl vessels with certain gear and species exceptions. Gear Exception: Vessels with an LE trawl permit using the following gears would not be required to cover their groundfish catch with QP: exempted trawl, [a] gear types defined in the coastal pelagic species FMP, gear types defined in the highly migratory species FMP, salmon troll, crab pot, and LE fixed gear when the vessel also has a LE permit endorsed for fixed-gear (longline or fishpot) AND has declared that they are fishing in the LE fixed-gear fishery. Species Exception: The following would be an exception from the QP requirement longspine thornyheads south of 34º27' N latitude, minor nearshore rockfish (north and south), black rockfish (WOC), California scorpionfish, cabezon, kelp greenling, shortbelly rockfish, and the "Other Fish" category of groundfish. *This definition of the scope allows an LE trawl vessel to switch between trawl and nontrawl groundfish gears, including fixed-gear, for the purpose of catching their QP ("gear switching"). It also allows a nontrawl vessel to acquire a trawl permit, and thereby use trawl QP to catch the LE trawl allocation using nontrawl gear*.[b]
A-1.2	IFQ Management Units, Including Latitudinal Area Management		QS will carry designations for the species/species group, area, and trawl sector to which it applies (see A-1.3 for the list of trawl sectors). The QP will have the same species/species group, area, and sector designations as the QS on the basis of which the QP was issued. QP will not be used in a trawl sector other than that for which it was issued,[c] and will not be used in a nontrawl sector (i.e., by vessels without trawl permits).[d] QP will not be used in a catch area or for a species/species group other than that for which it is designated. For those species within the scope of the program, the QS/QP species groupings and area subdivisions will be those for which OYs are specified in the acceptable biological catch (ABC)/OY table that is generated through the groundfish biennial specifications process and those for which there is an area-specific precautionary harvest policy[e] QS for remaining minor rockfish will be aggregated for the shelf and slope depth strata (nearshore are excluded from the scope, see Section A-1.1). Changing the management units. After initial QS allocation the Council may alter the management units by changing the management areas or subdividing species groups. Section A-2.1.6 provides methods for reallocating QS when such changes are made after initial implementation of the program.[f] *Hereafter, all references to species include species and species group, unless otherwise indicated.*

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-1.3	General Management and Trawl Sectors		Unless otherwise specified, status quo regulations, other than trip limits for species within the scope of the IFQ program, will remain in place. If individual vessel overages (catch not covered by QP) make it necessary, area restrictions, season closures, or other measures will be used to prevent the trawl sector (in aggregate or the individual trawl sectors listed here) from going over allocations.[g] The IFQ fishery may also be restricted or closed as a result of overages in other sectors. There will be three trawl sectors: shoreside, MS, and CP. However, as per Section A-1.1, IFQ will be required only for the shoreside trawl sector. The MS and CP sectors will be managed using co-ops, as specified in the co-op section of the trawl rationalization program. If the industry organized voluntary co-op program for the CP sector collapses, IFQ will be required for the CP sector, as specified in the co-op program described for that sector. *Allocation among trawl sectors has been determined in FMP Amendment 21. Those allocations not covered by Amendment 21 will be addressed in the biannual specifications process.* *Trawl vessels fishing IFQ with nontrawl gear will be required to comply with the RCA lines applicable for that gear. Such restrictions, as necessary, will be determined in a separate process.*
A-1.4	Management of Nonwhiting Trips		Nonwhiting trips are those with less than 50 percent whiting. No changes to management measures, other than those identified in Section A-1.3, have been identified at this time.
A-1.5	Management of Whiting Trips[h]		Whiting seasons will not be changed under the IFQ program, and so the current spring openings will be maintained to control impacts on ESA-listed salmon.[i] When the primary whiting season is closed for shoreside deliveries, cumulative whiting catch limits will apply and shoreside QP will be required to cover whiting incidental catch.
A-1.6	Groundfish Permit Length Endorsements		Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained; however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e., length endorsements will not change when a trawl-endorsed permit is transferred to a smaller vessel).

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2. IFQ System Details			
A-2.1	Initial Allocation and Direct Reallocation		
A-2.1.1	Eligible Groups	a Groups and Initial Split of QS	***Eligible Groups*** The initial allocation of QS will be made either only to permit owners and processors, as follows. Whiting QS: 80 percent to permits, 20 percent to processors and zero percent for adaptive management. Nonwhiting QS: 90 percent to permits, zero percent to processors, and 10 percent for adaptive management. *After initial allocation, trading will likely result in changes in the distribution of shares among permit owners and processors. Additionally, entities that are neither permit owners nor processors may acquire QS (see below: "IFQ/Permit Holding Requirements and IFQ Acquisition").*
		b Permits	Landing history will accrue to the permit under which the landing was made. The owner of a groundfish LE permit at the time of initial allocation will receive the QS issued based on the permit. (Also, see Section A-2.1.4 on permit combinations and other exceptional situations.)
		c Processors and Processing Definition	A special definition of "processor" and "processing" will be used for initial QS allocation. A main intent of the definition is to specify that only the first processor of the fish be credited for the history of that delivery when the initial allocation formula is applied (see footnote for definition).[j]
		d Attributing and Accruing Processing History	For an allocation for **shoreside processors (applies only to whiting):** attribute history to the receiver reported on the landing receipt (i.e., the entity responsible for filling out the state fishticket), except history may be reassigned to an entity not on the landings receipt, if parties agree or through an agency appeals process. *The intent of this option is to provide an opportunity for catch history to be assigned to the entity that actually processed the fish.* For shoreside processors, allocations go to the processing business and successor-in-interest will be recognized. NMFS will develop criteria for use in determining the successor in interest with respect to the entities listed on the landings receipts or otherwise eligible for an initial QS allocation based on being the first processor of the fish.[k]
A-2.1.2	Recent Participation	a Permits (including CP permits)	Recent participation is not required in order for a permit to qualify for an initial allocation of QS.
		b Processors (motherships)	Not applicable because a co-op program was provided for this sector rather than IFQs. *(This header is being left in the document so that paragraph numbering will correspond to numbering in the analysis.)*
		c Processors (shoreside)	Recent participation is required to qualify for an initial allocation of whiting QS: 1 mt or more of deliveries from whiting trips in each of any two years from 1998-2004.

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2.1.3	Allocation Formula	a Permits with catcher vessel history	QS will be issued for all fish management units within the scope of the program (see Section A-1.2) based on equal division and permit history, as follows:[l] **Equal Division:** There will be an equal division of the buy-back permits' pool of QS among all qualifying permits *(except the incidentally caught overfished species other than canary)*. Qualifying permits include all catcher vessel permits, including those that have been used only in the MS sector. (The QS pool associated with the buyback permits will be the buyback permit history as a percent of the total fleet history for the allocation period. The calculation will be based on total absolute pounds with no other adjustments and no dropped years.) **Permit History:** The remaining QS *(the QS left after setting aside amounts for equal allocation)* will be allocated based on each permit's history (see following formulas). **For the portion of the allocation based on each permit's history.** For **nonwhiting** trips, permit history used for QS allocation will be calculated: **For nonoverfished species**: using an allocation period of 1994-2003. Within that period use relative history and drop the three worst years.[m] **For overfished species taken incidentally:**[n] using target species QS as a proxy based on the following approach: Apply fleet average bycatch rates to each permit's depth and latitude distributions and target species QS allocations. Fleet average bycatch rates for latitudinal areas[o] divided shoreward and seaward of the RCA will be developed from West Coast Observer Program data for 2003-06. For the purposes of the allocation, a permit's QS for each target species will be distributed shoreward and seaward of the RCA and latitudinally based on the permit's logbook information for 2003-06. If a permit does not have any logbooks for 2003-06, fleetwide averages will be used.[p] For **whiting** trips, permit history used for QS allocation will be calculated as follows: **For whiting**, use an allocation period of 1994-2003. Within that period, use relative history and drop the two worst years. [q] **For bycatch species** (if IFQ is used for bycatch species): use the whiting history as a proxy (i.e., allocation will be pro rata based on the whiting allocation). **Area Assignments:** Landings history will be assigned to catch areas based on port of landing.[r] **Relative history (percent).** For each sector, the permit history for each year is measured as a percent of the sector's total for the year. **Initial allocations will be constrained by accumulation limits.** See Section A-2.2.3.e for a discussion of the limits and divestiture requirements.
.		b Permits with CP history	Not applicable because a co-op program was provided for this sector rather than IFQs. *(This header is being left in the document so that paragraph numbering will correspond to numbering in the analysis).*
		c Processors (motherships)	Not applicable because a co-op program was provided for this sector rather than IFQs *(This header is being left in the document so that paragraph numbering will correspond to numbering in the analysis).*
		d Processors (shoreside)	For whiting: • Allocate whiting QS based on the entity's history for the allocation period of 1998 [s]-2004 (drop two worst years) and use relative history. **Initial allocations will be constrained by accumulation limits.** See Section A-2.2.3.e for a discussion of the limits and divestiture requirements.

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2.1.4	History for Combined Permits and Other Exceptional Situations		Permit history for combined permits will include the history for all the permits that have been combined. For history occurring when two or more trawl permits were stacked, split the history evenly between the stacked permits. History for illegal landings will not count toward an allocation of QS. Landings made under nonwhiting Experimental Fishing Permits (EFPs) that are in excess of the cumulative limits in place for the nonEFP fishery will not count toward an allocation of QS. Compensation fish will not count toward an allocation of QS.
A-2.1.5	Initial Issuance Appeals		There will be no Council appeals process on the initial issuance of IFQ. NMFS will develop a proposal for an internal appeals process and bring it to the Council for consideration. Any revisions to an entity's fishtickets must be approved by the state in order to be accepted. Any proposed revisions to fishtickets should undergo review by state enforcement personnel prior to finalization of the revisions.
A-2.1.6	Direct Reallocation and Future Allocations After Initial Issuance		**Reallocation With Change in Overfished Status**: When an overfished species is rebuilt or a species becomes overfished there may be a change in the QS allocation within a sector (allocation between sectors is addressed in the intersector allocation process). When a stock becomes rebuilt, the reallocation will be to facilitate the re-establishment of historic target fishing opportunities. When a stock becomes overfished, QS may be reallocated to maintain target fisheries to the degree possible. That change may be based on a person's holding of QS for target species associated with the rebuilt species or other approaches deemed appropriate by the Council. **Reallocation With Changes in Area Management** (Changes in management lines are expected to be rare; however, when they occur the following provides for the reallocation of QS in a manner that will give individual QS holders with the same amounts of total QP before and after the line changes.) **Area Subdivision**: If at any time after the initial allocation an IFQ management unit is geographically subdivided, those holding QS for the unit being subdivided will receive an amount of QS for each newly created area that is equivalent to the amount they held for the area before it was subdivided. **Area Recombination**: When two areas are combined, the QS held by individuals in each area will be adjusted proportionally such that (1) the total QS for the area sums to 100 percent, and (2) a person holding QS in the newly created area will receive the same amount of total QP as they would if the areas had not been combined.

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2.1.6	Continued		**Area Line Movement**: When a management boundary line is moved, the QS held by individuals in each area will be adjusted proportionally such that they each maintain their same share of the trawl allocation on a coastwide basis (a fishing area may expand or decrease, but the individual's QP for both areas combined wouldn't change because of the change in areas). In order to achieve this end, the holders of QS in the area being reduced will receive QS for the area being expanded, such that the total QP they would be issued will not be reduced as a result of the area reduction.[t] Those holding QS in the area being expanded will have their QS reduced such that the total QP they receive in the year of the line movement will not increase as a result of the expansion (nor will it be reduced). **Reallocation With Subdivision of a Species Group**: If at any time after the initial allocation an IFQ management unit for a species group is subdivided, those holding QS for the unit being subdivided will receive an amount of QS for each newly created IFQ management units that is equivalent to the amount they held for the species group before it was subdivided. For example, if a person holds one percent of a species group before the subdivision, that person will hold one percent of the QS for each of the groups resulting from the subdivision. **Future Allocation of Groundfish Outside the Scope of the IFQ Program:** For the "Other Fish," category of groundfish, if at some time in the future the Council adds it to the IFQ system, the initial allocation would be determined using the same history criteria as was used for other IFQ species (i.e., 1994-2003 history), unless otherwise specified by a future Council action.
A-2.2	Permit/IFQ Holding Requirements and Acquisition (after initial allocation)		
A-2.2.1	Permit/IFQ Holding Requirement		1. Only vessels with LE trawl permits are allowed to fish in the trawl IFQ fishery. 2. For a vessel to use QP, the QP must be in the vessel's QP account. 3. All catch a vessel takes on a trip must be covered with QP within 30 days of the time that data or documentation from the trip shows there is an overage unless the overage is within the limits of the carryover provision (Section A-2.2.2.b), in which case the vessel has 30 days or a reasonable time (to be determined) after the QP for the following year are issued, whichever is greater.[u] 4. For any vessel with an overage (catch not covered by QP), fishing that is within the scope of the IFQ program (Section A-1.1) will be prohibited until the overage is covered, regardless of the amount of the overage. Vessels which have not adequately covered their overage within the time limits specified in paragraph 3, must still cover the overage before resuming fishing, using QP from the following year(s), if necessary. If a vessel covers its overage, but coverage occurs outside the specified time limit (paragraph 3), the vessel may still be cited for a program violation. 5. For vessels with an overage, the LE permit may not be sold or transferred until the deficit is cleared.

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2.2.2	IFQ Annual Issuance	a Annual Quota Pound Issuance	QP will be issued annually to QS holders based on the amount of QS held.[v] *As specified above, QS holders will have to transfer their QP to a vessel account in order for those QP to be used.*
		b Carryover (Surplus or Deficit)	To the extent allowed by the conservation requirements of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), a carryover allowance will allow surplus QP in a vessel's QP account to be carried over from one year to the next or allow a deficit in a vessel's QP account for one year to be carried over and covered with QP from a subsequent year. Surplus QP may not be carried over for more than one year. A vessel with a QP **surplus** at the end of the current year will be able to use that QP in the immediately following year, up to the limit of the carryover allowance (see below). However, if there is a decline in the OY, the amount of QP carried over as a surplus will be reduced in proportion to the reduction in the OY. A vessel with a QP **deficit** in the current year will be able to cover that deficit with QP from the following year without incurring a violation if (1) the amount of QP it needs from the following year is within the carryover allowance (see below), and (2) the QP are acquired within the time limits specified in A-2.2.1.[w] **Carryover Allowance**: Limit of up to 10 percent carryover for each species. This applies to both nonoverfished species and overfished species. The percentage is calculated based on the total pounds (used and unused) in a vessel's QP account for the current year. The percentage used for the carryover provision may be changed during the biennial specifications process.
		c QS Use-or-Lose Provisions (Deleted)	*This section has been deleted but the numbering is being maintained as a placeholder so as not to change section numbering and corresponding references in the analysis.*[x]
		d Entry Level Opportunities	Under the MSA, the Council is required to consider entry level fishermen, small vessel owners, and crew members, and in particular the possible allocation of a portion of the annual harvest to individuals falling in those categories. No special provisions have been identified for analysis. New entry is addressed indirectly by allowing crew, captains and others to acquire QS in small increments.
A-2.2.3	IFQ Transfer Rules	a Eligible to Own or Hold	No person can acquire quota shares or quota pounds other than 1) a United States citizen, 2) a permanent resident alien, or 3) a corporation, partnership, or other entity established under the laws of the United States or any State, that is eligible to own and control a U.S. fishing vessel with a fishery endorsement pursuant to 46 USC 12113 (general fishery endorsement requirements and 75 percent citizenship requirement for entities). However, there is an exception for any entity that owns a MS that participated in the west coast groundfish fishery during the allocation period and is eligible to own or control that U.S. fishing vessel with a fishery endorsement pursuant to sections 203(g) and 213(g) of the AFA.

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2.2.3	continued	b Transfers and Leasing	QS/QP will be transferable and transfers must be registered with NMFS. NMFS will not differentiate between a transfer for a lease and a permanent transfer.[y] Each year, all QP must be transferred to a vessel account. A penalty for not meeting this transfer requirement has not been recommended; however, this requirement is intended to encourage its availability for use by the fleet. QP can only be transferred into vessel accounts. Once in a vessel account QP can be transferred from one vessel account to another.
		c Temporary Transfer Prohibition	NMFS may establish temporary prohibitions on the transfer of QS, as necessary to facilitate program administration. QS will not be transferred in the first two years of the program (QP will be transferable).
		d Divisibility	QS will be highly divisible and the QP will be transferred in whole pound units (i.e., fractions of a pound may not be transferred).
		e Accumulation Limits (Vessel and Control)	Limits[z] may vary by species/species group, areas, and sector. The values for the limits are provided in Table D-2. The vessel unused QP limits may be revisited in the first biennial specifications process after implementation of the program. **Vessel Use Limit (Vessel Limit)**: A limit on the total QP that may be registered for a single vessel during the year. This element will mean that a vessel could not have more used and unused quota pounds registered for the vessel than a predetermined percentage of the QP pool. **Vessel Unused QP Limit**: A limit on the amount of unused QP that may be registered to the vessel at any time. This limit applies only for overfished species and Pacific halibut. **QS Control Limit:** A person, individually or collectively, may not control QS in excess of the specified limit (because there is no the grandfather clause). QS controlled by a person shall include those registered to that person, plus those controlled by other entities in which the person has a direct or indirect ownership interest, as well as shares that the person controls through other means.[aa] The calculation of QS controlled by a person will follow the "individual and collective" rule. Individual and Collective Rule: The QS that counts toward a person's accumulation limit will include 1) the QS or QP owned by them, and 2) a portion of the QS owned by any entity in which that person has an interest. The person's share of interest in that entity will determine the portion of that entity's QS that counts toward the person's limit.[bb] **Grandfather Clause and Divestiture:** There will not be a grandfather clause for the QS control limits, however, an adjustment period is provided through the following divestiture rules. QS will be issued for amounts in excess of aggregate and species control limits only for holders of permits transferred by November 8, 2008, if such transfers have been registered with NMFS by November 30, 2008. The holder of any permit transferred after that time will be eligible to receive an initial allocation for that permit of only those QS that are within the aggregate and individual species control limits. Anyone who qualifies for an initial allocation of QS in excess of the control limits will be allowed to receive that allocation but required to divest themselves of that excess QS sometime during years three and four of the IFQ program (the two years after the QS transfer moratorium specified in Section A-2.2.3.c). Holders of QS in excess of the limits

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
		e Accumulation Limits (Vessel and Control) (continued)	may receive and use the QP associated with that excess, up to the time their divestiture is completed. However, QP for year five of the program will not be issued for QS held in excess of the limits. At the end of year four, any QS still held in excess of the species or aggregate limits in place at the time of the initial QS allocation will be revoked and redistributed to the remainder of the QS holders in proportion to their QS holdings. No compensation will be due for any revoked shares. Divestiture transfers will be allowed in accordance with the provisions established here and the transfer rules and processes implemented by NMFS. Permit transfers will not be limited or required by the divestiture provision. **Calculation of Aggregate Nonwhiting QS Holdings:** To determining how much aggregate nonwhiting QS an entity holds, an entity's QS for each species will be converted to pounds. This conversion will always be conducted using the trawl allocations applied to the 2010 OYs, until such time as the Council recommends otherwise. Specifically, each entity's QS for each species will be multiplied by the shoreside trawl allocation for that species. The entity's pounds for all nonwhiting species will then be summed and divided by the shoreside trawl allocation of all nonwhiting species to get the entity's share of the aggregate nonwhiting trawl quota. *Note: QS that is not allocated because of the accumulation limits and absence of the grandfather clause will be distributed to other eligible recipients in a manner that maintains the distribution among groups specified in A-2.1.1 and based on the allocation formulas specified in A-2.1.3.*
A-2.3	Program Administration		
A-2.3.1	Tracking, Monitoring and Enforcement		It is the Council intent to provide NMFS flexibility sufficient to design and implement a tracking and monitoring program that will achieve the goals and objectives of the trawl rationalization program. **Discarding by Shoreside Sector** Nonwhiting – Discarding of IFQ species allowed, discarding of IBQ species required, discarding of nongroundfish species allowed. Whiting Maximized retention vessels: Discarding of fish covered by IFQ or IBQ, and nongroundfish species prohibited. Vessels sorting at-sea: Same as for nonwhiting. **At-Sea Catch Monitoring for Shoreside Sector** Nonwhiting – The sorting of catch, the weighing and discarding of any IBQ and IFQ species, and the retention of IFQ species must be monitored by the observer. Whiting For maximized retention vessels: video monitoring as proposed under Amendment 10. Observers would be required in addition to or as a replacement for video monitoring. For vessels that sort at-sea: The sorting, weighing and discarding of any IFQ or IBQ species must be monitored by an observer with supplemental video monitoring. Shoreside Landings Monitoring The sorting, weighing and reporting of any IFQ species must be monitored by a shoreside landings monitor (IBQ will have been discarded at sea).

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2.3.1	continued		**Catch Tracking Mechanisms for Shoreside Sector** **Electronic vessel logbook report** VMS-based electronic logbook required to be transmitted from vessel. At-sea entry by vessel personnel required including catch weight by species and if retained or discarded. **Vessel landing declaration report** Mandatory declaration reports. **Electronic ITQ landing report** Mandatory reports completed by processors and similar to electronic fishticket report. **Processor production report** Mandatory reports (possible inclusion of proprietary data included to be recommended as option is fleshed out). **Cost Control Mechanisms for Shoreside Sector** **Shoreside landing hour restrictions** Landing hours may be restricted. **Shoreside site Licenses** Mandatory license for shoreside deliveries. License can be issued to any site that meets the monitoring requirements. **Vessel Certification** Mandatory certification. Certificate can be issued to any vessel that meets the monitoring requirements. **Program Performance Measures for Shoreside Sector** Integrate into the tracking and monitoring program the collection of data on cost, earnings and profitability; economic efficiency and stability; capacity measures; net benefits to society; distribution of net benefits; product quality; functioning of quota market; incentives to reduce bycatch; market power; spillover effects into other fisheries; contribution to regional economies (income and employment); distributional effects/community impacts; employment in seafood catching and processing; safety; bycatch and discards; administrative, enforcement, and management costs. (See A-2.3.2)
A-2.3.2	Socio-Economic Data Collection		The data collection program will be expanded and submission of economic data by harvesters and processors will be mandatory. Random and targeted audits may be used to validate mandatory data submissions. See footnote for a full description[cc] Information on QS transaction prices, will be included in a central QS ownership registry. *NOTE: Data collection started before the first year of implementation would be beneficial, in order to have a baseline for comparison.*
A-2.3.3	Program Costs	a Cost Recovery	Fees up to three percent of exvessel value, consistent with 303A(e) of the MSA may be assessed. Cost recovery shall be for costs of management, data collection, analysis, and enforcement activities.
		b Fee Structure	To be determined. The TIQC recommended a fee structure that reflects usage. A fee structure that allows for equitable sharing of observer costs for smaller vessels may be developed.

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-2.3.4	Program Duration and Modification		The Council shall begin a review of the IFQ program no later than 5 years after implementation of the program. The review will evaluate the progress the IFQ program has made in achieving the goal and objectives of Amendment 20. The result of this evaluation could include dissolution of the program, revocation of all or part of quota shares, or other fundamental changes to the program. Holders of quota shares should remain cognizant of this fact when making decisions regarding their quota shares, including buying selling, and leasing of these shares. The Council shall consider the use of an auction or other nonhistory based methods when distributing quota share that may become available after initial allocation. This may include quota created when a stock transitions from overfished to nonoverfished status, quota not used by the adaptive management program, quota forfeited to "use it or lose it" provisions, and any quota that becomes available as a result of the initial or subsequent reviews of the program. The specific form of the auction or other method of distribution shall be designed to achieve the goals of Amendment 20, specifically including minimizing the adverse effects from an IFQ program on fishing communities to the extent practical. After the initial review, there will be a review process every four years. A community advisory committee will take part in the review of IFQ program performance.
A-3	**Adaptive Management (also see Section A-9)**		Ten percent of the nonwhiting QS will be reserved to facilitate adaptive management in the shoreside nonwhiting sector. Therefore, each year 10 percent of the shoreside trawl sector nonwhiting quota pounds will be available for use in adaptive management (adaptive management QP). The set aside will be used to address the following objectives. o Community stability o Processor stability o Conservation o Unintended/Unforeseen consequences of IFQ management. o Facilitating new entrants. **Years One and Two.** During the first two years in which the IFQ program is in place, the method to be used in distributing QP in years three through five will be determined, including. o The decision making and organization structure to be used in distributing the QP set aside[dd] o The formula for determining community and processor eligibility, as well as methods for allocation, consistent with additional goals. o The division of QP among the states. o Whether to allow the multi-year commitment of QP to a particular project. **Years Three through Five.** QP will be distributed through the organizational structure, decision process, formulas and criteria developed in years one and two and implemented through subsequent Council recommendation and NMFS rule making processes. Consideration will be given to the multiyear commitment of QP to particular projects (three year commitments). **Review and Duration.** The set aside of QP for the identified objectives will be reviewed as part of the year five comprehensive review and a range of sunset dates will be considered, including 10, 15, 20 year and no sunset date options.

Table D-1 cont. Full description of the IFQ program

	Element	Sub-element	
A-4	**Pacific Halibut IBQ—nonretention**		IBQ for Pacific halibut bycatch in the trawl fishery will be established. The IBQ will be required to cover legal and sublegal sized Pacific halibut bycatch mortality in the area north of 40°10 N latitude. It is the intent of the Council that halibut IBQ mortality be estimated on an individual vessel basis. Such IBQ will be issued on the basis of a bycatch rate applied to the target species QS an entity receives in a manner similar to that described in Section A-2.1.3.a, for overfished species caught incidentally. Area-specific bycatch rates may be used for allocation but halibut IBQ will not be geographically subdivided.

[a] California halibut gear of 7.5" or greater used in state waters would be exempted.

[b] Mandatory gear conversion (the permanent switching from trawl to some other gear) was considered but not included at this time.

[c] Since the shoreside trawl sector covers all shoreside deliveries, this implies that IFQ issued for the shoreside trawl sector may not be used for at-sea deliveries (i.e., may not be used to cover deliveries made to motherships or catch by catcher-processors).

[d] Not withstanding this provision, a vessel with a LE trawl permit may catch the trawl QP with a nontrawl gear, as per Section A-1.1.

[e] At present there are no groundfish species for which the harvest in the trawl fishery is managed differently by geographic area. An example of an area specific precautionary policy from outside trawl fishery management is the geographic differential recommended by the Scientific and Statistical Committee for lingcod. Lingcod is monitored and managed differently in different geographic areas though there is a single coastwide ABC and OY for lingcod. Since there are no geographic subdivisions in the trawl management measures for lingcod, it is assumed that lingcod trawl IFQ will not be geographically subdivided.

[f] Such changes in latitudinal area management may occur as a result of changes in the management areas for species/species complexes in the ABC/OY table or as a result of separate Council action to change the trawl QS by area. In either case, specific Council action will be required to change the management areas and such action will be accompanied by appropriate supporting analysis and public comment opportunity.

[g] The Council authority to establish or modify RCAs will not be changed by this program.

[h] A whiting QP rollover provision was considered but rejected from further analysis. This provision would have allowed unused QP to be reclassified so that they could be used in any whiting sector.

[i] The current process for changing the whiting fishery opening dates involves a regulatory amendment developed under the FMP through a framework process. Implementation of an IFQ program should not change this process.

[j] "**Processors"** are defined as follows:
An at-sea processor is a vessel that operates as a mothership in the at-sea whiting fishery or a permitted vessel operating as a catcher-processor in the at-sea whiting fishery.

A shoreside processor is an operation, working on US soil, that takes delivery of trawl-caught groundfish that has not been "processed at-sea" and that has not been "processed shoreside"; and that thereafter engages that particular fish in "shoreside processing." Entities that received fish that have not undergone "at-sea processing" or "shoreside processing" (as defined in this paragraph) and sell that fish directly to consumers shall not be considered a "processor" for purposes of QS allocations.

"Shoreside Processing" is defined as either of the following:

1. Any activity that takes place shoreside; and that involves: cutting groundfish into smaller portions; OR freezing, cooking, smoking, drying groundfish; OR packaging that groundfish for resale into 100 pound units or smaller for sale or distribution into a wholesale or retail market.

Table D-1 cont. Full description of the IFQ program

OR

2. The purchase and redistribution into a wholesale or retail market of live groundfish from a harvesting vessel.

[k] Transfer of physical assets alone should not be considered a basis for successor in interest. Business relationships such as transfer of the company name and customer base might be reasonable evidence of successor in interest.

[l] Due to the divestiture provision of Section A-2.3.2.e, it is relatively unlikely that accumulation limits will constrain the amount of QS an entity receives in the initial allocation. However, if an entity qualifies for QS in excess of accumulation limits and is does not qualify to receive that QS under the divestiture provision, the initial allocation will be constrained by first applying the aggregate limits and then, if necessary, the individual species limits. In using this approach, the entity's QS allocation should not be scaled back more than necessary to stay within limits and any QS not allocated will be reallocated to other QS recipients.

[m] State landings receipts (fishtickets) will be used to assess landings history for shoreside deliveries. In some cases, fishticket records do does not identify species to the same level of detail used for the IFQ management units (e.g., reports "unspecified rockfish"). Under such circumstances standard species composition routines usually used at the port level have been applied to vessel level data to estimate the species composition of such landings. In some instances, even after applying species composition information there may be some fishticket records with a species groundfish categorization that does not match with one of the IFQ management units. Under such circumstances, when the initial allocations are made, other information on the landings records and in logbooks might be used to assign the landing to its most probable species category.

[n] The intent is to provide an allocation method for QS for overfished species which addresses the vessel's need to have the QS to cover incidental catch in fisheries that target healthy stocks. The method would attempt to allocate the species to those who will be receiving QS for related target species. By allocating overfished species QS to those most in need of it, such an allocation would be expected to reduce transition costs. Currently, the list of overfished species that fall into this category is as follows: canary rockfish, darkblotched rockfish, Pacific Ocean perch, widow rockfish, and yelloweye rockfish. This list may change by the time the program is ready to be implemented. If a major target species became overfished, it would not be intended that such a species would be allocated via an alternative method (for example species such as Dover sole, sablefish, or Pacific whiting).

[o] The four areas are as follows: (1) north of 47°40 N latitude; (2) between 47°40 N latitude and 43°55 N latitude; (3) between 43°55 N latitude and 40°10 N latitude; and (4) south of 40°10 N latitude.

[p] In order to determine an amount of aggregate target species to which bycatch rates will be applied, each vessel's QS will be multiplied by the trawl allocation at the time of implementation.

[q] State landings receipts (fishtickets) will be used to assess landings history for shoreside deliveries.

[r] Catch area data on fishtickets are not considered appropriate for this purpose. The catch area field is often filled out by fish receivers that do not know the area in which the vessel fished. Additionally catch area is often left unspecified. Therefore, it will be assumed that all catch comes from ocean areas near the port of landing.

[s] March 2010. Changed from 1994-2004 to 1998-2003 to reflect Council action of November 2008.

[t] Unless there is a change in the total OY or other factors affecting trawl allocation for the areas involved, in which case their change in QP would be proportional to the change in the trawl allocation.

[u] QP from a subsequent year may not be accessed until such QP have been issued by NMFS.

[v] Including QS that an entity received in excess of accumulation limits in place at the time of initial allocation (see Section A-2.2.3.e).

[w] Carryover of deficits provides some flexibility to use pounds from a year to cover a deficit from a previous year. Without a carryover provision, a vessel would still need to use pounds in a subsequent year to cover an overage but would incur a violation.

[x] The following is the text deleted from this section: "No QS use-or-lose provision has been specified. The need for this provision will be evaluated as part of program review process, and the provision could be added later, if

necessary. *Section A-2.2.3.b contains a provision mandating the transfer of QP to vessels each year. This is intended to encourage QP use."*

[y] QS may be transferred on a temporary basis through private contract (leased) but NMFS will not track lease transfers differently than any other transfer.

[z] The "vessel" accumulation limit was originally termed a "permit" limit. The term "permit" was changed to "vessel" to be consistent with Section A-2.1.3, which indicates that QP go into vessel accounts, not permit accounts. The term "own or control" was shortened to "control" for simplicity. "Control" includes ownership and therefore is inclusive of "ownership."

[aa] It is the Council intent that control limits should not constrain the formation of risk pools to help the fishermen deal with overfished species constraints, so long as the pools do not undermine the effectiveness of the accumulation limits. A risk pool is one in which two or more people enter into an agreement whereby if one person does not have the QP the others would agree to provide the QP, if they have them. Whether these kinds of agreements are informal or formal, as other considerations and conditions are added to the agreements they may begin to constitute control. It is the Council intent to allow for these pooling agreements, so long as they do not become control.

[bb] For example, if a person has a 50 percent ownership interest in that entity, then 50 percent of the QS owned by that entity will count against the individual's accumulation limit unless it is otherwise determined that have effective control of a greater or lesser amount.

[cc]**Expanded data collection** would include:

mandatory submission of economic data for LE trawl industry (harvesters and processors),

voluntary submission of economic data for other sectors of the fishing industry,

transaction value information in a centralized registry of ownership, and

formal monitoring of government costs.

Mandatory Provisions: The Pacific Fishery Management Council and NMFS shall have the authority to implement a data collection program for cost, revenue, ownership, and employment data, compliance with which will be mandatory for members of the west coast groundfish industry harvesting or processing fish under the Council's authority. Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA.

A mandatory data collection program shall be developed and implemented as part of the groundfish trawl rationalization program and continued through the life of the program. Cost, revenue, ownership, employment and other information will be collected on a periodic basis (based on scientific requirements) to provide the information necessary to study the impacts of the program, including achievement of goals and objectives associated with the rationalization program. These data may also be used to analyze the economic and social impacts of future FMP amendments on industry, regions, and localities. The program will include targeted and random audits as necessary to verify and validate data submissions. Additional funding (as compared to status quo) will be needed to support the collection of these data. The data collected would include data needed to meet MSA requirements (including antirust).

The development of the program shall include: a comprehensive discussion of the enforcement of such a program, including discussion of the type of enforcement actions that will be taken if inaccuracies are found in mandatory data submissions. The intent of this action will be to ensure that accurate data are collected without being overly burdensome on industry in the event of unintended errors.

Voluntary Provisions: A voluntary data collection program will be used to collect information needed to assess spillover impacts on nontrawl fisheries.

Table D-1 cont. Full description of the IFQ program

Central Registry: Information on transaction prices will be included in a central registry of QS owners. Such information will also be included for LE permit owners/lessees.

Government Costs: Data will be collected and maintained on the monitoring, administration, and enforcement costs related to governance of the trawl rationalization program.

[dd] The following are three options for the sequences of agency involvement in decision making for the distribution of adaptive management QP after year 2..

1. NMFS
2. State → Council →NMFS
3. Council →NMFS

Table D-2. Control and vessel limit options: Council preferred alternative.

Species Category	Vessel Limit (Applies to all QP in a Vessel Account, Used and Unused)	Vessel Unused QP Limit	QS Control Lim
Nonwhiting Groundfish Species	3.2%		2.7%
Lingcod - coastwide	3.8%		2.5%
Pacific Cod	20.0%		12.0%
Pacific whiting (shoreside)	15.0%		10.0%
Pacific whiting (mothership)	30.0%		20.0%
Sablefish			
N. of 36° (Monterey north)	4.5%		3.0%
S. of 36° (Conception area)	15.0%		10.0%
PACIFIC OCEAN PERCH	6.0%	4.0%	4.0%
WIDOW ROCKFISH *	8.5%	5.1%	5.1%
CANARY ROCKFISH	10.0%	4.4%	4.4%
Chilipepper Rockfish	15.0%		10.0%
BOCACCIO	15.4%	13.2%	13.2%
Splitnose Rockfish	15.0%		10.0%
Yellowtail Rockfish	7.5%		5.0%
Shortspine Thornyhead			
N. of 34°27'	9.0%		6.0%
S. of 34°27'	9.0%		6.0%
Longspine Thornyhead			
N. of 34°27'	9.0%		6.0%
COWCOD	17.7%	17.7%	17.7%
DARKBLOTCHED	6.8%	4.5%	4.5%
YELLOWEYE	11.4%	5.7%	5.7%
Minor Rockfish North			
Shelf Species	7.5%		5.0%
Slope Species	7.5%		5.0%
Minor Rockfish South			
Shelf Species	13.5%		9.0%
Slope Species	9.0%		6.0%
Dover sole	3.9%		2.6%
English Sole	7.5%		5.0%
Petrale Sole	4.5%		3.0%
Arrowtooth Flounder	20.0%		10.0%
Starry Flounder	20.0%		10.0%
Other Flatfish	15.0%		10.0%
Other Fish	7.5%		5.0%
Pacific Halibut	14.4%	5.4%	5.4%

* If widow rockfish is rebuilt before initial allocation of QS, the vessel limit will be set at limit will be 1.5 times the control limit.

D.4 Whiting At-sea Trawl Sector: Cooperative Program (Appendix B of the EIS)

The at-sea whiting sector co-op program is described generally below. Table D-3 provides an outline of the sections of the program. A full description of the co-op programs follows Table D-3, beginning with a section on management of the whiting fishery and followed by sections on the MS and CP sectors of the whiting fishery (the "at-sea" sectors).

The Council considered but did not adopt a co-op program for the shoreside whiting fishery. Instead, the shoreside whiting sector was merged with the nonwhiting sector, both to be managed with IFQs. However, section placeholders for the shoreside whiting co-op program are maintained in this document so that the numbering system will correspond to the numbering of the alternatives and sections of the analysis as they are laid out in the EIS.

D.5 Overview of Co-op Program Elements

D.5.1 At-sea Whiting Sector Management under Co-ops

While co-ops will be used to control the harvest within the at-sea whiting sectors, a number of management measures will still be required to control competition between the whiting sectors. This section covers those measures along with other measures that will apply to all sectors managed under co-ops, such as observer requirements and mandatory submission of economic data. The description of the co-op management program for each at-sea whiting sector starts in Section D.5.2.

The existing allocation of whiting between the shoreside, MS, and CP sectors will not change under the rationalization program (42, 24, and 34 percent, respectively).

Provisions also address bycatch in the at-sea whiting fishery (particularly that of certain overfished species). The Council is recommending incidental groundfish species caps for each of the whiting sectors, for the co-op and non-co-op fisheries within the MS sector, and for the co-ops within the MS sector. Within sectors, bycatch allocations would be pro rata, based on the amount of whiting allocated to that sector.

Area closures may be used to control the pace of the fishery. For the MS sector, the fishery will be divided into a co-op fishery and a non-co-op fishery (for those who do not desire to take part in a co-op). Participants in the non-co-op fishery will not have a claim to a particular amount of the fish allocated to that fishery; therefore the vessels will likely race to harvest the available allocation.

NMFS will close the whiting fishery, a particular sector, the co-op or non-co-op fishery within a sector, or individual co-ops, as appropriate, when it is projected that a whiting catch or bycatch limit will be reached. With respect to co-ops, inseason monitoring and closure will be needed only at the highest level of aggregation of the co-ops. For example, if individual co-ops join together to form an inter-co-op that covers the entirety of one of the whiting sectors, then NMFS will track and close at the sector level. Nevertheless, vessel level monitoring will still be required to ensure that catch is accurately recorded.

Given the high level of monitoring already in place in the whiting fishery, only moderate changes in monitoring are needed to implement this program for the at-sea whiting fishery. For the at-sea segment of the fishery, 100 percent coverage aboard MS and CP will continue. A program for the mandatory submission of economic data is also included to facilitate monitoring program performance.

D.5.2 Co-ops for Catcher Vessels Delivering to Motherships

Under this program, those who hold whiting-endorsed permits for catcher vessels in the MS sector will choose each year whether to be part of a co-op or to register to fish in the non-co-op portion of the fishery. The holders of catcher vessel permits with mothership whiting endorsements will form the co-ops. Based on its catch history, each permit that qualifies for a mothership whiting endorsement will be capped at a portion of the history (endorsement share) of the MS sector allocation of whiting and bycatch species. Each year, NMFS will distribute a catch allocation to each catcher vessel co-op based on the sum of the endorsement shares for the permits registered to that co-op. NMFS will also distribute a catch allocation each year to the non-co-op portion of the fishery, based on the collective endorsement shares of the permits opting to participate in the non-co-op fishery.

The co-op organization will coordinate harvest by its members. Although co-op agreements will include a mandatory clause that the catch allocation made to a member must equal the amount that the member brings into the co-op, co-op members may transfer catch allocations among themselves. Similarly, if multiple co-ops join to form an inter-co-op, one co-op will be have to transfer catch allocation to another co-op within that inter-co-op. NMFS will not necessarily have to track transfers among co-op members or within an inter-co-op.

The class of motherships will be closed by creating a LE permit for mothership vessels. There will be restrictions limiting a vessel's ability to both catch and operate as a mothership in the whiting fishery in the same year. This will limit the ability of processing vessels to move between the CP and MS sectors.

Prior to the start of each season, each catcher vessel permit desiring to participate in the co-op fishery will obligate itself to deliver its catch to a particular MS. The obligation to a particular co-op or MS will not carry over from one year to the next, it may be changed at the catcher vessel permit owners discretion based on its preseason declaration. While catch may be transferred among participants in a co-op or inter-co-op, such transfers would not change the MS to which the catch is obligated, unless a mutual agreement is reached.

As in the IFQ program, accumulation limits will be imposed to prevent excessive concentration of catch allocations. They will cap the proportion of whiting that an individual or entity can process, the proportion of whiting an individual or entity could accumulate via ownership of catcher vessel permit(s), and the amount that can be landed by any catcher vessel.

D.5.3 Co-ops for Catcher-Processors

Under the CP co-op program, as under status quo, a voluntary CP co-op may continue to be formed by CP permit holders. This system will continue as long the existing co-op system continues to operate successfully, or until the FMP is otherwise amended. If the voluntary co-op system fails, it will be replaced with an IFQ system. Currently the co-op operates under a private contract that includes division of the harvest among participants according to an agreed schedule. If the co-op system fails, IFQ will be allocated equally to each CP permit (equally divided among all CP endorsed permits).

Under the CP co-op program, the main Council recommendations are the creation of a CP endorsement to close the CP fishery to new entrants and the assignment of an allocation to the voluntary CP co-op. The endorsement will be granted to LE permits registered to CP vessels if the vessels meet specified qualification criteria. Only vessels with a CP LE permit will be allowed to harvest fish from the CP sector's allocation. LE permits with CP endorsements will continue to be transferable. NMFS will not establish an allocation of catch or catch history among CP permits unless the co-op fails. NMFS will

specify the assignment of the CP sector allocation to the CP sector co-op in regulation. If necessary, a closure will be used to keep the CP sector from exceeding its allocation of whiting and bycatch species.

D.6 Detailed Specification of Co-op Program Elements

Table D-3 Overview of the co-op program.

B.1	***Whiting Sector Management Under Co-ops***
B-1.1	Whiting Management

B-4.2	Co-op Formation and Operation Rules
B-4.3	NMFS Role

B-1 Whiting Sector Management Under Co-ops

B-1.1 Whiting Management

Under the co-op program, catcher vessel permits for the MS sector will be endorsed for deliveries to motherships and amounts of history assigned to each catcher vessel permit based on past harvest in the fishery. Catcher-processor permits will be endorsed for participation in the CP sector.

The whiting catch history calculation for each mothership-endorsed catcher vessel permit [CV(MS)] will be assigned to a pool for the co-op in which the permit will participate, or to a pool for the mothership non-co-op fishery. NMFS will make an allocation assignment to the CP sector co-op based on the allocation to the CP sector. Co-ops are responsible for monitoring and enforcing the catch limits of co-op members.

NMFS will monitor the catch in the mothership non-co-op fishery, the mothership co-op fishery, the CP fishery, and the overall whiting catch of all at-sea sectors. NMFS will close each segment of the fishery based on projected attainment of whiting catch. Additionally, all at-sea sectors will be subject to closure based on attainment of the overall trawl whiting allocation.

B-1.2 Annual Whiting Rollovers

There will not be a rollover of unused whiting from one sector to another.

B-1.3 Bycatch Species Management

For the near future, the whiting fishery will be managed under bycatch limits (hard caps) for widow, canary, darkblotched rockfish, and Pacific ocean perch. The catch of all groundfish will be accounted for and tracked against the OY.

The ESA-listed salmon bycatch management measures—that is, the 11,000 Chinook threshold, 0.05 rate threshold, and triggered 100 fathom closure—will also continue to be in place.

The goal of bycatch management is to control the rate and amounts of rockfish and salmon bycatch to ensure that each sector is provided an opportunity to harvest its whiting allocation.

There will be a set aside of Pacific halibut for the at-sea whiting fishery, as specified in the intersector allocation process (Amendment 21).

B-1.3.1 Bycatch Allocation Subdivision

Subdivide bycatch species managed with hard caps (widow, canary, darkblotched rockfish, and Pacific Ocean perch) among each of the whiting sectors; within the sectors subdivide between the co-op fishery and non-co-op fishery (subdivision for the non-co-op fishery does not apply to the CP co-op program); and subdivide among co-ops.

Only those species with hard caps will be subdivided for bycatch management, and bycatch will be allocated to each permit and co-op pro rata in proportion to its whiting allocation. The MS sector's bycatch allocation will be divided between its co-op and non-co-op fishery, based on the allocations made to the permits participating in each portion of the fishery.

B-1.3.2 Bycatch Management

All sectors and co-ops will close based on projected attainment of the at-sea whiting fishery bycatch cap for any one species. The mothership co-op fishery, non-co-op fishery, and CP fishery will each be closed based on projected attainment of their individual allocation. Additionally, each co-op will cease fishing when its bycatch allocation is reached.

The Council may also use area closures (seasonal or year-round) to manage overfished stocks in the co-op and non-co-op fisheries. The area closures may be the same or different for different species. Area closures may be year-round, seasonal, or triggered automatically by the attainment of certain levels of catch.

Unused bycatch may be rolled over from one sector to another if the sector's full allocation of whiting has been harvested or participants in the sector do not intend to harvest the remaining sector allocation.

.

B-1.4 At-sea Observers/ Monitoring

At-sea Whiting Fishery: 100 percent observer coverage aboard MS and CP will continue. Observers would be required in addition to or as a replacement for video monitoring.[6]

For some coverage, cameras may be used in place of observers (feasibility to be determined). It is the Council's intent to provide NMFS flexibility sufficient to design and implementation a tracking and monitoring program that will achieve the goals and objectives of the trawl rationalization program.

B-1.5 Mandatory Data Collection

The following are the central elements of the data collection program that will be implemented as part of the co-op program.

- Mandatory submission of economic data for LE trawl industry (harvesters and processors).
- Voluntary submission of economic data for other sectors of the fishing industry.
- Include transaction value information in a centralized registry of ownership.
- Formal monitoring of government costs.

Mandatory Provisions. The Council and NMFS shall have the authority to implement a data collection program for cost, revenue, ownership, and employment data, compliance with which will be mandatory for members of the west coast groundfish industry harvesting or processing fish under the Council's authority. Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA.

[6] February 2010: The second sentence of this paragraph was adopted as part of the Council's November 2008 motion, but it was located under the section on the IFQ program rather than the section on the mothership co-op program.

A mandatory data collection program shall be developed and implemented as part of the groundfish trawl rationalization program and continued through the life of the program. Cost, revenue, ownership, employment and other information will be collected on a periodic basis (based on scientific requirements) to provide the information necessary to study the impacts of the program, including achievement of goals and objectives associated with the rationalization program. These data may also be used to analyze the economic and social impacts of future FMP amendments on industry, regions, and localities. The program will include targeted and random audits as necessary to verify and validate data submissions. *Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA*. Additional funding (as compared to status quo) will be needed to support the collection of these data. The data collected would include data needed to meet MSA requirements (including antirust).

The development of the program shall include a comprehensive discussion of the enforcement of such a program, including discussion of the type of enforcement actions that will be taken if inaccuracies are found in mandatory data submissions. The intent of this action will be to ensure that accurate data are collected without being overly burdensome to industry in the event of unintended errors. Annual reports will be provided to the Council.

Voluntary Provisions: A voluntary data collection program will be used to collect information needed to assess spillover impacts on nontrawl fisheries.

Central Registry: Information on transaction prices will be included in a central registry of whiting endorsed permit and MS permit owners. Such information will also be included for sales and lessees.

Government Costs: Data will be collected and maintained on the monitoring, administration, and enforcement costs related to governance of the rationalization program.

B-1.6 Adaptive Management

There will not be an adaptive management set aside for the at-sea whiting fisheries. *(This section is being maintained as a placeholder so that numbering will correspond to that used in the alternatives and analysis of the EIS.)*

B-1.7 Length Endorsement

Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained; however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e., length endorsements will not change when a trawl endorsed permit is transferred to a smaller vessel).

B-2 Whiting Mothership Sector Co-Op Program

Overview. Qualified permits will be endorsed for MS co-op participation. Each year the holders of those permits will choose whether their vessels will fish in the co-op fishery, in which individual co-ops will direct harvest, or fish in a non-co-op fishery that will be managed by NMFS as an Olympic style fishery. The co-op will be obligated to deliver its fish to specific MS processors based on the obligations of each permit in the co-op determined based on preseason declarations. LE permits will be issued for motherships and required for a mothership to receive whiting from catcher vessels.

B-2.1 Participation in the Mothership Sector

a. Catcher Vessels

Vessels with CV(MS)-endorsed permits may participate in either the co-op or non-co-op portion of the mothership fishery. They will choose annually which fishery they will participate in for the coming year. Additionally, any groundfish LE trawl permitted vessels may participate in the co-op portion of the fishery if they join a co-op (as described in Section B-2.3.3).[7] No other catcher vessels may participate in the mothership fishery.

A vessel may not engage in the processing of whiting during any year in which a catcher vessel (mothership) (CV[MS]) endorsed permit is registered for use with the vessel.

b. Processors

Only motherships with a mothership LE permit may receive deliveries from catcher vessels participating in the co-op or non-co-op portions of the MS sector whiting fishery. [Note: motherships may acquire such permits by transfer; see Section B-2.2.2.]

c. Vessels Excluded[8]

Motherships also operating as a CP may not operate as a mothership: during a year in which it also participates as a CP.

[7] When such permits participate in a co-op, the co-op will not be allocated any additional fish based on participation by such a vessel.

[8] A vessel that has been under foreign registry after the date of the AFA and that has participated in fisheries in the territorial waters or exclusive economic zones of other countries will not be eligible to participate as a mothership in the mothership sector of the Pacific whiting fishery, as per the AFA's modification of Section 12102(c)(6) of the USC. Section 12102(c)(6) of the USC has since been renumbered.

B-2.2 Permits/Endorsement Qualification and Characteristics

B-2.2.1 Catcher Vessel Mothership (CV[MS] Whiting Endorsement)

a. Endorsement Qualification and History Assignment

Permits with a qualifying history will be designated as CV(MS) permits through the addition of an endorsement to their LE groundfish permit. At the time of endorsement qualification, each permit will also be assigned a catch history that will determine the share of the mothership whiting allocation associated with that permit.

Qualifying for a CV(MS) Whiting Endorsement. A LE permit will qualify for a CV(MS) whiting endorsement if it has a total of more than 500 mt of whiting deliveries to motherships from 1994 through 2003.

Catch History Assignment (Identification of Endorsement Related Catch History). The initial catch history calculation for CV(MS) whiting endorsements will be based on whiting history of the permit for 1994 through 2003, dropping two[9] years. A permit's history for each year will be measured as a share of the fleet history for that year (i.e., "relative pounds" will be used). This catch history will be used by NMFS to assign both whiting and bycatch species allocations to the co-ops and non-co-op fishery pools, as per section B.1.3.2.

For the purpose of the endorsement and initial calculation, catch history associated with the permit includes that of permits that were combined to generate the current permit.

b. Whiting Permit and Endorsement Transferability and Endorsement Severability

The CV(MS) whiting endorsement (together with the associated catch history) *may not be* severed from the groundfish LE trawl permit. Catch history associated with the whiting endorsement may not be subdivided. CV(MS) permits may be transferred two times during the fishing year, provided that the second transfer is back to the original catcher vessel (i.e., only one transfer per year to a different catcher vessel).

c. Accumulation Limit

CV(MS) Permit Ownership: No individual or entity may own CV(MS) permits for which the allocation total is greater than 20 percent.
Catcher Vessel Usage Limit: No vessel may catch more than 30 percent of the MS sector's whiting allocation.

[9] February 2010: The word "worst" was removed in line with the Council's April 2009 action specifying that the permit owner would be allowed to select the years dropped from the calculation.

d. Combination

CV(MS) Permit Combination to Achieve a Larger Size Endorsement. When a CV(MS)-endorsed permit is combined with another permit (including unendorsed permits), the resulting permit will be CV(MS) endorsed.[10]

B-2.2.2 Mothership Processor Permit

a. Qualifying Entities

The owners of qualifying motherships will be issued MS permits. In the case of bareboat charters, the charterer of the bareboat will be issued the permit.

b. Qualification Requirements

A qualifying mothership is one which processed at least 1,000 mt of whiting in each of any two years from 1997 through 2003.

c. Transferability

1. MS permits will be transferable.
2. MS permits may be transferred to a vessel of any size (there will be no size endorsements associated with the permit). MS permits **may not** be transferred to a vessel engaged in the *harvest* of whiting in the year of the transfer.
3. Limit on the Frequency of Transfers: MS permits may be transferred two times during the fishing year provided that the second transfer is back to the original mothership (i.e., only one transfer per year to a different mothership).

d. Usage Limit

No individual or entity owning a MS permit(s) may process more than 45 percent of the total MS sector whiting allocation.

B-2.3 Co-op Formation and Operation Rules.

B-2.3.1 Who and Number of Co-ops

Co-ops are not required but may be voluntarily formed among CV(MS) permit owners. The number of co-ops will be indirectly limited by the limit on the minimum number of vessels able to form a co-op (see Section 2.3.3-b).

[10] Specifically, a CV(MS)-endorsed permit that is combined with a LE trawl permit that is not CV(MS) endorsed or one that is CV(Shoreside) [CV(SS)] endorsed will be reissued with the CV(MS) endorsement. If the other permit is CV(SS) endorsed, the CV(SS) endorsement will also be maintained on the resulting permit. However, CV(MS) and CV(SS) catch histories will be maintained separately on the resulting permit and be specific to participation in the sectors for which the catch histories were originally determined. If a CV(MS) permit is combined with a CP permit, the CV(MS) endorsement and history will not be reissued on the combined permit. The size endorsement resulting from permit combinations will be determined based on the existing permit combination formula.

B-2.3.2 When

Each year at a date certain prior to the start of the fishery, MS and CV(MS) permit holders planning to participate in the MS sector must register with NMFS. At that time CV(MS), permit holders must identify which co-op they will participate in or if they plan to participate in the non-co-op fishery.

B-2.3.3 Co-op Agreement Standards

a. Submissions to NMFS and the Council

Co-op permit and agreement. Federal co-op permits will be issued for co-op agreements approved by NMFS. Signed copies of the cooperative contracts must be filed with the Council and NMFS and available for public review before the co-op is authorized to engage in fishing activities.[11] Any material changes or amendments to the contract must be filed annually with the Council and NMFS by a date certain.

Letter to Department of Justice. Co-ops must also file with the Council and NMFS a copy of a letter from the co-op requesting a business review letter on the fishery cooperative from the Department of Justice and any response to such request.

b. Number of Participants in Each Co-op (Including Inter-co-ops)

CV permits may join together in separate harvester co-ops. A minimum of 20 percent of the CV(MS) permit holders are required to form a co-op.[12] Co-ops may form co-ops with other co-ops. Within one of the whiting sectors, these co-ops may be formed to manage directed catch and/or bycatch. Whiting and bycatch allocations may be transferred among co-ops through inter-co-op agreements.

c. Catch History Distributions among Permits

Co-op agreements must stipulate that catch allocations to members of the co-op be based on their catch history calculation by NMFS used for distribution to the co-op.

d. Participation by Non-CV (MS) Endorsed Permits

Through temporary arrangements a co-op allocation may be harvested by any catcher vessel holding a valid LE trawl permit which has joined the co-op (including one that does not have a CV(MS) endorsement).[13]

e. Other Required Co-op Agreement Provisions

The Council's intent is to have MS sector participants work with NMFS to develop and describe a process and co-op agreement requirements to include in implementing regulations for this action.

[11] During council discussion, this was flagged by NOAA GC as a potential legal problem.

[12] The minimum threshold number of participants required to form a co-op balances the potential advantages for multiple co-ops while limiting implementation and management costs and administrative requirements for managing this sector.

[13] As a member of the co-op, such a vessel would be subject to Section B-2.4 and the indicated processor obligations.

A co-op agreement must include:

1. A list of all vessels, and which must match the amount distributed to individual permit holders by NMFS.
2. Signature of all permit holders participating in the co-op.
3. A plan to adequately monitor catch and bycatch.
4. Adequate enforcement and penalty provisions to ensure that catch and bycatch overages do not occur.
5. Measures designed to reduce bycatch of overfished species.
6. An obligation to manage inseason transfers of catch history.
7. A requirement that agreement by at least a majority of the members is required to dissolve a co-op (**During council discussion this was flagged by NOAA GC as a potential legal problem**).
8. An obligation to produce an annual report to the Council and NMFS by a date certain documenting the co-op's catch and bycatch data and inseason transfers (the report is to be available for review by the public).
9. Identification of a co-op manager who will:
    a. serve as the contact person with NMFS, the Council and other co-ops,
    b. be responsible for the annual distribution of catch and bycatch,
    c. oversee transfers,
    d. prepare annual reports, and
    e. be authorized to receive or respond to any legal process against the co-op.
10. Provisions that prohibit co-op membership by permit holders that have incurred legal sanctions that prevent them from fishing groundfish in the Council region.
11. A provision that requires new owners to comply with membership restrictions in the co-op agreements.

f. Additional Provisions for Inter-co-op Agreements

1. In the case of two or more cooperatives entering into an inter-cooperative agreement, the inter-co-op agreement must incorporate and honor the provisions of the individual co-op agreements unless all such agreements (or modifications thereof) are resubmitted for approval.
2. The requirements of Sections 2.3.3.a-2.3.3.e apply to the inter-co-op agreement, except that for the purpose of Section 2.3.3.e., subparagraph 7, the members of the inter-co-ops are the co-ops and not the participants in each co-op.

B-2.3.4 Annual Allocation Transferability

a. The annual allocations received by a co-op based on catch history of the whiting endorsements held by its members may be transferred among co-op members and from one co-op to another so long as obligations to processors are met (as per Section B-2.4). Additionally, in order to transfer annual allocation from one co-op to another there must be a NMFS approved inter-co-op agreement.
b. Allocations may not be transferred from the MS sector to another sector.

B-2.4 Obligations to Processors (Processor Ties)

Each year, a permit will obligate to a processor all of its catch for a coming year.

B-2.4.1 Formation and Modification of Processor Tie Obligations

There will not be a processor tie that carries from one year to the next. CV(MS) permits will be obligated to a single MS permit for an entire year but may change to a different MS permit through a preseason declaration of intent.

Between September 1 and December 31 of the year prior to implementation and every year thereafter, each CV(MS) permit is required to contact NMFS and indicate whether CV(MS) permit will be participating in the co-op or non-co-op fishery in the following year. If participating in the co-op fishery, then CV(MS) permit must also provide the name of the MS permit that CV(MS) permit will be linked to in the following year (i.e., annual catcher vessel, mothership linkage that may be changed each year without requirement to go into the "non-co-op" fishery). Once established, the catcher vessel, mothership linkage shall remain in place until changed by CV(MS) permit. By September 1 of the year prior to implementation and every year thereafter, if CV permit would be participating in the co-op fishery in the following year, then CV permit must notify the MS permit that the CV permit QP will be linked to in the following year.[14]

Mothership Permit Transfer. If a mothership transfers its MS permit to a different mothership or different owner, the CV(MS) permit obligation for that year remains in place and transfers with the MS permit to the replacement mothership unless the obligation is changed by mutual agreement. The obligation does not extend beyond the fishing year.

B-2.4.2 Flexibility in Meeting Obligations to Processors

a. Temporary Transfer of the Annual Allocation Within the Co-op or from One Co-op to Another

When CV(MS) permit owners transfer co-op allocations from one co-op member to another within the co-op or from one co-op to another within an inter-co-op such allocations must be delivered to the mothership to which the allocation is obligated through the preseason declaration, unless released by mutual agreement.

b. Mutual Agreement Exception

By mutual agreement of the CV(MS) permit owner and mothership to which the permit is obligated, a permit may deliver to a licensed mothership other than that to which it is obligated.

B-2.4.3 Mothership Processor Withdrawal

If a mothership withdraws subsequent to quota assignment, then the CV(MS) permit that it is obligated to it is free to participate in the co-op or non-co-op fishery. The MS permit shall notify NMFS and linked CV(MS) permits of its withdrawal, and CV(MS) permits shall notify NMFS of their intent to participate in the co-op or non-co-op fishery thereafter. If continuing in co-op fishery, then CV(MS) permit shall provide NMFS with the name of the new MS permit to which it will be obligated for that season.

[14] February 2010: The last sentence of this paragraph was part of the November 2008 Council motion and was inadvertently omitted from previous drafts of the Council's final preferred alternative. At its June 2010 meeting, the provision was modified to specify September 1 as the notification date. Previously the date was July 1.

B-2.5 NMFS Role

B-2.5.1 Permit and Endorsement Issuance

NMFS will issue all necessary permits and endorsements under the rules specified under this program. Appeals processes will be provided as appropriate and necessary.

B-2.5.2 Fishery Registration and Co-op Approval

NMFS will announce a deadline before which all co-op agreements must be received for the coming year. NMFS will review and approve or reject co-op agreements based on standards provided here and other standards that it deems necessary to achieve the policy intent of the Council's actions.

B-2.5.3 Annual Allocation to Co-ops and the Non-co-op Fishery

a. Co-op Allocation

Each year NMFS will determine the percent of the mothership sector's harvest allocation to be given to each co-op based on the catch history calculation of CV(MS) permits registered to participate in the co-op that year. NMFS does not allocate to the individual permit holder; rather, NMFS allocates an aggregate amount of harvest tonnage annually to the co-op based on the catch histories associated with the members of the co-ops.

b. Non-co-op Allocation

Each year NMFS will determine the distribution to be given to the non-co-op fishery based on the catch history calculation of permit holders registered to participate in that fishery.

B-2.5.4 Fishery Management and Co-op Monitoring

1. NMFS will track all permit transfers and the invocation of mutual agreement exceptions. Permit transfers will not be valid until registered and acknowledged by NMFS.

2. NMFS will monitor catch and close segments of the fishery as necessary to ensure catch limits are not exceeded for:
   a. the whiting mothership co-op fishery
   b. the whiting mothership non-co-op fishery
   c. the mothership whiting sector as a whole
3. NMFS will not necessarily monitor, but will investigate and enforce as it deems necessary, the permit and co-op obligations to motherships.
4. NMFS will not necessarily monitor or enforce (except as it deems necessary):
   a. an individual permit's progress towards its catch allocations (permit level catch control will be at the co-op level and enforced through execution of the private contract)
   b. a co-op's progress toward its catch allocation[15]

[15] This assumes that there is an inter-co-op agreement in place that covers the entire co-op fishery. If such an agreement is not in place covering both catch and bycatch, NMFS may have to monitor catch by each individual

c. actual performance of the co-op agreement (the parties to the contract will resolve through private contract and remedies any deviation from provisions such as that requiring that a vessel have the opportunity to harvest the catch allocated to the co-op based on that vessel's permit, Section B-2.3.3.c)

5. NMFS will monitor other program provisions as needed. In some situations, there may need to be a declaration procedure to determine where a permit is delivering its obligated catch, for example, if a mothership withdraws without transferring its permit or reaching a mutual agreement for the transfer of obligated deliveries to a different mothership.

B-3 Whiting Shoreside Sector Co-Op Program (placeholder, not recommended)

The shoreside whiting sector will be managed with an IFQ program. This section header is being maintained so that section numbering here will correspond to section numbering in the alternatives and analysis in the EIS.

B-4 Catcher-Processors Co-op Program

Catch by the CP sector will be controlled primarily by closing the fishery when a constraining allocation is reached.[16] As under status quo, vessels may form co-ops to achieve benefits that result from a slower-paced, more controlled harvest. The main recommendations are the creation of a limited number of CP endorsements, the requirement that a CP co-op qualify for a Federal co-op permit, and the specification in regulation of the amounts that will be available for harvest by the voluntary co-op. A new entrant will have to acquire a permit with a CP endorsement in order to enter the fishery. If the co-op system fails, it will be replaced by an IFQ program and the initial issuance of IFQ will be allocated equally among the permits (equally divided among all CP endorsed permits).

B-4.1 Participation in the Catcher-Processor Sector , Endorsement Qualification and Permit Transferability.

Catcher-processor (CP) Endorsement. The class of CP endorsed permits (CP permits) will be limited by an endorsement placed on a LE permit. LE permits registered to qualified CP vessels will be endorsed as CP permits. A qualified permit is one that harvested and processed in the CP sector of the Pacific whiting fishery at any time from 1997 through 2003. Only CP vessels with a CP endorsed LE permit will be allowed to process whiting at-sea as part of the CP sector. LE permits with CP endorsements will continue to be transferable.

Participation as Mothership. A CP cannot operate as a mothership during the same year it participates in the CP fishery.

CP Permit Combination to Achieve a Larger Size Endorsement. A CP permit that is combined with a LE trawl permit that is not CP endorsed will result in a single CP permit with a larger size endorsement. (A CV(MS) endorsement on one of the permits being combined will not be reissued on the resulting

co-op (but not by the individual vessels in the co-op).

[16] All references to catcher-processors in this section references to vessels operating in the catcher-processor sector. Vessels under 75' which catch and process at-sea as part of the shoreside sector are not covered here.

permit.) The resulting size endorsement will be determined based on the existing permit combination formula.

CP Permit Transfers to Smaller Vessels. Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained, however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e., length endorsements will not change when a trawl endorsed permit is transferred to a smaller vessel).

Number of Transfers Per Year. CP permits may be transferred two times during the fishing year, provided that the second transfer was back to the original CP (i.e., only one transfer per year to a different CP).

B-4.2 Co-op Formation and Operation Rules

Annual registration. As under status quo, co-op(s) will be formed among holders of permits for CP. Participation in the co-op will be at the discretion of those permit holders. If eligible participants choose to form a co-op, the CP sector will be managed as a private voluntary cooperative and governed by a private contract that specifies, among other things, allocation of whiting among CP permits, catch/bycatch management, and enforcement and compliance provisions. The co-op will submit an application to NMFS for a Federal co-op permit. NMFS will not establish an allocation of catch or catch history among permits unless the sector fails to organize itself under a single co-op agreement that qualifies for a Federal co-op permit. If the co-op system fails, it will be replaced by an IFQ program and the initial issuance of IFQ will be divided equally among all CP endorsed permits.

Annual Reporting Requirements. The CP cooperative will submit an annual report to the Council at their November meeting. The report will contain information about the current year's CP fishery, including the CP sector's annual allocation of Pacific whiting; the CP cooperative's actual retained and discarded catch of Pacific whiting, salmon, rockfish, groundfish, and other species on a vessel-by-vessel basis; a description of the method used by the CP cooperative to monitor performance of cooperative vessels that participated in the CP sector of the fishery; and a description of any actions taken by the CP cooperative in response to any vessels that exceed their allowed catch and bycatch. The report will also identify plans for the next year's CP fishery, including the companies participating in the cooperative, the harvest agreement, and catch monitoring and reporting requirements.

B-4.3 NMFS Role

B-4.3.1 Permit and Endorsement Issuance

NMFS will issue all necessary permits and endorsements under the rules specified under this program. Appeals processes will be provided as appropriate and necessary.

B-4.3.2 Annual Allocation

Harvest amounts for the co-op will be specified in regulation. If the co-op breaks up, IFQ will be issued and divided equally among the 10 permits.

The CP sector allocation may be divided among eligible CP vessels (i.e., those CP vessels for which a CP permit is held) according to an agreed CP cooperative harvest schedule as specified by private contract.

B-4.3.3 Fishery and Co-op Monitoring

1. NMFS will track all permit transfers. Permit transfers will not be valid until registered and acknowledged by NMFS.
2. NMFS will monitor catch and close the CP sector fishery as necessary to ensure catch limits are not exceeded.

ANALYSIS OF THE IMPACT OF THE INITIAL QUOTA SHARE ALLOCATION ON LONG-TERM QUOTA SHARE DISTRIBUTION

Acronym	Definition
IFQ	individual fishing quota
OY	optimum yield
QP	quota pound
QS	quota share

E.1 Introduction

This appendix contains a detailed analysis of the impact of the initial quota share (QS) allocation on long-term QS distribution. We start with some conceptual groundwork in Section E.2 ("Raw Fish Markets and Resource Rent Dissipation or Capture under Status Quo") and Section E.3 (" QP Markets and Interaction with Raw Fish Markets"). The discussion within these sections is presented in the following order:

1. Identify general economic principles.
2. Identify how those principles play out when the fishing industry is highly competitive (i.e., composed of many entities acting independently).
3. Identify what happens if one sector or the other is not highly competitive and define market power.

After that groundwork, we will get into the specific factors affecting QS flow in Section E.4 ("QS Flow among Groups (Independent of the Initial Allocation)"). Each subsection contains the following:

1. A description of the factors of interest and their conditions under status quo
2. A description of how those factors may change under an individual fishing quota (IFQ) program and influence the flow of QS (under fully competitive and less competitive conditions)

Finally, we will summarize the factors affecting flow of QS and consider the effect of the initial QS, allocation on these factors, and the long-term distribution of QS, assuming fully competitive and less than competitive conditions (Section E.5).

This provides the background for the section of Appendix A on the initial allocation among groups (Section A-2.1.1), the impacts of that allocation, how the impacts vary depending on who is given the QS, and differences between the short-term and long-term effects.

As we go through this discussion, it will be important to keep in mind that the markets of focus will be the raw fish market, the exchange between harvesters and processors, and the QS/quota pound (QP) market. Any discussion of the wholesale fish market (market into which the processors sell) will be noted when relevant. Some parts of the discussion will be simplified by focusing primarily on IFQ held as QP. QP are issued annually to those holding QS. Where it is necessary to consider the long-term stream of harvest opportunity, we will focus on IFQ held as QS.

Note: When this analysis was developed, the Council control limit options would have applied such limits to both the ownership of QS and QP. Under such circumstances, the QS control limits would have limited the amount of fish any owner of harvesting operations could take. With the decision to apply the control limit only to QS, entities would be restricted in the amount of QS they could own, but there would be no limit on the total amount of QP they could harvest on their vessels, so long as no individual vessel violates the vessel QP limit. Therefore, an entity could own as many vessels and harvest as much fish as it wanted (subject to antitrust considerations), but it would have to acquire all the QP it needs each year from those entities holding the QS. This change in policy will alter the conclusions in this appendix regarding the limitations of the QS system on processor ability to vertically integrate and harvester ability to horizontally integrate through ownership of additional vessels.

E.2 Raw Fish Markets and Resource Rent Dissipation or Capture under Status Quo

The price of QP will interact with the reported market price for fish. To understand these interactions and how breakdowns in the assumptions about perfect competition affect the expected outcome for QP, it is useful to first address status quo raw fish markets and the dissipation of resource rents.

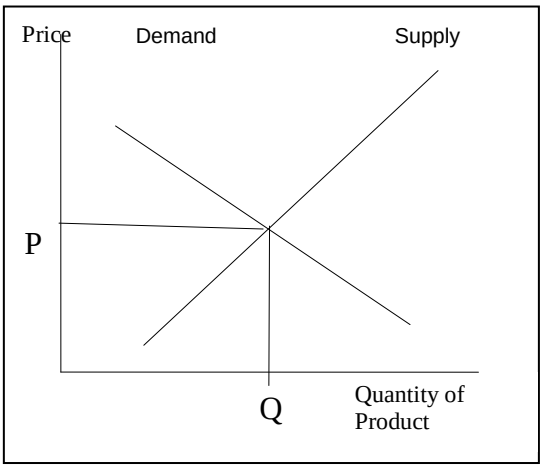

Figure E-1. Market price (P) and quantity (Q) at equilibrium (quantity supplied matches quantity demanded).

In a competitive market situation, the quantity of an item produced or demanded (the horizontal axis in Figure E-1) is related to its price (the vertical axis in Figure E-1). This is true for consumer goods and for factors of production (the inputs businesses need to support production and manufacturing). In input markets, the price a firm is willing to pay for an additional unit of an input (for example, raw fish) is related to the additional revenue that the firm will be able to generate as a result. The amount of an input supplied is determined by its marginal cost, the cost of supplying each additional unit of the input (the supply line ("curve") in Figure E-1). In general, as total production increases, the cost of producing each additional unit increases, resulting in an upward slope for the supply line. With respect to the demand line, or "curve," as in the market for consumer goods, as price increases, purchasers buy less. However, at higher prices, suppliers are willing to supply more. Conceptually, when the amounts supplied and demanded are identical, an equilibrium price is reached (price "P" and quantity "Q" in Figure 1). In practice, a stable equilibrium is seldom reached. However, this conceptual construct is still useful as an entry point for understanding the dynamics and interactions of the raw fish and QP markets under fully competitive conditions and conditions that are less than fully competitive.

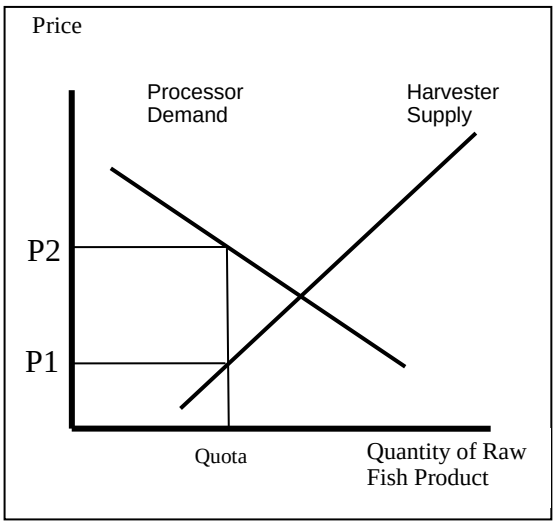

Figure E-2. Harvester cost (P1) and raw fish market price (P2) when harvest is constrained by a quota and rents are not dissipated through harvester capital investment.

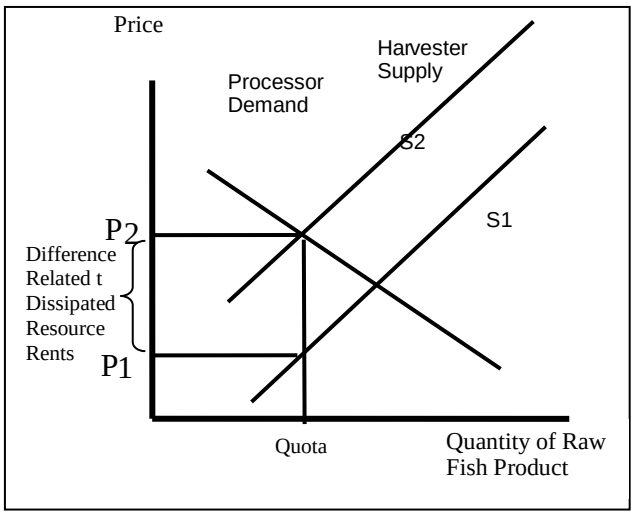

Figure E-3. In this example, it is assumed that harvesting and processing sectors are fully competitive and that harvester costs increase from S1 to S2, dissipating potential resource rents (see text for discussion of processor competition on the position o the processor demand curve and the resulting price).

Fisheries managers impose constraints to protect a resource. These constraints are generally below the amounts that fishermen would produce in the absence of a regulatory restriction ("Quota" in Figure E-2). In Figure E-3, the quota could be produced by harvesters at a cost of P1 and processors would be willing to pay price of P2. The difference between P1 and P2 reflects the rents that could be charged for the resource. However, these rents are not extracted. Therefore, processors and harvesters will struggle during price negotiations to exert bargaining power and capture a portion of the potential rents. However, to the degree that they are successful in capturing some of the difference between P1 and P2, their above-normal profits will cause them to expand their operations, and new entrants may be attracted, expanding industry capacity.

Under fully competitive conditions, new harvester entry and increasing competition raises harvest costs and dissipates rents, as illustrated by the shift from supply curve S1 to S2 in Figure E-3. The resulting price in this example is P2. The competition for harvest may also require processors to increase their investment in capital to levels above that necessary to process the fish. For example, if the fishery becomes season limited (e.g., becomes an Olympic fishery like the current shoreside and mothership sector whiting fisheries) processors with insufficient capacity to handle the product available during the season would invest in additional capacity to allow them to process in a time frame that matches the vessels' harvesting time frame.

The use of additional capital and variable inputs to increase their production capacity increases their costs and may reduce the price they are willing and able to pay for the product. In Figure E-3 this would be reflected by a downward shift of the processor demand curve. If the supply curve shifts up and the demand curve shifts down, the result would be that the lines would intercept above quota at some point between P1 and P2 for fully competitive harvesting and processing sectors, and all resource rents would be fully dissipated. In the shoreside nonwhiting fishery, cumulative trip limits have been implemented specifically to constrain the pace of the fishery. Therefore, there is not currently a race for fish, and the need for processors to invest in additional capacity is limited. Nevertheless, there may be some overcapitalization in the fishery due to the dramatic declines in optimum yields (OYs) for certain species

since the late 1990s. While there is not a race for fish in this fishery harvest sector, overcapitalization in this fishery has resulted from the investments occurring prior to the cumulative limit management regime imposed in the early 1990s, declining OYs, continuation of Olympic fishing conditions in other fisheries in which trawl vessels also participate, and government programs encouraging investment in domestic fishing capacity.

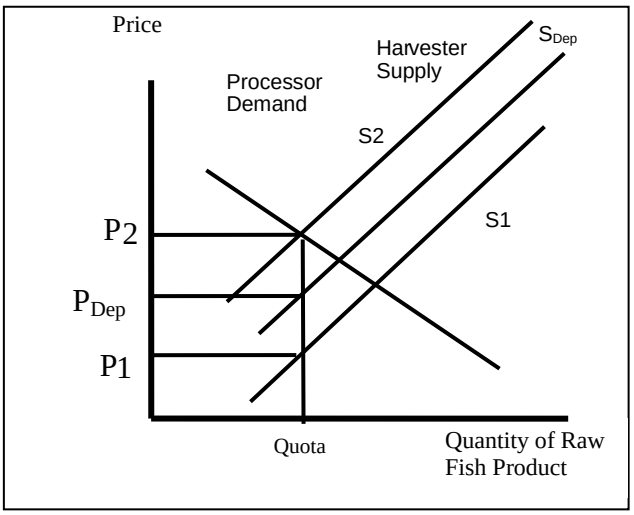

Figure E-4. Capture of a portion of the available rents (difference between P2 and PDep) through the example of a possible buyer (processor) exercise of market power.

In the case that either sector has market power, resource rents might not be fully dissipated. Market power means that members of at least one of the sectors can influence price to move away from the competitive equilibrium and use that power to capture a portion of the resource rent. Factors that make it likely that a sector will be able to exert market power are discussed in more detail in the section on QS flow among groups (page E-8). For harvesters, the effective exercise of market power to capture rents would also require some additional self-restraint or constraints such as barriers to entry.[1] Otherwise, we would expect harvesters to use the resource rents they capture as profits to support their competition for harvest, thereby raising their cost curve and, over time, dissipating the rents.

Suppose a quota constraint creates an opportunity to capture rents and the rents are not dissipated. If processors were able to exercise market power and capture all the rents, the price for raw fish would be P1 (Figure E-4). If processors are able to use market power to capture only a portion of the rent, they might be able move the raw fish price to an intermediate position. For example at an intermediate equilibrium, denoted P_{Dep}, processors would capture the difference between P2 and $P_{Dep.}$ If vessels were able to exert market power, they would capture the difference between P1 and $P_{Dep.}$ Unless the coordination that allowed them to exert the market power also enabled them to constrain their competition with one another, the difference between P1 and P_{Dep} would be dissipated as the industry increases capital investment and costs, thereby shifting the supply curve from S1 to S_{Dep} in Figure E-4. Along the same lines, returning to Figure E-3, if the harvesters are able to capture all of the available rent and not dissipate it with increased capital investment (the supply line remains at S1), the price for raw fish would be P2, and the rents captured by harvesters would be an amount associated with the difference between P2 and P1. If harvesters were to dissipate all of the rent in the race for fish, the harvester supply line would rise to S2.

E.3 QP Markets and Interaction with Raw Fish Markets

The IFQ program would create a new input that a vessel would have to acquire to bring raw fish to shore for sale: the QP. On one hand, harvesters will experience a cost associated with this new input; on the other hand, rationalization of the fishery is expected to drive down other costs of production. Figure E-5 picks up where Figure E-3 left off and assumes an equilibrium price has been established at P2 (for now

[1] The license limitation program provides some constraint on expansion of harvesting capacity and possibly supports increased cooperation among harvesters in that regard. However, there are still some permits that are unused or relatively unused. In addition, for the whiting fishery, where the race for fish continues, there continues to be an opportunity for capital stuffing (i.e., increasing the amount of capacity used with permits within the constraints of that permit).

ignore lines S3 and D2 and price P3), holding the product mix and quality constant. The net effect of an IFQ program is that the harvest supply curve depicted in Figure E-5 would stay at S2 with a price of P2, and the costs for all inputs except the QP would decline, perhaps back to S1.[2] The difference between P1 and P2 would reflect the value of the QP.[3] For those who must buy QP to participate in the fishery, the QP cost is a direct price that they would pay (their cost curve would be S2), and their profits would not vary much from competitive market equilibrium. For those who receive an initial allocation, the cost of the QP would be the opportunity cost (by holding on to the QP they lose the opportunity to gain revenue by selling the QP). They will collect the difference between P1 and P2 as rent as long as they remain in the fishery and continue to hold their initial allocations.

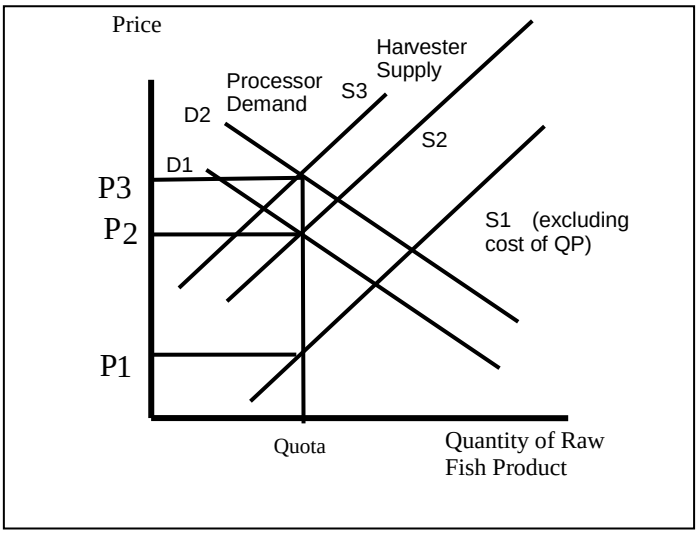

Figure E-5. Effect of a price increase through change in quality (movement of demand from D1 to D2) on value of the QP (difference between P1 and P3). (Line S1 would be the supply line of an efficient fleet if it did not have to pay for QP).

Often, the imposition of an IFQ program also creates an opportunity to increase revenues through increasing the product quality, selling when prices are higher, etc. In such a case, under competitive conditions, processor demand for the higher value products would be expected to be higher, for example, at D2 as compared to D1 in Figure E-5. This would result in an increase in the raw fish price from P2 to P3. In this example, it is assumed that the harvester costs exclusive of the QP would be expected to remain relatively unchanged (line S1 in Figure E-5), and the price of the QP would be expected to increase by the difference between P2 and P3 (increasing the harvester supply curve from S2 to S3). Thus for those who must buy QP, as the exvessel price goes up, their profit margins do not increase substantially. Those who already hold QS/QP experience an increase in financial profits. However, the firms with QS/QP still incur an opportunity cost by holding and not selling their shares. Therefore, from a theoretical perspective, in terms of assessing net economic performance, they, too, would not experience a substantial increase in real profits, though they would experience financial profits (because they do not have to buy the QP) and an increase in wealth in the form of the value of the QS asset that they hold.

[2] For purposes of simplicity, here it will be assumed that prices decline to S1. However, there will be other costs associated with harvester participation in the IFQ program. One major cost will be that of carrying observers.

[3] Assuming that industry bears the cost of observers, the cost curve would be higher, diminishing the difference between raw fish price and operating costs (excluding cost of buying QP). As this difference diminishes, the amount fishermen would be willing to pay for QP would decline, decreasing the market price of the QP.

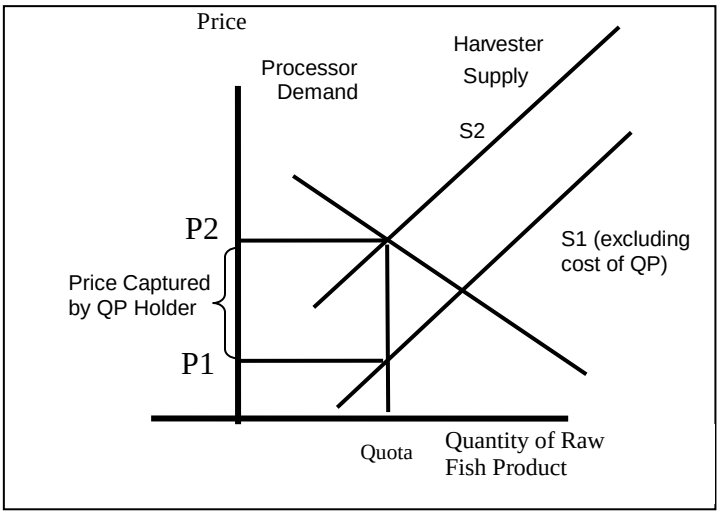

Figure E-6. Price captured by QP holder.

The actual market transaction prices reported for raw fish will be affected by who provides the QP for a transaction and the terms and conditions under which the QP is provided. In a competitive market (a large numbers of sellers and buyers acting independently), vessels not having to pay for QP will be willing to fish if they receive at least P1 for their deliveries of fish (their marginal costs excluding the cost of the QP), and processor will be willing to pay P2 for the raw fish (Figure E-6). If markets are functioning effectively, the person holding the QP should be able to sell QP to the harvester or the processor for the difference between P1 and P2 and capture the resource rent.[4] The QP holder could be the permit owner, vessel owner, crew, processors, communities, or others. The following examples show how reported raw fish price outcomes may vary depending on who provides the QP, assuming that both the harvesting and processing sectors are competitive.

- If a vessel holds its own QP, the price for the fish would likely be reported as P2, and it would include the value of the QP supplied for the transaction (in Figure E-6). P2 is composed of the vessel marginal cost (the minimum the vessel would fish for, P1 in Figure E-6) plus the price of the QP supplied by the vessel (the difference between P2 and P1).[5]

- If a processor holds the QP and buys from an independent vessel, the transaction price would vary depending on the arrangements made to transfer the QP to the vessel account (i.e., whether the QP price was wrapped together with the fish price). For example, if a processor provides the QP at no charge, then the exvessel price would be expected to be the vessel marginal cost (P1 in Figure E-6). If a processor sells the QP to the vessel, it would be expected that the price of the QP would be recovered in the exvessel price, which we would expect to be P2 if both sectors are fully competitive (Figure E-6).

Under a fully competitive situation, if both parties hold some of the QP that will be used in a particular landing, actual prices may be between the two extremes (P1 and P2). However, we would expect the amount of resource rent collected by each side to be the same as if the two parties had entered into separate sales agreements (i.e., both parties are expected to enter into the agreement only if they can earn as much revenue as they would working with a party who brought no QP to the transaction). Table E-1 contains **hypothetical** information used to illustrate the negotiating dynamic when both sides are competitive. In this table expected ex-vessel prices are shown based on the amounts of QS held by vessels and processors assuming the following:

1. Processor marginal revenue $0.40 per pound
2. Vessel marginal cost $0.30 per pound

[4] If the fishery is overcapitalized, the QP holder may not only capture a portion of the resource rent, but also a portion of the profits expected to otherwise accrue to harvesting capital, and possibly processing capital. This issue will be addressed in the section on impacts and the equity of the initial QS allocation.

[5] The difference between P2 and P1 represents the vessels opportunity cost for the QP (a profit it could have made by not fishing and selling the QP to someone else).

- In Scenario 1, all the QP is held by the vessel, and the expected price would be the processor marginal revenue ($0.40/lb) (i.e., the price would include the vessels marginal cost and the value of the QP, P2 in Figure E-6).
- In Scenario 2, all the QP is held by the processor, and the expected price would be the vessel marginal cost ($0.30/lb) (P1 in Figure E-6).
- In Scenario 3, the total transaction and the QP held are the sum of scenarios 1 and 2. The expected exvessel price would be an amount that brings both the processor and the vessel an amount of rent at least equal to what they would have earned if they entered into separate transactions with other partners; otherwise, they would not enter into the transaction. Only one price satisfies this condition, $0.366/lb.

Table E-1. Hypothetical example of price negotiations between harvesters and processors where both sectors are fully competitive.

	QP Owned by		Total Landing	Exvessel Price	Exvessel Value	Vessel Marginal Cost ($.30/lb)	Processor Marginal Rev ($.40/lb)	Rents for QP Collected by	
	Vessel	Processor						Vessel	Processor
Scenario 1	2,000 lbs	0	2,000 lbs	0.40	$800	$600	$800	$200	$0
Scenario 2	0	1,000 lbs	1,000 lbs	0.30	$300	$300	$400	$0	$100
Scenario 3	2,000 lbs	1,000 lbs	3,000 lbs	0.366	$1,100	$900	$1,200	$200 ($.066/lb)	$100 ($.033/lb)

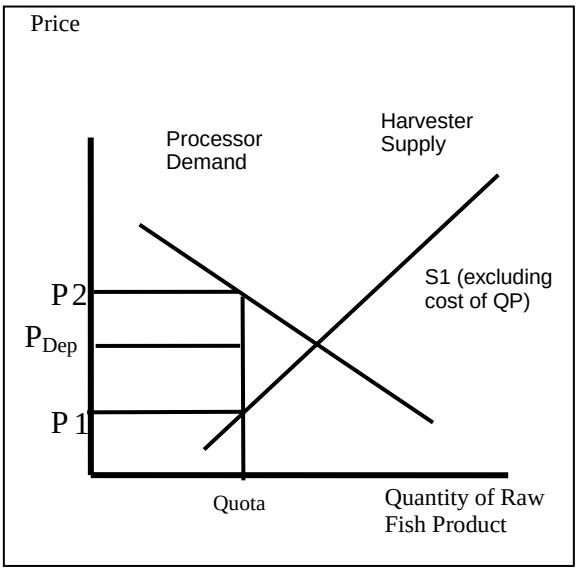

Figure E-7. Capture of a portion of the available rents (difference between P2 and P_{Dep}) through the exercise of market power by a buyer (processor). QP holders capture difference between P_{Dep}. and P1.

If the raw fish market is not fully competitive, there are two situations to consider. First, consider the situation of the entity that comes to the negotiating table with QP and desires to use his/her market power to increase profits. For this example, assume that entity is a harvester, and he/she is facing a fully competitive processing sector.[6] That entity can do no better than the price P2 in Figure E-7[7] At price P2, the entity receives its full marginal cost of harvesting (excluding the value of the QP, P1) plus the value of the QP (difference between P2 and P1). Similar logic shows the same result for a processor bringing QP to the table. If the processor tries to depress the price below P2, it will cut into the amount that is paid to the QP holder. In either situation, if the source of the price leverage is the QPs held, then the party attempting to excerpt market power could only cut into what it would reimburse itself for its own QP. This, then, implies that in an IFQ program where one side is fully competitive, the only way for the other side to gain from the exertion of market power is through the influence of the prices of transactions for which it does not

[6] For now, we will also assume the processing sector is fully rationalized, so there is no excess capacity.

[7] Unless it is able to achieve price discrimination (i.e., to charge firms for whom the delivery is more valuable more than other firms). Price discrimination is difficult to achieve and usually only arises in certain monopoly-type situations. Unless price discrimination can be achieved, the harvester can do no better than P2 with respect to a delivery for which it has QP.

hold the QP. For example, if a processor without QP was able to get a harvester to settle for a price of P_{Dep}, in Figure E-5, that processor would capture the QP related value reflected by the difference between P2 and P_{Dep}, the harvester would get P_{Dep} (before paying for the QP), and the QP holder would get the difference between P_{Dep} and P1. Of course, if the QP holder is not the harvester, the QP holder may decide to not take part in the transaction and seek an alternative buyer. Similarly, if a harvester without QP faced a processor and were able to get the processor to pay a price of P_{Dep} for raw fish, the harvester would earn his/her normal return of P1 plus additional profits reflected by the difference between P_{Dep} and P1, the processor would pay the price of P_{Dep}, and the QP holder would get the difference between P_{Dep} and P2. In both these situations, the entity exerting the market power is not the QP holder, and the QP holder loses the value unless the QP holder refused to participate in the transaction and accepts a better offer, which would be likely if the QP market is competitive.

Finally consider a possible case where both parties are in a position to exert market power (perhaps one sector is highly concentrated, and the other has many entities but is organized and working together cooperatively. Any exertion of market power by one side will come out of the value of the QP held by the other side or a third party. If the source of one side's power is that it holds a large amount of QP relative to the other side, the amount of additional rents it can extract is limited by the amount of QP held by the other side. If the QP holder is a third party (harvester or the processor), the QP holder's own ability to preserve his/her return on his/her QP holdings will depend on the competitiveness of the QP market and the QP holder's ability to exert power in price negotiations.

E.4 QS Flow among Groups (Independent of the Initial Allocation)

After the initial allocation, QS will be traded between members of the groups initially receiving the QS and any other entity eligible to own a U.S. documented fishing vessel (whether or not they actually own one). Traditional economic thinking holds that in the absence of transaction costs (the cost of buying and selling something) the QS will end up in the hands of those able to derive the greatest benefit from it independent of the initial allocation (Coase 1-44). However, transaction costs do exist. Recently, it has been demonstrated that other factors are at work such that the initial allocation may affect the long-term distribution of a resource (Hurwicz 49-74). In this section, we seek to put the question of initial allocation in the context of the expected flow of QS among groups no matter who receives the initial allocation. Once we cover the dynamics affecting this flow, we will be in a position to look at how the initial allocation might alter those dynamics.

In our previous discussion, we focused on the QP, which are issued each year to those holding QS. Our focus now turns to QS. The value of the QS is directly related to the value of the QP that will be issued for those QS in the future. We will consider the following factors from the perspective of their influence on the flow of QS among groups, independent of the initial allocation (also see the hexagons in Figure E-8).

1. Relative efficiency and intramarginal rents (page E-11)
2. Vertical integration, quasi-rents, and economic rents (page E-13)
3. Market power, horizontal integration and market share consolidation (page E-17)
4. Access to capital (demand) (page E-35)
    a. Time preference
    b. Risk
    c. Planning horizon
5. Access to capital (supply) – risk (page E-38)

Above, we identified that resource rents in the form of profits will be captured by the owner of the QS under an IFQ program, regardless of the nature of that entity (vessel, processor, crew, etc.). This result

changes only if a party not holding QP is able to exert market power, causing the price to deviate from the equilibrium for raw fish. In the following discussion, it will be important to consider other sources of profit and how they vary within and between sectors. This includes discussion of normal profits and intramarginal rent (see relative efficiency), as well as quasi-rents and economic rents (see vertical and horizontal integration). The following table provides a brief overview of these economic concepts and the technical terms we use for them.

Table E-2. Explanation of Terminology: return on investment, profits, and rents.

General Term and Description of the Concept	Economic Term
Normal Return on Investment: The level of profit required to compensate for capital investment (compensate the owners of capital). For industries that involve greater risk, greater return is required to compensate or attract capital investment. If the industry profit level is not sufficient to compensate capital, there will not be new investment.	Quasi-rents
Efficiency Profits: Profits earned by firms that are more efficient than others.	Intramarginal Rents
"Reasonable" Profit Level: Income necessary to pay for all labor, supplies, capital, and entrepreneurial expertise used by a firm at going market prices. This includes normal return on investment (quasi-rents).	Normal Profits (Zero Economic Rent or Zero Economic Profit)
Extra Profits (Abnormal Profits): Any earnings above normal profits are considered "economic profits" or "economic rents." Economic profits or rents attract new entrants.	Economic Rents (Above Normal Profits)
Cost of the Resource: Amount paid for the use of a raw resource. In open access fisheries management, no one collects resource rents; therefore, resource rents show up as economic rents, which attract new entrants until efficiency decreases to the point that only normal or less than normal profits are earned.	Resource Rents

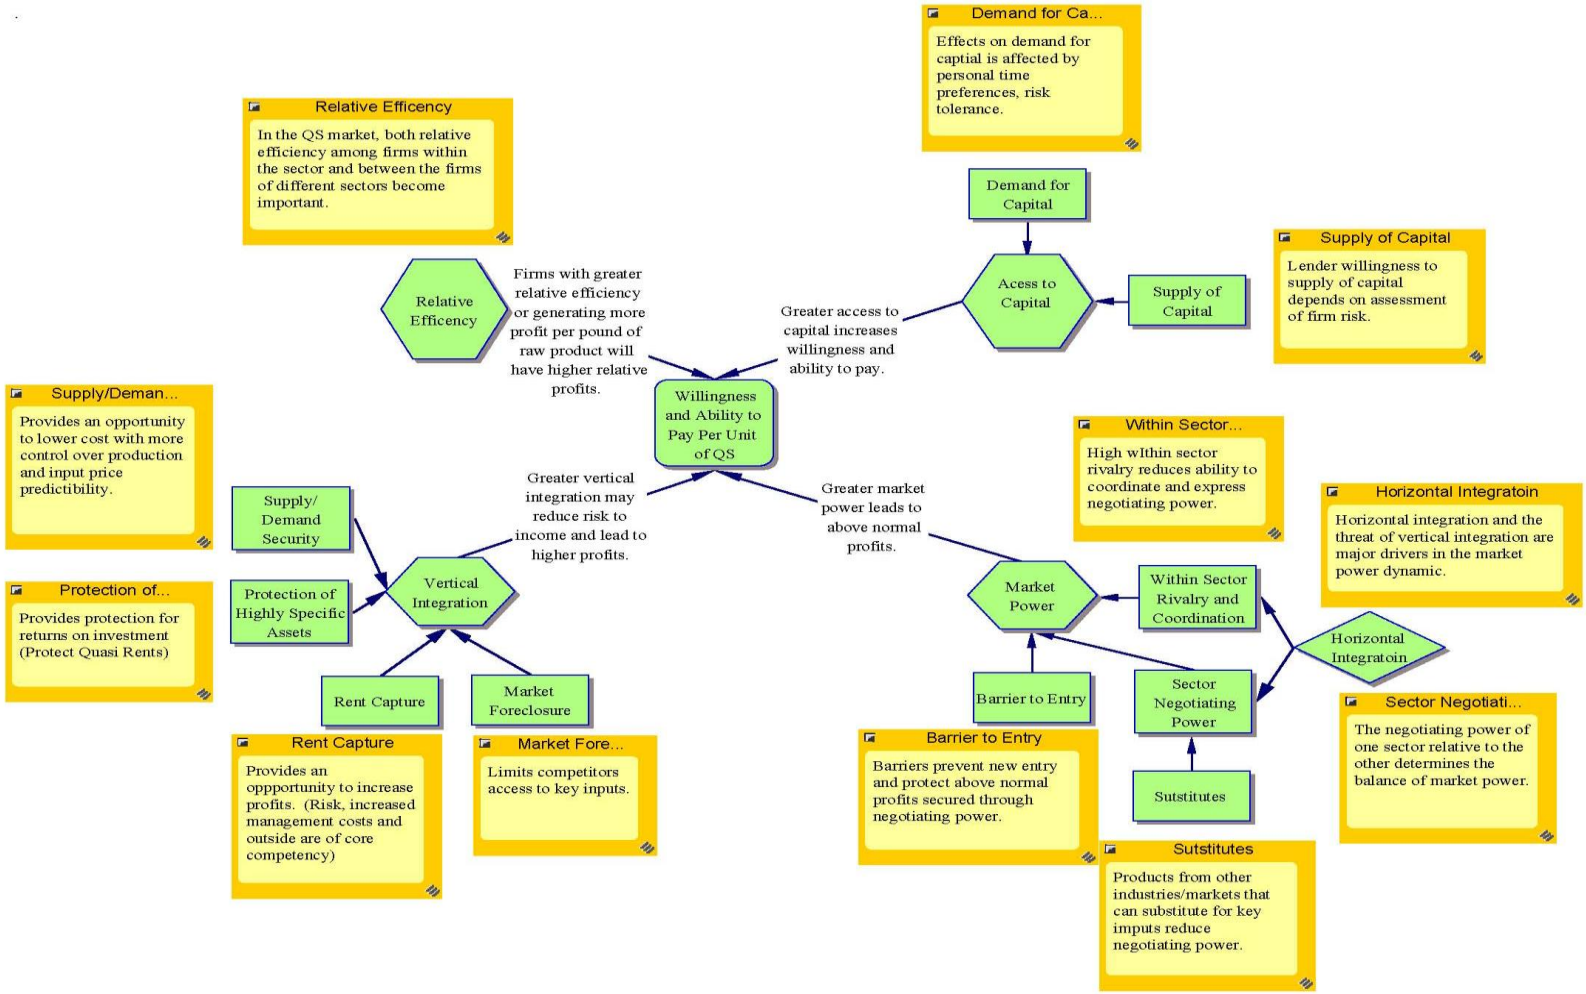

Figure E-8. Factors influencing QS flow among groups.

E.4.1 Relative Efficiency (Intramarginal Rents) and Profit Per Unit of Physical Input

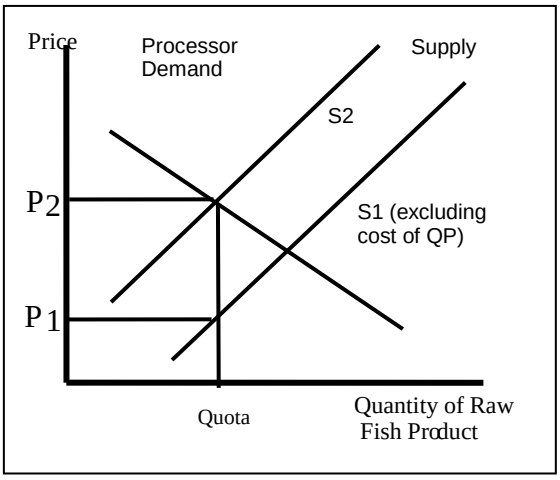

Figure E-9. Sector supply and demand curves and a point that represents a sale by a firm capturing intramarginal rents (difference between P1 and Pi).

If the harvesting and processing sectors are competitive, and the market and sectors achieve a long-run equilibrium, we would expect all participants in both sectors to be equally efficient. For both processors and harvesters, "economic" profits would be zero (all entities would have "normal" profit levels). In reality, however, even if an equilibrium market price is reached due to constant change, it is likely that some firms will be more efficient than others.[8] Additionally, it is possible for the business models of two firms to be equally efficient but produce different levels of total revenue per unit of input of a key raw produce. Those firms that are relatively more efficient and those firms that produce more value per unit of a key input (raw fish) are more likely to accumulate QS over the long run.

Firms that are more efficient than others in a sector earn extra profits, sometimes identified as intramarginal rents. Intramarginal rents are represented as the area between the price and the supply curve in Figure E-9 (the area between the horizontal line running out from P2 and the supply line S2, or the horizontal line running out from P1 and the supply line S1).[9]

Implementation of the QS program itself may affect both the harvester supply and processor demand curves. The harvester supply curve (excluding the cost of the QP) should go down as vessel efficiency improves, scale of operations increase, and less efficient capital leaves the fishery. The cost of complying with the program will limit cost savings and downward shift. If processors are overcapitalized or involved in the race for fish, the height of the processor demand curve under IFQs may increase as the amount of capital and other costs decline (as processor costs decline, the they would be expected to be willing to pay for acquisition of raw fish product increases). The IFQ program may have a differential effect on the profits of one sector as compared to that of another. The IFQ program appears to provide more direct mechanisms for the harvesting sector to improve operational efficiency as compared to processors (Table E-3). A harvester without QP would be forced to leave the fishery, while there is no mechanism that directly forces some processors to leave their sector.

[8] The long-term equilibrium in which all firms are equally efficient is rarely, if ever, reached.

[9] This explanation is a simplification to illustrate the main point. For a complete and technically accurate explanation of intramarginal rents and their relation to resource rents, see Coglan and Pascoe (Coglan and Pascoe 219-28).

Table E-3. Conditions leading to overcapitalization and opportunities for efficiency improvements for harvesters and processors in the nonwhiting and whiting sectors.

	Nonwhiting		Whiting	
	Status Quo	**IFQS**	**Status Quo**	**IFQs**
Harvesters	The race for fish occurred primarily in the 1980s and early 1990s. Imposition of 2-month cumulative limits and license limitation strongly muted capitalization. Overcapitalized state compounded by harvest contraction. Operational inefficiencies from constraints of 2-month cumulative limit management.	The IFQ program directly provides an opportunity for increased efficiency through consolidation of QS, transfer of operations to more efficient producers, flexibility in determining harvest strategies (timing and species mixes), regulatory stability and more direct control over planning.	Overcapitalized in race for fish. Operational inefficiencies from race for fish.	Same as for the non-whiting fishery with the addition of the opportunity to improve efficiency through more control over the pace of fishing and improved product quality with better handling.
Processors	Overcapitalized through harvest contraction. Operational inefficiencies from constraints of 2-month cumulative limit management.	Processors will have less certainty about the expected flow of product except to the degree they can influence product flow through the prices they offer or by acquiring QS. Over time, excess capital will diminish but the IFQ does not provide a direct mechanism for consolidation of processing opportunity (processors without QS can continue to compete for deliveries by vessels with QS).	Overcapitalized in race for fish. Operational inefficiencies from race for fish.	Processors will be gain efficiency with the slower pace of harvest and may be able to increase the value of their product with better handling or the development of higher value product forms. Over time, excess capital will diminish but the IFQ does not provide a direct mechanism for consolidation of processing opportunity (processors without QS can continue to compete for deliveries by vessels with QS).

See Sections 4.9 and 4.10 for discussions of the efficiency effects of the IFQ program on the trawl and processing sectors, respectively. Note that the existence of differences in relative efficiency within a sector depends on the industry not reaching a complete equilibrium and is independent of whether a sector has been able to exert market power and influence price away from the market equilibrium.

One of the factors determining the flow of QS will be the amount of profit a firm is able to generate with that QS on a per unit of raw product basis. Profit per unit of raw product and overall efficiency may vary from one another. By way of providing a conceptual example, consider grain farming and the production of bread. Assume that both the grain growing and grocery industries are competitive, both with normal returns on investment, and that grain is the key input without which there would not be a loaf of bread to sell (there are no substitutes for grain). We know that there are only a few cents worth of grain in a loaf of bread that may cost several dollars. Moreover, we know that on a per unit basis the farmer's profit is a fraction of those few cents, while the grocer's profit is a larger amount, some fraction of the several dollars that the loaf of bread costs. Thus, in a competitive market, the financial profit both earn may be similar, but the amount of profit per unit of the raw product may be substantially different. If each are now offered the opportunity to insure their profit based on a rate per unit of grain, the grocer will be willing to pay more because he has a greater dollar profit at risk per unit of grain. From this viewpoint, it is possible to demonstrate the potential for two companies operating at different points in the production

chain with equal relative efficiency on a dollar basis to generate different levels of profit on the basis of units of raw fish. The point of this discussion is not to identify a particular direction that QS is likely to move, but to establish conceptually relative profitability per unit of a key raw product could operate to drive the distribution of QS in a direction away from the firms with greatest relative efficiency when all inputs are taken into account. If processors have greater profit per unit of raw product, they may be willing to pay more for QS to secure access to the resource. On the other hand, to maximize profits, it is likely that they will hire the most efficient vessels to use the QP they are issued each year.

A number of other factors that affect efficiency will be influenced by the creation of an IFQ program. Some of these are discussed below in sections on integration and access to capital.

E.4.2 Vertical Integration, Return on Investment (Quasi-rents), and Above-normal Profits (Economic Rents)

Vertical integration or control occurs when a firm owns or exerts control over its suppliers or customers.[10] Businesses may vertically integrate to increase technical efficiency,[11] increase economic efficiency by internalizing transaction costs, and/or seek to exert market power (Perry 183-255). A processor that also owns a harvesting operation is a vertically integrated company. In commercial fisheries, some factors that may encourage vertical integration are as follows:

- Supply/demand market security
  - Price
  - Quantity
  - Quality
  - Timing
- Protection of profits from assets that are not easily employed in some other use ("highly specific" or "nonmalleable" assets)
- The capture of profits from another level of the production chain (rent capture)
- Preventing competitors from acquiring a key input – for increasing market share (market foreclosure)

(adapted from Dawson 1-125)

Increased management costs and the risks entailed in expansion beyond areas of core competence may be a downside of vertical integration.

QS ownership does not provide harvesters with a direct opportunity to vertically integrate in that QS are required for harvesting and provide no opportunity to direct or control processing operations.[12] Therefore, discussion of the opportunities that an IFQ program may create for harvesters to vertically integrate is taken up in the context of the IFQ program's effect on market power (see section, "Market Power, Horizontal Integration, and Consolidation" in the following).

---

[10] Vertical integration or vertical control: Ownership or control of (1) suppliers (backward integration, e.g., a buyer owning a vessel), (2) buyers (forward integration, e.g., a vessel owning a buyer). Some companies engage in both forward and backward integration (balanced integration). Horizontal integration is the term used for one firm owning another that is producing the same outputs (e.g., one harvesting company owning another harvesting company).

[11] An example of technical efficiency is the integration of the steel production process such that already heated material does not have to be reheated for the next phase of the production process. At this point, technical efficiencies have not been identified with respect to the harvester processor interface.

[12] Once the IFQ program is created, the ownership of QS itself might be considered a type of vertical integration (i.e. ownership of the QS gives the harvester direct control of an essential factor of production, the QP). Elsewhere in this document, ownership of QS is sometimes referred to as a form of vertical integration.

There are a number of reasons to expect that processor vertical integration might increase under IFQs:

- The opportunity to own QS may provide a less expensive way for processors to respond to existing pressures for vertical integration (pressures to ensure market security or protecting assets that may not be easily transferred to other uses, nonmalleable assets).
- If there are above normal profits in the harvesting sector because of existing market power, or an increase in harvester market power as a result of the IFQ program (see following section, page E-17), the opportunity to capture these profits (rent capture) would create additional incentive for vertical integration through direct ownership of a harvesting operation. Acquisition of additional QS would be expected to accompany this integration.
- The exclusivity of QS provides a new opportunity for processors to increase their market share by acquiring QS and, thereby, foreclosing the opportunity of competing processors.

Processors that are already vertically integrated through ownership of vessels might have more incentive to acquire QS to protect their profits than firms that are not vertically integrated. For entities that own vessels, the acquisition of QS will protect both the profits from their harvesting operations and processing operations.

While there are reasons to expect that an IFQ program might lead processors to acquire QS in response to changing incentives and opportunity for vertical integration, control limits applied to QP would substantially limit a given processor's ability to use IFQ ownership to vertically integrate. For some processors, control limits could even reduce existing levels of vertical integration (immediately, if there is no grandfather clause, or over time as the grandfather clauses expire). Vertical integration through direct ownership of vessels would be constrained by control limits applied to QP. For example, assume a processor owns vessels that operate using amounts of QP that put the processor at a QP control limit. The processor would not be able to expand its vertical integration by acquiring additional vessels because it would not be able to acquire additional QP for additional vessels, since any such acquisition would put the processor over its QP control limit. Therefore, a control limit applied to QP would limit some processors' ability to acquire both QP and additional vessels. In its final preferred alternative, the Council applied control limits only to QS, not to QP. Therefore, a processor desiring to expand its harvesting operation will be able to do so but will not be able to support those operations with QS (each year it will have to acquire QP from other QS holders).

Vertical integration entails a firm taking on management costs related to merging the newly acquired means of production. If a firm is already vertically integrated and is just expanding the amount of that integration, there may be little additional risk. However, if the firm were extending beyond its area of core competency for the first time, it would be taking risks that could lead to higher production costs until full competency is developed. Managing a skilled crew and operation of a fishing vessel requires knowledge substantially different from the operation of a processing facility. The implementation of an IFQ program would provide processors of raw fish some opportunity to extend their control over supply production without necessarily having to incur the management costs and risks associated with control over a fishing vessel. By holding QS, a processor would be able to offer QP to the available fleet and have more leverage to control the timing of the delivery of those QP. However, while holding the QP provides the processor with an additional degree of vertical control, it is not enough to entirely free the processor from uncertainty about the price it would have to pay to get the raw fish delivered in the fashion it desires. The vessel would still be an independent operation. For example, even if the processor holds the QP, if the vessel also has its own QP, or there are competing processors in the area, it may still have to offer a higher price for the raw fish to get the desired delivery terms (time and quantity). Ownership of the underlying QS would secure QP price certainty for the processor and provide substantial leverage, but not complete certainty with respect to the raw fish price.

E.4.2.1 Supply/Demand Market Security

In general, price, quantity, quality, and timing are market security issues that can be addressed through vertical integration. With respect to quantity in a delivery, quality, and timing, processors can influence the delivery of an independent harvester through price negotiations or general market offerings. However, doing so involves transaction costs, which can be avoided with vertical integration. Vertical integration allows the producer to plan and control production and, most important, to know price (Arrow 173-83). For example, with respect to timing and quantity, the producer can more efficiently allocate labor and assets that are fixed for the period. It is also easier for a processor to control production quality when the employees work for the processor rather than the harvester. In situations where investment to support production for an upcoming period must be made with only partial or uncertain information about market price for key inputs, there will be a tendency for firms to vertically integrate. Moreover, in such a situation, this tendency for vertical integration will also encourage horizontal integration and the exertion of market power (Arrow 173-83). Under an IFQ program, the opportunity to own QS would provide processors a lower cost means for vertically integrating for market security.

E.4.2.2 Asset Specificity (Malleability) and Quasi-rents

Highly specific (unmalleable) assets are those that cannot be easily transferred to other uses if access to a key input is lost. The value of the asset that is not recoverable through transfer to another use is considered a sunk cost or sunk portion of the asset. Consideration of asset specificity has to take into account not only the alternative use of the asset but also the cost of moving the asset into the alternative use. The difference between the value of the asset in its current use and its value in the next best use is the *quasi-rent*.[13] Quasi-rents are considered a part of "normal rents" or "normal profits." They represent the return on investment that is necessary to attract and maintain capital in an industry.

The profit a buyer needs to pay a return on capital investment (quasi-rents) may be subject to capture when the number of suppliers is limited. For example, if one of a very limited number of suppliers selling an input knows a customer has equipment that must have that input (that there are few substitute inputs) and that the customer's equipment is not easily transferred to a different use, that supplier may be able to negotiate a higher price and capture some of the buyer's profit otherwise needed for a return on investment. Alternatively, a customer who is buying from a supplier that has a very unmalleable asset might be able to capture some of the suppliers return on capital investment. Such a circumstance might arise if there are a limited number of customers and a product that is highly specific in its use and its availability. An example would be a vessel with a hold full of fish and no pre-agreed-upon buyer. In this case, the fish are the unmalleable asset. Thus, specific assets earn a return that is subject to capture when there are market imperfections. The capture of these profits can only be sustained over the short term; otherwise, the firm losing the profit will not earn enough to replace its capital and will eventually be forced to leave the industry.

In the section above on the interaction of QS and raw fish markets (page E-4), we noted that when the raw fish market is fully competitive the QP owner would be expected to capture resource rents. With fully competitive markets and overcapitalization, the QP owner may capture both the resource rents and some of the quasi-rents. In an overcapitalized situation, firms seeking to ensure they have sufficient product for optimal production levels will bid away some of the profits (quasi-rents) that would otherwise go to returns to capital. However, this would be a short-term phenomenon. As assets age, deteriorate and are not replaced—all else being equal—QP prices would be expected to decline. The decline in QP prices would yield back the profits for return on investment to induce new investment. [This dynamic is

[13] The terms "economic profits" or "economic rents" occur when profits are above normal. See the following section for additional discussion of economic rent.

discussed in more detail in A-2.1.1.a, in the sections on "Investment, Dependence, and Disruption," and impacts on "Buyer/Processors."]

E.4.2.3 Rent Capture and Economic Profit (Economic Rent)

Vertical integration is also a way for one sector to capture another sector's economic profit (economic rent). Economic rent is any profit that is earned above that necessary to pay all costs, including the cost of recouping the original capital investments. Economic rents are termed "above normal" profits.[14] Vertical integration may be through forward integration (a harvester buying a processor) or backward integration (processor buying a harvester). In determining whether vertical integration will increase its profits, a firm would have to consider increased management costs and risk associated with expansion of the business beyond its area of core competence.

When both sides of a market are competitive and at equilibrium, there would be no above-normal rents to capture through vertical integration. However, if one or both sides are exerting market power under status quo, or become able to exert power as an outcome of the IFQ system, then there is an increased incentive to vertically integrate to capture rent (see the following section on market foreclosure and the section discussing horizontal integration, starting on page E-17). Firms able to capture economic rent will place more value on QS and have more incentive to buy QS to secure access to their key input.

E.4.2.4 Market Foreclosure

Firms may vertically integrate to limit their competitor's supply. While vertical integration occurs under status quo, use of that integration to foreclose a competitor's market is difficult. Any additional harvesting capacity acquired by a processor competes with existing harvesting operations, effectively reducing the two-month cumulative limits (or the season length, in the case of catcher vessels participating in the whiting fishery). It might be argued that the license limitation program makes it difficult to add capacity. However, latent permits and permits that are not used to full capacity offer opportunity to expand capacity. Further, even if a processor acquires a fully utilized permit and vessel, capacity could be expanded if the competitor losing deliveries from that permit and the vessel compensate by bringing one of the latent or underutilized operations on line. Whether or not IFQ would become a key production input for which there is no substitute, the creation of an IFQ system would provide a new opportunity for entities to foreclose a competitor's access to another key input (raw fish) and expand market share through vertical integration by the purchase of QS. Alternatively, if prevented from acquisition of QS through accumulation limits, a processor might secure a contract for delivery by a vessel with QS. Since no one else could purchase the fish associated with the QS assigned to that vessel, this would be a form of vertical control and market foreclosure. However, use of such contracts by processors could be counted toward a processor's QS/QP accumulation limit. Whether accumulation control limits would apply to marketing commitments secured by this type of a contract would have to be determined.[15] Foreclosing a competitor's access to an essential input (raw fish) will become more feasible under an IFQ program. This could lead to further consolidation in the processing sector, as discussed in the following section on market power.

---

[14] Economic rent does not include quasi-rent since quasi-rents are necessary to maintain an asset in the industry over the long run (i.e., to provide incentive for future investment). The intramarginal rents earned by firms that are more efficient than others may be economic rents (discussed in the section on relative efficiency, page E-11). In addition, above-normal profits earned by firms exerting market power would be considered economic rent.

[15] While under a control limit, fishery managers would not directly monitor these contracts. If suspicion arises that an entity is exceeding a control cap via the use of private contracts, that circumstance could be investigated, and at that time, contracts would be evaluated as potential violations of the control cap.

E.4.3 Market Power, Horizontal Integration, and Consolidation

"Market power is viewed as the ability to maintain ***long-term abnormal profit…***" (Poole and Van de Ven -429). Market power enables firms to move price away from the competitive, market-determined equilibrium. In a fully competitive market, no firm or sector has market power because none can influence price away from the equilibrium. If a firm is able to achieve above normal profits through the expression of market power, they will be willing and able to place a higher value on the QS because the QS represents a larger stream of profit to them than to other firms. Thus if a firm or sector has market power under status quo and it is maintained under the IFQ program, or if the firm or sector establishes market power under the IFQ program, QS will flow in the direction of the entities with market power.

Market power is influenced by the following:

- Rivalry and coordination within a sector (page E-17). Effective exertion of market power requires coordinated action and coordinated action is affected by the degree of rivalry within a sector.
- Relative bargaining (negotiating) power between sectors (page E-21). The bargaining power of the sector vís-a-vís another sector is affected by current conditions and threats of longer-term recourse. This topic will be addressed in three parts:
  - Threat of substitutes
  - Harvester bargaining power
  - Buyer/processor bargaining power
- Barriers to entry (page E-23). Unless barriers to entry can be maintained, higher profit will attract new entry that will then disrupt market power.
  (adapted based on (Porter))

One of the major themes that shows up in the consideration of rivalry, coordination, and bargaining power is sector concentration (the number of firms and whether market share is relatively evenly spread among the firms, or is spread among just a few). As concentration in a sector increases, ability to exert market power increases. Two processes affect concentration:

- Horizontal integration—occurs when one firm in a sector acquires another or when firms within a sector merge.
- Market consolidation—occurs when existing firms expand market share (with other firms losing market share and potentially exiting the business).

In the following sections, we will address each of the factors influencing market power and then turn to the question of how implementation of an IFQ program may change these factors and thereby influence market power. These sections help to set the stage for addressing the question of how the initial allocation of QS affects the longer-term distribution of QS.

E.4.3.1 Rivalry and Coordination

Market power requires some form of coordinated action within the sector to move the price away from the market equilibrium (away from the price that results when there are many independent participants on both sides of the market transaction). In some situations, there may be legal issues if that coordination is jointly planned. On the other hand, sometimes a single firm acts as a price setter with other members of the sector following that firm's lead. Such coordination through smaller firms following the lead of larger firms is occasionally seen in the airline industry and some other industries with a structure similar to that of west coast groundfish processors. Coordination also may occur among many entities, as was attempted with mixed success during the mid-coast groundfish trawl vessel tie-up during price negotiations in

March-April 2007. Ability to coordinate within a sector depends on rivalry. For example, rivalry among harvesters increases the threat that a harvester might lose its market to a competitor during difficult price negotiations with a particular processor. A number of factors affect degree of rivalry. These factors are described in the following text box (Porter).

Within-sector Rivalry (Porter) (this summary adapted from http://www.quickmba.com/strategy/porter.shtml)
The intensity of rivalry is influenced by the following industry characteristics:

1. **A larger number of firms** increases rivalry because more firms must compete for the same customers and resources. The rivalry intensifies if the firms have similar market share, leading to a struggle for market leadership.
2. **Slow market growth** increases rivalry as firms fight for market share in order to continue growing. A firm's growth does not rely on market share competition in a growing market.
3. **High fixed costs** result in an economy of scale effect that increases rivalry. When total costs are mostly fixed costs, the firm must produce and sell at near capacity to attain the lowest unit costs. Rivalry intensifies as firms fight for customers for their production.
4. **High storage costs or highly perishable products** cause a producer to sell goods as soon as possible. If other producers are attempting to unload inventory at the same time, competition for customers increases rivalry.
5. **Low switching costs** increases rivalry. When a customer can freely switch from one product to another, there is a greater struggle to capture and retain customers.
6. **Low levels of product differentiation** are associated with higher levels of rivalry. Brand identification, on the other hand, differentiates production and tends to constrain rivalry.
7. **Strategic stakes are high** when a firm is losing market position or has potential for great losses or gains. This intensifies rivalry.
8. **High exit barriers** exist when there is a high cost for abandoning production. This intensifies the rivalry to remain in the sector. High exit barriers cause a firm to remain in an industry, even when the venture is not profitable. A common exit barrier is asset specificity. When the plant and equipment required for manufacturing a product are highly specialized, they are difficult to liquidated when demand within the sector is weak and the assets cannot easily be used in other industries.
9. **A diversity of rivals** with different cultures, histories, and philosophies make an industry unstable. There is greater possibility for mavericks and for misjudging rival's moves. Rivalry is volatile and can be intense.
10. **Industry shakeout** periods intensify rivalry. When an industry becomes crowded with competitors, and there are insufficient key inputs or insufficient product demand to support all participants a shakeout ensues, with intense competition, price wars, and company failures.

The factors affecting rivalry are listed in Table E-4 with a qualitative evaluation for the harvesting and processing sectors. This evaluation indicates that conditions for high rivalry would be expected in both sectors. High rivalry leads to shake out, which can lead to concentration of the type that is seen in the processing sector (greater concentration reduces rivalry because of the interdependence it creates among the firms as they deal with suppliers and customers).

Table E-4. Assessment of factors influencing within sector rivalry for harvesters and processors.

Factor Causing Greater Rivalry	Harvesters	Processors
1. A larger number of firms with similar market shares	+ More harvesters than processors. + Entities with similar market shares. *Note: Potential sector participants include latent permit holders.*	- Fewer processors than harvesters, Small number of firms. Very restricted in some localities. - Market shares highly concentrated, going mainly to a few companies.
2. Slow market growth	+ Yes	+ Yes
3. High fixed costs relative to variable costs	? Possibly	+ Yes
4. High storage costs or highly perishable products	+ Yes	+ Yes
5. Low cost for customers to switch suppliers	+ Yes	+ Yes
6. Low levels of product differentiation	+ Yes	N/A
7. Strategic stakes are high	+ Moderate for nonwhiting, high for whiting	+ Yes
8. High exit barriers	+ Yes	+ Yes
9. A diversity of rivals	o Uncertain	o Uncertain
10. Industry shakeout.	- Constrained by current management system	o Uncertain. Shakeout may have already occurred.
Summary	Many reasons to expect high rivalry. However, license limitation constrains threat of new entrants; and for nonwhiting, 2-month limits minimize opportunity to compete for market share	Many reasons to expect high rivalry. However, high concentration indicates shakeout may have already occurred; and threat of intense competition may discourage strong moves to expand market shares.

Harvester Rivalry. In the shoreside nonwhiting sector, the number of harvesters is small but is large relative to processors (about 100 to 120 vessels compared to 5 to 10 processing companies of significant size). Fixed costs for harvesters may be high relative to variable costs, leading to a strong incentive to maximize the use of capital. However, for the nonwhiting fishery the two-month cumulative limits prevent this from serving as an incentive for rivalry.

Strategically, license limitation and trip limit management provide limited opportunity for direct market share competition or much industry shakeout in the nonwhiting harvester sector. Assuming that the market is capable of fully absorbing the harvest (i.e., there are no market limits), within a two-month period, no vessel can preempt the harvest opportunity of another. However, if the market is limited (e.g., a limited ability to absorb Dover sole) and if processors use limited markets as leverage by making the delivery of other products (e.g., crab) dependent on negotiations over groundfish deliveries, there may be a strategic stake in maintaining a relationship with a processor.

Competition is more intense in the whiting derby. Specialized capital with a limited market creates an exit barrier (high cost of leaving the fishery). Total capital invested in a harvesting operation is likely to be lower for harvesters than processors. However, the relative exit cost per dollar of capital (i.e., non-recoverable investment) could be higher than for processors, depending on the alternative activities available for the vessel and other assets of the fishing firm as compared to processors. Lack of unified action among harvesters during the 2007 mid-coast trawler tie-up, which occurred during the price negotiations with processors, indicates that rivalry may be strong enough to prevent coordinated action. The tie-up lasted for 43 days (70 percent of the bimonthly period), but 44 vessels were active during the tie-up, and 35 vessels were active only after the tie-up. About 55 percent of the landings were made during the last 18 days off the tie-up (Table E-5). Participation varied geographically (
Table E-6).

Table E-5. Landings and deliveries for vessels during and after the mid-coast vessel price negotiation tie-up (3/1/07 to 4/12/07).

Period	MT		Exvessel Value		Days		MT/Day	Vessels
3/1/2007 – 4/12/2007	1,194	45%	1,428,863	46%	43	70%	28	44
4/13/2007 – 4/30/2007	1,474	55%	1,699,901	54%	18	30%	82	79
Total	**2,668**		**3,128,764**		**61**		**44**	**94**

Table E-6. Number of vessels delivering and not delivering during the tie-up by port area.

Port Area	Did Not Deliver During Tie-up (3/1/2007-4/12/2007)	Delivered During Tie-up (4/13/2007-4/30/2007)
Northern Puget Sound	4	2
Coastal Washington	1	2
Columbia River	17	5
Newport	7	6
Coos Bay	6	8
Brookings	3	4
Crescent City	5	1
Eureka	5	7
Fort Bragg	2	2
Bodega Bay		1
San Francisco	1	9
Monterey		2

Processor Rivalry. The processing sector also appears to have many characteristics that would lead one to expect intense rivalry within that sector. However, one characteristic in particular indicates that rivalry would *not* be expected: a few processors handle a large share of the raw fish market. It may be that previous shakeouts in the industry have reduced rivalry. If rivalry tends to be low, price setting for raw product may still be competitive or it may be that prices are set as smaller firms follow the prices set by larger firms. While processors do not publish information on offering prices for raw product, the fishing community within a port tends to be small, and it is likely that information on offering prices is readily available by word of mouth. Additionally, the processing sector is structured in such a way that it is unlikely firms can set prices independently, even if they wanted to. For example, if one of the larger processors were to increase the price it offers for fish in order to expand its market share, other processors may also increase their prices in order to preserve their shares. If this happens, the firm that started the price increase will not have gained production but would have higher costs and lower profits. Similarly, if that processor were to cut its price, it would have to guess about what it expects its competitors would do. If it believes its competitors would not also cut the prices they offer for raw fish, then by dropping its price, it may increase profits per unit of production but lose total production. On the other hand, if other processors also drop their price, then all processors may gain. The situation in which a firm is not a monopoly but also cannot change its own price without the possibility of affecting the market prices is typically characterized as an "oligopsony." In situations like this, rivalry may be lower because the major firm must consider the responses of others to any price changes. In a fully competitive situation, other firms do not usually respond directly to one firm's price changes.

E.4.3.2 Bargaining or Negotiating Power

In the previous section, we focused on the within-sector coordination required to establish market power. Here we discuss factors affecting bargaining power between sectors. These include the following:

- Threat of substitutes
- Supplier (harvester) power
- Buyer (processor) power

Substitutes. The threat of substitutes refers to substitutes from outside the industry. An oft-used example is the substitutability of glass, metal, and plastic containers for one another. When there is a substitute available from outside the sector, the negotiating stance of the suppliers is weakened. In the raw fish market on the west coast, substitutes appear relatively limited. Processors that are vertically integrated into the wholesale chain may be able to substitute production from other geographic areas to meet customer needs and may utilize some portion of their processing capacity if they have access to "imported" raw product. However, there are not a lot of substitute activities for the profit centers represented by coastal processing facilities. It is likely that locally available resources are fully exploited and that supply facilities would be idle more of the time without trawl-caught groundfish. If processors raise prices, they also face the possibility that their customers will find substitute fish products from other geographic areas or in the form other protein products. Substitute fisheries for vessels are also limited. While vessels may move into other fisheries, they will likely have to continue to deal with the same processors if they do so in fisheries on the west coast, particularly if they stay within a restricted geographic range. If they are negotiating with a processor that is a major buyer for several west coast fisheries, substitutes that would credibly allow them to threaten to sever relations with a local processor may be limited. This situation could also pertain if a processor faced a harvesting company that is dominant in a number of fisheries.

Table E-7. Indicators of harvester bargaining power.

Indicators of Higher Supplier Bargaining power (Based on Porter)	Evaluation
Suppliers can credibly threaten forward integration (ability to buy or control processing facilities).	No (Yes, at-sea whiting)
Suppliers are reasonably safe from threat of backward integration (a processor purchasing a vessel).	No
Production is concentrated among a few suppliers.	No
Sales are spread among many processors.	No
There is a significant cost for processors to switch to a different supplier.	No
The processor's customers are powerful and willing to boycott in support of the suppliers.	No
Suppliers' products are highly differentiated from one another.	No

Supplier (Harvester) and Buyer (Processor) Power. The focus here is on relative power between the sectors.

Table E-7 provides indicators of supplier (harvester) power. Several of the factors related to rivalry within the sector have corollaries in the consideration of supplier and buyer power. For each indicator of supplier power, an inverse statement describes buyer power.[16] One of the indicators of power is the ability of each group to take on the functions of the other (forward and backward integration). Some processors have successfully integrated harvesting operations, but, while there have been attempts, there are not many examples of harvesters successfully developing processing operations at a significant level. When activity in one sector is aggregated, that sector will be more powerful, and its relative power is greater if the sector on the other side of the market is disaggregated. Buying power is higher when suppliers sell products that are not highly differentiated from those of other suppliers and when the cost to a processor of switching from one supplier firm to another is low. This statement characterizes the situation of harvesters versus processors in the west coast groundfish fishery.

The 2007 mid-coast trawler tie-up may provide another indicator of sector bargaining power. Some vessels, both processor-owned and others, did not participate in the tie-up. The tie-up ended when vessels returned to fishing to avoid losing the catch opportunity represented by an entire two-month cumulative limit period. It was anecdotally reported that there was some disruption in the local wholesale markets, with other products filling in for west coast groundfish and that, when supply returned, those markets had to be regained and the alternative supply displaced.

E.4.3.3 Barriers to Entry

If a sector is able to establish above-normal profits by overcoming rivalry, coordinating action, and exerting power in negotiations, then maintenance of that profit over the long term requires barriers to entry. Barriers to entry can be classified as follows:

1. Government created
2. Patents and proprietary knowledge
3. Asset specificity (capital malleability)
4. Economies of scale

Conclusions on barriers to entry with respect to the harvesting and processing sectors are provided in Table E-8.

16

Indicators of Higher Buyer Power	Evaluation
Buyers are safe from a credible threat of forward integration by suppliers (harvesters are unlikely to acquire processing facilities).	Yes (no for at-sea)
Buyers can credibly threaten backward integration.	Yes
Supply is spread among many suppliers.	Yes
There are a few buyers with significant market share.	Yes
There is not a significant cost to switch suppliers.	Yes
Buyers purchase a significant portion of the suppliers output.	Yes
The product is standardized.	Yes

Table E-8. Summary of barriers to entry.

Barriers to Entry	Harvesters	Processors
Government Regulation	Limited number of permits but some "latent." Heavily regulated.	Fishery management related regulations less heavy than for harvesters, but also face environmental regulations (waste discharge).
Special Proprietary Knowledge	Fishing locations.	None identified.
Asset Specificity (Malleability)	Very specific (geographic relocation possible).	Very specific. Shoreside--not mobile; some utility in other sectors. At-sea—mobile.
Economies of Scale (fixed costs of attaining efficient production)	Smaller than for processors.	Larger than for harvesters.

Government Created. Government action may affect barriers to entry by directly restricting participation or indirectly imposing regulations that increase capital or operating costs. The primary direct barrier for the west coast trawl fishery is the limited entry permit requirement. This permit limits the number of harvesting vessels in the fishery and, with Amendment 15 to the groundfish FMP, restricts the movement of vessels among the shoreside nonwhiting, shoreside whiting, mothership whiting, and catcher-processor sectors. A buyback program in 2003 dramatically reduced the number of trawl permits, but, even with that reduction, some permits remain relatively inactive and presumably available for purchase or lease by someone who might want to bring a new vessel into the fishery. Both harvesters and processors operate in a highly regulated environment and face compliance costs.

Patents and Proprietary Knowledge. Control of technology and proprietary knowledge provides competitive advantage where it is not readily available to others. Knowledge of fishing grounds is an example of specialized proprietary knowledge that fishermen often seek to protect. We have not determined whether some processing firms have unique knowledge that would create a barrier for new entrants.

Asset Specificity (Capital Malleability). Both harvesters and processors utilize some highly specific assets (vessels and processing facilities, respectively). Alternative uses for a vessel generally involve switching to a different fishery. If the firm retains ownership of the vessel, switching fisheries may mean geographic relocation and the need to acquire new expertise about fishing grounds, fish behavior, and gear operation. When the alternative fisheries are under a license limitation program, permits must be purchased from other vessels. If the vessel only needs a part-time opportunity, but the prices for permits in a particular fishery are driven by their value when used full time, the permit cost may be a barrier that prevents the vessel from to switching to the alternative fishery.[17] In Chapter 3, information is provided on the degree to which trawl vessels participate in multiple fisheries. Processors also have some assets that may be specific to certain species (e.g., skinning machines) and other assets that may be more versatile (e.g., cold storage facilities) and may be used for a variety of fish species within the region, as well as for agricultural and nonagricultural products. Some processors may receive product from other geographic areas, and processors that have vertically integrated into the wholesale sector may meet their customers' needs with products from other sources.

Economies of Scale. Critical here is "minimum efficient scale." The barrier will be greater if achieving the minimum size required for cost-efficient production requires a large investment in capital, personnel, and development of organizational structure. Under circumstances where there is a very high initial cost, it may be more likely that a competitor will enter from another geographic area, related industry, or

[17] On the other hand, if the alternative fishery is under an IFQ program, the costs of the harvest rights necessary to switch into that fishery will likely be more proportional to the vessel's needs.

through vertical integration as opposed to building from the ground up. Another vehicle for initial entry would be to use a different business model, for example, relying on a higher degree of product differentiation, i.e., a company might start up by selling into a small specialty niche market and then increase scale, expanding into less differentiated fish products. Shoreside processing businesses tend to involve larger commitments of capital than harvesting operations, indicating a greater challenge for new entrants.

E.4.3.4 IFQ Program Effects on Market Power and QS Flow

The following three tables and subsequent text describe how implementation of an IFQ Program may influence the determinants of market power (rivalry, bargaining power, and barriers to entry). For each of these determinants, the tables review the same indicators covered in previous sections, evaluating how these indicators would change with the implementation of an IFQ program.

Rivalry	(Section E.4.3.1)	Table E-9
Bargaining Power	(Section E.4.3.2)	Table E-10
Barriers to Entry	(Section E.4.3.3)	Table E-11

Firms in a sector with more market power are more likely to accumulate QS up to the maximum limits; such firms will be willing and able to pay more for QS, thereby influencing the flow of QS in their direction. Horizontal integration, vertical integration, and consolidation have a primary influence on market power, and barriers to entry are necessary to maintain that power. The text following the tables explains some of the results summarized in the tables. In section E.5 we will see how these results are influenced by the initial allocation of QS.

Table E-9. Effects of IFQ program on the degree of competition and co-operation within a sector (within sector rivalry) ("-" = indicator or less rivalry "+" = indicator of more rivalry, "o" = no change).

Factor Causing Greater Rivalry	Harvesters	Processors
1. A larger number of firms with similar market shares	- A decrease in the number of active harvesting vessels and harvesting companies (subject to accumulation limits). Much of the rivalry for market share will be focused on the QS/QP market. However, for harvesters who do not own their own QS this competition may also involve rivalry in the raw fish market. - Limited opportunity for latent capacity in the sector to become more active, except through direct voluntary reductions by active vessels through QS/QP transfers.	+ Decreased geographic isolation of markets, increasing number of participants within a market. + Some pressure for consolidation in response to existing overcapitalization and threat of harvester market power. - However, if there are effective accumulation limits growth of market share for larger firms will have to occur without the advantage offered by QS ownership.
2. Slow market growth	o	o
3. High fixed costs	+ Increased fixed costs (e.g. camera systems), but for harvesters the increase influences rivalry in the QS/QP market more than the raw fish market (though if a harvester is negotiating to access QP held by a processor, the two markets could be linked). - Incentive to exert market power in the raw fish market to increase profits and recover fixed costs.	o Minor increase relative to vessels*.
4. High storage costs or highly perishable products	o	o
5. Low cost for customers to switch suppliers	o	o
6. Low levels of product differentiation	o	N/A
7. Strategic stakes are high	o	+ Increased strategic stakes, expansion requires direct displacement of competitors, more limited vertical integration opportunities.
8. High exit barriers	o	o
9. A diversity of rivals	o	o
10. Industry Shakeout.	± Expected (more stable over the long term)	± Possible (not certain)
Summary	After an initial shakeout, rivalry will decrease because of fewer harvesters and accumulation limits constraints. The need to cover fixed costs (including cameras and observers) may stimulate rivalry in the QP market and cooperation in the raw fish market. Rivalry in the raw fish market will occur to the degree that processors provide QP linked with raw fish exvessel price negotiations.	Rivalry will increase as a decrease in the geographic isolation of raw fish markets expands the number of effective participants, processors position themselves to defend against the possible exercise of harvester market power, competition for market share requires direct displacement of other processors, and accumulation limits constrain existing and potential vertical and horizontal integration.

*The IFQ program is likely to increase some processor fixed costs related to compliance with regulations, but those costs are not expected to be nearly as substantial as for vessels. To the degree that fixed costs increase, there will be an incentive for processors to increase production, thereby increasing rivalry and posing a higher barrier to new entrants.

Table E-10. Effects of IFQ program on the bargaining power of one business sector in relation to the other (bargaining power) ("-" = indicator or less power, "+" = indicator of more power, "o" = no change).

Indicators of Sector Power	Harvester (Supplier) Evaluation	Processor (Buyer) Evaluation
Threat of vertically integrating with other sector (See section on vertical integration for more detail)	+ Harvesters may vertically integrate by retaining ownership of fish while they are being processed (demanding custom processing services). + Harvesters may exert vertical influence by using QS to encourage new entry by processing concerns.	+ Increased incentive. - Threat limited by accumulation limits. - Possible reduced vertical integration for firms with strong vertical integration.
Business sector concentration (See #1 of table on "rivalry" for more detail)	+ Increased concentration. + Reduction of potential for competition through activation of latent permits.	- Decreased geographic isolation of markets (QP liquidity). + Pressure for consolidation/integration. - Consolidation/integration constrained by accumulation limits.
Switching Costs (processor to a different supplier or supplier to a different processor)	o	O
Processor customer power	O	N/A
Harvester products are highly differentiated from one another	O	O

Table E-11. Effects of IFQ program on the ability of a sector to protect any advantage it gains in bargaining power (barriers to entry) ("-" = indicator or less rivalry "+" = indicator of more rivalry, "o" = no change).

Changes to Barriers to Entry	Harvesters	Processors
Government Regulation	+ Increased fixed costs. + Absolute barrier to entry and expansion	+ Increased fixed costs. Relatively minor compared to harvesters.
Special Proprietary Knowledge	O	O
Asset Specificity (Malleability)	O	O
Economies of Scale (fixed costs of attaining efficient production)	+ The cost of achieving any given level of scale will be increased by the need to acquire QS.	+ If processors in the industry acquire QS, the cost to new entrants to reach a similar level of scale, efficiency, and risk control will be increased by the need to purchase QS. Accumulation limits create absolute barrier in ability to protect higher production levels through ownership of IFQ.

Harvesters. Regardless of who is given the QS, implementation of an IFQ program will result in a shakeout in the harvester sector, leading to consolidation of harvest among vessels in the long term. If most of the harvest were also concentrated among a few of the remaining harvesters, rivalry would be further reduced; however, accumulation limits would be expected to limit concentration. While rivalry may be reduced, the IFQ system is not, itself, one in which intense rivalry among harvesters who acquire QS would be expected. To expand their market share, harvesters would have to compete in two markets: (1) the QS/QP market, to gain the needed access rights; and (2) the raw fish market.[18] Once a harvester secures QS/QP, the need to compete with other harvesters for a share of the raw fish market may be minimal (i.e., it is expected that, in general, the trawl groundfish allocation will be fully utilized—that markets will exist or be developed for all of the reasonably marketable catch).[19] Moreover, since harvesters' ability to expand revenue through increased harvest will be limited by their QS/QP holdings, there is a strong incentive for them to cooperate in raw fish price negotiations with processors as a main means of increasing their revenue for the catch for which they have QS/QP. However, the degree of direct competition and rivalry among harvesters for shares of the raw fish market will depend on the long-

[18] The need to gain access rights in the form of QS/QP and the effects on the market are closely related to the creation of a barrier to entry, discussed in the following paragraph.

[19] For some species, such as Dover sole, supply may exceed demand at prices that harvesters are willing to make a delivery.

term distribution of QS among harvesters and processors. Some harvesters may not acquire all the QS they need for their optimal production levels. If some QP are available from processors (e.g., those processors not using the QP holdings from their own vessels), the negotiations over QP and raw fish prices may be linked.

Under the IFQ program, there is not likely to be latent license capacity for a processor to threaten to draw on if negotiations fail. This affects rivalry among harvesters, bargaining power, and entry barriers. Under status quo, by using a latent permit, a new harvester might come online without directly taking fish deliveries away from another harvester.[20] The need to hold QS/QP forms an absolute barrier to entry, and new entry can only occur to the degree that the production of an existing participant is first removed through the acquisition of QS/QP. While the barrier to activation of latent capacity may increase the opportunity for a harvester with its own QS to exert power, harvesters may still have to be concerned about linkages between their harvest of groundfish and deliveries from other fisheries (e.g., Dungeness crab).

Fixed costs affect both rivalry and barriers to entry; here we will discuss harvester rivalry. Categorization of fixed costs depends on the time frame of reference. For example, costs may be fixed for a year, a trip, or a day of a trip. An increase in fixed costs, particularly those related to compliance and costs that are fixed per day of fishing, such as observer costs, would be expected to increase rivalry in the QS/QP market but increase cooperation in the raw fish market. [21,22] Increased fixed costs will likely lead vessels to seek to expand their production per trip, requiring more QS/QP. However, if there is a willing buyer for any QS/QP acquired (i.e., vessels need not compete for a market for their raw fish), the increased fixed costs would give vessels a greater incentive to coordinate marketing in the raw fish market in the hopes of generating higher profits to recover increased fixed costs.

Harvester market power may also increase with an increased opportunity to exert vertical control through (1) retaining ownership of fish and hiring custom processors, and (2) acquiring QS and using those QS to encourage new processors to enter the west coast market by guaranteeing raw fish deliveries. Custom processing has been seen in the IFQ system in British Columbia. [23] This initial increase in vertical control through custom processing could allow vessels to develop some of the marketing expertise, which might then put them in a better position to more completely step into vertical integration by taking on direct ownership of processing facilities. If harvesters encourage entry of a new processor, that processor would still have to compete with existing processors in the wholesale market, but their risk could be substantially reduced if harvesters with QS are willing to make long-term commitments.

With respect to entry barriers, there will likely be certain government required compliance costs, e.g., camera systems, that will raise the cost of entry. Harvesters wishing to achieve efficiencies related to any particular scale of production will also have to purchase an amount of QS commensurate with that scale of production (the effect of the initial allocation in this regard will be discussed in Section E.5).

---

[20] While the two-month landing limits mutes some rivalry, under status quo, if a licensed vessel holds out during negotiations, a buyer may be able to find another licensed vessel to make that delivery, activating a latent permit if necessary (there are a number of permits available that are not used or not used to their full capacity).

[21] The cost of the QS/QP itself does not represent a fixed cost because they can be sold (the QP in particular) during the season.

[22] With consolidation of production among fewer vessels, it is likely that some of the existing permits will go unused and may be available for purchase by new entrants (reducing the cost of entry with respect to permit price). However, the higher the fixed compliance costs for participating in the program, the more QS/QP a new entrant will need to buy to achieve the level of efficiency necessary to pay the cost of the QS/QP. The fixed costs and need to purchase QS/QP will result in a net increase in the cost of entry (barrier to entry).

[23] Under a custom processing arrangement, vessels retain ownership of the fish, which is processed for them under contract. The harvesters then sell the fish into the wholesale or retail market. In this way, harvesters begin vertical integration and the capture of some rents from other parts of the production chain.

Processors. With an IFQ program, rivalry would be expected to increase among processors for a number of reasons (note: this portion of the analysis does consider the effect of the initial allocation).

First, processor rivalry may be increased by a decrease in the geographic isolation of markets that effectively raises the number of participants. In the discussion box below, a hypothetical construct is provided to explain how the liquidity of QP may link markets that had been previously geographically isolated, thereby expanding the number of participants. Table E-13 through Table E-16 provide information on processors that operate in multiple ports and the size of processors in each port as measured by their average metric tons for 2004 to 2006 for the whiting and nonwhiting fisheries.

Second, the potential for increase in harvester market power will encourage processing firms to integrate horizontally and vertically. With respect to vertical integration, acquisition of QS could provide a lower-cost means for processors to (1) compete with one another for market share (foreclosing competitors' access to supply and consolidating processors' market shares), (2) vertically integrate to secure supply,[24] and (3) hold out during negotiations. However, while there may be more incentive for horizontal integration and consolidation, actual integration may be limited by accumulation limits.[25]

Finally, rivalry may also increase due to direct strategic conflict. Direct strategic conflict would be associated with the foreclosure effect caused by any firm that tries to expand operations, the effects of accumulation limits on current industry structure, and a firm's ability to integrate horizontally and vertically. With respect to the foreclosure effect, under status quo, a processor can expand its operations by acquiring access to an unused or underutilized limited entry permit and vessel. Other processors are displaced indirectly as managers reduce vessel two-month cumulative limits in response to the increased effort, and processors compete with one another to sell their products in the wholesale market. Under IFQs, competition will be direct. A processor can secure more product only if the raw product going to a competitor is directly and immediately reduced (i.e., acquisition of QP or harvester delivery commitments directly reduce a competitor's market share by foreclosing its access to supply of a key input). Accumulation limits will alter the existing and potential horizontal and vertical integration, possibly shifting power balances within the sector and leading to strategic repositioning. Fish buyers at their QS accumulation limits who are vying to maintain or increase production will have to compete with one another for the production of existing vessels with less latitude in the means available for securing harvest commitments. They would not be able to offer their own QS/QP to cover additional harvester (see paragraph below on the limits to vertical integration).[26]

[24] Facilitating planning for more efficient production.

[25] In its final preferred alternative, the Council applied accumulation limits on control limits only to QS; this substantially reduced the constraint that the control limits would have imposed on vertical integration by processors and horizontal integration by harvesters. Under the final preferred alternative, such integration can occur limited only by antitrust laws and the ability of the firm to acquire QP each year from other QS owners.

[26] The situation under IFQs and status quo would be similar for vessels that max out their two-month limits with deliveries to a particular buyer. One buyer can bid production away from those vessels only at the cost of a direct reduction in raw product delivered to another buyer.

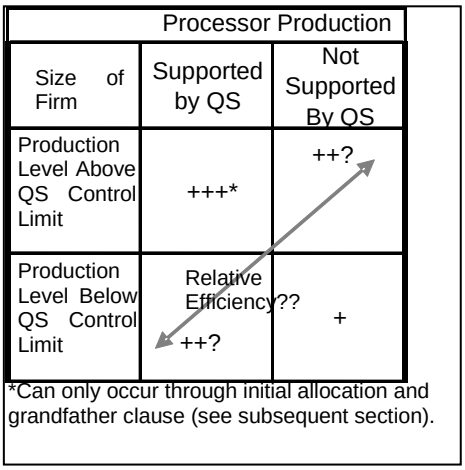

Figure E-10. Relative efficiency (including risk factors) based on size of firm and whether production is supported by QS.

For processors that are at their control accumulation limits, horizontal integration could occur only through the acquisition of firms that do not control QS, and expansion (consolidation) can occur only through increasing the proportion of production unsupported by processor-owned QS. When at the control limit, a processor that expands production decreases the portion of its production supported by QS controlled by the processor (such a processor would be increasing the amount of its QS in the upper right hand cell of Figure E-10). At the same time, processors that are not at their limits may acquire additional firms that own QS or support expanded production by securing additional QS (expand activity in the lower left hand cell of Figure E-10). Therefore, unless firms at their QS accumulation limits have other advantages (e.g., are already more efficient than firms that are below their accumulation limits, gain enough efficiency through expansion to compensate for the costs and risks of production unsupported by QS, or have better access to capital), firms that are below their accumulation limits may gain more advantage through consolidation (growth). However, with respect to consolidation, firms with no QS may be less expensive to acquire than those with QS, making them more likely candidates for acquisition by firms at their accumulation limits that wish to extend their horizontal integration. Processors at accumulation limits will be more likely to expand if, for them, the relative efficiency of an additional increment of production not supported by QS is greater than the same increment of additional production by a firm operating at a lower level of overall production, but with support of its own QS (the upper right-hand cell of Figure E-10 is *greater* than the lower left-hand cell). On the other hand, if the relative profitability is the opposite, it will be more likely that smaller firms will acquire QS and expand up to accumulation limits (the upper right-hand cell of Figure E-10 is *less* than the lower left-hand cell). Section A-2.2.3-e provides data on the number of fish-buying firms that would be expected to be above and below accumulation limits under various allocation formulas.

Processors at their accumulation limits may not be able to further integrate vertically through acquisition of harvesting vessels. If control limits apply to both QS and QP, a processor at its control limit that decided to vertically integrate by purchasing a groundfish trawl vessel would not be able to acquire additional QP to place on the vessel.[25] The definition of control will also be important in determining the nature of harvester-processor relations. For example, if exclusive contracts for delivery are considered "control," then processors at their limits may not be able to enter into this type of contract with a harvester. At the same time, it would be less expensive for processors not at the control caps to vertically integrate though acquisition of QS (as compared to integration by acquisition of a vessel), increasing the viability of a threat by the processors to integrate vertically. However, it is more likely to be the smaller processors that will not be at their accumulation limits, and they may not control enough of the processing capacity to exert much market power.

While processor rivalry may increase for the reasons described above, some of the same factors will decrease bargaining power, specifically the decrease in the threat for backward integration due to the effect of accumulation limits and the expanded geographic scope of the market due to the liquidity of QP and interaction between the QP and raw fish markets. At the same time, the threat of the potential for harvesters to exert market power will provide incentive for increased cohesion among processors. However, processors' ability to act together is very limited because of antitrust law constraints. Harvesters, on the other hand, are able to coordinate their marketing under provisions of the Fishermen's Collective Marketing Act.

Those processors that own QS may be more competitive than those that do not (depending on acquisition costs); therefore, the possible need for new entrants to acquire some QS to be competitive may add to the cost of entry, creating a barrier to entry. Differences in processor profit opportunities before and after implementation of the IFQ program may also create a short-term barrier. If existing processors have some market power before implementation of IFQs, and that market power still exists, but at a diminished level after IFQ implementation, new entrants will be at a disadvantage in their ability to recover their investment compared with those who may have recovered their investments at a time of relatively greater profit.

The above paragraphs deal with conditions that would encourage or discourage the exertion of market power among processors. In this context, if the raw fish market is competitive before and after implementation of IFQs, and the processing sector is overcapitalized because of recent declines in OY or the race for fish in the whiting sector, that sector may bid away some of the profits associated with capital investment to secure access to harvest and QS. Also, if processors currently have market power in the raw fish market, but do not after IFQs are implemented, they will also be likely to bid away some of their profits. In both cases, a new entrant will face the situation of attempting to recover capital investment in an environment in which existing firms are not making enough profit to cover their capital costs. While this situation may present a temporary barrier to entry during a period of processor rationalization, it is not relevant to the market power evaluation, since there would be no market power for an entry barrier to preserve.

Box: Decreasing the Geographic Isolation of Local Raw Fish Markets

Consideration of the factors influencing market power requires careful definition of the scope of the market and assessment of whether that scope changes with the implementation of an IFQ program. In the market for raw fish, part of a processor's ability to exert market power may be based on transaction costs that imply less than perfect mobility in harvesting operations. The cost of moving harvesting and raw fish marketing activities between geographic areas or from one owner to another reduces mobility, or in some sense, creates "stickiness" in the system. This stickiness determines the scope of the individual markets. There may be numerous processors coast wide, but if there is only one or a very limited number of processors in a particular port, under status quo, the processors in that port may have more bargaining power than if they compete on a coast wide basis. While they have some latitude to offer lower prices within a port, that latitude may be limited if there is a processor in another port willing to offer a higher price. In such a case, if the processor in the vessel's preferred port offers a price that is lower than the price available in an alternative port by an amount greater than the cost of delivering to the alternative port, the preferred port processor might lose that delivery.* In aggregate, if one processor operates in many ports coast wide, coordinating prices between its plants, and if that sector operates similar to other sectors with a single dominant player (with smaller processors following the prices of the larger processors), then the opportunity for a vessel to find a higher price elsewhere along the coast may be limited.

The introduction of QP changes the situation by reducing the cost of moving production between ports, thereby reducing stickiness. QP may move from one port to another at relatively low cost. Consider a hypothetical status quo situation In which there are five ports (yellow, red, blue, white, and orange [in north to south order]), and there are processors in each port. Within each port, there are only a few processors, and the costs of moving fish between ports isolates the local market and provides the processors in each port with some latitude to follow price setting by the dominant processor in that port. If the dominant processor in each port is processor A, then prices may be coordinated among the somewhat separated markets. Now consider a QP market. Since QP can move easily between ports, there may be really a single market for QP along a major section of the coast. Now if Processor A wants to offer a lower price for vessels delivering fish in say, Port Orange, vessels can consider transferring QP to a willing buyer in any one of the other ports without catching the fish themselves. With respect to relations with a particular vessel in Port Orange, Processor A has to contend not only with Processor F and possibly D, but also with Processors C, B, and E. If one of those processors is willing to offer a higher exvessel price for the fish, the QP can easily be transferred to the alternative port, with the vessel in Port Orange receiving the higher profits associated with the QP.

Table E-12. Hypothetical markets for raw fish and quota pounds.

Raw Fish				Quota Pounds	
Market	**Processors**			**Market**	**Processors**
Port Yellow	A B C			Coast wide or Regional (e.g., north of 40 10)	A B C D E F
Port Red	A				
Port Blue	A B E				
Port White	A D				
Port Orange	A F				

Whether the price-setting situation hypothesized here exists and whether the additional mobility provided by QP is enough to break down such price setting are open for discussion. If processors are able to exert market power, they will be in a stronger position to buy QS up to accumulation limits or negotiate strong contracts for delivery of QS fish.

There are some limits to QP mobility that influence the result and have to be considered:

(1) There will be some transaction costs associated with the QP transfers (even if much lower than for the movement of the vessels or fish).

(2) There may be non-pecuniary benefits to fishing (lifestyle benefits associated with the fishing activity that are not financially rewarded) such that a fisherman will have some additional tolerance to fishing at a profit lower than what he might receive by not fishing and selling the QP in an alternative market (i.e., a fishermen might be willing to give up some of his quasi-rents).

(3) If this transfer of QP went on for a period, and if the vessel owner were not able to cover its fixed costs through other fishing activities, over time, the vessel owner would reduce the size of its capital investment (the vessel owner would likely sell the vessel).

Table E-13 through Table E-16 provide information on processors that operate in multiple ports and the size of processors in each port as measured by their average metric tons for 2004 to 2006 for the whiting and nonwhiting fisheries.

*Other factors would also come into play such as negotiations over the suite of raw product a vessel might want to deliver to its preferred port on a year-round basis.

Table E-13. Trawl non-whiting groundfish buyers active in multiple ports (A = active buyer in the port) and single ports (count of single port buyers in each port), and distribution their buying activities among ports (based on 2004 to 2006 fish tickets).

E.4.4 Access to Capital (Demand) - Discount Rates

The purchase of QS requires access to financial capital. Such purchases may occur by using wealth that a firm or individual already holds or through commitment of future earnings in return for access to capital held by someone else (e.g., commitment of future payments in return for a loan from the bank). The focus of this section is on factors that affect how much individuals and businesses are willing to pay for access to capital (demand) and how that affects their access to QS. The focus of the following section is on factors that affect how much lenders are willing to supply capital and how that affects the ability of individuals and businesses to get loans for the purchase of QS.

All else being equal, QS will flow toward people or businesses that have a low personal discount rate (Francis et al. 217-33). [Note: personal discount rates are related but different from market interest rates that must be paid to borrow. Interest rates will be discussed in a following section.] Discount rates play a major role in determining how much an individual is willing to pay for QS. The value of QS to the individual represents the expected stream of income from QP issued for that QS, discounted based on preferences between future and present income. People or businesses that have a strong preference for earnings in the current year as opposed to future years are said to have high discount rates.

Here we will first discuss discount rates in general and then discuss factors affecting discount rates, including the following:

- Time preference
- Risk

To illustrate the effect of differential discount rates of QS values, consider a person who places a relatively high value on current consumption as compared to next year's consumption, say a 25 percent discount rate. That person would prefer to receive $80 this year rather than waiting and receiving something less than $100 next year ($80 + (25 percent x $80)) but would give up $80 this year in order to gain something more than $100 next year. To illustrate the effect of differences in discount rates, consider an amount of QS that is expected to generate $100 of net revenue each year. To simplify this illustration, we will limit the duration of time considered to five years. Now assume there are individuals with discount rates of 5, 10, and 20 percent. Table E-17 shows how much these individuals would be willing to pay for the QP in each subsequent year and in total, assuming that they had to buy QP for all five years up front. As can be seen, a person with a discount rate of 5 percent would be willing to pay $452 now for the QS compared to $269 that a person with a 20 percent discount rate would be willing to pay for that same QS (i.e., the person with the lower discount is willing to pay 68 percent more).

Table E-17. Example of the effect of personal discount rate on willingness to pay for a five-year stream of revenue.

		Year					Present Value
	Personal Discount Rate	**1**	**2**	**3**	**4**	**5**	**(5 years summed)**
		Values by Year($)					
	Nominal Values	**100**	**100**	**100**	**100**	**100**	**500**
Person A	Values Discounted at 5%	100	95	90	86	81	452
Person B	10%	100	86	73	63	53	375
Person C	20%	100	68	47	32	22	269

People with lower discount rates are likely to pay more for QS even if they expect to derive similar revenue. The following sections discuss factors affecting personal discount rates.

Literature based on IFQ trading shows fishermen have fairly high discount rates (Asche 403-10). Table E-18 displays the relationship between the ratio of QS value and QP value and the implied discount rate.

Table E-18. Discount rate associated with different relationships between quota value and QP value (adapted from Asche, 2001).

QS/QP Value	**3/1**	**4/1**	**5/1**	**6/1**	**10/1**	**11/1**	**15/1**
Discount Rate	0.50	0.33	0.25	0.20	0.11	0.10	0.07

In the mid 1990s, ratios reported for the Iceland IFQ system varied from 3.5/1 to 9.2/1 depending on the species. This would place discount rates between 11 and 50 percent. These rates would be determined by those able to participate in the market. In Iceland, the system is designed to discourage absentee ownership of ITQ (ownership by those who do not participate as harvesters). Therefore, the rates may better reflect time preferences of fishermen. If members of other sectors of the fishing industry or the broader economy also participated in the market, the ratios might be different. We will now look at some factors that influence the general discount rate.

E.4.4.1 Personal Time Preferences

We are using the term "time preference" here to reference personal time preferences unrelated to risk and other factors that influence discount rates. Factors affecting time preference include income, wealth, innate patience, and education (Becker and Mulligan 729-58).[27] Individuals with low income will often have higher time preferences (value current consumption over future consumption) due to a greater desire to meet immediate needs. Research on fishermen time preferences is available but limited. When asked to respond to hypothetical profit decreases and increases for a series of years, fishermen in the north Irish Sea answered in ways that indicated a range of time preferences that were fairly high (Curtis 775-78). Thirty-seven percent of all fishermen had discount rates of greater than 50 percent, and 40 percent had discount rates of between 30 percent and 50 percent. It seems likely that crewmembers will be less wealthy than business owners and, therefore, more likely to discount future earnings and less likely to acquire QS. Level of expected future income also affects time preference (if one expects income to rise in the future, one may have a higher preference for current consumption). Similar to an individual, managers of a business under financial stress may place a higher value on current income that is needed to survive, compared to the value that a healthier business might place on current relative to future income. Simple patience is another personal characteristic affecting time preference. While QS is more likely to flow in the direction of those with lower time preferences, the IFQ system itself, independent of the initial allocation, is not expected to directly affect personal time preferences.

E.4.4.2 Risk

The aspect of risk of concern here is a person's assessment of future risk. Considerations include ability to enjoy/utilize future income and personal assessment of the likelihood that future earnings will be realized. Those who face greater risk in their activities or otherwise believe the future is riskier will discount QS and be less likely to buy than those who see more certainty, unless the acquisition of QS overcomes that risk. The IFQ program will create an opportunity for individuals (e.g., crew), businesses, or other entities (e.g., communities) to increase the security of their income by acquiring QS to ensure access to harvest. A QS owner may earn income from the sale or direct use of the QP associated with the QS, or use it as leverage to ensure access to employment or other economic activity (e.g., a community ensuring the continuation of fishing activity in its port). This is closely related to risk reduction through vertical integration, discussed in a previous section (page E-13). Assessments of the degree to which ownership of QS might increase security will also involve consideration of the likelihood that there will be changes to the program or changes in the fishery resource. Other factors affecting risk under IFQs are discussed in Chapter 4. These include a harvesting firm's assessment of the risk that it will encounter a disaster tow for limiting overfished species or that another vessel will encounter such a tow and cause portions of the trawl IFQ fishery to be closed, even though some QP have not been harvested.[28]

E.4.5 Access to Capital (Demand) – Planning Horizon and Investment Recovery

Another factor determining the value a person will place on QS is the length of time over which the person will value the asset. A person with a shorter planning horizon may tend to place a lower value on QS; however, future resource rents can be captured by the firm at any time through the sale of the QS (assuming competitive sectors). Therefore, in order for the planning time horizons to make a difference,

[27] Note: Individuals who expect to have higher incomes in the future or have less utility for income in the future (e.g., the anticipation of a more limited ability to enjoy the income) will also have higher discount rates than those without such expectations.

[28] Another aspect of risk is simply the risk a person attributes to the possibility that they will not be around or will have less ability to enjoy the income in the future than they do in the present.

the firm must be earning some rents that are not reflected in the QS value (representing resource rents) or place some additional value on the QS that will not be captured in sale of the QS.

To illustrate, assume that the following:

- There are two individuals who each have a discount rate of 5 percent (person A in the previous example).
- They both own QS and earn resource rents (the difference between P1 and P2 in Table E-19**Error! Reference source not found.**).
- They are equally efficient and earning intramarginal rents (see Section E.4.3).
- The $100 value that they anticipate earning each year is derived from owning the QS (rents) *and* participating in the fishery (intramarginal rents).

When they leave the fishery, they will be able to sell their QS and capture future resource rents. However, they will no longer capture the intramarginal rent. If we assume the intramarginal rents are $20, that the general market price for the QP is $80, and that a person plans on leaving the business after three years,[29] that person would value the QS at only $419 as compared to $452 for someone who plans to remain in the fishery for all five years (the actual time horizons over which QS is valued are likely longer; the five-year horizon is being used to illustrate the concept).

Table E-19. Example of the effect of planning horizon on willingness to pay for a f-year stream of revenue (both cases assume that QS are sold at the end of the five-year period, but that Person A-2's intramarginal rents are based on exceptional fishing skill and will not be captured upon sale of the business).

		Year					Present Value
	Personal Discount Rate	1	2	3	4	5	(5 years summed)
		Values by Year($)					
Person A-1	Nominal Value	100	100	100	100	100	500
	Discounted Values at 5%	100	95	90	86	81	452
Person A-2	Nominal Value	100	100	100	80	80	$460
	Discounted Values at 5%	100	86	73	69	65	419

In this example, we have considered a planned exit. Other factors may also affect planning horizons, for example, the amount of time required to recover the cost of a capital investment. If one of the reasons a firm holds QS is to increase its security in recovering on a capital investment, the longer it takes to recover on that capital investment, the longer the stream of benefits the firm will necessarily take into account and the more it may be willing to pay for the revenue security the QS provides, as compared to other firms with a shorter time horizon.

E.4.6 Access to Capital (Supply)

The main concern here is what it costs to borrow money (access to capital) for the purchase of QS. These costs are generally reflected in the interest rates charged by lending institutions. Risk, at the industry and borrower level, is major determinant of willingness to lend. At the industry level, an IFQ program is expected to reduce risk by stabilizing the industry economically, allowing for better long-term planning, and improving stock conservation through improved information and more precise control over total

[29] Also assumed here is that the source of the person's intramarginal profits is such that he/she will not be able to capitalize on those profits through sale of the business (receive a price for the firm that takes into account the firm's greater efficiency relative to other firms). An example of this would be if the individual leaving the industry is also the vessel operator and the source of his/her rents is superior skill.

removals. The IFQ program may also increase the potential for harvesters to exert market power (or decrease the effectiveness of processor market power), thereby increasing the risk that processor profits may decline. Therefore, all else being equal, the cost of capital for processors could increase.

At the individual firm level, some of the factors that affect willingness to lend are the borrower's equity (including the liquidity of that equity), size, diversification, and viability of the business plan. The nature of a firm's equity determines the firm's ability to offer up collateral as security for a loan. When a loan is sought for the purchase of an asset, the asset itself sometimes serves as security for the loan (e.g., borrowing for a real estate purchase). Our primary concern here is a firm's access to capital under an IFQ program and how that affects QS flow. Access to capital is necessary for the purchase of QS. If a firm does not already have the capital, it will have to borrow money if it wants to purchase QS. To secure a loan to purchase QS, the QS itself may be of limited use as collateral because the value of the QS may fluctuate with changing stock conditions, prices, and regulations (including increases in costs caused by regulations and possible changes to the QS system). In deciding whether to lend for the purchase of QS, , a lender is more likely to evaluate the loan applicant's overall financial condition, including total equity and its liquidity, because the value of the QS may be somewhat tenuous. A firm without QS or with insufficient QS to support its business plan will be viewed as a higher risk.[30] Thus, QS may be of limited value as security for the loan itself, but ownership of QS may reduce the firm's risk profile, giving it cheaper access to capital secured by other assets.[31]

Table E-20. Influences of the IFQ program on QS flow through effect on demand and supply of capital.

	Harvesters	**Processors**	**Crew**	**Communities**
Demand for Capital				
Time Preference	Those with high time preference will not be willing to pay as much for QS.			
	Indication of high time preferences.	Uncertain	Low income may lead to high time preference.	Uncertain
Risk	Those who believe that the future holds greater risk than others will have a lower willingness to borrow, unless ownership of QS overcomes the risk. The fishery managed with IFQs will have inherently less risk. There is no basis to distinguish among groups.			
Planning Horizon and Investment Recovery	Those who have a longer planning horizon for the use of an asset may be willing to pay more to acquire it (as compared to someone acquiring the same asset with a shorter horizon). (This outcome depends on there being a limited ability to recover future earnings through sale of the asset at the end of the planning horizon.) There is no basis to distinguish among groups.			
Supply of Capital	The overall financial position of a firm will be evaluated in determining loan worthiness. Firms are likely to receive more favorable terms for a loan if they are larger, diversified, and have assets that may be used as security and are of value outside the industry. In general, the IFQ program will likely decrease risk in the industry. QS are of tenuous value as collateral, but are important to the viability of a firms business plan. Firms with cheaper access to capital will be more likely to accumulate QS.			
	Harvesters less likely to have capital useful in other industries. Of generally smaller total size than processors. Risk and cost of accessing capital may decrease with greater stability and possible increase in market power.	Firms more likely to have capital that may be useful in other industries Firms often of larger size than harvesting firms. Processors may experience a risk increase associated with harvester market power, increasing the cost of accessing capital.	Not likely to have fishing business related assets for use as collateral. This may mean higher costs of borrowing.	May have cheaper access if the governing body is viewed as lower risk.

[30] Not receiving a sufficient allocation in itself would raise a question in the lender's mind as to the status of the firm in the industry and viability of its business plan.

[31] Anonymous interviews with bank lenders and industry analysts. March 2008.

In evaluating the liquidity of a firm's assets, one of the factors that banks consider for the fishing industry is whether an asset can be used outside the industry (is malleable to other uses). In general, harvesting firms tend to have fewer assets usable outside the fishing business, relative to processing firms. Harvesting firms generally have a vessel and vessel-related assets (gear) and may have some shorebased equipment (e.g., a truck). Processing companies may own a number of assets that are not industry specific, potentially including land, buildings, cold storage, heavy equipment (e.g., lift trucks), trucks, and cars. [Note: Some companies may lease some of these assets (e.g., land and buildings in a port).]

Size and diversification of the firm are other factors considered in evaluating risk. Processing companies tend to require greater capital investment than harvesting companies. Their business operations may also be more diversified in that some assets may be used temporarily in non-fish industry employment (e.g., cold storage), and they may satisfy customer needs and to some extent utilize processing capacity with product from outside the geographic region. On the other hand, vessels are more mobile and so have some opportunity for diversification through geographic relocation.

E.5 Summary of Influences on the Flow of IFQ among Groups and Effect of Initial Allocation of QS

The following is a summary of the general way in which the flow of QS is influenced by the initial allocation for each of the above topics.

- **Relative efficiency**. Initial allocation will provide an infusion of capital. Those receiving an initial allocation will have an opportunity to make investments to increase their efficiency over competitors. Greater profits will then enhance their ability to accumulate more QS up to accumulation limits.
- **Vertical Integration**. Under IFQs, there will be an increased incentive for vertical integration. Those receiving an initial allocation will experience an increase in resources to support vertical integration (for processors, vertical integration includes the acquisition of QS). If there is a grandfather clause, initial allocations may lock in certain efficiency advantages among firms, until the grandfather clause expires. However, to the degree that control accumulation limits are effective, this differential will not allow the firms at their accumulation limit to acquire more QS; moreover, processing firms with higher levels of vertical integration may have to divest themselves of some harvesting opportunities.
- **Market Power**. An increase in market power among those receiving an initial allocation will increase their profits and ability to acquire additional QS. The initial allocation will affect within-sector rivalry, bargaining power, and barriers to entry.
- **Access to Capital**. Those receiving an initial allocation will have enhanced access to capital, which, in turn, will allow them to accumulate QS more rapidly. An initial allocation may increase the recipients' demand for capital, and it may be less expensive for them to acquire capital (lower borrowing costs) and thereby QS. Harvesters not receiving enough initial allocation may be viewed as high risk if they go to borrow.

The following text and tables (Tables E-21 and E-22) review these results in more detail, discussing some of the differences between sectors. Where there are a number of contingencies that will determine the expected outcome, key questions are provided to help the reader develop their own assessment of expected outcomes. A final summary table provides an overview of differences in the outcomes for harvesters and processors.

E.5.1 Relative Efficiency

For initial recipients, the initial QS allocation will give them an ongoing advantage over those who did not receive an initial allocation. The initial allocation constitutes a "free" infusion of capital and all else being equal, the firm receiving that infusion will experience greater opportunity to increase efficiency compared to firms not receiving an initial allocation. For example, assume there are two firms with similar relative costs and revenues, but the first receives an initial allocation of QS, and the second does not. If industry profitability allows the second firm to purchase QS with the expectation of being able to recover its investment in the QS, then it is implied that the firm receiving the initial allocation of QS will have a similar opportunity to make a capital investment and either expand its operations through the acquisition of yet more QS, or make other acquisitions to enhance its business activities. If this investment further advances that firm's efficiency, it will then have a competitive advantage in the acquisition of even more QS or in other areas of competition. In this way, the initial allocation may create a self-perpetuating and potentially expanding difference between firms receiving and not receiving the allocation.

Table E-21. Influences of status quo, IFQ program, and initial allocation relative to efficiency on profit distribution and QS flow (shaded cells repeats information in previous sections).

	Harvesters	Processors
Status Quo	At a competitive equilibrium, both sectors would be expected to have comparable profit levels. Because a full competitive equilibrium is never reached, in every sector, some firms are more profitable than others, and one sector as a whole may have greater profits than the other. Changes in the fishery may affect profits for firms in each sector differently. For example, the effect of the contraction of the fishery in the last decade may have affected harvesting and processing firms to different degrees.	
IFQ Program	IFQs are another change that is expected to affect the sectors differently. If one sector gains more efficiency than the other, all else being equal, we would expect that QS would initially flow toward the sector that has a greater efficiency gain. In the short term, the IFQ Program will probably provide more direct opportunity for vessels to increase their efficiency than for processors.	
Initial QS Allocation	***A self-perpetuating "leg up."*** *The initial allocation constitutes a "free" infusion of capital, and, all else being equal, the firm receiving that infusion will experience greater opportunity to increase efficiency compared to firms not receiving an initial allocation.*	

Note: An initial allocation to crewmembers or communities might also give them a leg up in an effort to accumulate wealth.

Key questions to assess the direction of future QS flow are as follows:

- At present, do we believe that one sector tends to be more efficient than the other?
- Do we think that one will gain more efficiency under IFQs than the other?
- If there is a difference between the sectors, and the less efficient sector is gaining efficiency, do we think the gain will be enough to overcome the initial deficit?

E.5.2 Vertical Integration, Quasi-rents, and Economic Rents

The initial allocation of QS will be an asset that processors may use to increase their vertical integration, placing them in a stronger financial position and strengthening their competitive stance.

Under the accumulation limit grandfather clause, processors (buyers) receiving an initial allocation of QS (based on permits they hold or direct allocation for processing history) that exceeds the accumulation limits will have a unique advantage over later entrants who will not be able to achieve the same level of vertical integration. However, while that advantage will allow them to horizontally integrate (although with the support of QS for the expanded operation) or otherwise increase their competitiveness, because of control accumulation limits, they will not be able to acquire more QS beyond the grandfather clause ceiling. Once the business ownership changes, the grandfather clause expires, and the amount in excess of the accumulation limit will flow back onto the market. When 25 percent of the QS is allocated to

processors, a greater proportion of the QS received by processors will exceed the accumulation limits than that of firms that harvest only (see Sections A-2.1.1 and A.2.2.3.e). With the grandfather clause, the more allocated directly to processors, the more of the total QS will be held by firms in excess of accumulation limits. Because any QS that a firm at its accumulation limit divests itself of cannot be repurchased, the QS held by those over accumulation limits is more likely to remain off the market than QS held by those below the accumulation limits.

If there is no grandfather clause, an already strongly vertically integrated company may be weakened by the need to divest itself of harvesting assets. One aspect of the competitive position among processors would be evened out; all processors (existing and new entrants) would be restricted to the same amount of vertical integration. This change in the within sector strength of competitors would affect the future distribution of QS within the processing sector.

Table E-22. Influences of status quo, IFQ program, and QS initial allocation on vertical integration and QS flow (shaded cells repeats information in previous sections).

	Harvesters	Processors
Status Quo	Reasons for vertical integration are market security, protecting profits associated with specialized assets, rent (profit) capture, and market foreclosure (preempting a competitor's access to a market). Under status quo, firms can acquire assets to engage on either side of the raw fish market (harvesters can acquire processing assets and processors can acquire harvesting assets). Expansion into the other sector also requires management time and expertise. In practice, there appears to be more acquisition of harvesting assets and little significant entry into processing by harvesting firms.	
IFQ Program	Harvester vertical integration will not be constrained by accumulation limits. Vertical integration for harvester is covered more completely under market power.	Under IFQs vertical integration and QS access motivated by vertical integration may increase as follows: • The opportunity to own QS may provide a less expensive way for processors to respond to existing pressures for vertical integration (ensuring market security or protecting unmalleable assets). • As harvester profits increase, harvesters may become more of a target for vertical integration. • The exclusivity of QS provides a new opportunity for processors to increase their market share by acquiring QS and thereby foreclosing the opportunity of competing processors. At the same time, accumulation limits may substantially limit processor ability to vertically integrate and could even reduce existing levels of vertical integration. Accumulation limits would prevent processors from supporting as great a proportion of their production as harvesters, because processors handle larger volumes than harvesters do on a per operation basis. Vertical integration through direct ownership of vessels would also be constrained by accumulation limits because any QP put on the vessel would count against a processor's accumulation limits. Any processor with vessel capacity that substantially exceeds the accumulation limits may divest themselves of some of those vessels.
Initial QS Allocation	*Firms receiving an initial allocation will be in a stronger financial position to vertically integrate, thereby strengthening their financial position and competitive stance.*	
		Under the grandfather clause, processors (buyer) receiving an initial allocation of QS that exceeds the accumulation limits will have a unique advantage over later entrants. However, accumulation limits will prevent those grandfathered in from using that advantage to acquire QS. Once the grandfather clause for those QS expires, there will be a new flow of QS onto the market. *The more allocated directly to processors the more of it that will be held by firms in excess or at accumulation limits (if there is no grandfather clause). Because any QS divested cannot be repurchased, the QS held by those at accumulation limits is more likely to remain off the market than QS held by those below the accumulation limits.* *If there is not a grandfather clause, an already strongly vertically integrated company may be weakened by the need to divest itself of harvesting assets and affect the future distribution of QS within the processing sector.*

Key Question:

1. If there is no grandfather clause, to what degree will smaller processing companies be strengthened? If larger companies receive fewer QS and is a relative strengthening of smaller companies, would those companies use that strengthening to buy QS up to the accumulation limits?

E.5.3 Market Power, Horizontal Integration, and Consolidation

To simplify the discussion in this section we will address the initial allocation issue from the perspective of its effect on QS flow in the long term as the amount of QS allocated to processors increases. Our concern in that regard is how the initial allocation affects market power. The more market power a sector has, the more likely it is that QP will flow toward that sector.

This discussion provides additional detail on the effects of the initial allocation on market power, as displayed in tables each on the factors that determine market power, as follows.

Rivalry	(Section E.4.3.1)	Table E-23
Bargaining Power	(Section E.4.3.2)	Table E-25
Barriers to Entry	(Section E.4.3.3)	Table E-26

Readers are encouraged to review the tables, then look to the discussion to provide additional information on the findings displayed in the tables.

Discussion of Results in Tables

For harvesters, competition in the raw fish market will increase as the amount of the initial QS allocation to harvesters declines and that to processors increases. If processors cannot reach agreements with existing harvesters, latent permits may be activated to meet processor needs, increasing the number of active harvesters. As the allocation to processors increases, the financial health of the largest producing vessels and financially weakest firms may be diminished. The largest producing harvesters may not achieve the level of production they would have if there had been a 100 percent allocation to harvesters and a grandfather clause.[32] The largest harvesters need the benefit of the grandfather clause if they are to attain close to their historic production levels. The only way they can benefit from the grandfather clause is through what they receive in the initial allocation. If the amount of QS they receive as part of the initial allocation diminishes as a result of the allocation to processors, the level at which they are grandfathered in will be lower. If harvesters are grandfathered in at lower levels, the level of concentration in the sector will be closer to what would be expected over the long term as the grandfather clause expires.

To achieve previous production levels, some harvesters may have to borrow money to acquire QS or enter into raw fish delivery price negotiations with processors. This will have a more significant adverse effect on the weaker firms than on the stronger firms and will move the harvesting sector through its shakeout and adjustment period more quickly. At the same time, any QS received will reduce the barrier to exiting; thus, as the amount harvesters receive goes down, the incentive to stay in the fishery will increase. A more rapid adjustment period with more stress on financially weak firms and higher exit barriers will increase strategic stakes, and rivalry will be more intense during initial phases of the program. Negotiations with processor for access to processor-held QP may be an important factor in determining which harvesting firms survive. With less of an initial allocation, harvesters will be in a somewhat

[32] Processors do not need QP to produce and so can achieve their historic production levels even if they do not receive an initial allocation.

weaker position with respect to the assets they have available to threaten more vertical integration as part of their price negotiations. The initial allocation will also provide harvesters with a competitive advantage vís a vís new entrants. On one hand, that advantage diminishes as the amount of QS going to processors increases; on the other hand, the importance of the initial allocation as an advantage in competition in the raw fish market for access to processor-held shares increases.

The grandfather clause has less significance for competition within the harvester sector than it does within the processing sector. Within the harvesting sector, harvesters able to take advantage of the grandfather clause will have a cost advantage but will not be able to use that cost advantage to compete for QS or in the raw fish market because they will not be able to add QS or QP to their existing holdings. Processors will not experience the same limitations in using their advantage to expand market share.

With respect to rivalry within the processing sector, rivalry generally decreases as the concentration of market shares increase. Market share concentration will likely be influenced by the concentration of the initial allocation of QS. Some processors own permits and will, therefore, receive an initial allocation regardless of whether there is an explicit allocation to processors. If there is no direct allocation to processors, there will be greater differences in the allocations among processors (five processors that also own permits would receive an initial allocation). QS will be most evenly distributed among processors if there is an allocation to processors, but no grandfather clause, thus increasing rivalry. Under such circumstances, smaller processors (processors that would not receive enough initial allocation to put them above the accumulation limits) will receive a greater initial allocation, increasing the security of their access to raw product and putting them in a better position to acquire additional QS and compete with larger processors. Rivalry will likely decrease if there is an allocation to processors and a grandfather clause. More of the QS will be concentrated among larger processors than without a grandfather clause.

The initial allocation will also lower the exit barrier, providing compensation for leaving the fishery and reducing the intensity of the competition to remain in the fishery. Those choosing to leave the fishery will provide remaining participants with an opportunity to consolidate and expand operations. At the same time, the additional endowment will also give all existing processors receiving an initial allocation an advantage over any new entrant (raising the entry barrier). For larger processors, in particular, the initial allocation (with a grandfather clause) will provide an opportunity to produce at a larger scale with a lower risk profile, increasing the competition barrier for new entrants. Over time, a decreased exit barrier and increased entry barrier would be expected to increase consolidation.

With respect to processor bargaining power, as the amount of QS allocated to processors increases, their position in negotiating raw fish prices with harvesters will improve because of their option to use their own QP on their own vessel or to activate a latent permit. If all QS goes to harvesters, for as long as the QS remains in harvester hands, at least initially, direct harvester competition for market share in the raw fish market should be minimal.

The initial allocation also provides an asset to support increased vertical and horizontal integration by smaller companies. Those receiving large amounts of QS would be limited in their ability to use it to acquire QS because of their accumulation limits. However, even for those larger initial recipients, the capital infusion could provide an advantage in the acquisition of processors that do not hold QS. Whether this occurs would likely depend on the relative efficiency gain when a large processor acquires a new facility without additional QS to support production at that facility as compared to a smaller company acquiring the same facility, but with the benefit of QS to support the production. If the efficiency gains for a large company expanding without QS are sufficient, then the capital infusion represented by QS may allow them to aggregate additional processing operations (or expand existing operations).

Table E-23. Influences on rivalry of status quo, IFQ program and QS initial allocation (as more QS goes to processors) (shaded text repeats previous tables) ("-" = indicator or less rivalry "+" = indicator of more rivalry, "o" = no change.

Factor Causing Greater Rivalry		Harvesters	Processors
1. A larger number of firms with similar market shares	Status Quo	+ Under status quo: larger than number of processors. + Entities with similar market shares. Potential sector participants include latent permit holders.	- Small number of firms. Very restricted in some localities. Market shares highly concentrated, going mainly to a few companies.
	IFQS	- A decrease in the number of active harvesting vessels and harvesting companies (subject to accumulation limits). Much of the rivalry for market share will be focused on the QS/QP market. However, for harvesters who do not own their own QS, this competition may also involve rivalry in the raw fish market. - Limited opportunity for latent capacity in the sector to become more active, except through direct reductions by active vessels through QS/QP transfers.	+ Decreased geographic isolation of markets, increasing number of participants. + Some pressure for consolidation in response to existing overcapitalization and threat of harvester market power. - However, if there are effective accumulation limits growth of market share for larger firms will have to occur without the advantage offered by QS ownership.
	Initial QS Allocation	*+ Latent permits may be activated to handle processor owned QP, increasing the number of participants.* *As more QS goes to processors, and those processors receive more allocation than can be serviced with processor owned vessels, then there will be more competition among harvesters for the opportunity to utilize latent capacity to deliver raw fish on processor owned QP.* *The long-term distribution may be achieved more quickly in that there will not be as many permits receiving QS as high above the accumulation limits.*	*? Concentration of market shares will be influenced by the QS allocation. If there is a grandfather clause, there will be greater concentration of the QS allocation among processors regardless of whether there is an initial allocation to processors (because of processor-held LE permits). If there is no grandfather clause, an allocation to processors will result in a more even distribution of QS until the grandfather clause expires.* *The initial allocation will be an asset to support growth for smaller firms. For larger firms (at accumulation limits), use of the initial allocation as an asset to support further horizontal consolidation will depend on the relative incremental efficiency of a large firm expanding without QS compared to a small firm expanding with QS.*
2. Slow market growth	Status Quo	+Yes	+Yes
	IFQs	O	o
	Initial QS Allocation	O	*o*
3. High fixed costs	Status Quo	+Yes	+Yes
	IFQs	+ Increased fixed costs (e.g., camera systems), but for harvesters with QS, the increase influences rivalry in the QS/QP market more than the raw fish market. - Incentive to exert market power in the raw fish market to increase profits and recover fixed costs.	o Minor increase relative to vessels.
	Initial QS Allocation	*o*	*o*
4. High storage costs or highly perishable products	Status Quo	+Yes	+Yes
	IFQs	O	o
	Initial QS Allocation	O	*o*

Table E-24. Influences on rivalry of status quo, IFQ program and QS initial allocation (as more QS goes to processors) (shaded text repeats previous tables) ("-" = indicator or less rivalry "+" = indicator of more rivalry, "o" = no change. (continued)

Factor Causing Greater Rivalry		Harvesters	Processors
5. Low cost for customers to switch suppliers	Status Quo	+Yes	+Yes
	IFQs	O	O
	Initial QS Allocation	O	*o*
6. Low levels of product differentiation	Status Quo	+Yes	N/A
	IFQs	O	o
	Initial QS Allocation	O	*o*
7. Strategic stakes are high	Status Quo	+Moderate for nonwhiting, high for whiting	+Yes
	IFQs	O	+ Increased strategic stakes, expansion requires direct displacement of competitors, more limited vertical integration opportunities.
	Initial QS Allocation	*+ Increase as more goes to processors. More rapid shakeout. Those able to partner with processors to acquire QP and increase scale of their operations are more likely to survive over the long term.*	*Change and uncertainty may increase action based on perceived strategic stakes.*
8. High exit barriers	Status Quo	+Yes	+Yes
	IFQs	o	o
	Initial QS Allocation	*+As more of the initial allocation goes to processors, exit barriers will be higher.*	*-Reduced exit barriers. Selling the QS may be a way to clear off debts/accumulate savings and leave the industry.*
9. A diversity of rivals	Status Quo	o Uncertain	o Uncertain
	IFQs	O	o
	Initial QS Allocation	O	*o*
10. Industry Shakeout.	Status Quo	- Constrained by management system	o Uncertain
	IFQs	+ Expected	o Possible
	Initial QS Allocation	*+As more goes to processors, the intensity of the initial adjustment and speed of the shakeout will increase. There will not be as many firms as high above the accumulation limits (assuming a grandfather clause); financially weaker firms will drop out more quickly.*	*The initial distribution will alter the balance of competitive advantages among existing processors and may lead to new entry, a shakeout, or stabilize existing participants.*
Summary	Status Quo	Many reasons to expect high rivalry. However, license limitation constrains threat of new entrants; for nonwhiting, two-month limits minimize opportunity to compete for market share.	Many reasons to expect high rivalry. However, high concentration indicates shakeout may have already occurred; and threat of intense competition may discourage strong moves to expand market shares.
	IFQs	After an initial shakeout, rivalry will decrease because of fewer harvesters and accumulation limits constraints. The need to cover fixed costs may stimulate rivalry in the QP market and cooperation in the raw fish market. Rivalry in the raw fish market will occur to the degree that processors provide QP linked with raw fish exvessel price negotiations.	Rivalry will increase as a decrease in the geographic isolation of raw fish markets expands the number of effective participants, processors position themselves to defend against the possible exercise of harvester market power, competition for market share requires direct displacement of other processors, and accumulation limits constrain existing and potential vertical and horizontal integration.
	Initial QS Allocation	*+As more QS goes to processors, rivalry in the raw fish markets will increase as harvesters vie for processor held QP needed to achieve the larger scale of operations and efficiency needed survive the initial shakeout. Exit barriers will be higher increasing the intensity of the competition to remain in the fishery.*	*Quite a bit of uncertainty about effect, some of it related to the decision on a grandfather clause for processors. Some shift in the balance of power within the sector could lead to a shakeout (particularly if larger firms are disadvantaged by accumulation limits and no grandfather clause).*

Key Questions:

Which will be more profitable, taking into account variation in risk?

- A processing facility purchased by a small company that can also acquire QS for a significant amount of the facility's raw product needs?
- The same processing facility purchased by a larger processing company that cannot acquire additional QS to cover the facility's raw product needs?

If the former is more profitable, the IFQ program may inhibit further consolidation in the processing sector. If the latter is more profitable, consolidation may continue and may accelerate with the infusion of capital represented by IFQs (depending on balance with other factors such as changes in harvester market power and ability to vertically integrate).

Will there be a grandfather clause for processors? If not, an initial allocation to processors may advantage small processors relative to larger processors.

Table E-25. Influences of status quo, IFQ program and QS initial allocation (as more QS goes to processors) on bargaining power status and QS flow (shaded text repeats previous tables; "-" = indicator or less power, "+" = indicator of more power, "o" = no change).

Indicators of Sector Power		**Harvester (Supplier) Evaluation**	**Processor (Buyer) Evaluation**
Threat of vertical integration is addressed in more detail the section above on vertical integration. Sector Concentration is addressed in more detail in the above table on rivalry.			
Threat of vertically integrating with other sector	Status Quo	- Not much threat	+ Threat
	IFQ Program	+ Harvesters may vertically integrate by retaining ownership of fish while they are being processed (demanding custom processing services). + Harvesters may exert vertical influence by using QS to encourage new entry by processing concerns.	+ Increased incentive. - Threat limited by accumulation limits - Possible reduced vertical integration for firms with strong vertical integration due to accumulation limits.
	Initial QS Allocation	Financial resources for threatening vertical integration diminish.	Increased viability of vertical integration for firms not at QS accumulation limits.
Sector concentration	Status Quo	- More firms than processors. - Even distribution of market share	+ Relatively few. + High market share concentration
	IFQ Program	+ Increased concentration. + Reduction of potential for competition through activation of latent permits.	- Decreased geographic isolation of local markets. + Pressure for consolidation/integration - Consolidation/integration constrained by accumulation limits.
	Initial QS Allocation	*- Potential for activation of latent permits or capacity to service processor held QS increases number of possible participants*	*+ Processor held QP can be used to activate latent permits, decreasing harvester sector concentration.* *? Effect on processor concentration is uncertain. More concentration if larger firms expanding without the support of QS gain more profits than smaller firms expanding the same amount but with the support of QS, and a grandfather clause applies to the accumulation limits. The initial allocation will be an asset that may support consolidation.*

Table E-24. Influences of status quo, IFQ program and QS initial allocation (as more QS goes to processors) on bargaining power status and QS flow (shaded text repeats previous tables; "-" = indicator or less power, "+" = indicator of more power, "o" = no change). (continued)

Indicators of Sector Power		Harvester (Supplier) Evaluation	Processor (Buyer) Evaluation
Switching Costs (buyer to a different supplier or supplier to a different buyer)	Status Quo	- No significant costs.	+ No significant costs.
	IFQ Program	O	O
	Initial QS Allocation	*O*	*O*
Buyer customer power (customer willingness to boycott in support of supplier)	Status Quo	- No	N/A
	IFQ Program	O	N/A
	Initial QS Allocation	O	*N/A*
Harvesters' products are highly differentiated from one another	Status Quo	- No	+ No
	IFQ Program	o	O
	Initial QS Allocation	*o*	*O*

Table E-26. Influences of status quo, IFQ program and QS initial allocation (as more QS goes to processors) on the ability of a sector to protect any advantage it gains in bargaining power (barriers to entry) and QS flow.

Changes to Barriers to Entry		Harvesters	Processors
Government Regulation	Status Quo	Limited number of permits but some "latent." Heavily regulated.	Fishery management related regulations less heavy than for harvesters but also face environmental regulations (waste discharge).
	IFQ Program	+Increased fixed costs. +Absolute barrier to entry and expansion.	Minor increased fixed costs.
	Initial QS Allocation	The QS needed for participation will not be affected by who receives an initial allocation. Relative advantage for initial recipients is addressed under economies of scale.	Relative advantage for initial recipients is addressed under economies of scale.
Special Proprietary Knowledge	Status Quo	Fishing locations.	None identified.
	IFQ Program	o	o.
	Initial QS Allocation	o	O
Asset Specificity (Maleability)	Status Quo	Very specific (geographic relocation possible)	Very specific Shoreside—not mobile some utility in other sectors. At-sea—mobile
	IFQ Program	o	O
	Initial QS Allocation	o	O

Table E-25. Influences of status quo, IFQ program, and QS initial allocation (as more QS goes to processors) on the ability of a sector to protect any advantage it gains in bargaining power (barriers to entry) and QS flow. (continued)

Changes to Barriers to Entry		Harvesters	Processors
Economies of Scale	Status Quo	-	
	IFQ Program	+ The cost of achieving any given level of scale will be increased by the need to acquire QS.	+ If processors in the industry acquire QS, the cost to new entrants to reach a similar level of scale, efficiency, and risk control will be increased by the need to purchase QS. Accumulation limits create an absolute barrier in ability to protect higher production levels through ownership of IFQ.
	Initial QS Allocation	*The effect of the initial allocation on the barrier to entry for harvesters will not be as great as for processors.* *+Harvesters receiving an initial grant will have some short-term financial advantage over new entrants in competition to acquire additional QS and achieve greater economies of scale. This advantage will be diminished as more of the initial allocation goes to processors, but will also become more important as competition in the raw fish market increases with an increasing allocation to processors.* *o Those harvesters grandfathered in at greater levels of production may have greater profit opportunity than others; however, they will not be able to use those profits for the expansion of their harvesting operations. Therefore, it will not cause a competition barrier for new entrants.*	*+ If processors receive an initial allocation, over the short term, the barrier to new entrants may increase because of the relative financial advantage provided by the grant of the asset.* *+ If some processors receive an initial allocation of QS, grandfathered in above the accumulation limits, those processors may have efficiencies of scale that provide them with greater profits than would be available to new entrants or those who could only achieve a similar level of production without the benefit of support of their own QS.*

E.5.4 Access to Capital

Demand.

- **Time Preference.** The initial allocation will raise individuals' wealth level. If their income was relatively low, this may decrease their time preference, leading them to be willing to pay more for QS.
- **Risk.** Those receiving an initial allocation of QS will have more secure access to their expected fishery related income. This may increase their willingness to incur additional debt in order to purchase more QS (giving them an advantage over those who do not receive QS).
- **Planning Horizon and Investment Recovery.** The initial allocation is not expected to have an effect on planning horizons or amount of investment a firm needs to recover.

Supply. Those receiving an initial allocation will experience an increase in wealth. They will be viewed as lower risk borrowers than they were before they received the initial allocation. A lower risk profile will give them cheaper access to capital and enable them to more easily accumulate additional QS, up to accumulation limits. It will also put them in a better position to acquire capital for other improvements, which may lead to further business growth and additional QS purchases. Harvesters need access to QS/QP in order to produce. A harvester under economic stress that does not receive enough of an initial allocation for its business plan may find it difficult to acquire financing to purchase more QS and would, therefore, have to cease production or rely on QP provided by others to stay in business. Processors do not need direct access to QS for processing activities; therefore, QS/QP is not a key input. At the same time, processors with an initial allocation may be viewed as less risky, particularly if it appears that after IFQ program implementation harvesters may be in a position to exert market power. An initial allocation

to crew would likely represent a substantial boost in their capital, increasing their ability to accrue additional capital, including QS. The funding base for communities is large enough that an initial allocation of QS is not likely to affect their access to capital. See Table E-26.

Table E-27. Influences of status quo, IFQ program and QS initial allocation on access to capital and QS flow.

		Harvesters	Processors	Crew	Communities
Demand for Capital					
Time Preference	SQ	Those with high time preference will not be willing to pay as much for QS.			
		Indication of high time preferences.	Uncertain	Low income may lead to high time preference.	Uncertain
	IFQ Program	No change.			
	Initial QS Allocation	*Increased wealth of initial recipients may increase their willingness to pay for QS.*			
Risk	Status Quo	Those who believe that the future holds greater risk than others believe will have a lower willingness to borrow.			
	IFQ Program	The fishery managed with IFQs will have inherently less risk. Personal assessment of future risk may change for those who acquire QS.			
	Initial QS Allocation	*Increased income security of those receiving an initial allocation of QS may increase their willingness to incur additional debt in order to purchase more QS.*			
Planning Horizon and Investment Recovery	Status Quo	Those who have a longer planning horizon for the use of an asset may be willing to pay more to acquire it (as compared to someone acquiring the same asset with a shorter horizon). [This outcome depends on there being a limited ability to recover investment through sale of the asset at the end of the planning horizon.]			
	IFQ Program	Those who have a longer planning horizon or need a longer time to recover a capital investment or have a larger capital investment (for which QS can help secure their return) will be willing to pay more for QS. There is no basis to distinguish among groups.			
	Initial QS Allocation	*The initial allocation is expected to have no effect.*			
Supply of Capital					
	Status Quo	The overall financial position of a firm will be evaluated in determining loan worthiness. Firms are likely to receive more favorable terms for a loan if they are larger, diversified, and have assets that may be used as security and are of value outside the industry.			
		Harvesters less likely to have capital useful in other industries. Of generally smaller total size than processors.	Firms more likely to have capital that may be useful in other industries. Firms often of larger size than harvesting firms.	Not likely to have fishing business related assets for use as collateral. This may mean higher costs of borrowing.	May have cheaper access if the governing body is viewed as lower risk.
	IFQ Program	In general, the IFQ program will likely decrease risk in the industry, reducing the cost of access to capital. QS are of tenuous value as collateral but important to the viability of a firms business plan. Firms with cheaper access to capital will be more likely to accumulate QS.			
		Risk may decrease with greater stability & possible increase in market power.	Processors may experience a risk increase associated with harvester market power, increasing capital costs.		
	Initial QS Allocation	*Initial recipients will experience increased wealth and be viewed as lower risk borrowers. Cheaper access to capital will likely spur their growth and lead to future QS purchases up to limits.*			
		QS/QP is needed for production. Firms under financial stress will be viewed as high risk and may find it difficult to acquire financing to purchase QS/QP they do not receive as part of the initial allocation.	*Direct access to QS/QP is not needed for processing activities.* *An allocation of QS may increase security of access to raw product, reducing risk and cost of capital.*	*An initial allocation would likely represent a substantial boost in the capital owned by crewmembers and increase their ability to accrue additional capital, including QS.*	*An initial allocation appears unlikely to change the communities standing the capital market.*

F.0 Fixed Term and Auction Analysis and Contractor Report

This appendix contains an analysis of an option considered by the Council which would place a 15- or 16-year limit on the duration of quota share (QS) and introduce biennial auctions of 20 percent of the QS starting in year 15 or 16. The option is more fully described in Appendix A, Section A-6. The analysis was developed for the Council by a contractor (Syldon Inc) and is provided in full in this appendix. The Council's Scientific and Statistical Committee reviewed the contractor's analysis and provided the Council with the following evaluation at its November 2008 meeting.

> The SSC . . . received a presentation . . . from Drs. Gil Sylvia and Michael Harte (Oregon State University) concerning an analysis they conducted of the option for a fixed-term auction of quota shares.
>
> The SSC discussed the issue of fixed-term auctions and reviewed the associated analysis contained in Appendix F. Drs. Silvia and Harte presented their analysis to the SSC. The SSC notes that the rationale and goals of a fixed-term auction are not fully developed in the Preliminary DEIS; thus, it is difficult for the SSC to discuss the degree to which its goals would be met. Generally speaking, fixed-term auctions would capture for the public a portion of the rents generated by rationalization. Fixed-term auctions also affect the distribution of the economic benefits and may, to some degree, decrease the overall size of those benefits. Both of these latter effects would vary with the percentage of QS that reverts to an auction. There are many different ways that fixed-term auctions could be implemented; the outcomes will depend on the details of the implementation.
>
> Appendix F analyzes the potential effects of a fixed-term auction. A fixed-term auction increases the amount of uncertainty and risk associated with holding QS. This will tend to decrease the amount of investment QS holders are willing to make in the fishery and, in turn, reduce the economic benefits of rationalization. However, the conclusions in the appendix are stated too strongly and fail to acknowledge the uncertainty involved in predicting the outcomes.
>
> There are several factors that may mitigate reductions in investment and economic benefits. First, the length of the initial allocation of QS is 15 or 16 years. This is a rather long time horizon, and much of the fleet consolidation will likely take place well in advance of the 15 or 16 years. Thus, the remaining QS holders will tend to have larger QS holdings due to consolidation, and they will be the most efficient, profitable, and innovative operators. Second, most businesses operate in risky and uncertain environments regarding costs of inputs, and they tend to take actions to mitigate those risks. QS holders, for instance, could engage in contracts or purchase quota in the private market in anticipation of the auction. Third, investment time horizons may be shorter than those suggested in the appendix because returns on business investments usually have to be realized more rapidly. Generally, the effects of an auction on investment and economic benefits will depend on the percentage that is auctioned. If it is 1 to 5 percent, there may be very small effects. If it is closer to 20 percent, the effects would be larger.
>
> The SSC also discussed the effect of fixed-term auctions on stewardship. The appendix asserts that fixed-term auctions would have a negative effect on stewardship because the returns to stewardship would be partially dissipated by any loss of QS that is not replaced. However, it is unclear to the SSC how large the stewardship incentive associated with QS ownership would be, even if held in perpetuity. The expected number of vessels that will operate in the rationalized fishery may be so large and the percent of the quota owned by a single operator so small (due to accumulation limits) that the private gains to stewardship may not be significant enough to change operations in a meaningful way.

> The SSC notes that the analysis in Appendix F is qualitative. As such, the analysis does not support the firm conclusions regarding the magnitudes of the effects, as stated in the report and described in Table 5.1 and Figure F-1.

The SSC is the Council's primary authority on scientific matters and determination of the best available information. The following is one of the primary charges of the SSC:

> Provide the Council advice in the development, collection, evaluation, and peer review of such statistical, biological, economic, social, and other scientific information as is relevant to the Council's development and amendment of any Fishery Management Plan in accordance with the Magnuson Stevens Fishery Conservation and Management Act (MSA) and the National Standards as amended through January 12, 2007 (Council Operating Procedure #4).

After reviewing the contractor analysis and the SSC report cautioning the Council on the strength of some of the conclusions of the report, the Council chose to include the following provision as part of its final preferred alternative (Section A-2.3.4).

> The Council shall begin a review of the TIQ program no later than 5 years after implementation of the program. The review will evaluate the progress the TIQ program has made in achieving the goal and objectives of Amendment 20. The result of this evaluation could include dissolution of the program, revocation of all or part of quota shares, or other fundamental changes to the program. Holders of quota shares should remain cognizant of this fact when making decisions regarding their quota shares, including buying selling, and leasing of these shares.
>
> The Council shall consider the use of an auction or other non-history based methods when distributing quota share that may become available after initial allocation, such as quota that results after a stock transitions from overfished to non-overfished, when Quota share from an AMP is no longer needed, when "use it or lose it" quota shares are forfeited, and if any quota is available after the initial or subsequent reviews of the program are completed.
>
> The specific form of the auction or other method of distribution shall be designed to achieve the goals of Amendment 20, specifically including minimizing the adverse effects from an IFQ program on fishing communities to the extent practical.

The following rationale was provided in support of including this provision:

> This [provision] promotes the idea that the fisheries resources are the property of the citizens of the United States and not perpetual grants to the QS holders. This also recognizes that we are not developing the perfect system. It puts the QS holders on notice that there may be changes to the program that could involve their QS and affect them. There will be a review in four or five years. At that point in time, the Council could consider what is going on in the fishery, including whether there are adverse effects on communities, new entrants are effectively prohibited due to costs of entry, or there are other adverse affects. If the adaptive management program is not adequate, the Council could consider an auction of some of the QS to correct these things or to deal with other results of the review. There are concerns that under the auction those with the deepest pockets will get it all. The last paragraph addresses ways to limit the auction so as to not disrupt communities, e.g., limiting the auction to small vessels. The motion does not require the Council to have an auction; it is a specific item that the Council would consider after the initial review. . . . The earliest the auction that might be implemented would likely be six to eight years after implementation. There would be no additional action or analysis at this time.

Acknowledgements

Syldon Inc would like to thank the staff of the Pacific Fishery Management Council for their assistance in understanding Council needs, clarifying EIS requirements, and formatting the report. We would also like to thank George Khalis for pointing us toward the non-fishery management literature highlighting the importance of asset values for addressing asymmetrical information and collateralizing small firm financing.

Executive Summary

This report analyzes the Pacific Fishery Management Council's preferred option for the West Coast Limited Entry Groundfish Trawl Fishery rationalization plan against a nonpreferred alternative that combines a fixed term privilege (15 or 16 years) with post-term biennial auctions for up to 20 percent of quota shares. Our analysis looks at 5 percent or 20 percent auctions of quota shares for comparative purposes. The report includes a 1) description of the fishery, processors, and communities; 2) a review of literature on fixed term systems and auctions for fisheries and other natural resources; 3) an analysis of the preferred option relative to the fixed term/auction options on fishery rents, resource stewardship, and communities; 4) an analysis of the preferred option relative to the fixed term/auction options on key groundfish management objectives; and 5) a summary of the impacts of the alternative options on 37 related groundfish management goals, objectives, and standards.

The literature review demonstrates that fixed term tenure systems and auctions can be successfully used in allocating and managing natural resources depending on management objectives, resource characteristics, and design of the tenure and auction systems. Fixed term privileges can provide management flexibility and perception of public ownership but can reduce incentives for long term investment and resource stewardship. Auctions can be an efficient mechanism for allocating homogeneous resources and collection of royalties, but may be more difficult to employ when equity and social objectives are important objectives. Fixed term privileges combined with auctions, however, are not commonly used in fisheries management. Auctions are rarely used in allocating fishery assets due ostensibly to the heterogeneity and complexity of fishery resources, uncertain status of fishery stocks, number of management goals, and unpopularity of auctions by resource users. The review suggests that combining fixed privileges with post tenure auctions may reinforce the weaknesses of each approach, particularly for multispecies fisheries.

Analysis of the Council's preferred option relative to the combined fixed term/auction options reveals that the preferred option generates greater benefits across almost the entire range of management objectives. These results are influenced by key characteristics of the West Coast Limited Entry Groundfish Trawl Fishery including: 1) the large number and complexity of assemblages and species; 2) stock rebuilding and bycatch constraints; 3) management focus on protecting small firms; 4) effects of the self-financed buyout program; and 5) number and diversity of dependent/engaged communities. The Council's preferred option results in higher rents and economic efficiency through incentives for entrepreneurial innovation and reduction in risk. In contrast, the fixed term/auction alternatives generate less profit and rent and lead to greater risk due to "wasting effects" and disincentives for rent creation. These effects are magnified over time due to the inherent challenges in managing asset portfolios in a complex multispecies fishery. In addition, the reduction in asset values undermines the ability of family-owned firms to finance operations and manage risk. The fixed term/auction alternatives reduce incentives for stewardship, and negatively impacts communities by increasing risk and inhibiting long term contracting. The auction system may provide for moderate gains in new entrants and price discovery but this is a benefit only if secondary quota markets are failing to function efficiently. The review of the summary results for 37 groundfish management goals, objectives, and standards reveals that the fixed term/auction alternatives have a moderate to significant negative effect on 22 objectives, a slight negative or zero effect on 14 objectives, and a positive effect on only one potential objective (royalty payments).

F.1 Introduction & Scope of Work

The Pacific Fishery Management Council (here after "the Council") is evaluating management alternatives in preparation for rationalizing the West Coast Limited Entry Groundfish Trawl Fishery. The Council chose a preliminary preferred alternative at their June 6–13, 2008, meeting in Foster City, California. They adopted Individual Fishing Quotas (IFQ) for the non Pacific whiting shoreside sector, either IFQs or co-ops for the shoreside whiting sectors, and cooperatives for the at-sea whiting sectors. One proposed alternative to the preferred option is allocating individual fishing quotas (IFQs) for a fixed term (15 or 16 years) and then auctioning off a portion of the quota (up to 20 percent) on a biennial basis.

F.1.1 The Council's Preferred Option and Fixed Term and Auctions Option

The IFQ alternative preferred by the Council provides an amount of catch (IFQ) that would be available for use on each trawl limited entry vessel (PFMC 2008a). The IFQ would be transferable and divisible. The timing of harvest and amounts taken would be restricted primarily by each vessel's individual quota. Each vessel would have both flexibility and individual accountability. IFQ transfers would be tracked by NMFS and checked against vessel catch. An initial allocation may be given to processors. The Council may decide to use an adaptive management provision to provide processor compensation, mitigate against adverse impacts to communities, assist new entrants, or to achieve bycatch reduction and habitat protection goals, among others.

One proposed alternative is allocating individual fishing quotas (IFQs) for a fixed term and then auctioning off a portion of the quota. The alternative is described as:

> *"The IFQ program could optionally include a 15 or 16 year limit on all the QS that has been issued. Starting with Term-2 of the program, every 2 years up to 20 percent of all QS will be returned to NMFS for reissuance via an auction. The specific form of the auction would be decided by the Council in the period between trawl rationalization implementation and the first auction. It would be designed to achieve the goals of the trawl rationalization program, including reducing bycatch; increasing operation flexibility; and producing measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry."* (PFMC 2008a, page 11).

As with all options it must be evaluated according to goals, objectives and standards found in the Pacific Coast Groundfish Management Plan (2008c), the Trawl Rationalization Plan (2000a), the MSA (NOAA Fisheries 2006), and other standards relevant in conducting Environmental Impact Statements (EIS).

F.1.2 Scope of this Report

This report compares and analyzes the Council's preferred option relative to the fixed term/auctions option. The report includes:

- A review of auctions for renewable and non renewable resources with reference to using fixed term/proportional auction strategies relative to the goals of economic efficiency, resource conservation, and minimizing environmental and community impacts.
- Discussion of literature and key concepts associated with fixed terms and quota auctions relative to economic, social, and environmental objectives of the West Coast Limited Entry Groundfish Trawl Fishery.
- A comparative qualitative analysis of the fixed term/auction alternative for the West Coast Limited Entry Groundfish Trawl Fishery including evaluation of the costs and benefits

advantages/disadvantages of this option relative to relevant management goals, objectives, and standards. Analysis includes the potential impacts of this alternative on 1) the creation, size, and capture of fishery rents; 2) effects on voluntary resource stewardship and fishery investment; 3) flexibility of private and public management; and new entry into the fishery. The evaluation also includes impacts to various stakeholders including, but not limited to, trawl harvesters, non-trawl harvesters, processors, communities, groundfish resources, and management agencies.

F.1.3 Caveats and Assumptions

Because of the range and complexity of the options, including differences between the Pacific whiting and non-whiting sectors, and the uncertainty regarding how the fixed term/auction would be applied, the following caveats/assumptions have been made:

- For purposes of the comparative analysis, it is assumed that the only options being analyzed are the fixed term/auction options versus the Council's preferred option(s). Where options are not preferred or equally preferred, and the option may impact the comparative analysis, the analysis includes the specific alternative options. The analysis is not intended to analyze alternative rationalization plans or option design in order to achieve higher goals, objectives, or benefits.

- The fixed term/auction option does not specify an amount to be auctioned beyond "up to twenty percent." For the purpose of comparative analysis we assume either 5 percent or 20 percent of the quota is surrendered and auctioned.

- The Pacific whiting sector includes cooperative and non-cooperative options. Given uncertainty about whether the fixed term/auction option would apply to cooperatives, the analysis is conducted assuming that all sectors of the Pacific whiting fishery are managed under the IFQ preferred option.

- While this report discusses basic types and design features of auctions, it is beyond the scope of this work to analyze or recommend design elements for an auction mechanism for the West Coast Limited Entry Groundfish Trawl Fishery.

F.1.4 Structure of the Report

The Report is structured in six major sections. The next section briefly describes key characteristics of the West Coast Limited Entry Groundfish Trawl Fishery, the processing sector, and coastal communities. Based on a review of the literature, Section 3 summarizes comparative advantages and disadvantages of fixed term privileges and auctions for natural resources including fisheries. Section 4 analyzes the predicted impacts of the fixed term/auction option relative to the Council's preferred option on resource rents, environmental stewardship, and coastal communities. Section 5 summarizes specific impacts on key federal and west coast fisheries management objectives. Attachment A provides a literature review of fixed term privileges and auctions for managing natural resource industries including fisheries. Attachment B is a brief discussion of resource rent creation, an issue central to much of Sections 3, 4, and 5. Chapter 1 in the main document lists the Council's objectives for groundfish management and groundfish rationalization that provides the basis for the comparison of the Council's preferred IFQ option against the fixed term/auction alternative.

F.2 Characteristics of the West Coast Limited Entry Groundfish Trawl Fishery

F.2.1 Introduction to the Limited Entry Groundfish Trawl Fishery

From almost any perspective, the West Coast Limited Entry Groundfish Trawl Fishery is a complex fishery that has undergone major and sometimes wrenching change over the last thirty years. It is part

of a broader network of west coast fisheries that stretch over four states (including the distant water fishery primarily fishing in Alaska) involving thousands of fishing firms, hundreds of seafood processors and support industries; and scores of "engaged" "dependent", and "at-risk" communities. The trawl fishery harvests from major fish assemblages representing widely varying habitats and life histories that include over 80 species, of which more than half are commercially harvested and sold.

The fishery has transitioned through five major periods during the last 30 years:

- Pre-MSA (before late 1970s): characterized by open access management and domination by foreign fleets;

- Post MSA (1980s - early 1990s): development of a groundfish management plan, domestication of the fleet, foreign-domestic joint ventures, regulated open access management, priority for year-round landings and processing;

- Limited Access (mid 1990s): development of a limited access permit fishery, domestication and allocation of the Pacific whiting fishery, creation of the Pacific Whiting Cooperative;

- Overcapitalization (late 1990s): disaster declaration, biological limits and overfished status for some stocks, overcapitalized fleet, self financed permit buyback program;

- Conservation and Rationalization (present): implementing rebuilding plans for overfished stocks, establishing rockfish conservation zones (RCA) and essential fish habitats, rationalizing the fishery using Limited Access Privileges.

After the establishment of the Exclusive Economic Zone (200-mile limit) and passage of the MSA, the groundfish trawl fleet grew to more than a thousand vessels that were ultimately permitted into the limited entry groundfish trawl fishery. But with the exception of Pacific whiting, harvest and total revenue dropped 30-50 percent from the 1980s to the present. For example, shoreside landings by nonwhiting nontribal commercial sectors totaled only 25,000 mt, in 2004 compared to landings of 60,000 mt in 1995 and 1996, respectively. Groundfish trawl permits for the shoreside sector which totaled nearly 400 when the Limited Entry plan was initially developed decreased to 183 by 2003 due to the purchase and aggregation of permits by the at-sea whiting catcher processing vessels and the self financed buyout program which retired more than 40 percent of the permits active in the fishery at the time.

The growth and decline in non-Pacific whiting groundfish trawl harvests paralleled the growth and reduction of the groundfish seafood processing sector (http://www.pcouncil.org/groundfish/gfspex/07-08/ch7.pdf.) The number of firms engaged in processing trawl-caught groundfish in the three west coast states totaled approximately 140-150 in the mid eighties but declined by 60 percent to 55 companies by 2005. Besides fewer processors, the processing industry also significantly consolidate with the top three companies processing 77 percent of the product and the top six companies processing some 90 percent. To some extent, however, these numbers are skewed due to the large proportion by weight of Pacific whiting, which is a large industrial processing operation dominated by a few companies.

F.2.2 Harvesting, Processing, and Communities

The west coast has an active commercial and recreational groundfish fishery made up of thousands of shore based trawl, at sea trawl, fixed gear, tribal and recreational charter and recreational private vessels. Trawl and fixed gear vessels make most of their landings in Oregon. Newport, Astoria, and Charleston (Coos Bay), Oregon were three of the largest four ports for landed weight and exvessel revenue during the 2000–2003 period.

Port Districts have invested significantly in infrastructure to support the trawl fishery and processing sectors in these ports. Nevertheless this investment is always at risk from environmental and market factors and also from changes in the regulatory regime for trawl fisheries. For example, because of the trawl buyback program, some port communities, mainly smaller ports, appear to have lost relatively more groundfish trawl vessels than other ports.

Vessels participating in shore-based groundfish fisheries deliver to shore-based processors along the entire west coast. However, processing capacity has been both consolidating and declining in recent years. Many small ports have lost both processors and on-site buyers, and trucking groundfish from these ports to larger communities for processing has become common place. Nevertheless, processing remains an important source of employment and regional income. From 2000 to 2004 seafood processing on the west coast generated approximately 380 to 420 million dollars in wages and employed over 10,000 workers.

The capital and associated infrastructure invested by industry and port districts is not easily transported to other sectors or locations should changes occur in the groundfish fishery due to new harvest or market conditions or new management plans. Significant port capital is fixed in location and designed to handle fishing vessels and fish products. When landing volumes fall below the economic capacity of a plant, operators have little choice but to consolidate operations, often leaving plant and infrastructure to rapidly deteriorate in prime waterfront communities. Maintaining working waterfronts that efficiently use valuable real estate to support fewer vessels and consolidation in processing capacity is an ongoing challenge for port districts and the seafood industry

This dependence on the seafood industry and limited resilience to change means that many coastal communities are potentially vulnerable to changes in the management of the groundfish fishery. The Council identifies some 38 cities and 18 counties as vulnerable commercial and/or recreational fishing communities. Four cities and six counties are identified as the most vulnerable. The cities are: Garibaldi, Ilwaco, Moss Landing, and Neah Bay. The counties are: Coos, Grays Harbor, Humboldt, Lincoln, Mendocino, and Pacific (Pacific Fishery Management Council 2006). Focusing just on dependency on the commercial groundfish fishery, Neah Bay is identified as a most vulnerable area. Other vulnerable areas include Astoria, Bellingham, Coos Bay, Crescent City, Eureka, Fort Bragg, Moss Landing, Pacific City, and Port Orford.

F.2.3 Key Characteristics of the Groundfish Fishery

The history and description of the groundfish fishery, processing, and community sectors reveals some of the complex characteristics relevant for this analysis. These include:

- Large number of assemblages and species: The fishery targets a variety of assemblages and species (e.g., flatfish, rockfish, deep water, and mid water (primarily Pacific whiting) across different habitats found along more than a 1,200 mile coastline. Individual species and assemblages may be either complements or substitutes, and targets or nontargets depending on the fishing strategy, quotas, market demand, geography, habitat, and captain's skill.

- Complex quota: Each of the assessed species have associated quotas. Even within assemblages, these quotas may be substantially different across species, given biologically intrinsic differences for each species/stocks and different stock status. This heterogeneity creates significant costs to develop fishing strategies consistent with harvesting the "optimal" proportion of each stock given regulations, market demand, and environmental conditions.

- Heterogeneity in species productivity: One distinguishing characteristics of some of the groundfish stocks is their relatively slow growth. This is particularly true of some of the rockfishes which may grow to be over 100 years old. In contrast, other stocks may be relatively

fast growing (e.g., ling cod). Still other stocks may have moderate to fast growth but show significant variability in recruitment (e.g., Pacific whiting).

- Rebuilding stocks and bycatch: Seven groundfish stocks are presently listed as "overfished" and have been placed on rebuilding plans. Quota for some of these stocks is less than 100 metric tons for the entire west coast. These severe limits have required harvesters to dramatically alter fishing behavior in order to keep below individual and aggregate bycatch quotas. In some case the bycatch is the most significant binding constraint on the fishery and has resulted in early closures of the fisheries.

- Family owned firms: Most of the vessels landing product are relatively small family firms. Average vessels range from 60-80 feet with rights to harvest less than 1-2 percent of the total available quotas given existing regulations. Some permits are owned by seafood processors who hire vessels to land the permitted catch. Very large vessels sometimes greater than 200 feet in length characterize the at-sea whiting catcher processing industry, which is dominated by large seafood firms.

- Complex interactions of west coast fisheries: Many west coast trawl groundfish vessels also own permits and licenses in other fisheries in order to maximize profits and manage risk. Recent history has demonstrated that major changes in the west coast limited entry trawl fishery can create rippling or "cascading" effects in other fisheries.

- Self financed buyout program: In 2003, almost half of the West Coast Limited Entry Groundfish Trawl Fishery permits were retired as part of a voluntary government-backed loan and auction buyback scheme. Remaining permit holders must repay the loan based on a tax on landings.

- Cooperation in science and management: Members of the West Coast Limited Entry Groundfish Trawl Fishery have invested time and money over the last 30 years in cooperative science and management through the Council process and formation of harvester and processor organizations. West coast trawl vessels are now used in conducting groundfish surveys for assessment purposes by NMFS. The Pacific Whiting Cooperative conducts collaborative science including monitoring of Pacific whiting pre-recruitment.

This brief snapshot of the history and key features of the groundfish fishery provides a limited sense of the complex and interdependent biological, economic, and social issues that impact this industry. These features will prove important in influencing the impact of the rationalization options which are analyzed in the remaining portions of this report.

F.3 An Overview of Fixed Term Rights and Auctions as Resource Management Policy Options

This section provides a general background to the evaluation of the costs and benefits of the limited term/auction alternative for the West Coast Limited Entry Groundfish Trawl Fishery described in Section I. Drawing on relevant literature (documented more extensively in Attachment A) it explores the use of fixed term rights and auctions of natural resources to promote the goals of economic efficiency, resource conservation, and minimizing negative environmental and community impacts. The evaluation of auctions and fixed term privileges are each conducted separately. It should be noted that there are few instances where the literature addresses the combination of these policy options. Our analysis in Sections 4 and 5, however, are based on the combined effects of fixed term privileges and auctions in the context of the specific biological, economic and social context of the West Coast Limited Entry Groundfish Trawl Fishery.

F.3.1 Fixed Term Fishing Rights versus "Permanent" Rights

Privileges to extract a public resource may either be of permanent duration or be time-limited. Although permanent privileges, or more accurately "conditional" permanent privileges, are the tool of choice in fisheries around the world, fixed term privileges are common in other public resource industries.

The choice of duration of the privilege can have implications for:

- The flexibility that managers have in addressing policy goals.
- The level of transaction costs for the managed sector.
- The incentives that resource users face for investment in, and conservation of, public resources.

F.3.1.1 *Permanent privileges may reduce transaction costs*

Transaction costs are the resources dedicated to establish, operate, and enforce a market system (Lee and Jouravlev 1998). Permanent privileges are homogenous in duration so their value is determined solely by the factors underlying supply and demand. Privileges subject to a fixed-term, however, are a "wasting asset" i.e. their value diminishes with time (Hodgson 2006) . Higher information and renewal costs may be associated with renewing or replacing fixed term assets. These costs will be higher the greater the degree of uncertainty associated with the status and/or management of the resource. Permanent privileges can help avoid potentially contentious, time-consuming, and costly future re-allocations (Libecap 2006; Morgan 1995) .

F.3.1.2 *Permanent privileges can encourage efficient investment*

Secure rights to a resource reduce risk, thereby promoting long term investment and technological improvements(White 2006). Investment and innovation by firms collectively improve the economic efficiency and competitiveness of a sector (Bess 2006; Harte, *et al.* 2008; Harte and Barton 2007).

For example, if a fishing entity does not know if they will have the right to fish in five years time it is less likely to make new capital investments in equipment and durable assets. In sectors where markets take a long time to establish, permanent or long term access to the resource is more conducive to the formation of more-efficient business arrangements (Bess 2006).

F.3.1.3 *Permanent privileges can promote resource and environmental stewardship*

Secure privileges to harvest natural resources may encourage stewardship for the resource and the environment it is found in (Morgan 1995). The longer the duration of the privilege, the larger the stake the user has in the industry and the greater the user's desire to engage in long term stewardship behavior (Beddington, *et al.* 2007; Costello, *et al.* 2008; Grafton, *et al.* 2006; Griffith 2008; Townsend and Shotton 2008).

In contrast, Macinko and Bromley (2001) argue that the degree of long term stewardship that a user will exercise is determined not by the duration of the privilege but by the user's rate-of-time preference -- that is, how an individual evaluates present income versus future income. Individuals with a higher discount rate are less likely to care for the long term health of a resource. If enough fishery participants have a high discount rate, the economic incentive to ensure the long term sustainability of a resource will be much reduced because the sector believes short term gains are better employed in other uses (Clark 1990). Page (1977) calls this the "iron law of the discount rate." The effects of this iron law may mean that time limited privileges have the same implications for resource and environmental stewardship behavior as do permanent privileges, provided they are of sufficient length.

F.3.1.4 *Fixed terms can provide opportunities for change*

Problems can arise from the initial allocation of privileges. For example, allocations made by administrative decision are almost never economically efficient (Morgan 1995). There may also be concern over excessive market share situations developing. Both of these concerns may be mitigated by a system of time-limited privileges, since there is a defined future opportunity for managers to adjust the structure of the regulated sector (Lee and Jouravlev 1998).

Although administrative allocations may not be efficient in the short-term, secondary markets can be designed or allowed to develop that result in more efficient resource allocations over time. Excessive market share concerns can be addressed through caps on ownership or other methods. Changes in conditions attached to permanent privileges after they have been allocated can generate significant uncertainty and may undermine secondary markets for privileges (Lee and Jouravlev 1998). The conditions attached to any system of privileges need to be clear from the beginning.

Fixed-term rights also offer potential flexibility to resource managers. Necessary changes in policy may be implemented more easily, and with less resistance under a system of time-limited rights (Macinko and Bromley 2001). Fixed terms provide managers with predictable regular intervals at which to make changes to the management program in light of new developments. Privilege holders also have a high degree of certainty about when changes to the system will be made and can plan accordingly. There may also be less resistance to changes in management procedures if the privilege holders do not hold a permanent, vested share in the industry.

In the context of the rapidly changing understanding of the oceans and the shift towards ecosystem-based science and management (Upton, *et al.* 2007), this flexibility may make it easier for adaptive management to occur. For example, The United States Commission on Ocean Policy (2004) recommended assigning:

> *...quota shares for a limited period of time to reduce confusion concerning public ownership of living marine resources, allow managers flexibility to manage fisheries adaptively, and provide stability to fishermen for investment decisions.*

Fixed term privileges may also provide industry with increased flexibility, especially when there is uncertainty about the status or management of a resource. For example, the lower cost and protected nature of fixed term contracts for water use reduces the farmer's exposure to risk in the event of a long term drought where farming is unviable. Flexibility in this case comes at the expense of long

term security. But in an industry where seasonal flows are often highly variable, the amount of long term security from having permanent access to water may be negligible. Sometimes the duration of the right may depend on the level of uncertainty regarding the right. For example, in Iowa, the legislature restricts the term of water use rights to 10 years if the aquifer capacity is uncertain (Hodgson 2006).

The durability of the privilege depends not just on the length of time it is issued for, but also on the privilege holder's perceptions of a program's management and whether or not long term expectations for the resource will be met. For example, a fixed-term privilege granted for a short period but with a strong presumption of renewal may be just as durable and will confer the same or greater economic benefits than a privilege granted for 20 years but carries with it an expectation that the government will fundamentally change aspects of the management program within that period.

F.3.1.5 *Equity considerations*

A concern about permanent privileges is that they capitalize the value of the fishery and therefore, when traded, confer benefits to the initial recipients in the form of windfall gains (if the initial allocation is free or cheap). These may be viewed as inequitable from society's standpoint.

The Redstone Group (2007) modeled the economic gains of implementing a Limited Access Privilege Program in the snapper-grouper fishery under the jurisdiction of the South Atlantic Fishery Management Council (SAFMC). They found that implementing the LAPP would provide $15-20 million in benefits, much of which would come from consolidation and de-capitalization in the fishery. However, they also found that most of these gains could be taken out of the fishery in the form of quota purchased from exiting privilege holders.

Macinko (2008) states that the effect of the LAPP would be: *"...transferring the entire future (enhanced) value of the fishery into the hands of those chosen by the particular qualification scheme..."* This is known as the transitional gains trap, when the initial recipients of privileges are able to capitalize a portion of the stream of future benefits and extract these from future participants in the fishery, thereby depriving them of these same benefits. Fixed term privileges may help avoid this transitional gains trap.

However, this rather simplistic view of the transitional gains trap argument reflects a misunderstanding of the concept of resource rents and confuses several important issues. First it may be equating the creation of desirable resource rent with undesirable monopoly rents. Monopoly rents arise when a sole supplier or buyer can charge a higher price to buyers or pay a lower price to suppliers due to their market position. This situation leads to inefficient resource allocations and concerns about equity. However, monopolies rarely exist in fisheries and even if there is a concentration of ownership in one region or sector, the availability of the same or similar fish from other countries and regions mean a commercial seafood company is generally a price taker and unable to generate monopoly rents.

Second, and more importantly, it views rents as somehow unearned and a windfall to those who receive them. However, a significant portion of the asset value of a resource arises from rents generated by the innovation and enterprise of the resource extracting sector (see Attachment B for a more detailed discussion of the concept of Resource Rent). These resource rents are very different from unearned monopoly rents or windfall gains and arise because natural resources, like any other economic good, are scarce and can be sold for a price which is higher than the costs of extraction. Without investment and innovation the resource would remain underutilized with little or no rent generated. Neither are resource rents independent of the prevailing regulatory regime. Regulation affects the amount of resource rent generated because it either creates incentives or disincentives for investments and innovation.

Unlike monopoly rents and windfall gains, resource rents can represent efficiency and sustainability and therefore are a benefit to society. Creating a Limited Access Privilege System with either fixed duration or a relatively unlimited or "rolling" duration does two things:

- It allows those who have created an asset value for the resource through investment, innovation and entrepreneurship to capture a portion of that value through the sale or leasing of privileges.
- It encourages new entrants to enter a sector because they now have the potential to extract a proportional share of the future benefits created from rents generated by their ongoing investment, innovation and entrepreneurship.

From this perspective, individuals arguing against the unfairness of the "transitional gains trap" may be overstating the inequality aspects of the issue. In fact, rather than creating an inequality, a Limited Access Privileges Program may address an existing inequality where participants in a fishery have previously been unable to capitalize the benefits generated by their investment, entrepreneurship and innovation (Harte and Barton 2007). By establishing a tradable privilege with an asset value, participants can now obtain some of the benefits they have created.

Another equity issue regarding permanent privileges is that of the perceived private ownership of a public resource. Even though marine organisms in U.S. waters are the property of the people of the U.S. until they are captured, and will remain so under a Limited Access Privilege Program, fixed term privileges may have a moderating effect on public concerns regarding this issue (Macinko 2008).

F.3.1.6 *Interplay of duration, economic, ecological and institutional variables*

Recent modeling work by Costello and Kaffine (2008) shows that the value, growth characteristics and duration of the harvest privilege all impact incentives for resource stewardship and economic efficiency. Modeling the abalone and spiny lobster fisheries in Baja California, Mexico the authors demonstrate how limited duration privileges could induce resource stewardship. However for slower growing stocks, either a long tenure period or high certainty of renewal is required to induce stewardship. This finding is consistent with work by Larkin et al. (2006) who showed that stock growth rates fundamentally impact the economically efficient management strategy for overfished stocks required to meet a mandated rebuilding target. Importantly, Costello and Kaffine show that a tenure system will encourage stewardship depending on the tenure length, the probability of renewal (as a function of the probability of achieving a predetermined "escapement" level), and the economic and biological characteristics of the fishery. Although modeled for relatively high value single species fisheries, this work demonstrates the context specific nature of the complex relationship between stock characteristics, duration of fishing privileges and the certainty of privilege renewal.

F.3.1.7 *International treatment of the duration of fishing privileges*

Globally there is no consistent pattern to the duration of fisheries privileges. They range from annual to perpetual. For example, in New Zealand privileges are held in perpetuity (Harte, *et al.* 2008) while in the Falkland Islands privileges are held for 25 years (Harte and Barton 2007). In Canada, privileges are granted "annually" while in Australia they vary from fishery to fishery depending on the duration of the management plan (Arnason 2001).

With few exceptions (notably several fisheries in Chile) privileges have what Anderson and Holliday (2007) call *rolling conditional permanence.* For example, in both the Canadian and Australian situation the continual renewal of short-term privileges has resulted in the expectations by holders and management agencies that the privileges are a form of rolling conditional privileges. Holders of such privileges have a legal or procedural expectation based on precedence that their basic privilege to access a fishery will be renewed before or when it expires. As noted earlier it is the certainty associated with the management of the fishery that matters as much as the statutory duration of the privilege when it comes to the perception of its value by the asset owner and the broader marketplace.

F.3.2 Auctions for Privileges to Extract Public Resources

Most initial allocations of public resources have been undertaken using historical participation rules. Such first possession rules are politically popular but are complicated and often involve perceptions of wrangling and back-room dealings. They do have desirable characteristics, in that they benefit socially desirable industry pioneers, and optimal share sizes might have been determined through years of use (Libecap 2006). The allocating authority may also have tighter control over who actually ends up with the privileges (Morgan 1995). However, there are drawbacks to this method of allocation. First, they may discriminate against new entrants, initial allocations are often economically inefficient, and undesirable market situations often exist as a result of them. Auctions may not produce these effects to the same degree.

Auctions are market institutions with explicit sets of rules determining resource allocation and prices on the basis of bids from market participants (McAfee.R.P. and McMillan 1987). In the United States they have been used to sell treasury notes, landing slots at busy airports, parts of the electromagnetic spectrum for use by cellular phone companies, electricity transmission time slots, pollution licenses, mineral leases such as oil and gas, timber plots for harvest, leases on grazing lands, and surface water rights. There were auction "experiments" in Estonia and Russia for allocating fishery privileges, and they are currently in use in Chile for one fishery.

Auctions have several desirable attributes. They can:

- Promote economic efficiency in the allocation of privileges.
- Generate revenue for public expenditure.
- Provide price information to market participants.
- Be designed to promote social and political goals.

F.3.2.1 *Auctions can promote economic efficiency in the allocation of scarce resources.*

Auctions can be economically desirable because those bidders with the highest and best use for the resource (i.e. those with the lowest production costs or the ability to gain a price advantage) will be willing to pay the most for the privilege of utilizing the resource therefore promoting economic efficiency (Libecap 2006; McMillan 1994; Morgan 1995). However, efficiency in the auction process itself may not guarantee an efficient industry (Longo 2003). An economically efficient sector depends as much on the operating rules that are made by the management authority as the initial allocation of privileges.

F.3.2.2 *Auctions may be a suitable royalty recovery mechanism.*

Many argue that the public should be compensated by private companies via royalties for the right to use a public resource (Anderson and Holliday 2007). Auctions may be an effective mechanism for collecting royalties as the resource users themselves establish the level of rent they think is present in the bids they submit (Morgan 1995). Auctions were used to great effect in collecting resource rent from the sale of radio spectrum licenses in 1994, when over $10 billion in revenue was collected (McMillan 1994).

It can be difficult to establish the amount that society should be compensated for a right to access a resource. As owners of the resource the public is clearly due a portion of the rents generated in a fishery (see Attachment B for a more detailed discussion of resource rents). But resource rent is a dynamic concept rather than a simple fixed amount. Industry may generate new rents through innovation, lower production costs, market development, and improved science and resource management. Leaving a proportion with the industry provides an incentive to invest in the fishery and improve economic performance. Total rents accruing to both the public (through general taxation and reinvestment in the economy) and private sectors will increase. If an auction extracts all forms of

rents then this incentive is removed. Allowing industry to retain a portion of rents may actually optimize the total rents that could be accrued by government (a concept analogous to an "optimal" tax rate and backward bending supply of tax revenue). Allowing industry to retain rents can be especially important when access to capital is limited and/or external investors view the sector as risky.

A second and related issue is that it is difficult to identify the rent that is due to the public ownership of the fishery. Rents are the residual that remain after subtracting costs of production from gross revenue. They include the "highliner rents" ("inframarginal" rents) earned by participants who have unique skills or knowledge that enables them to produce at lower costs than other companies operating under the same conditions. It would be a mistake if rent recovery policies sought these rents.

Anderson (2001, p.36) sums up this debate:

> *The rent from a fishery is determined by the size and reproductive capacity of the fish stock and the types and amounts of fixed and variable inputs that are used to catch, process, and market the fish. It is difficult if not impossible, to state how much is due to the fish stock and how much is due to the choice of inputs. The creation of rights-based fishing if done correctly provides the incentives for owners to select the appropriate inputs. Care must be taken to insure that incentives to seek out and implement new ways of production are not unduly weakened.*

F.3.2.3 *Auctions are particularly useful when asymmetries of information exist*

When one party has more information than another, the auction provides a mechanism to communicate that information in a simple way. All the available information underlying supply and demand is incorporated into the price of that item so all that a buyer or seller needs to know to make a rational decision is that price. They may also be desirable when the government has little idea about the value of the privileges for sale.

F.3.2.4 *Auctions may be designed to take social and political goals into account*

As compared to administrative allocations that often occur behind closed doors, auctions are a transparent method of allocating public resources. The auction process is generally an open one, with the rules set in advance, and can avoid claims of favoritism, influence by politically powerful movers, and corruption. This may be extremely important in gaining public acceptance for the process of allocating a public resource. Auctions were used in Russia partly as a way of bringing the allocation process into the public eye and allegations of corruption were reduced (Anferova, *et al.* 2005).

Favoring certain bidders may be justified if willingness-to-pay does not reflect social value (McMillan 1994). For instance, the preservation of disadvantaged small-scale communities may be desirable. Similarly minority groups, small companies, or other previously disadvantaged groups may not be able to compete at auction. There are several ways that they can be taken into account:

- Entry restrictions help ensure that only certain targeted participants can take part in an auction
- A price preference can be granted to certain classes of bidders, such as small scale operators, minorities, or firms that exhibit better than normal environmental stewardship.
- Set-asides for some or all of the resource can be created. A certain amount of privileges may be withheld from the general auction for side-auctions (or perhaps allocation by another method) to designated bidders.

It can be the case that existing participants in an industry will cooperate with each other to create favorable market distortions. In these cases, it may be desirable to introduce new entrants. Auctions can be a fair and transparent way of re-allocating privileges (Anferova et al. 2005).

Although auctions are generally held to be an economically efficient method of allocating resources, they may also be designed to provide political flexibility. The simple auction design of "highest bidder wins" does not have to follow, and governments can manipulate auction design to address policy goals in a variety of ways. Social objectives can be incorporated into auction design, but any such alteration of the unrestricted auction structure to incorporate these considerations will likely entail a loss of economic efficiency. There is, therefore, a tradeoff between the efficiency benefits of auctions and their ability to achieve social objectives.

Having many benefits, auctions also have limitations:

- Auctions may be subject to collusion or gaming by potential bidders and may not reflect actual rents generated.
- Auctions for annual or short term privileges give no or limited security of access to holders and may lead them to focus on exploitation rather than value added activities, and in poorly enforced fisheries, may lead to over-fishing.
- Small fishing companies may not have access to the finance or subsidies that larger entities have access to, handicapping them in auctions. Arrangements that favor smaller companies distort the auction market and may lead to lower rents being generated or a smaller proportion of the rents being collected.
- Auctions for long term rights will result in one-off payments to the government that then requires the government to invest wisely if a long term income stream is desired.
- Bid prices for long term rights may be highly discounted by the commercial industry given the financial risk involved in many fisheries.

F.3.2.5 *Examples of auctions for fishery privileges*

Fishery privileges were auctioned in the Russia Far East from 2001-2003 (Anferova et al. 2005), in Estonia from 2001-2003(Vetemaa, *et al.* 2001; Vetemaa, *et al.* 2005), and in Chile for the Patagonian toothfish fishery (Gonzales, *et al.* 2001).

In 1991 Chile introduced an auction system for privileges in a new, large-scale industrial fishery targeting Patagonian toothfish (Gonzalez et al. 2001). The auction system was designed to provide equal opportunities for bidders, provide revenue for the state budget, and to avoid monopolies in the market for fishing rights. It was also seen as a way of minimizing complaints and conflicts among fishing interests. As the fishery was fairly new, no change in the structure or distribution of the fishery was needed. Fishing companies in the fishery at the time the auction system was implemented were granted prior-use rights. Initially they were allowed to continue their fishing activities for a period of three years, and after this period were granted permits totaling 10 percent of the allowable catch. These permits had a term of 10 years. The fraction of the allowable catch allocated to firms decreased by 10 percent each year and the 10 percent was then re-auctioned

Auctions for fishery quota in Estonia were first implemented in 2001 (Vetemaa et al. 2001; Vetemaa et al. 2005). Prior to 2000, fishing privileges were of indefinite duration. However, with the new system privileges depreciated by 10 percent annually and the 10 percent reclaimed was to be sold at annual auction. This was intended to promote new entry and provide revenue to the government. The other 90 percent was allocated according to historical participation criteria. Despite its apparent success in meeting its objectives for revenue generation and transparency, the auction system was abolished for political reasons in 2003.

Auctions for fishing quota were employed in Russia from 2001-2003 (Anferova et al. 2005). The main purposes of the Russian auctions were to allocate fishery quota in a fair, transparent manner, and to increase the share of resource rents accruing to government. A maximum of 20 percent of the quota would be allocated by auction on a yearly basis. There was a considerable increase in state

revenues as a result of the auctions, and it was felt that the auction system was transparent. However, although the auction system proved successful in increasing state revenues, it was abolished due to ongoing implementation issues and its perceived negative impact on the economic performance of the fishing fleet.

F.3.3 Discussion

A review of the literature suggests that both permanent privileges and limited term privileges have advantages and disadvantages. Permanent privileges have two potential benefits:

- The homogenous nature of the privileges may reduce the level of transaction costs at which the industry operates.
- Permanent privileges are more secure privileges, and may increase incentives for long term investment in the industry, and for resource stewardship.

Fixed terms privileges have the benefit of potentially providing:

- Flexibility for managers to adjust the regulatory environment.
- A balance between the benefit of clear, appropriate and enforceable private privileges and the public ownership of many natural resources.

Limited access privilege type systems operate around the world with a high degree of variability in their statutory duration. Most, if not all, are considered successful in promoting resource stewardship and economic viability of the fishery. This suggests that it is the overall "quality" of the privilege that matters. A high quality title is certain and secure. Certainty and security are increased proportionately with the predictability of the privilege. The more certain and secure the privilege the more likely are fishers to invest in capital and the fisheries to enhance the quality of their catch. Furthermore, the more certain and secure the privileges, the more likely that financial institutions will accept title as collateral against loans.

Limited duration privileges are often promoted on the grounds that they increase management flexibility because the system can be changed on the expiry of rights. In practice, the management system is always under review. This occurs in two ways:

- Through the monitoring of individual companies' compliance behavior and performance.
- Through going oversight of the management system by management agencies, the industry and other stakeholders.

This means any issues arising from the limited access privilege system will be identified and regulations and policies changed in response. Adaptive management provisions are common in fisheries legislation and fisheries management plans around the world.

Many amendments can be introduced into the auction system that may serve social or community goals well but some of the economic efficiency benefits might be lost. For example, set-asides or price preferences for minority groups or small fishing communities may introduce distortions that may be politically desirable, but the economic benefits of auctions could be significantly reduced. In these cases where social and community objectives are more important than economic efficiency and government revenue generation, alternative allocation methods may be more suitable.

Efficient re-allocations may also be made through a functional secondary market, such as that for North Pacific halibut and sablefish IFQs. In Iceland, electronic auctions are held which has the effect of broadening the participation in the auction and increasing competition. Increased competition decreases the chance of collusion occurring and also increases the prices that privileges sell for (Arnason 2001).

Auctions can be efficient revenue raisers for management agencies, transferring a portion of the rents generated in a fishery to the government. A one-off auction of initial rights will see a one-off collection of royalties. Rolling auctions through the take back of privileges from existing holders produce a steady revenue flow but can have considerable distributional and equity consequences for fishery participants.

Auctions are commonly used to allocate natural resources, but rarely in fisheries. Trondheim (2004) suggests fishery privileges have heterogeneous product attributes that have various values. Knowledge about the current status of the fishery resource and its future status is very limited compared to other natural resources such as forests, minerals, water and oil and gas. And while auctions may occur on a stock by stock basis, these stocks are also economically and ecologically interdependent. Auction design may be many times more complicated for fisheries resources than for other natural resources and the potential for unintended consequences far greater.

Auctions appear most effective in new fisheries with few participants or a significant history of industry participation, such as the Chilean Patagonian toothfish fishery, and where catch history allocations have not been made in the past. They can be designed to take a range of policy goals into account.

The allocative efficiency properties of auctions are highly desirable in situations where economic efficiency and fleet capacity reduction are important policy goals. In situations where auctions for fishing privileges have been used, initial allocative efficiency appears to have been achieved. Their limited use in fisheries appears due to concerns about distributional impacts, perceived complexity of design and administration and a lack of popularity with fishery participants and administrators vis-à-vis non-auction alternatives.

F.4 Analysis of Fixed Term/Auction Option versus Council's Preferred Option: Cross Cutting Issues

F.4.1 Introduction

The previous sections of this report described the characteristics of the West Coast Limited Entry Groundfish Trawl Fishery and reviewed the advantages and disadvantages of fixed term tenure and auction systems for achieving alternative objectives in managing fisheries and other natural resources.

This section and section 5 evaluate the advantages/disadvantages and costs/benefits of the fixed term/auction alternative relative to the Council's preferred auction given the specific characteristics of the trawl fishery. Particular emphasis is given to the potential dynamic effects on the fishery from combining fixed term quota shares with an auction of up to 20 percent of the quota shares previously held by participants in the fishery. Previous sections, in contrast, focused on the benefits and costs of auctions and limited duration privileges as independent policy options.

The analysis is based on two assumptions regarding intent of the Council:

- The Council is attempting to strike a balance between pure economic efficiency, environmental protection, and support for social needs and communities in order to increase net regional and national benefits. This assumption is consistent with the first goal in the Trawl Rationalization Plan (see Chapter 1 in the main document). It is also consistent with the combination of preferred alternatives that are not solely focused on efficiency (e.g., relatively small ownership caps on individual IFQs), and concern about communities (e.g., holdback of 10 percent of quota to be distributed to selected communities).

- The Council will continue to use adaptive techniques to improve management of the limited entry trawl fishery including tools and incentives in addition to those incorporated in the preferred option of the West Coast Limited Entry Groundfish Trawl Rationalization Plan.

F.4.2 Wealth Creation (Rents) and Economic Efficiency

The comparative analysis on the limited term/auction option versus the Council's preferred option with respect to rents and economic efficiency rests on the following assumptions:

- Rents and economic efficiency are dynamic concepts. Rents in the trawl groundfish fishery are created over time due to the entrepreneurial activity of industry and supporting sectors given prevailing institutions, incentives, and regulations. Rents can result from investment in all key aspects of the fishery including production, management, and science.

- The amount and time stream of rents are influenced by many factors including the design of the management system and fishing privileges. These design features include all the tools which the Council uses to manage groundfish including tools that influence harvest, allocation, and rationalization.

A more detailed discussion of resource rents and their creation can be found in Attachment B.

The remaining part of this analysis is based on the comparative advantages and disadvantages of the two options based on Section 3 and Attachment A. For each of the major issues, we provide a comparative discussion and analysis given the fundamental features of the west coast limited entry groundfish trawl fishery.

F.4.2.1 *Impact of a Wasting Asset*

As described in Section 2, the west coast limited entry trawl fishery is a complex fishery characterized by multiple assemblages and species, multiple sectors, severely binding quotas (rebuilding rockfish), multiple biological habitats, and coastal communities with supporting infrastructure spread over a 1,200 mile of coastline. Under the preferred alternative, the "rolling conditional permanence" LAPP (Anderson and Holliday 2007) would allow quota holders over time to build a complex portfolio of species to meet their specific business needs and the unique characteristics of their operations (geography, markets, personal expertise, and capital configuration (e.g., vessel size and design)). Quota holders would be expected to alter the quota configurations (both leases and assets) in response to changing resource conditions and changing environments, markets, and regulations. Quota holders would also be expected to invest in new markets and technologies -- and as their past history demonstrates -- engage in co-management, science and cooperative ventures with industry, agency, and community partners. Given the complexity of the challenges and the slow growth of some stocks, returns on investment could take 10, 20, and 30 years or more. Given the assurance of "rolling conditional permanence" quota holders would be willing to invest in projects that increase profits and create entrepreneurial rents over relatively long periods of time.

In contrast to the Council's preferred alternative, the fixed term/auction alternative causes the IFQ quota to become a "wasting asset" as describe in Section 3. This implies that its asset and rental value will decline over time as the end point approaches (in this case end points given that 20 percent of the quota must be given up every two years). Flexibility would be reduced and economic theory suggests that quota holders would be less likely to invest in their operations, research, or management as the end point approaches given diminishing opportunities to realize a return on investment. An individual wishing to acquire additional catch shares, or enter the fishery, could decide to wait until future allocations take place, leaving potential sellers at a disadvantage.

Asset values would significantly drop and approach the annual lease price value. Although many fishermen might plan to stay in the fishery and bid for quota, asset values and total rents would remain lower than the Council's preferred option. True entrepreneurial rents, that is those rents created due to the investment and innovation of the industry would be reduced. Given the absence of empirical data on this option, it is impossible to determine the relative degree of loss rents; but based on the complexity and heterogeneity of the fishery it could be significant, particularly if 20 percent of the operator's IFQ was auctioned.

F.4.2.2 *Limiting and extracting entrepreneurial rents*

Unless carefully designed, one of the challenges of fixed tenure or auctions is that they can reduce the amount of rents created in the fishery due to disincentives. Anderson and Holliday (2007), in their discussion of LAPPS and rent recovery schemes, cautioned against weakening incentives for rent creation and "destroying the goose that lays the golden egg." Possibly a more apt analogy would be "destroying the goose with potential to lay two, three, or more golden eggs." Wilen (2005) estimated that worldwide, fisheries managed under rights-based schemes could generate $80 billion in rents, an amount $30 billion higher than comparable studies. He bases his estimate on the rent-creating potential of fisheries due to entrepreneurial innovation.

The fixed term/auction option can limit entrepreneurial creation of rents in two ways: 1) through disincentives associated with the fixed term that would discourage investment and innovation; and, 2) an auction design that after years 15 or 16 would take 20 percent of the quota and associated resource rent and return it to the government every two years. The rents associated with potential entrepreneurial innovation in the trawl fishery, whether it is in production, marketing, science, or management, would be lost in forced auctions to those who did not create them (government). This would discourage the very creation of the rents and wealth in the first place (which is why patent laws protect intellectual property for a reasonable period of time, e.g., 30 years). A fundamental question is whether an average quota term of five to six years (portfolios would include a mix of termed assets ranging from 10 to 2 years or less) is a long enough period to induce innovation and return on investment?

There may be configurations of auctions and/or tenure that could potentially optimize rents and rent creation while sharing rents with the public. The type of auction and tenure system embodied in this alternative, however, appears to create disincentives to entrepreneurial rent creation.

F.4.2.3 *Increasing risk and uncertainty*

Fishing is a risky business and high risks have the potential to reduce rents. Given fishing's inherent risk, a primary objective of fishery management should be to reduce risks, or at a minimum, not exacerbate risks through poorly conceived management strategies, (dis)incentives, and institutions.

Given ownership caps, most quota will be owned by family-owned firms with (presumably) less access to financial tools to manage risks relative to larger companies (the exception being larger processors and the catcher-processing sector of the at-sea Pacific whiting fleet). Due to information asymmetries and relatively higher proportional transaction costs, small firms must also rely, to a greater degree than large firms, on the value of their assets to collateralize loans (Brewer 2007; Hutchinson 1999). The complex and high risk nature of the west coast trawl fishery suggest that fishermen in an IFQ fishery will attempt to address risks through the types of quota portfolios they inherit and purchase over time. Some of these risks may be substantial given the complex substitute/complement nature of the assets and the constraints associated with bycatch and overfished stocks. Having an extra 100 pounds of canary or yelloweye rockfish may be critical to both asset value and risk management strategies. One would expect that each fishermen holding quota would build an "optimal" quota portfolio that matched their business and risk management strategies.

The fixed term/auction alternative may increase risks in potentially three ways. First, as the fifteen year term unfolds, asset values will be influenced, not only by changes in the normal activities of the quota markets, but through the influence of the "wasting" characteristics of the asset. This will become more pronounced as the term expires and quota holders relinquish twenty percent of their portfolios. Given the potentially "balanced" nature of the quota holdings, this could increase the risks associated with holding and trading quota given changing market conditions. Secondly, the quota holders will face risk given their uncertain financial situation when the expected first auction takes place. Quota holders will be forced to relinquish and then buy back quota regardless of their financial situation—this will also create risk. And third, prices at the auction may be uncertain given the large amount of quota available at the auction and the limited 10 year tenure associated with 20 percent of the quota. Risk/uncertainty may also be increased due to high and possibly speculative prices for bycatch constraining stocks.

Given the impacts on risks/uncertainty, the fixed term/auction alternative will reduce rents relative to the Council's preferred option. This may even be true for the 5 percent auction given the critical importance (and presumably high price) of the constraining bycatch stocks.

F.4.2.4 *Summary*

The comparative qualitative analysis indicates that on balance, the Council's preferred option relative to the fixed term/auction results in significantly higher rents and economic efficiency through incentives for entrepreneurial innovation, rent creation, and reduction in risk and uncertainty. In contrast the fixed term/auction alternatives generate less rent due to the disincentives for rent creation and greater risk and uncertainty. The auction system may provide for moderate gains in new entrants and price discovery but this depends on whether secondary market will function efficiently. The analysis suggests that developing LAPP systems perceived as "fair" while also producing significant entrepreneurial rents is an important challenge.

The qualitative results of the analysis can also be represented if Figure 4.1. Over time rents will increase for the Council's preferred option due to creation of entrepreneurial rents and reduction in risk and uncertainty. The fixed term/auction alternatives generate less initial rents and rents decrease over time due to the "wasting effects" of the fixed term, decrease in entrepreneurial rents, and greater risk and uncertainty due to the timing and structure of the auction system. As shown by the 5 percent and 20 percent auction curves, the loss of economic rents increases as the auction approaches.

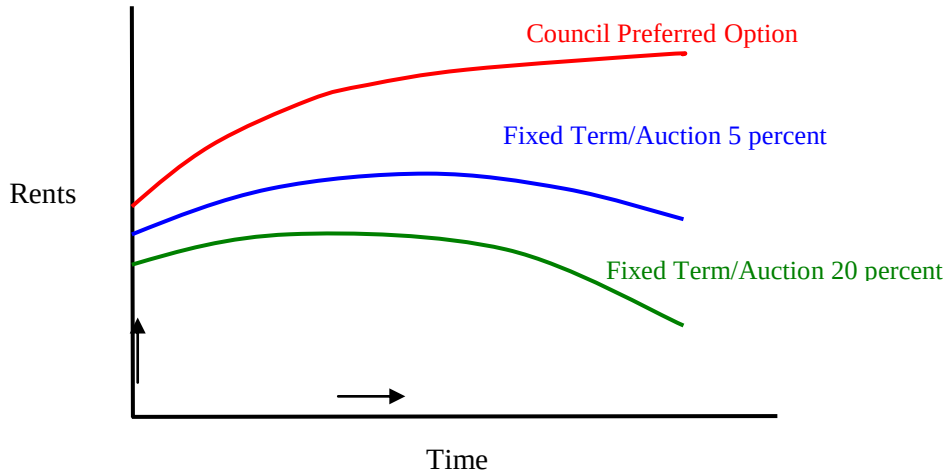

Figure F-1. The level of rents across time as a function of the Council's preferred option, fixed term/5 percent auction, and fixed term/20 percent auction.

F.4.3 Incentives for Resource Stewardship

The history of the west coast groundfish trawl fishery demonstrates the difficult and sometimes contentious issues associated with conserving stocks and managing anthropogenic effects on marine ecosystems. The Council has made major efforts in managing these effects including mandating MSY stock levels, eliminating trawl roller gear, creating rockfish conservation zones, establishing trawl closure areas, reducing effort through vessel and permit buybacks, and rebuilding overfished stocks. Many of these decisions were difficult and at times wrenching given their economic and social impacts. Some of these efforts were required under the MSA, while others were developed by the Council as the best approach to conserve groundfish stocks and ecosystems.

As discussed in Section 3 and Attachment A, the creation of rights and privileges is expected to generally have a "stewardship effect" if the assets are relatively well defined, have long duration, and are reasonably secure. These features induce asset holders to conserve the stock over time in order to enhance overall profits, increase entrepreneurial rents, and maximize quota (asset) value. Reviews of rights based fisheries in New Zealand, the United States, Canada, and other nations generally provide supporting evidence for conservation and stewardship of the targeted resource and habitats.

Conversely, inadequate stock conservation and protection of supporting habitats and ecosystems could potentially reduce long term profits, rents, and asset values. As Section 3 points out, some analysis believe that even a well designed rights based system may not lead to long term conservation of stocks and ecosystems if fishermen have high rates-of-time-preference (high discount rates) and/or stocks are relatively slow growing and unproductive.

Whether the Council's preferred option would have stronger stewardship effects relative to the fixed term/auction is partially determined by the types of impacts that the groundfish industry could produce. Most of these effects would not be generated by a single fisherman but would be produced in aggregate by all groundfish trawlers owning assets or annual leases. These impacts would fall into three classes:

- Class I: Adverse resource impacts caused by a user group's collective "club" good (e.g., groundfish quota holders) which reduces the productivity of the groundfish resource and lowers the asset value of their user privilege. This might take the form of excessively targeting units of the resource important for reproduction and recruitment (e.g., "big fat old females") or destroying habitats important for spawning and feeding (rocky reefs).

- Class II: Adverse impacts are caused by a second party's activities (e.g., a second group of fishermen) that reduce the productivity of the resource and lower the asset value of the first group's property right. This might include fishermen targeting important prey species or damaging the environment through inappropriate use of gear.

- Class III: Adverse impacts are caused by a user group's activities but do not influence the productivity of the asset-related resource, nor directly lower the asset value of their user right. For example, quota owning trawl fishermen may fish using methods that do not significantly impact the productivity of the commercially targeted groundfish but may adversely impact other aspects of the resource (e.g., excessive bycatch of non quota species).

For class I and II impacts, the groundfish quota holders will have incentives to collectively "internalize" the externalities -- even without direct intervention by the Council -- including voluntary management and enforcement. For Class II impacts, groundfish quota holders would be expected to lobby the Council or use LAPP systems and quota markets (if broadly developed) to alter the behavior of the second party. Class III impacts may require the active leadership, participation, and "coercion" of the Council and regulatory/enforcement bodies in order to alter fishermen behavior.

The remaining part of this analysis is based on the comparative advantages and disadvantages discussed in Section 3 and Attachment A. For the two "stewardship" related issues discussed below we provide a comparative analysis given the fundamental features of the west coast limited entry groundfish trawl fishery.

F.4.3.1 *Stewardship effects of a wasting asset*

Similar to the discussion on rents, the fixed term/auction alternative would have a "wasting asset" effect on quota values due to potentially inadequate investment in stewardship. Assuming that the long term health of the stock and supporting environment has an important positive affect on groundfish asset values, under the preferred option one would expect LAPP groundfish quota holders to invest in voluntary resource conservation, habitat protection, and scientific research leading to improved resources, environments, and asset values. This would be especially true for Type I and Type II impacts. Given the difficult problems associated with bycatch of rebuilding stocks, one would also expect strong investment in conserving and avoiding quota-based "bycatch" stocks. The expected high quota value of bycatch rebuilding stocks, coupled with the high costs of exceeding bycatch quota, would reinforce active stewardship behavior.

In contrast, the fixed term/auction options would induce a "wasting asset" effect, reduce rents and entrepreneurial innovation, and inhibit efforts to reduce Type I and Type II resource and environmental impacts. As time progressed toward the 15th year, incentives for stewardship would decrease, and given the inhibitory effects of the biennial auctions on entrepreneurial rent creation, would decrease conservation investment. The degree of effects could be similar to those illustrated in Figure 4.1.

Two additional points should be noted. The first is that for Type III impacts, neither option would necessarily induce a stewardship effect. Second, is that other tools used by the Council to incentivize or regulate stewardship behavior, combined with market influences to reward stewardship, could somewhat mitigate stewardship differences between the two options. In general, however, relatively secure rights with higher rent creative potentials should induce a stronger stewardship effect than options without these virtues.

F.4.3.2 *Stewardship effect of impacts on discount rates*

As discussed in Section 3 and Attachment A, some analysts argue that the "iron law of the discount rate" favors fixed tenure systems. This "law" suggests that fishermen with high discount rates would under-invest in stewardship regardless of tenure length, particularly for slower growing stocks. Given this problem, they argue that tenure systems coupled with auctions would provide an opportunity for resource managers to adjust the system to better encourage stewardship through improved regulation and incentives for conservation-based participants.

There is, however, little empirical evidence supporting the argument that fishing industries have higher intrinsic discount rates than other sectors of society, particularly with respect to financial activities and investment. It is true that fishermen can be observed engaging in risky and destructive behaviors that put fishery resources at risk. However, these behaviors usually reflect poorly crafted institutions that create open access conditions and race-for-the-resource business strategies. Fishermen reflect their institutions, and apparent destructive behaviors are as much a function of the management system than any inherent high discount rate. In general, poorly regulated or open access fisheries will tend to attract individuals with high discount rates who "prosper" in such systems (at least in the short run). Conversely, well managed fisheries with incentives and rights that motivate entrepreneurship and innovative will tend to attract risk averse fishermen and quota asset holders with lower discount rates. Studies of New Zealand's rights based fisheries including groundfish (Harte, *et al.* 2008) suggests that implicit discount rates based on the observed ratio of nominal lease and asset

prices are quite reasonable, (8 to 22 percent), particularly given the inherent risk in using and managing marine natural resources.

Given these arguments there is no prior reason to expect that the fixed tenure/auction option will increase stewardship and conservation relative to the Council's preferred option; in fact the converse is probably true. In addition, as a backstop measure, any behavior by fishermen leading to violation of MSA conservation standards would result in the revocation of the privilege or additional regulation constraining harvest activities.

F.4.4 Impacts on Communities

Pacific Management Council staff identify some 38 cities and 18 counties as vulnerable commercial/and or recreational fishing communities. Four cities and six counties are identified as most vulnerable. The cities are: Garibaldi, Ilwaco, Moss Landing, and Neah Bay. The counties are: Coos, Grays Harbor, Humboldt, Lincoln, Mendocino, and Pacific counties (Pacific Fisheries Management Council 2006).

The rationalization of the Groundfish limited entry trawl fishery is anticipated to have the following impacts on communities (Pacific Fisheries Management Council 2008):

- More economically efficient vessels are expected to remain in the fishery, while less efficient vessels leave the fishery. Communities with inefficient vessels or operators may see greater levels of exit behavior.

- Ports that have a higher degree of fishing support business (agglomeration) make it easier and more efficient for operators to conduct day-to-day activities and may favor some communities over other communities.

- All things being equal, communities with vessels that have a longer travel time to fishing ground will be at a disadvantage when compared to other regions.

- Ports that are adjacent to fishing grounds with a high abundance of over-fished stocks subject to rebuilding mandates would also be at a disadvantage encouraging operators to move to areas with lower abundance.

Fixed term privileges and the auctioning of up to 20 percent of Quota Shares every two years will likely have three effects:

- It will exacerbate the disadvantages already faced by communities and ports with vessels that have a long travel time to fishing grounds, have less successful operators, more costly vessels, and fewer few support businesses.

- The negative impacts of the fixed term/auction alternative will be felt earlier in the most vulnerable communities compared to less vulnerable communities.

- It will create disincentives for collaborative community initiatives such as the creation of statutory Fishing Communities and Regional Fisheries Associations. These disincentives will be felt more strongly in disadvantaged communities.

These expectations are due to the increased uncertainty associated with both the loss of harvest privileges and the need to have access to sufficient capital to participate in the auction to regain or increase quota share holdings. Operators with marginally profitable businesses are more likely to form a higher proportion of operators in disadvantaged communities. They are more likely to sell their Quota Shares and exit the fishery long before the fixed term duration of the privilege turns it into

a wasting asset. Purchasers of these privileges are more likely to be based in more prosperous fishing communities and have access to the capital necessary to take full advantage of the auction system.

Moreover, fishing communities and ports make infrastructure investments with a 30-plus year time horizon. This is well beyond the proposed 15 year fixed term for quota shares. Disadvantaged communities face a higher degree of uncertainty about future level of participation in the groundfish fishery than other fishing communities and may therefore be more risk adverse when deciding about infrastructure investment. This may result in a declining infrastructure base in disadvantaged communities that is increasingly less attractive compared to other communities. Operators will then be more likely to move to ports and communities with better infrastructure to support their operation.

It can be argued that the fixed term/auction alternative potentially allows operators or port-owned entities in disadvantaged communities to form a cooperative-type entity to bid for quota shares and thus retain fishery participants. The MSA provides for both the creation of formal Fishing Communities and Regional Fishery Associations. However, as long as there are efficient secondary markets in privileges these entities will be able to do this in the absence of fixed term privileges and auctions. Cooperative entities will also still face competition in auctions from operators and entities based in more prosperous communities. Irrespective of an efficient secondary market for privileges and the opportunity to acquire quota shares through auction, the loss of up to 20 percent of quota shares every two years may also create major disincentives for any operator, community or port to enter into a cooperative arrangement, This is because of the need for ongoing funds required to sustain the cooperatives' overall holding of privileges. These disincentives become larger the greater the size of the quota takeback.

The Management Council's preferred option contains an Adaptive Management provision. This creates a potential mechanism to assist disadvantaged fishing communities by setting aside 10 percent of the Quota Poundage each year to create incentives for community development, among other purposes. If used to assist communities to remain viable competitive ports, the imposition of fixed term/auction alternative in 15 years could undermine the adaptive management program. This is because the increased uncertainty created by the fixed term/auction alternative disproportionately impacts disadvantaged communities undermining potential gains from the adaptive management program.

F.5 Analysis of Fixed Term/Auction Option versus Council's Preferred Option: Management Goals and Objectives

This section first evaluates the Council's preferred option against the fixed term/auction option with respect to key management goals and objectives for the West Coast Groundfish Trawl Fishery. This evaluation is informed by discussion and analysis in Sections 3 and 4. The goals and objectives for Groundfish Management and Groundfish Rationalization are listed in Chapter 1 of the main document. Second, the section qualitatively scores the relative strengths and weaknesses of the fixed term/auction against the preferred option in Table 4.1. It concludes with a brief discussion of key findings.

F.5.1 Conservation (also see Section 4)

The Council's preferred option provides greater incentives to conserve resources, habitats, and ecosystems than the fixed term/auction alternative. Due to wasting effects, reduction in entrepreneurial rents, and greater risks and uncertainty, the fixed term/auction alternatives significantly reduces resource and habitat conservation efforts over time. Although auctions could be designed to reward conservation efforts, this would be at potentially high costs in lost economic efficiency. There is no evidence that fishermen or quota holders have intrinsically high discount rates that would inhibit them from investing in habitat and resource conservation efforts having moderate or long pay back periods. Class III type environmental impacts may not result in environmental or conservation efforts for either option but would require Council regulatory action and enforcement

including revocation of LAPP privileges. The negative impacts are greater with the 20 percent relative to the 5 percent auction.

F.5.2 Net Economic Benefits (also see Section 4)

The Council's preferred option relative to the fixed term/auction results in significantly higher rents and net economic benefits through incentives for entrepreneurial innovation, rent creation, and reduction in risk and uncertainty. In contrast the fixed term/auction alternatives generate less rent due to the disincentives for rent creation and greater risk and uncertainty. Net economic benefits are lower with the 20 percent auction option relative to the 5 percent.

The auction system may provide for moderate gains due to price discovery and rebalancing price asymmetries but this depends on whether secondary market will function efficiently. The analysis suggests that developing LAPPS systems perceived as "fair" while also producing significant entrepreneurial rents is an important challenge.

F.5.3 Disruption

Compared to the Council's preferred option, the fixed term/auction option will cause significant disruption to the fishing, marketing procedures, and the environment. This is because of the uncertainty that the loss of up to 20 percent of privileges introduces to harvest plans, processing volumes and marketing agreements. It also undermines the operators' potential commitment to the long term sustainability of the fishery and industry. The disruption could take three forms compared to the preferred option:

- Barriers to long term beneficial investments and partnerships because of the uncertainty created by the pending auction.
- Non-productive rent seeking behavior by sector participants in advance of the fixed term expiration and auction to 1) prevent its implementation 2) to gain strategic advantage to minimize losses from the auction processes and/or) maximize individual gains at the expense of the sector as a whole.
- Disruption to existing harvesting, processing and marketing plans following the auction as some operators fail to replace quota, others gain it and new entrants learn about the fishery and sector.

Though it is possible to predict the severity of this disruption, there is no possibility of these disruptions under the preferred option unless they come about from economic or environmental factors exogenous to the Limited Access Privilege Program.

F.5.4 Excessive shares

With respect to excessive shares there is unlikely to be a net difference between the Council's preferred option and the fixed term/auction alternative. This is because the accumulation limits (vessel and control) apply under both options. Operation of secondary markets in Quota Shares will create the same conditions affecting consolidation and quota concentration as an auction. The proposed accumulation limits should prevent any tendency for excessive geographic or consolidation occurring in either the harvesting or processing sector.

F.5.5 Fairness and Equity

A fixed term/auction system could promote fairness and equity through:

- The operation of a transparent and competitive allocation mechanism.
- Returning a share of the rents generated from the exclusive use of a public resource.

Nevertheless, exiting inequities with respect to fishing community wellbeing, market position and access to capital could be exacerbated with an auction system leading to a bigger gap between the best performing operators and communities and the poorer performer operators and their communities. On balance the larger the takeback of quota shares the larger the potential for negative impacts on fairness and equity in the groundfish fishery.

F.5.6 Sector Health

The Council's preferred option would promote greater sector health than the fixed term/auction alternatives. The preferred option would promote significantly greater efficiency, resource and habitat conservation, and reduced risk and uncertainty to the harvesting and processing sectors and the service sectors that support them. Quota holders would be expected to develop "optimal" portfolios of quota that met specific business needs. Harvesters and processors would be encouraged to develop long term relationships based on dependable quotas to address market needs and opportunities. Communities and ports could engage with harvesters, processors, and other quota holders to develop long term arrangements and contracts that "underwrite" community investment in critical fishing and seafood industry infrastructure.

F.5.7 Community (also see Section 4)

Overall, communities and disadvantaged communities will be no better off under the fixed term/auction duration compared to the Council's preferred alternative, and disadvantaged communities could be significantly worse off vis-à-vis more prosperous fishing communities.

- It will exacerbate the disadvantages already faced by communities and ports with vessels that have a long travel time to fishing grounds, have less successful operators, more costly vessels, and fewer few support businesses.
- The negative impacts of the fixed term/auction alternative will be felt earlier in the most vulnerable communities compared to less vulnerable communities.
- It will create disincentives for collaborative community initiatives such as the creation of statutory Fishing Communities and Regional Fisheries Associations. These disincentives will be felt more strongly in disadvantaged communities.

F.5.8 Labor: Captains, Crew and Processing Plant Workers

The Council's preferred option contains provisions for an adaptive management program and secondary markets in Quota Shares and Quota Poundage will also operate giving labor opportunities for greater ownership of privileges in the fishery. The limited term/auction option although potentially increasing the availability of quota to captains and crew will also result in the loss of quota shares to operators and captains and crew already holding shares. This could negatively impact captains and crew both directly through the loss of quota they have already acquired and indirectly if the vessels they captain or crew lose access to quota.

Processing staff workers may see lower wages and less secure jobs because of the uncertainty generated by the fixed term/auction system. Because no processing company can predict the outcome of the auction process with up to 20 percent of quota shares changing hands, winners and losers from the auction process will be equally impacted by the uncertainty created by the auction process.

Impacts of a fixed term/auction system on vessel safety are difficult to anticipate relative to the Council's preferred option. A Limited Access Privilege Program generally has positive impacts on vessel safety because it ends the race to fish. A fixed term/auction system may reduce these anticipated benefits because:

- Increased uncertainty may delay or stop investment in new vessels and gear which may be safer to operate.
- Prior to an auction, operators may fish harder to make sure there they have no uncaught quota poundage if there is the possibility of losing access to the poundage the following season.

All of the potential impacts to labor are sensitive to the size of the auction and associate loss of quota from existing portfolios. The closer the auction to the proposed 20 percent quota share maximum, the greater the impact will be.

F.5.9 Small Entities and New Entrants

Due to the more limited access to capital and the smaller quota holdings, smaller entities are in a more disadvantaged position compared to larger entities under the fixed term/auction option. In particular small entities are potentially more vulnerable to the consequences of being outbid in the auction process and therefore losing up to 20 percent of their harvest privileges. This disruption of their quota portfolio could lead to an unviable business, causing them to exit the fishery and cash in their remaining quota shares. Small entities will be especially impacted by high prices for constraining stocks. Constraining stocks may have a low exvessel price but a high quota value because the availability of quota poundage or quota shares is limited because they are a constraint on the harvest of stocks with a higher exvessel price.

An auction does provide opportunities for new entrants but small-owner operators are likely to be a small minority of new entrants. Moreover, the functioning of an efficient secondary market for quota shares should provide an ongoing opportunity for new entrants to the fishery and only in the case of thin markets would an auction greatly assist new entrants.

The larger the take-back and the amount of quota auctioned each year the greater the impact on small entities and new entrants. For nonconstraining stocks the larger the auction of quota the potential for new entrants increases. At the same time a larger takeback may severely impact small entities that could end up with quota share holdings too small to fish themselves, forcing them to lease quota or exit the fishery. For constraining stocks the effects on small entities could be significant at even relatively low auction percentages.

Although auctions could provide for more efficient entrants, this may not be the case for the trawl fishery for two reasons: 1) the west coast groundfish fishery undertook a self financed buy out program that eliminated 40 percent of the fishing vessels -- theoretically this should have eliminated less efficient fishing firms; and 2) the auction occurs after 15 or 16 years of trading on the secondary market which, if operating reasonably successfully, should also function to eliminate inefficient firms.

F.5.10 Auctions and Cost recovery

The Council's preferred option provides for cost recovery of up to 3 percent of ex-vessel costs for program costs but does not provide for a system to collect royalties. This raises the question of whether or not the collection of royalties is a high priority for the Council. If it is, then the fixed/term auction option is superior to the Council's preferred option. However, there are many royalty collection mechanisms that could be built into the preferred option without the need to resort to an auction. As discussed previously, setting the level of rent extraction through a royalty mechanism is fraught with difficulty. Set too high and the mechanism may reduce rents in a fishery as it acts as disincentive to innovation, investment and entrepreneurship.

Given that any royalties collected go into the Limited Access Administrative Fund and are then made available by appropriation, there is no guarantee that this revenue will be available to promote fisheries management in the Council's management area. Royalties are a transfer payment and therefore provide no net gain to the nation but are a potential loss to the region. Moreover by

removing beneficial resource rents from the industry it reduces the capital available for reinvestment in the seafood or other wealth creating economic sectors in the region.

F.5.11 Program Performance and Management

Compared to the Council's preferred option, the fixed term/auction alternative potentially imposes significant additional administrative costs on the Management Council. Not only will an effective auction system need to be designed, set up, and operated but an administrative system must be established for taking back up to 20 percent of quota across multiple stocks and multiple owners. Outsourcing this task to the private sector could reduce administrative complexity but will still require significant regulatory oversight.

Fixed duration privileges can create the appearance of increased management flexibility because the system can be changed on the expiry of rights. However in practice, groundfish management is always under review. This means any issues arising from the Limited Access Privilege Program based system will be identified and regulations and policies changed in response.

F.5.12 Summary

Results of the qualitative comparative analysis are shown in Table 5.1. The Table highlights the relative impacts with respect to key groundfish management goals, objectives, and standards (GOS). Results demonstrate that:

- For major conservation objectives the Council's preferred option outperforms the fixed term/auctions. The lower conservation performance of the alternative option is due to the fixed term "wasting effects" and disincentives stemming from the auction's effects inhibiting conservation investment. Information effects and impacts on nongroundfish mortality are considered similar due to Type III environmental impacts.

- Net benefits and efficiency are all considered to be significantly lower for the fixed term/auction option. This is a result of the wasting effects of the fixed term, the rent creation inhibiting effects of the auction, and greater risk and uncertainty. The 20 percent auction impacts are significantly greater than the 5 percent effects.

- The fixed term/auction option will cause significant disruption to fishing and marketing strategies, and the broader business environment. This is because of the uncertainty that the loss of up to 20 percent of privileges introduces to harvest plans, processing volumes and marketing agreements. It also undermines the operators' potential commitment to the long term sustainability of the fishery and industry.

- With respect to excessive shares there is unlikely to be a net difference between the Council's preferred option and the fixed term/auction alternative. This is because the accumulation limits (vessel and control) apply under both options.

- Fairness and inequities with respect to fishing community wellbeing, market position and access to capital could be exacerbated with an auction system leading to a slightly bigger gap between the best performing operators and communities and the poorer performing operators and their communities. There would be no expected difference between the Council's preferred option and the fixed term 5 percent auction.

- The Council's preferred option would promote greater sector health than the fixed term/auction alternatives. The preferred option would promote greater efficiency, resource and habitat conservation, and reduced risk and uncertainty to the harvesting and processing sectors and the service sectors that support them. Year round marketing would be similar under both options.

Table F-1. Benefits and cost of fixed term/auction option compared to the Council's preferred auction.

Assessment Criteria	Criteria reference	Benefits (+) & Costs (–) of Fixed Term/Auction Option Compared to the Council's Preferred Auction	
		Magnitude of difference 0 No difference – or + Low – – or ++ Moderate – – – or + + + High	
		5% Auction	20% Auction
Conservation

		Magnitude of difference 0 No difference – or + Low – – or + + Moderate – – – or + + + High	
		5% Auction	20% Auction
Communities			
Consider importance of fishing to communities in order to provide sustained participation and to minimize adverse impacts	MSA - National Standard 8 GF FMP Objective 16 A-20 Objective 5	–	– –
Consider basic cultural and social framework of the fishery.	MSA – 303A(c)(5)(B)	–	–
Include measures to assist, when necessary and appropriate… fishing communities through set-asides of harvesting allocations… or economic assistance in the purchase of quota	MSA – 303A(c)(5)(C)	–	– –
Small Vessels, Small Entities, and New Entrants			
Promote sustained participation of small owner-operated fishing vessels	MSA – 303A(c)(5)(B)(i)	– –	– – –
Include measures to assist, when necessary and appropriate, entry level and small vessel owner-operators . . . through set-asides of harvesting allocations… or economic assistance in the purchase of quota	MSA – 303A(c)(5)(C)	0	–
Avoid unnecessary adverse impacts on small entities	GF FMP Objective 15	–	– – –
Auctions and Cost Recovery			
Auctions, or other systems to collect royalties, shall be considered for initial or any subsequent allocation	MSA – 303A(d)	+ +	+ + +
Assess and provide a program of fees paid by the quota holders that will cover the costs of management, data collection and analysis, and enforcement activities	MSA – 303A(e)	0	0

Table F-1 continued

Assessment Criteria	Criteria reference	Benefits (+) & Costs (–) of Fixed Term/Auction Option Compared to the Council's Preferred Auction	
		Magnitude of difference 0 No difference – or + Low – – or + + Moderate – – – or + + + High	
		5% Auction	20% Auction
Program Performance Monitoring and Modification			
Take into account the management and administrative costs of implementing and overseeing the IFQ or co-op program and complementary catch monitoring programs, and the limited state and federal resources available.	A-20 Constraint 9	– –	– –
Regular review and monitoring of the program for progress in meeting the goals, 5 year formal review	MSA – 303A(c)(1)(G)	0	0
Privileges may be revoked, limited or modified at anytime. Provide for revocation	MSA – 303A(b)(2), MSA – 303A(c)(1)(K)	0	0

- The limited term/auction, option although potentially increasing the availability of quota to captains and crew, will also result in the loss of quota shares to operators and captains and crew holding shares. The 20 percent auction will have only small negative effects on labor and plant workers' employment benefits and safety.

- Fixed term privileges and the auctioning of up to 20 percent of Quota Shares every two years will likely have negative effects on communities by exacerbating the disadvantages already faced by communities and ports, disproportionally impacting vulnerable communities, and creating disincentives for long term collaborative community initiatives with fishermen, processors, and quota holders.

- Due to the more limited access to capital and the smaller quota holdings, smaller entities are in a more disadvantaged position compared to larger entities under the fixed term/auction option. In particular small entities are potentially more vulnerable to the consequences of being outbid in the auction process and therefore losing up to 20 percent of their harvest privileges.

- Both alternatives collect cost recovery fees to pay for administering the LAPP program. If collection of royalties is a priority or objective for the Council, then the fixed/term auction option is superior to the Council's preferred option.

- Compared to the Council's preferred option, the fixed term/auction alternative potentially imposes significant additional administrative costs and program performance monitoring costs on the Council. Not only will an effective auction system need to be designed, set up, and operated but an administrative system must be established for taking back up to 20 percent of quota across multiple stocks and multiple owners.

JUNE 2010

Summary of Proposed Changes to the Content of the Groundfish FMP

As part of implementing the trawl rationalization program, the Groundfish FMP must be amended. This would be Amendment 20 to the FMP. Parts of Chapters 1, 6, and 11 of the FMP have to be modified. In addition, an appendix would be added to the FMP containing a detailed description of the IFQ and co-op programs. The specific changes to FMP text are shown in the next section and summarized below.

A brief description of the amendment is added to Chapter 1, along with a reference to Appendix E to the FMP, containing a detailed description of trawl rationalization program provisions.

Chapter 6 in the FMP describes the range of management measures available to the Council, organized according to major categories. Section 6.9 of the chapter describes measures to control fishing capacity, including permits and licenses.

- Section 6.9.1 describes general provisions for permits. A section is added to cover the new requirement for processor permits for the mothership fishery.

- Section 6.9.3, "Individual Fishing Quota Programs," was incorporated into the FMP by Amendment 18 and authorizes an IFQ program. It has been rewritten to cover trawl rationalization in general (both IFQs and co-ops), and a separate subsection was created to preserve the language referencing IFQs as they would apply to other sectors.

Chapter 11 describes the license limitation program and the division that program created between the limited entry and open access segments.

- Section 11.2.1 identifies the Federal permit requirements and the regulations that apply when vessels with limited entry permits use open access gears. That language is modified to indicate that when a vessel with a trawl permit uses an exempted gear IFQ regulations apply, except with respect to those gears for which the IFQ program provides and exception (see Section A-1.1 of the IFQ program for the gear exceptions).

- Section 11.2.5 identifies the requirements for gear endorsements. Paragraph 6 of this section has been rewritten to clarify the ability of vessels with limited entry permits to use gears for which they do not hold an endorsement and to incorporate language that provides for gear switching.

- A new section was added: "Section 11.2.6, Sector Endorsements." The existing sections on fixed gear sablefish were moved from Section 11.4 to this section, and sections were added on catcher processor (CP) endorsements, and Pacific whiting mothership catcher vessel (CV(MS))endorsements.

- Section 11.2.7 addresses the size endorsement. It has been modified to indicate that a trawl permit's size endorsement will not be reduced if it is transferred to a smaller vessel.

- Section 11.2.11 covers the rules for combining permits. A new paragraph was added to address the treatment of the new endorsements CP and CV(MS) endorsements when permit combination occurs.

- Section 11.5 contained the language implementing Amendment 15. As indicated in the first paragraph of that section, these provisions sunset with the creation of a trawl rationalization program for the Pacific whiting fishery. Therefore, this language has been removed.

Changes to the Groundfish FMP Incorporated by Amendment 20

Relevant FMP text is excerpted below. Insertions are marked by underline and deletions by strikeout. Double underline marks text stricken elsewhere and moved to a new location. Ellipses (…) indicate unchanged text omitted below.

1.0 INTRODUCTION

…

Amendment 20 was approved in [2010] and establishes the groundfish trawl rationalization program. Under this program groundfish limited entry trawl vessels making shoreside deliveries are managed with individual fishing quotas. Motherships and associated catcher-vessels in the at-sea Pacific whiting sector are managed under a system of regulated cooperatives. Pacific whiting catcher processors fish within a voluntary cooperative; the amendment establishes provisions to strengthen this cooperative. As noted above, Amendment 20 supersedes provisions in Amendment 15; corresponding text was replaced.

1.2 How This Document is Organized

…

- Appendix E contains a detailed description of the trawl rationalization program (see Section 6.9.3.1).

[N.B. Appendix D to the Trawl Rationalization EIS would become Appendix E to the Groundfish FMP.]

…

6.0 MANAGEMENT MEASURES

…

6.9 Measures to Control Fishing Capacity, Including Permits and Licenses

…

6.9.1 General Provisions for Permits

6.9.1.1 Commercial Fisheries Permits

All U.S. commercial fishing vessels are required by state laws to be in possession of a current fishing or landing permit from the appropriate state agency in order to land groundfish in the Washington, Oregon, and California area. Federal limited entry permits authorize fishing within limits and restrictions specified for those permits. Vessels without such permits are also subject to the specified limits and restrictions for the open access fishery. ~~Federal permits also may be required for groundfish processors.~~ In the event that a Federal fishing or access permit is required, failure to obtain and possess such a Federal permit will be in violation of this FMP.

6.9.1.2 Recreational Fisheries Permits

All U.S. recreational fishermen are required by state laws to obtain a recreational permit or license in order to fish for groundfish. In the event that a Federal license or permit is required, failure to obtain and possess such Federal permit will be in violation of this FMP.

6.9.1.3 Processor Permits

Federal permits also may be required for groundfish processors. Under the trawl rationalization program (see Section 6.9.3) mothership processors in the Pacific whiting fishery must possess a mothership (MS) permit. Like groundfish limited entry permits (see Chapter 11) Pacific whiting mothership (MS) permits are transferrable once initially distributed to qualifying vessels at the beginning of the trawl rationalization program. To qualify for initial issuance of an MS permit at the beginning of the program, a processing vessel must have processed at least 1,000 mt of Pacific whiting in each of any two years from 1997 through 2003.

6.9.2 Sector Endorsements

The Council may establish sector endorsements, such as with the limited entry fixed gear sablefish fishery (see Section 11.2.6). Sector endorsements would limit participation in a fishery for a particular species or species group to persons, vessels, or permits meeting Council-established qualifying criteria. Participants in a sector-endorsed fishery may be subject to sector total catch limit management. A sector endorsement, whether it is applied to vessels that already hold limited entry permits or to those in the open access or recreational fisheries, is a license limitation program.

6.9.3 Fishery Rationalization~~Individual Fishing Quota~~

6.9.3.1 The Trawl Rationalization Program~~s~~

The trawl rationalization program applies to vessels holding trawl-endorsed groundfish limited entry permits (and mothership processors registered to mothership permits). The program is intended to reduce fishery capacity, minimize bycatch, and meet other goals of the FMP. The program replaces most cumulative landing limits (in both whiting and nonwhiting shoreside limited entry trawl sectors) with individual fishing quotas. Under the Magnuson-Stevens Fishery Conservation and Management Act (MSA), "an 'individual fishing quota' means a Federal permit under a limited access system to harvest a quantity of fish, expressed by a unit or units representing a percentage of the total allowable catch of a fishery that may be received or held for exclusive use by a person." The Council may establish IFQ programs for any commercial fishery sector. ~~IFQ programs would be established for the purposes of reducing fishery capacity, minimizing bycatch, and to meet other goals of the FMP. Participants in an IFQ fishery may be subject to individual total catch limit management (Section 6.7.1).~~The Pacific whiting mothership sector is managed through a system of cooperatives (co-ops) under which catcher vessels choosing to fish in a co-op would be obligated to deliver their catch to an associated mothership processor. Each year motherships and catcher vessels must identify which co-op they plan to participate in. If they do not plan to join a co-op for that year they participate in a non-co-op fishery. The Pacific whiting catcher-processor sector operates as a single, voluntary co-op. If the voluntary catcher-processor co-op dissolves any allocation to the sector will be divided equally among the catcher-processor endorsed permits.

Appendix E describes the details of the trawl rationalization program that will be implemented in Federal regulations.

The trawl rationalization program described in Appendix E may be modified through regulatory amendments proposed by the Council per §303(c) of the MSA and reviewed by the Secretary per §304(b). Appendix E may be revised from time to time to reflect changes to the program, but such changes can be made without submitting such changes for review by the Secretary as described in §304(a) of the MSA. The Council will establish a process for considering recommended changes to the regulations.

6.9.3.2 Rationalization of Other Fishery Sectors

IFQ programs could be established in other fishery sectors for the purposes of reducing fishery capacity, minimizing bycatch, and to meet other goals of the FMP. Participants in an IFQ fishery may be subject to individual total catch limit management (Section 6.7.1).

11.0 GROUNDFISH LIMITED ENTRY

11.1 Introduction

…

11.2 Management, Allocation and General Rules on the Issuance and Use of Groundfish LE Permits, Gear Endorsements Size Endorsements, and Fixed Gear Sablefish Endorsements

…

11.2.1 Federal LE Permits Required Only for Gears Fishing on the Limited Access Quota

1. Federal groundfish LE permits will be required and issued only for those vessels catching Council-managed groundfish species[1/] with groundfish limited entry gears (trawl, longline or fishpot gear) under the limited access quota.[2/]

2. Vessels using exempted gears (all gears other than trawl, longline and fishpot) or using longline or fishpot gear[3/] without a permit endorsed for one of those gears may continue to catch groundfish under an open access system. However, catch by vessels with trawl-endorsed LE permits that use such gears may instead be managed with IFQs, as specified in the regulations for the IFQ program (see Appendix E). (Exempted, longline and fishpot gears used by vessels without endorsements for those gears are termed open access gears.)

11.2.2 Allocations between the Limited and Open Access Fisheries and Management of the Open Access Fishery

…

---

1 All references to "Council-managed groundfish" refer only to groundfish species specified in the Council groundfish FMP which are caught in the exclusive economic zone or adjacent state waters off Washington, Oregon and California.

2 References to longline, pot and trawl gear are references to legal groundfish gears as defined by the groundfish FMP.

3 Trawl gear may not be used without a permit because the open access fishery for limited entry gears is aimed at accommodating small producers and will likely be managed under restrictive trip limits. The fishing power of trawl gear would result in excessive discards under these trip limits. Additionally, while longline and fishpot vessels catching small quantities of groundfish will be prevented from qualifying by the structure of the minimum landing requirements (MLRs) (a day's landings must be greater than 500 pounds in order for the day to count toward meeting the MLR; Section 11.3.1.3), this structure will provide little barrier for most trawl vessels. Thus, there is no strong reason to provide the open access opportunity to compensate for the 500 pound per landing day threshold.

11.2.3 Initial Issuance of LE Permits

…

11.2.4 Ownership Restriction and Changes in Ownership

…

11.2.5 Gear Endorsements

…

[N.B. In the following, <u>double underline</u> indicates insertions corresponding to the deleted text in paragraph 6.]

6. ~~An LE permit will not allow the use of limited entry gears to catch any Council-managed groundfish unless a valid gear endorsement for the specific gear is affixed to the LE permit. Trawl gear and Council-managed groundfish may not be on board a vessel at the same time, nor may the gear be deployed, without an LE permit registered for the vessel and endorsed for trawl gear. If a vessel has longline or fishpot gear on board, an LE permit registered for the vessel and the permit is endorsed for the gear on board, regulations for the limited access fishery will apply.~~

<u>Gear endorsements are required for LE-permitted vessels to use limited entry gear types (see Section 11.2.1, paragraph 1) to catch groundfish under the regulations governing the limited entry fishery.</u>

<u>a. Longline and Fishpot Usage for Vessels with a Permit Endorsed for the Gear. If a vessel has longline or fishpot gear on board, and the vessel is registered to an LE permit that is endorsed for the longline or fishpot gear on board, regulations for the limited access fishery will apply to the vessel. If the vessel also has a trawl endorsement and has opted to participate for a period in the trawl rationalization program using the fixed gear (longline or fishopt) for which it holds an endorsement then the trawl rationalization portion of the limited entry fishery regulations will apply to the vessel for that period.</u>

<u>b. Exception for Longline and Fishpot Gear Usage for Vessels With a Limited Entry Permit not Endorsed for the Gear Being Used:</u>

<u>i. As specified in Section 11.2.1, paragraph 2, Limited Entry vessels may use longline and pot gear without an endorsement, in which case the use of the gear is governed by the open access fishery regulations unless the vessel's limited entry permit is endorsed for trawl gear.</u>

<u>ii. As specified in Section 11.2.2, if a vessel registered to a LE permit is fishing with longline or fishpot gear, but without an endorsement for that gear, the catch still counts against the limited entry fishery allocation (See Section 11.2.2).</u>

<u>iii. As specified in the trawl rationalization program (Section 6.9.3.1 and Appendix E) vessels registered to a trawl-endorsed LE permit and using longline or fishpot gear without a limited entry endorsement for those gears must cover their landings with trawl IFQ and comply with the provisions of the trawl IFQ program. Open access sector regulations will not apply to vessels participating under the IFQ program.</u>

<u>c. Trawl Gear Usage. Trawl gear and Council-managed groundfish may not be on board a vessel at the same time, nor may the gear be deployed, without an LE permit registered for the vessel and endorsed for trawl gear.</u>

…

11.2.6 Sector Endorsements

11.2.6.1 Fixed Gear Sablefish Endorsements

[N.B. Section 11.4, with the same title, is incorporated into this section as a housekeeping measure.]

1. The permit and gear endorsement requirements of the license limitation program limit the number of vessels which may participate in the groundfish fishery, however, there is still substantial opportunity for vessels to shift between segments of the groundfish fishery. One of the segments of the limited entry fishery subject to an increase in the number of vessels participating is the limited entry fixed gear sablefish fishery. To prevent the movement of vessels from non-sablefish segments of the limited entry fixed gear groundfish fishery to the sablefish segment of the fishery, a fixed gear sablefish endorsement for limited entry permits is required for longline and fishpot gear limited entry vessels to take sablefish against the fixed gear limited entry allocation and as part of the primary fishery, the major limited entry fixed gear sablefish harvest opportunities north of 36°N latitude. Such endorsements are not required to harvest under fixed gear limited entry daily-trip-limit or other regulations intended to allow low level or incidental harvest.

2. The fixed gear sablefish endorsement will be affixed to the permit.

3. The fixed gear sablefish endorsement will remain valid when the permit is transferred.

4. If permits are stacked such that a single permit has multiple sablefish endorsements, sablefish endorsements and associated cumulative limits may be transferred to other sablefish-endorsed permits so long as at least one sablefish endorsement and associated tier limit remains with the permit. Fixed gear sablefish endorsements may not be transferred from permits on which there is only one fixed gear sablefish endorsement.

5. Limitations which apply to the fixed gear sablefish endorsement and fishing thereunder shall not restrict the use of any trawl gear endorsement on the same LE permit, unless these restrictions are specific in their application to trawl gear.

6. Rules on the issuance of fixed gear sablefish endorsements and other characteristics of the endorsements are specified ~~in Section 11.4~~below.

[N.B. The following text is moved from Section 11.4, also entitled Fixed Gear Sablefish Endorsements]

The fixed gear sablefish endorsement is intended for operations participating in the fixed gear sablefish fishery which were significantly active and dependent on the fishery prior to the end of the qualifying period specified in paragraph 3. The following paragraphs describe qualifying criteria that were used for initial issuance of the fixed gear sablefish endorsement.

1. A fixed gear sablefish endorsement will be affixed to any LE permit which meets the fixed gear sablefish endorsement qualifying criteria.

2. The catch history used to determine whether a permit meets the fixed gear sablefish endorsement qualifying criteria is the permit catch history. Permit catch history includes the catch history of

the vessel(s) that initially qualified for the permit and the catch of any other vessels with which the permit rights were associated during the time the rights were associated with the vessel (if the current permit is the result of the combination of multiple permits, then for the combined permit to qualify for an endorsement, at least one of the permits which were combined must have sufficient sablefish history to qualify for an endorsement on its own; or the permit must qualify based on catch occurring after it has combined but within the qualifying period). Permit catch history also includes the catch of any interim permit held by the current owner of the permit during the pendancy of an appeal on a permit denied under the groundfish limited entry program, but only if (1) the appeal on which the interim permit was based was lost and (2) the owner's current permit was used by the owner in the 1995 limited entry sablefish fishery.

3. The fixed gear sablefish endorsement qualifying criteria are at least 16,000 pounds round weight of sablefish caught with longline or fishpot gear in one year from 1984 to 1994

4 All catch must be non-Indian harvest from Council managed areas. Harvest taken in tribal set aside fisheries does not qualify.

5. The NMFS issuing authority will have broad authority to examine information other than codes on landing tickets in determining whether the qualifying criteria is or is not met.

11.2.6.2 Pacific whiting Catcher-processor (CP) Endorsement

The class of CP endorsed permits (CP permits) is limited by an endorsement placed on an LE permit. LE permits registered to qualified catcher-processor vessels are endorsed as CP permits. A qualified permit is one that harvested and processed in the catcher-processor sector of the Pacific whiting fishery at any time from 1997 through 2003. A vessel that is 75 feet or less LOA that harvests whiting and, in addition to heading and gutting, cuts the tail off and freezes the whiting, is not considered to be a catcher/processor nor is it considered to be processing fish. Such a vessel is considered a participant in the shorebased whiting sector, and is subject to regulations and allocations for that sector (50 CFR 660.373(a)(3). Therefore, such vessels do not require a CP endorsement.

11.2.6.3 Pacific whiting Catcher Vessel (CV(MS)) Endorsement

Permits with a qualifying history are designated as CV(MS) permits through the addition of an endorsement to their LE groundfish permit. Only vessels registered to an LE permit with a CV(MS) endorsement may participate in the Pacific whiting mothership-processor fishery. A qualified permit is one that has a total of more than 500 mt of whiting deliveries to motherships from 1994 through 2003.

11.2.7 Size Endorsement Will Specify the Vessel Length

The LE base permit will be endorsed with the length overall (as defined for purposes of U.S. Coast Guard documentation) of the vessel for which the LE permit is initially issued. The length for which the LE permit is endorsed will be changed only when LE permits are combined, as per Section 11.2.11.[4] ~~, or, in the case of LE permits endorsed for trawl gear, when the size of the vessel used with the permit is more than five feet less than the originally endorsed length. In the latter case, the LE permit will be reissued with a size endorsement for the length of the smaller vessel. Regulations may be promulgated to waive this downsizing requirement if the permit was transferred to a smaller vessel for the purposes of stacking~~

[4] The FMP included an exception for when LE permits endorsed for trawl gear were transferred to a smaller vessel such that the LE permit will be reissued with a size endorsement for the length of the smaller vessel (from Amendment 6). This exception was removed by Amendment 20.

~~(see Section 11.2.4, paragraph 3).~~ Vessels which do not have documents stating their length overall will have to be measured by a marine surveyor or the U.S. Coast Guard and certified for that length.[5]

If the Council establishes a permit stacking program, that program may or may not require that permits stacked on top of the base LE permit be endorsed with the length overall of the vessel holding the permits.

11.2.8 An LE Permit and Necessary Gear Endorsements Will Be Held by the Owner of Record of the Vessel

…

11.2.9 Transfer of an LE Permit to Different Owners or Vessels of the Same Owner

…

11.2.10 Loss of a Vessel

….

11.2.11 Combining LE Permits

1. Two or more LE permits with "A" gear endorsements for the same type of limited entry gear (either trawl, longline or fishpot) may be combined (based on specific criteria) to "step-up" to a permit with a larger size endorsement. NMFS, with professional advice of marine architects and other qualified individuals, and after consultation with the Council and review board, will develop and implement a standardized measure of harvest capacity for the purpose of determining the appropriate endorsed length for LE permits created by combining two or more permits possessing smaller length endorsements. The capacity represented by the appropriate length endorsement for the combined permit should not exceed the sum of the capacities of the LE permits being combined.

2. LE permits may not be divided to "step-down" to more than one permit with smaller size endorsements.

3. Survival of Gear Endorsements. When LE permits are combined, "A" endorsements identical on both LE permits will remain valid. Provisional "A", "B" and designated species "B" gear endorsements will generally become invalid because they are not separable from the vessel for which they are initially issued. (See table below for examples.) ~~Fixed gear sablefish endorsements will remain valid only if all the longline or fishpot permits being combined have fixed gear sablefish endorsements.~~

1st Permit Endorsement on 1st LE Permit	+	2nd Permit Endorsements on 2nd LE Permit	=	Combined Permit Endorsements on the Combined LE Permit
"A" - Trawl		"A" - Pot		None
"A" - Longline		"A" - Longline		"A" - Longline
"A" - Trawl		Provisional "A" - Trawl		None
"A" - Pot		"B" - Pot		None
"A" - Trawl		Designated Species "B" - Shortbelly - Trawl		None

[5] While not an immediate cap on vessel capacity, the size endorsement places an upward limit on the amount by which the capacity used with an LE permit may increase.

4. Survival of Fixed Gear Sector Endorsements: Fixed gear sablefish endorsements will remain valid only if all the longline or fishpot permits being combined have fixed gear sablefish endorsements.

5. Survival of Trawl Sector Endorsements. When a CP-endorsed LE permit is combined with an LE trawl permit without a CP-endorsement a single CP-endorsed permit with a larger size endorsement will result. A CV(MS) endorsement on a permit being combined with a CP-endorsed permit will not be reissued on the resulting permit. If a CV(MS) endorsed permit is combined with a permit without a sector endorsement the CV(MS) endorsement is retained on the resulting permit. The resulting size endorsement will be determined based on the permit combination formula authorized in paragraph 1 above.

11.3 Multilevel Gear Endorsement System

…

~~11.4 Fixed Gear Sablefish Endorsement~~

[N.B. Text in this section moved to Section 11.2.6 as shown above.]

~~11.5 Limited Entry Program for the Pacific Coast Whiting Fishery~~

~~Until the implementation of a trawl IQ or cooperative management program in the Pacific whiting fishery, no vessel may participate in the shoreside, mothership, or catcher-processor sector of the Pacific whiting fishery unless that vessel meets the following participation requirements for such vessel in such sector:~~

~~For catcher vessels participating in the shore-based sector, the participation requirements are that the vessel with a limited entry trawl endorsed permit using mid-water trawl gear made at least one whiting delivery to a shoreside whiting processor in at least one primary whiting season for the shore-based sector between January 1, 1994, and January 1, 2007.~~

~~For catcher vessels participating in the mothership sector, participation requirements are that the vessel made at least one delivery to a mothership whiting processor during the at-sea processing season for the mothership sector between January 1, 1997, and January 1, 2007.~~

~~For catcher/processors vessels, participation requirements are having caught and processed whiting during the at-sea processing season for the catcher/processor sector in any one qualifying year from January 1, 1997, through January 1, 2007.~~

~~For mothership vessels, participation requirements are having received at least one delivery of whiting during the at-sea processing season for the mothership sector in any one qualifying year from January 1, 1997, through January 1, 2007.~~

~~A vessel may qualify for participation in each sector for which it meets the above standards.~~

~~Implementing regulations will specify the application procedures. NMFS will maintain a list of vessels or issue a certificate to vessels that qualify for participation in each sector.~~

Regulatory Impact Review and
Initial Regulatory Flexibility Analysis

Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery AND Allocation of Harvest Opportunity BETWEEN Sectors of the Pacific Coast Groundfish Fishery

National Marine Fisheries Service, Northwest Region
Initial Analysis May 2010

Executive Summary

The Pacific Fishery Management Council (Council) prepared a draft environmental impact statement for Amendment 20 to the Pacific Coast Groundfish Fishery Management Plan (FMP); a notice of availability was published on December 4, 2009 (74 FR 63751). The Council also prepared a draft environmental impact statement for Amendment 21 to the Pacific Coast Groundfish FMP; a notice of availability was published on January 29, 2010 (75 FR 4812). The trawl rationalization program would consist of (1) an IFQ program for the shore-based, limited entry groundfish trawl fleet and (2) cooperative programs (co-ops) for the at-sea whiting limited entry groundfish trawl fleet. The trawl rationalization program is intended to increase net economic benefits, create economic stability, provide full utilization of the trawl sector allocation, consider environmental impacts, and promote conservation through individual accountability for catch and bycatch.

A summary of the proposed action is as follows. The proposed action is to replace the current, primary management tool used to control the West Coast groundfish trawl catch—a system of two-month cumulative landing limits for most species and season closures for whiting—with a system requiring more individual accountability by the assignment of limited access privileges (LAPs). LAPs are a form of output control whereby an individual fisherman, community, or other entity is granted the privilege to catch a specified portion of the total allowable catch (TAC). The alternatives include (1) a catch-based IFQ system where all groundfish catch (landings plus bycatch) by limited entry trawl vessels would count against a vessel's IFQ holdings, which could be applied to the whole groundfish trawl fishery or selected trawl sectors; and (2) a system of co-ops that would be applied to one or more of the fishery sectors that target Pacific whiting. The status quo alternative (no action) could also be considered for application to one or more trawl fishery sectors, even if one or both action alternatives (IFQs or co-ops) are chosen for the other trawl sectors.

The description of purpose and need in section 1.2 of the Amendment 20 DEIS also outlines the objectives of the proposed action. The introductory paragraph in Chapter 1 and section 1.3 of the DEIS, background to the purpose and need provide information on the legal basis for the proposed action (proposed rule). The Council articulated the following goal for the trawl rationalization program: "Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch." The objectives supporting this goal are as follows: provide a mechanism for total catch accounting; provide for a viable, profitable, and efficient groundfish fishery; promote

practices that reduce bycatch and discard mortality, and minimize ecological impacts; increase operational flexibility; minimize adverse effects from an IFQ program on fishing communities and other fisheries to the extent practical; promote measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry; provide quality product for the consumer; and increase safety in the fishery.

As part of the proposed action, NMFS would place observers and/or cameras on board all catcher vessels in the shore-based sector (which combines the current shore-based whiting and non-whiting trawl sectors). Existing requirements for motherships, catcher vessels in the mothership sector, and catcher-processors would continue. Independently contracted processing plant monitors would track landings. There would also be new reporting requirements related to the tracking of QS and quota pounds (QP) in the shore-based fishery.

This proposed rule has been determined to be significant for purposes of Executive Order 12866.

An initial regulatory flexibility analysis (IRFA) was prepared, as required by section 603 of the Regulatory Flexibility Act (RFA). The IRFA describes the economic impact this proposed rule, if adopted, would have on small entities. A description of the action, why it is being considered, and the legal basis for this action are contained at the beginning of this section in the preamble and in the SUMMARY section of the preamble.

The Council has prepared two EIS documents: Amendment 20—Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery, which would create the structure and management details of the trawl fishery rationalization program, and Amendment 21—Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery, which would allocate the groundfish stocks between trawl and non-trawl fisheries. The two draft EISs prepared by the Council provide economic analyses of the Council's preferred alternatives and draft RIR and IRFAs. The draft RIR and IRFAs were updated and combined into a single RIR/IRFA, which comprises this document. Among other things, this single RIR/IRFA contains additional information on characterizing the participants in the fishery and on the tracking and monitoring costs associated with this program.

Due to the complexity of the proposed fishery management measures, the rule associated with this analysis proposes only certain key components that would be needed both to issue permits and endorsements in time for use in the 2011 fishery and to have the 2011 specifications reflect the new allocation scheme. Specifically, this rule would establish the allocations set forth under Amendment 21 and would establish procedures for initial issuance of permits, endorsements, and QS under the IFQ and co-op programs. NMFS plans to propose additional program details in a future proposed rule. Such additional details would include program components applicable to IFQ gear switching, observer programs, retention requirements, equipment requirements, catch monitors, catch weighing requirements, co-op permits/agreements, first receiver site licenses, quota share accounts, vessel QP accounts, further tracking and monitoring components, and economic data collection requirements. To encourage more informed public comment, this proposed rule includes a general description of these additional program requirements. NMFS is also planning a future "cost-recovery" rule, based on a recommended methodology yet to be developed by the Council.

The RIR/IRFA analyzes two alternatives—the No Action Alternative and the Preferred Alternative. The analysis of the no action alternative describes what is likely to occur in the absence of the proposed action. It provides a benchmark against which to compare the incremental effects of the proposed action. Under the no action alternative, the current, primary management tool used to control the Pacific coast groundfish trawl catch includes a system of two-month cumulative landing limits for most species and season closures for Pacific whiting. This management program would continue under the no action alternative. Only long-term, fixed allocations for Pacific whiting and sablefish north of 36° N. lat. would exist. All other groundfish species would not be formally allocated between the trawl and non-trawl sectors. Allocating the available harvest of groundfish species and species complexes would take place during the Council process of deciding biennial harvest specifications and management measures and, as such, would be considered short-term allocations.

The analysis of the preferred alternative describes what is likely to occur as a result of the proposed action. Under the preferred alternative, the existing shore-based whiting and shore-based non-whiting sectors of the Pacific Coast groundfish limited entry trawl fishery would be managed as one sector under a system of IFQs, and the at-sea whiting sectors of the fishery (i.e., catcher-processor sector and mothership sector, which includes motherships and catcher vessels) would be managed under a system of sector-specific harvesting co-ops. The catcher-processor sector would continue to operate under the existing, self-developed co-op program entered into voluntarily by that sector. A distinct set of groundfish species and Pacific halibut would be covered by the rationalization program. Amendment 20 would include a tracking and monitoring program to ensure that all catch (including discards) would be documented and matched against QP. The Council specified that observers would be required on all vessels, and shore-based monitoring (catch monitors) would be required during all off-loading (100 percent coverage). Compared to status quo monitoring, this would be a monitoring and observer coverage level increase for a large portion of the trawl fleet, particularly for nonwhiting, shore-based vessels.

The limited entry trawl fishery is divided into two broad sectors: a multi-species trawl fishery, which most often uses bottom trawl gear (hereafter called the non-whiting fishery), and the Pacific whiting fishery, which uses midwater trawl gear. The non-whiting fishery is principally managed through two-month cumulative landing limits along with closed areas to limit overfished species bycatch. Fishery participants target the range of species described above with the exception of Pacific whiting. By weight, the vast majority of trawl vessel groundfish is caught in the Pacific whiting fishery. In contrast, the non-whiting fishery accounts for the majority of limited entry trawl fishery ex-vessel revenues. On average for the period from 2000 to 2005, Pacific whiting accounted for about 75 percent of the quantity of groundfish landed in the limited entry trawl fishery, but only 21 percent of the value due to their relatively low ex-vessel price.

Non-whiting trawl vessels deliver their catch to shoreside processors and buyers located along the coasts of Washington, Oregon, and California. They tend to have their homeports located in towns within the same general area where they make deliveries, though there are several cases of vessels delivering to multiple ports during a year. Some Pacific whiting trawl vessels are

catcher-processors that, as their name implies, process their catch on-board, while other vessels in this sector deliver their catch to shoreside processors or motherships that receive Pacific whiting for processing but do not directly harvest the fish.

Over time, landings in the limited entry trawl fishery have fluctuated, especially on a species-specific basis. Pacific whiting has grown in importance, especially in recent years. Through the 1990s, the volume of Pacific whiting landed in the fishery increased. In 2002 and 2003, landings of Pacific whiting declined due to information showing the stock was depleted, and the subsequent regulations that restricted harvest in order to rebuild the species. From 2003 through 2007, estimated Pacific whiting ex-vessel revenues averaged about $29 million. In 2008, these participants harvested about 248,000 tons of whiting worth about $63 million in ex-vessel revenues, based on shore-based ex-vessel prices of $254 per ton, the highest ex-vessel revenues and prices on record. In comparison, the 2007 fishery harvested about 224,000 tons worth $36 million at an average ex-vessel price of about $160 per ton.

While the Pacific whiting fishery has grown in importance in recent years, harvests in the non-whiting component of the limited entry trawl fishery have declined steadily since the 1980s. Ex-vessel revenues in the fishery peaked in the mid 1990s at over $60 million. Following the passage of the Sustainable Fisheries Act (1996) and the listing of several species as overfished, harvests became increasingly restricted, and landings and revenues declined steadily until 2002. Since 2002, ex-vessel revenues have stabilized at approximately $23 to $27 million per year. In 2007, the Council estimated that 159 trawlers landed 94,000 metric tons (mt) of groundfish, earning $37 million in ex-vessel revenues, for an average of $234,000 per vessel.

Expected Effects of Amendment 21—Intersector Allocation

The allocation of harvest opportunity between sectors under the proposed regulation does not differ significantly from the allocation made biennially under the no action alternative. The primary economic effect of the long-term allocation under the proposed regulations is to provide more certainty in future trawl harvest opportunities, which would enable better business planning for participants in the rationalized fishery. As described elsewhere, the trawl rationalization program could create an incentive structure and facilitate more comprehensive monitoring to allow bycatch reduction and effective management of the groundfish fisheries. In support of the trawl rationalization program, the main socioeconomic impact of Amendment 21 allocations is longer-term stability for the trawl industry. While the preferred Amendment 21 allocations do not differ significantly from status quo ad hoc allocations made biennially, there is more certainty in future trawl harvest opportunities, which enables better business planning for participants in the rationalized fishery. This is the main purpose for the Amendment 21 actions. The economic effects of Amendment 21 arise from the impacts on current and future harvests. The need to constrain groundfish harvests to address overfishing has had substantial socioeconomic impacts. The groundfish limited entry trawl sector has experienced a large contraction, spurred in part by a partially federally subsidized vessel and permit buyback program implemented in 2005. This $46 million buyback program was financed by a congressional appropriation of $10 million and an industry loan of $36 million. Approximately 240 groundfish, crab, and shrimp permits were retired from state and Federal fisheries, and there was a 35 percent reduction in the groundfish trawl permits. To repay the loan, groundfish,

shrimp and crab fisheries are subject to landings fees. Follow-on effects of the buyback have been felt in coastal communities where groundfish trawlers comprise a large portion of the local fleet. As the fleet size shrinks, and ex-vessel revenues decline, income and employment in these communities are affected. Fishery-related businesses in the community may cease operations because of lost business. This can affect non-groundfish fishery sectors that also depend on the services provided by these businesses, such as providing ice and buying fish. An objective to the trawl rationalization program is to mitigate some of these effects by increasing revenues and profits within the trawl sector.

However, because further fleet consolidation is expected, the resulting benefits are likely to be unevenly distributed among coastal communities. Some communities may see their groundfish trawl fleet shrink further as the remaining vessels concentrate in a few major ports. Species subject to Amendment 21 allocations would be lingcod, Pacific cod, sablefish south of 36° N. lat., Pacific ocean perch, widow rockfish, chilipepper rockfish, splitnose rockfish, yellowtail rockfish north of 40° 10' N. lat., shortspine thornyhead (north and south of 34° 27' N. lat.), longspine thornyhead north of 34° 27' N. lat., darkblotched rockfish, minor slope rockfish (north and south of 40° 10' N. lat.), Dover sole, English sole, petrale sole, arrowtooth flounder, starry flounder, and Other Flatfish. While the preferred Amendment 21 allocations of these species do not differ significantly from status quo ad hoc allocations made biennially, there is more certainty in future trawl harvest opportunities, which enables better business planning for participants in the rationalized fishery. This is the main purpose for the Amendment 21 actions.

Based on ex-vessel revenue projections, Table 4-18 (Amendment 21 Intersector Allocation DEIS) shows the potential 2010 yield to trawl and non-trawl (including recreational) sectors under the Amendment 21 alternatives and the potential 2010 value of alternative trawl allocations. Under the status quo option Alternative 1, the projected ex-vessel value of the trawl allocation is $56 million while the projected ex-vessel value of the Council's preferred alternative is $54 million, indicating a potential increase to the non-trawl sectors and a potential decrease to the trawl sector.

In addition to the species above, halibut would also be specifically allocated to the trawl fishery. The proposed regulations include a halibut trawl bycatch reduction program in phases to provide sufficient time to establish a baseline of trawl halibut bycatch and for harvesters to explore methods (e.g., adjustments to time and/or area fished, gear modifications) to reduce halibut bycatch and bycatch mortality. Pacific halibut currently cannot be retained in any U.S. or Canadian trawl fisheries per the policy of the IPHC. The Council's intent on setting a total catch limit of Pacific halibut in Area 2A trawl fisheries is to limit and progressively reduce the bycatch to provide more benefits to directed halibut fisheries. The program establishes a limit for total Pacific halibut bycatch mortality (legal-sized and sublegal fish) by using an individual bycatch quota in the trawl fishery. The initial amount for the first two years of the trawl rationalization program would be calculated by taking 15 percent of the Area 2A total constant exploitation yield (CEY) as set by the International Pacific Halibut Commission (IPHC) for the previous year, not to exceed 130,000 pounds (lbs) per year for total mortality. For example, if the trawl rationalization program went into effect in 2013, the trawl halibut IBQ would be set at 15 percent of the Area 2A CEY adopted for 2012 or 130,000 lbs per year, whichever is less, for 2013 and 2014 (years 1 and 2 of the program). Beginning with the third year of implementation, the

maximum amount set aside for the trawl rationalization program would be reduced to 100,000 lbs per year for total mortality. This amount may be adjusted downward through the biennial specifications process for future years.

Currently there are no total catch limits of Pacific halibut specified for the west coast trawl fishery. Trawl bycatch of Pacific halibut, therefore, does not limit the trawl fishery. A phased-in halibut bycatch reduction program would provide sufficient time to establish a baseline of trawl halibut bycatch under the new rationalization program and would enable harvesters to explore methods (e.g., adjustments to time and/or area fished, gear modifications) to reduce both halibut bycatch and bycatch mortality. By limiting the bycatch of Pacific halibut in the limited entry trawl fisheries, Amendment 21 would control bycatch and could provide increased benefits to Washington, Oregon, and California fishermen targeting Pacific halibut. Reducing the trawl limit would also provide more halibut to those who participate in the directed tribal, commercial, and recreational halibut fisheries.

Effects of Amendment 20-Trawl Rationalization

Due to the lack of quantitative data, an overall comprehensive model was not feasible. Instead, a set of models designed to focus on specific issues was developed. For example, models were used to analyze the effects of the initial allocation of QS in the trawl IFQ program; project geographic shifts in fishery patterns; and illustrate the potential for reducing bycatch, increasing target catch, and increasing revenues. To illustrate the benefits of the IFQ program, a model projecting the expected amount of fleet consolidation in the shore-based non-whiting fishery was developed. This model illustrates the potential for the fleet to reduce bycatch and potentially increase the amount of target species harvested. This model is primarily based on bycatch reduction experiences in the Pacific whiting fishery and on the arrowtooth flounder fishery as carried out under an exempted fishing permit. The model accounts for the fact that trawlers harvest many species (multiple outputs). The model also uses fish ticket data and the data from the recently completed West Coast Limited Entry Cost Earnings Survey sponsored by the NMFS Northwest Fisheries Science Center. [For the other sectors, similar models could not be developed because the appropriate cost data were unavailable.]

Estimates of potential economic benefits are generated based on the predicted harvesting practices from the first step analysis. Because the west coast nonwhiting groundfish fishery is not a derby fishery, it is expected that economic benefits will come through cost reductions and increased access to target species that arise from modifications in fishing behavior (overfished species avoidance). The key output of this analysis is an estimate of post-rationalization equilibrium harvesting cost.

Changes in harvesting costs can arise from three sources. First, the total fixed costs incurred by the groundfish trawl fleet change as the size of the fleet changes. Since many limited entry trawlers incur annual fixed costs of at least $100,000, reductions in fleet size can result in substantial cost savings. In other words, fewer vessels in the fishery will lead to decreased costs through a decrease in annual fixed costs. Second, costs may change as fishery participation changes, no longer incurring diseconomies of scope (such as the costs of frequently switching gear for participating in multiple fisheries). Third, costs may change as vessels are able to buy

and sell quota to take advantage of economies of scale and operate at the minimum point on their long-run average cost curve (i.e. the strategy that minimizes the cost of harvesting).

The major conclusions of this model suggest that (with landings held at 2004 levels), the current groundfish fleet (non-whiting component), which consisted of 117 vessels in 2004, will be reduced by roughly 50 percent to 66 percent, or 40 to 60 vessels under an IFQ program. The reduction in fleet size implies cost savings of $18 to $22 million for the year 2004 (most recent year of the data). Vessels that remain active will, on average, be more cost efficient and will benefit from economies of scale that are currently unexploited under controlled access regulations in the fishery. The cost savings estimates are significant, amounting to 60 percent of the costs incurred currently, suggesting that IFQ management may be an attractive option for the Pacific Coast Groundfish Fishery. Assuming a 10 percent annual return to the vessel capital investment, estimates indicate that the 2004 groundfish fleet incurred a total cost of $39 million. The PacFIN data indicate fleetwide revenue at roughly $36 million in 2004. Therefore, fleetwide losses of about $3 million occurred in 2004. Based on a lower 5 percent return to vessel capital, the results suggest that the groundfish fleet merely broke even in 2004; i.e., dockside revenues were offset by the fleet wide harvesting costs. The results also suggest that a switch from the current controlled access management program to IFQs could yield a significant increase in resource rents in the Pacific Coast Groundfish fishery. For instance, the analysis finds that the 2004 groundfish catch generated zero resource rent. Instead, it could have yielded a substantial positive rent at about $14 million.

As the model was based on the 2004 fishery, it may be useful to show current trends in the fishery. In 2004, the shorebased non-whiting trawl fishery generated about $30 million in ex-vessel revenues. According to cost estimates discussed above, however, this fishery was at best breaking even or perhaps suffering a loss of up to $2 million. Since 2004, shorebased non-whiting trawl fisheries have increased their revenues to about $40 million. The increases in shorebased revenues have come from increased landings of flatfish and sablefish and significant increase in sablefish ex-vessel prices. Sablefish now accounts for almost half of the trawl fleet's revenues. While revenues were increasing, so were fuel prices. Fuel costs are about 30 to 40 percent of the vessels' revenues. The average 2005 to 2009 revenues were about $28 million, or 22 percent greater than 2004. The average 2005 to 2009 fuel price was about $2.81, 70 percent greater than that of 2004. Therefore, it appears that 2009 fishery may not be that much improved over that of 2004.

Based on the various models, ex-vessel revenues for the non-whiting sector of the limited entry trawl fishery are estimated to be approximately $30 to 50 million per year under the preferred alternative, compared to $22 to 25 million under the no action alternative. This revenue increase is expected to occur in a rationalized fishery, because target species quotas can be more fully utilized. Currently, in the non-whiting sector, cumulative landing limits for target species have to be set lower because the bycatch of overfished species cannot be directly controlled. Introducing accountability at the individual vessel level by means of IFQs provides a strong incentive for bycatch avoidance (because of the actual or implicit cost of quota needed to cover bycatch species) and prevents the bycatch of any one vessel from affecting the harvest opportunity of others. In addition, under the preferred alternative, the non-whiting sector would have control over harvest timing over the whole calendar year. Under the no action alternative,

the non-whiting sector would continue to operate under two-month cumulative landing limits, which reduces flexibility within the period, because any difference between actual limits and the period limit cannot be carried over to the next period. Finally, the ability for vessels managed under IFQs to use other types of legal groundfish gear could allow some increases in revenue by targeting higher-value line- or pot-gear-caught fish. This opportunity would mainly relate to sablefish, which are caught in deeper water, rather than nearshore species where state level regulatory constraints apply.

The preferred alternative may also increase ex-vessel revenues of non-whiting trawl harvesters by changing their bargaining power with processors over ex-vessel prices. Under the preferred alternative, the current two-month cumulative limits structure of the non-whiting trawl fishery would be replaced with QP that is available for a year, thereby extending the time horizon harvesters have to negotiate prices with processors without losing available fishing opportunity. The extended period would give harvesters greater latitude to hold out for better prices compared to the no action alternative. However, these negotiations will also be affected by the availability of target species, as well as the availability of bycatch.

Costs for the non-whiting sector of the limited entry trawl fishery are expected to decrease under the preferred alternative because of productivity gains related to fleet consolidation. Productivity gains would be achieved through lower capital requirements and a move to more efficient vessels. Operating costs for the non-whiting sector are predicted to decrease by as much as 60 percent annually. Based on estimates of current costs, this percentage decrease represents a $13.8 million cost reduction relative to the no action alternative.

The accumulation limits considered under the preferred alternative are not expected to introduce cost inefficiencies in the non-whiting sector, provided that current prices and harvest volumes do not decrease. However, the preferred alternative would impose new costs on the non-whiting sector that would not be incurred under the no action alternative. First, a landings fee of up to 3 percent of the ex-vessel value of fish harvested would be assessed under the preferred alternative to recover management costs, such as maintenance of the system of QS accounts. Second, new at-sea observer requirements would be introduced, and vessels would have to pay the costs of complying with these requirements, estimated at $500 a day if independent contractors are hired. The daily observer cost could place a disproportionate adverse economic burden on small businesses because such costs would comprise a larger portion of small vessels costs than that of larger vessels.

The increase in profits that commercial harvesters are expected to experience under the preferred alternative may render them better able to sustain the costs of complying with the new reporting and monitoring requirements. The improved harvesting cost efficiency under the preferred alternative may allow the non-whiting sector to realize profits of $14 to 23 million compared to $0 or less under the no action alternative. In addition, a provision that allows vessels managed under the IFQ program to use other legal gear (gear switching) would allow sablefish allocated to the trawl sector to be sold at a higher price per pound, possibly contributing to increased profits. The imposition of accumulation limits could reduce the expected increase in the profitability of the non-whiting sector by restricting the amount of expected cost savings, and the costs of at-sea observers may reduce profits by about $2.2 million, depending on the fee

structure. However, the profits earned by the non-whiting sector would still be substantially higher under the preferred alternative than under the no action alternative.

New entrants are likely to face a barrier to entry in the Pacific Coast groundfish limited entry trawl fishery in the form of the cost of acquiring QS (or a co-op share in the case of the at-sea whiting sector). This disadvantages them in comparison to those entities that receive an initial allocation of harvest privileges. Small entities may be particularly disadvantaged to the degree that they may find it more difficult to finance such quota purchases. Among the goals the Council identified for the adaptive management program was to use the reserved non-whiting QS to facilitate new entry into the fishery. In addition, the Council identified, as a trailing action, a framework to allow the establishment and implementation of community fishing associations as part of the adaptive management program. These entities could facilitate entry into the fishery by leasing QS at below market rates, thereby leveling the playing field in terms of costs between initial recipients of QS and new entrants.

The incremental effects of the preferred alternative on buyers and processors of trawl caught groundfish are detailed Sections 4.9 to 4.10 of the Rationalization of the Amendment 20 Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS. Even though processors may have to pay fishermen higher ex-vessel prices, processors may see cost savings under the preferred alternative to the degree that rationalization allows greater control over the timing and location of landings. Processors could use current plant capacity more efficiently, because available information suggests that processing facilities are currently underutilized. Fleet consolidation in the non-whiting sector could also provide cost savings for processors if landings occur in fewer locations, thereby reducing the need for facilities and/or transport. The preferred alternative would also impose new costs on processors that would not be incurred under the no action alternative. Processors would be required to pay some or all of the costs of plant monitors, who would verify landings. Similar to at-sea observers, these monitors would be independent contractors rather than direct employees of the processing firm.

In the non-whiting processing industry, harvest volumes may increase because of a decrease in constraining species bycatch and a subsequent increase in underutilized target species catch. This boost in target species catch may increase utilization of processing capital and processing activity. [It should be noted that if, under the current system, bycatch has been underreported, with 100 percent observer coverage under the new system, the gains in increased target catches may be less than expected.] Consequently, the possibility of capital consolidation in the non-whiting shore-based sector may be lower than in the shore-based whiting sector. However, shifts in the distribution of landings across ports as a result of fleet consolidation, industry agglomeration, and the comparative advantage of ports (a function of bycatch rates in the waters constituting the operational area for the port, differences in infrastructure, and other factors) could lead to consolidation in processing activity at a localized or regional scale, as well as an expansion in processing activity elsewhere. To mitigate harm to adversely impacted non-whiting shoreside processors, the adaptive management program provides a mechanism to distribute non-whiting QS to processors, thereby ensuring that some processors receive greater landings of groundfish than would otherwise be the case.

As noted above, the preferred alternative may reduce the power of non-whiting shoreside processors to negotiate ex-vessel prices with harvesters. The larger harvest volume due to bycatch avoidance may lower processor average costs, which could offset the negative effects on non-whiting shoreside processors of a shift in bargaining power. In addition, processors could purchase QS over the long term, thereby increasing their negotiation power. However, the accumulation limits included in the preferred alternative would limit the ability of processors to purchase substantial quantities of QS. Alternatively, the adaptive management provision could be used to allocate QS to non-whiting shoreside processors, thereby providing them additional leverage when negotiating terms with harvesters.

The allocation of 20 percent of the initial shore-based whiting QS to the shoreside processor portion of the groundfish fishery would give these processors more influence in negotiations over ex-vessel prices and would tend to offset the gains in bargaining power for harvesters. For example, a processor could use QS to induce a harvester that is short of QP for a Pacific whiting trip to make deliveries under specified conditions and prices. Because of a reduction in peak harvest volume, however, fewer processing companies and/or facilities may be necessary to handle harvest volumes of Pacific whiting, meaning some companies may find themselves without enough product to continue justifying processing operations of Pacific whiting.

Revenues from harvesting and processing trawl-caught groundfish are expected to increase. Total revenue from nonwhiting trawl fisheries was $25 million in 2007. Revenue is expected to increase 1.1 to 1.6 times in a rationalized fishery, depending on bycatch rate reductions and stock status. Revenue increases are mainly expected because, under rationalized fisheries, target species quotas can be more fully utilized. Currently, in the nonwhiting sector, cumulative landing limits for target species have to be set lower because the bycatch of overfished species cannot be directly controlled. Introducing accountability at the individual vessel level provides a strong incentive for bycatch avoidance (because of the actual or implicit cost of quota needed to cover bycatch species) and prevents the bycatch of any one vessel from affecting the harvest opportunity of others. Whiting fisheries are more directly managed through quotas and, in recent years, by limits on bycatch. Beginning in 2009, bycatch limits have been established for each of the three whiting sectors. For the shore-based and mothership whiting sectors, the fishery can potentially close before the whiting allocation is fully harvested because a bycatch cap is reached. [The catcher-processor sector currently operates as a voluntary co-op and is, therefore, better able to coordinate harvest strategy to avoid reaching bycatch limits.] However, in general, the whiting sectors have been able to harvest their sector allocations. Whiting vessels could increase revenues due to improved product recovery as a result of the ability to better control harvest timing. As mentioned above, the ability for vessels managed under IFQs to use other types of legal groundfish gear could allow some increases in revenue by targeting higher-value line or pot gear caught fish.

Harvester and possibly processor costs are expected to decrease because of productivity gains related to fleet consolidation. Cost savings would be due to lower capital requirements and a move to more efficient vessels in the nonwhiting sector. Costs are predicted to decrease by as much as 60 percent annually, which, based on estimates of current operating costs, would represent a $13.8 million decrease. Similar levels of consolidation are expected for shorebased and mothership catcher vessels. Proposed mitigation measures could reduce these costs savings.

For example, a 1 percent quota share accumulation limit could reduce cost savings by as much as 20 percent. However, the accumulation limits considered in the alternatives are not expected to introduce higher costs at current prices and harvest volume. The proposed action would introduce some new costs. First, up to 3 percent of the value of landings may be assessed to cover administrative and management costs. Second, new at-sea observer requirements would be introduced and vessels would have to pay the cost, estimated at $350 to $500 a day.

Processors may see cost-savings to the degree that rationalization allows greater control over the timing and location of landings. Processors could use current plant capacity more efficiently, because available information suggests that processing facilities are currently underutilized. Fleet consolidation could also drive some cost savings on the part of processors if landings occur in fewer locations. This would reduce the need for facilities and/or transport. Under the proposed action, processors would be required to pay the costs of plant monitors, who would verify landings. These monitors would not be directly employed by the processing firm but, similar to at-sea observers, would be independent contractors.

Rationalization of the groundfish trawl sector is expected to free up capital and labor because of increases in productivity. [Since the basic input, trawl-caught fish, is subject to an underlying constraint due to biological productivity, increases in labor and capital productivity are expected to reduce the amount of those inputs needed.] However, from a national net benefit perspective, these effects are neutral since capital and labor can be put to some productive use elsewhere in the broader economy. Also, current groundfish fishery participants who receive QS (trawl limited entry trawl permit holders and eligible shoreside processors) are compensated to the degree that the asset value of the QS covers capital losses.

The tracking and monitoring costs of this program will be provided in more detail during the "program components" rulemaking process. However, the RIR/IRFA to this rule contains some preliminary estimates. After a transition period, initial estimates of the annual Federal and state agency costs to run the shore-based fishery (including whiting) are about $5 million. Based on the observer cost of $500 per day, the annual costs of observers is about $4 million. At $350 per day, the compliance monitoring program is just over $1 million annually. These figures add up to just over $10 million. From a cost-benefit viewpoint, if consolidation leads to $14 million savings from reduced harvesting costs, and the new program increases the tracking and monitoring costs of $10 million, there is a projected net gain of about $4 million. This does not take into account expectations that costs will likely be reduced due to consolidation or the increases in expected revenues discussed above.

While the effect of the preferred alternative on revenues and costs in the whiting sector of the limited entry trawl fishery is more difficult to estimate, the lower motivation to "race for fish" due to co-op harvest privileges is expected to result in improved product quality, slower-paced harvest activity, increased yield (which should increase ex-vessel prices), and enhanced flexibility and ability for business planning. The overall effect of these changes would be higher revenues and profits for harvesters in the shoreside and mothership portions of the whiting fishery in comparison to the no action alternative. Under the preferred alternative, some consolidation may occur in the shoreside and mothership sectors of the Pacific whiting fishery, though the magnitude of consolidation is expected to be less than in the non-whiting sector. The

existing catcher-processor co-op would continue under the preferred alternative, with effects on the catcher-processor sector that look similar, or identical, to those of the no action alternative. However, the change from a vessel-restriction under Amendment 15 to the permit-based limit of Amendment 21 will provide additional flexibility that currently does not exist in the whiting fishery.

This proposed rule would regulate businesses that harvest groundfish and processors that want to process limited entry trawl groundfish. Under the RFA, the term "small entities" includes small businesses, small organizations, and small governmental jurisdictions. For small businesses, the Small Business Administration has established size criteria for all major industry sectors in the U.S, including fish harvesting and fish processing businesses. A business involved in fish harvesting is a small business if it is independently owned and operated, is not dominant in its field of operation (including its affiliates), and has combined annual receipts that do not exceed $4.0 million for all its affiliated operations worldwide. A seafood processor is a small business if it is independently owned and operated, is not dominant in its field of operation, and employs 500 or fewer persons on a full-time, part-time, temporary, or other basis, at all its affiliated operations worldwide. A business involved in both the harvesting and processing of seafood products is a small business if it meets the $4.0 million criterion for fish harvesting operations. A wholesale business servicing the fishing industry is a small business if it employs 100 or fewer persons on a full time, part time, temporary, or other basis, at all its affiliated operations worldwide. For marinas and charter/party boats, a small business is one with annual receipts not in excess of $7.0 million. The RFA defines a small organization as any nonprofit enterprise that is independently owned and operated and is not dominant in its field. The RFA defines small governmental jurisdictions as governments of cities, counties, towns, townships, villages, school districts, or special districts with populations of less than 50,000.

NMFS makes the following conclusions based primarily on analyses associated with fish ticket and limited entry permit data, available employment data provided by processors, information on the charterboat and tribal fleets, and available industry responses industry to ongoing survey on ownership. Entities were analyzed as to whether they were only affected by the Amendment 21 allocation processes (non-trawl), or whether they were affected by both Amendments 20 and 21 (trawl).

The non-trawl businesses are associated with the following fleets: limited entry fixed gear (approximately 150 companies), open access groundfish (1,100), charterboats (465), and the tribal fleet (four tribes with 66 vessels). Available information on average revenue per vessel suggests that all the entities in this group can be considered small.

For the trawl sector, there are 177 permit holders. Nine limited entry trawl permits are associated with the catcher-processing vessels that are considered large companies. Of the remaining 168 limited entry permits, 25 limited entry trawl permits are either owned or closely associated with a large shore-based processing company or with a non-profit organization who considers itself a large organization. Nine other permit owners indicated that they were large companies. Almost all of these companies are associated with the shorebased and mothership whiting fisheries. The remaining 134 limited entry trawl permits are projected to be held by small companies. Three of the six mothership processors are large companies. Within the

14 shorebased whiting first receivers/processors, there are four large companies. Including the shorebased whiting first receivers, in 2008, there were 75 first receivers that purchased limited entry trawl groundfish. There were 36 small purchasers (less than $150,000); 26 medium purchasers (purchases greater than $150,000 but less than $1,000,000); and 13 large purchasers (purchases greater than $1.0 million). Because of the costs of obtaining a processor site license, procuring and scheduling a catch monitor, and installing and using the electronic fish ticket software, these small purchasers will likely opt out of buying groundfish, or arrange to purchase fish from another company that has obtained a processing site license.

The major impacts of this rule appear to be on two groups: Shoreside processors, which are a mix of large and small processors; and shore-based trawlers, which are also a mix of large and small companies. The non-whiting shore-based trawlers are currently operating at a loss or, at best, are breaking even. The new rationalization program would lead to profitability, but only with a reduction of about 60 percent of the fleet. This program would lead to major changes in the fishery. To help mitigate against these changes, as discussed above, the agency has announced its intent, subject to available Federal funding, that participants would initially be responsible for 10 percent of the cost of hiring observers and catch monitors. The industry proportion of the costs of hiring observers and catch monitors would be increased every year so that, once the fishery has transitioned to the rationalization program, the industry would be responsible for 100 percent of the cost of hiring the observers and catch monitors by 2014. NMFS believes that an incrementally reduced subsidy to industry funding would enhance the observer and catch monitor program's stability, ensure 100 percent observer and catch monitor coverage, and facilitate the industries' successful transition to the new quota system. In addition, to help mitigate against the negative impacts of this program, the Council has adopted an adaptive management program (CFA) in which, starting in year three of the program, 10 percent of non-whiting QS would be set aside every year to address community impacts and industry transition needs. After reviewing the initial effects of ITQ programs in other parts of the world, the council had placed a short-term QS trading prohibition so that fishermen can learn from their experiences and not make premature sales of their QS. The Council also envisions future regulatory processes that would allow CFAs to be established to help aid communities and fishermen.

Regulatory Impact Review and
Initial Regulatory Flexibility Analysis

Proposed Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery AND Allocation of Harvest Opportunity BETWEEN Sectors of the Pacific Coast Groundfish Fishery
National Marine Fisheries Service, Northwest Region
Initial Analysis May 2010

1. INTRODUCTION

This document is a Regulatory Impact Review (RIR) and Initial Regulatory Flexibility Analysis (IRFA) that describes the expected economic impacts of selected alternatives contained in the following two proposed amendments to the Pacific Coast Groundfish Fishery Management Plan:

- *Amendment 20—Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery*. Amendment 20 would create the structure and management details of the trawl fishery rationalization program.

- Amendment 21—*Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery*. Amendment 21 would allocate the groundfish stocks between trawl and non-trawl fisheries.

The Northwest Region of the National Marine Fisheries Service (NMFS-NWR) is developing regulations that will, if approved by the U.S. Secretary of Commerce, implement the plan amendments. The rulemaking process must comply with Executive Order (EO) 12866 and the Regulatory Flexibility Act (RFA). The RFA requires the agency to prepare and make available for public comment an IRFA that describes the impact on small businesses, non-profit enterprises, local governments, and other small entities. The IRFA aids the agency in considering all reasonable regulatory alternatives that would minimize the economic impact on affected small entities. The EO covers a variety of regulatory policy considerations and establishes procedural requirements for RIRs that will contain analyses of the benefits and costs of regulatory actions.

Trawl Rationalization Program Structure

The trawl rationalization program would consist of (1) an individual fishing quota (IFQ) program for the shore-based trawl fleet and (2) cooperative (co-op) programs for the at-sea trawl fleet. The shore-based trawl fleet would include IFQ participants who land groundfish to shore-based processors or first receivers. The at-sea trawl fleet would include fishery participants harvesting whiting with midwater trawl gear (i.e., whiting catcher/processor vessels, whiting motherships, and whiting catcher vessels associated with motherships). The co-op programs for the at-sea trawl fleet are further divided as follows: (1) a single whiting catcher/processor co-op that forms; and (2) one or more whiting mothership co-ops that may form. Vessels may also choose to fish in an open access or non-co-op fishery that would be unaffiliated with a co-op. For the co-op and non-co-op fishery, vessel owners pool their harvest together.

The IFQ program for the shore-based fleet would require NMFS to make an initial allocation of harvest quota share (QS) (expressed as a percentage of the total sector amount) through a new QS permit to current owners of limited entry trawl permits and shore-based whiting first receivers who meet the qualifying criteria. Depending on a person's limited entry trawl permit history in qualifying years, the permit owner will receive an initial allocation for various target species/species groups (approximately 20 species), some with area designations. In addition, NMFS would allocate QS for overfished species based on a proxy of the amount of target species allocated to the quota shareholder. Shore-based whiting first receivers will receive an initial allocation of whiting only, based on their history of being the first receiver reported on state fish tickets (with an opportunity to reassign their history). Each year, based on the optimum yield (OY) amounts for each species and the amount of QS a holder has for a particular species/area, NMFS would allocate quota pounds (QP) to the QS account. The QS owner, in turn, must allocate QP to vessel accounts. Vessels are required to have IFQ or QP in an account to cover all IFQ landings and discards incurred while fishing under this program. In order to comply with the Magnuson-Stevens Fishery Conservation and Management Act (MSA), NMFS would track ownership interest in QS to determine if individuals are within set accumulation limits, both at the initial allocation stage and during the operation of the program. In Amendment 20, the Pacific Fishery Management Council (Council) has adopted limits (by species group and area) on the amount of QS an individual can control (i.e., control limits) and limits on the amount of QP that may be registered to a vessel for use in a given year.

For the at-sea whiting component of the trawl rationalization program, the Council has adopted a program that provides for a catcher-processor co-op and mothership co-ops that differ from how the co-ops have operated in the past. The catcher-processor co-op will not require an initial allocation of catch shares to individual vessels, provided that a co-op is established. However, whiting catch shares for the mothership fleet (called catch history assignments) would initially be allocated to qualifying limited entry trawl permits that were registered to catcher vessels in qualifying years and which were used in the mothership whiting fishery. The catch history assignments would be non-severable from the permit. Holders of qualifying permits that are allocated a whiting catch history assignment may choose to participate in the mothership co-op or non-co-op fishery. Similar to the shore-based IFQ program, NMFS would be required to track permit ownership interests in the mothership sector to determine if individuals comply with accumulation limits. For species subject to trawl rationalization, Amendment 21 would modify the way annual harvest guidelines are distributed. Under the current allocation strategy established in Amendment 6, a commercial harvest guideline (HG) is established. This commercial HG is then divided between limited entry and open access. Under Amendment 21, the limited entry fixed gear fishery would no longer receive a formal allocation. In addition, the commercial HG would be changed to a general HG, which would also apply to recreational fisheries.

Instead of deriving a commercial HG from OY, NMFS would establish a fishery HG applicable to both commercial and recreational fisheries. The HG would be derived by reducing OY in the manner currently described for the commercial HG, except that the recreational catch would not be subtracted; it would be included in the fishery HG. NMFS would then divide the fishery HG into allocations for the trawl and non-trawl fisheries. This differs from the current regime that divides between limited entry and open access. For some species under the proposed program,

the recreational fishery and the limited entry fixed gear fishery would share in the non-trawl allocation with the open access fleet. This proposed rule sets forth the specific percentages of the fishery HG for covered species that would be allocated to the trawl and non-trawl fisheries.

In order to implement the recommended IFQ and Co-op programs, it would be necessary for each of these trawl sectors to have a specific allocation of catch that could be divided among participants. While this could be accomplished through the specification process under the status quo, the council determined that a fixed allocation within the fishery management plan (FMP) would be preferable because it would promote predictability and the type of stability that facilitates successful relationships that make individual-based programs work. Thus, the Council recommended formal allocations in Amendment 21. In addition, Amendment 21 would establish total catch limits for Pacific halibut, as well as set-asides to accommodate the rationalized trawl fleet. The total catch limits would protect the directed fishery for halibut, as well as reducing overall halibut catch limits.

Species not covered by Amendment 21 would continue to be informally allocated through the biennial specifications process.

Introductory Note on the Analysis

Due to the complexity of the proposed fishery management measures, the rule associated with this analysis proposes only certain key components that would be necessary to have permits and endorsements issued in time for use in the 2011 fishery and to have the 2011 specifications reflect the new allocation scheme. Specifically, this rule would establish the formal allocations set forth under Amendment 21 and establish procedures for initial issuance of permits, endorsements, and quota shares under the IFQ and co-op programs. NMFS plans to propose additional program details in a future proposed rule. Such additional details would include program components applicable to IFQ gear switching, observer programs, retention requirements, equipment requirements, catch monitors, catch weighing requirements, co-op permits/agreements, first receiver site licenses, quota share accounts, vessel QP accounts, further tracking and monitoring components, and economic data collection requirements. In order to encourage more informed public comment, this proposed rule includes a general description of these additional program requirements. NMFS is also planning a future cost-recovery rule based on a recommended methodology yet to be developed by the Council.

To support the rulemaking described above, this analysis will be accordingly updated and revised. However, this initial analysis will assess the entire program by drawing heavily upon the Council's November 2010 document "Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery Draft Environmental Impact Statement," including its "Appendix H Preliminary Draft Regulatory Impact Review and Preliminary Initial Regulatory Flexibility Analysis." This analysis also updates the tracking and monitoring cost analysis found in Appendix A, Section A-2.3.3, Analysis of Components, Elements, and Options for the Individual Fishing Quota Alternative Trawl Individual Quota Components Analysis. This updated analysis also includes a discussion of the tracking and monitoring costs of the mothership and catch-processor sectors. This update is Attachment 1 to this document: "Update on Tracking and Monitoring Costs."

The analysis that follows constitutes both the RIR and IRFA as many of their required elements are the same. In terms of meeting the analytical requirements of an RIR and IRFA, the analysis adopts the following approach set forth in the 2007 *Guidelines for Economic Reviews of National Marine Fisheries Service Regulatory Actions*:

> At a minimum, the RIR and the [IRFA] should include a good qualitative discussion of the economic effects of the selected alternatives. Quantification of these effects is desirable, but the analyst needs to weigh such quantification against the significance of the issue and available studies and resources. Generally, a good qualitative discussion of the expected effects would be better than poor quantitative analyses.

The next two sections further describe the considerations and requirements of a RIR and IRFA.

2. REGULATORY IMPACT REVIEW CONSIDERATIONS AND REQUIREMENTS

NMFS requires the preparation of an RIR for all regulatory actions of public interest. The RIR provides a comprehensive review of the changes in net economic benefits to society associated with proposed regulatory actions. The analysis also provides a review of the problems and policy objectives prompting the regulatory proposals and an evaluation of the major alternatives that could be used to solve the problems. The purpose of the analysis is to ensure that the regulatory agency systematically and comprehensively considers all available alternatives, so that public welfare can be enhanced in the most efficient and cost-effective way. The RIR addresses many of the items in the regulatory philosophy and principles of EO 12866.

The RIR is designed to determine whether the proposed action could be considered a significant regulatory action according to EO 12866. EO 12866 requires that an RIR assess whether an action would be a significant regulatory action and mandates that the RIR identify the expected outcomes of the proposed management alternatives. An action may be considered significant if it is expected to 1) have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or state, local, or tribal governments or communities; 2) create a serious inconsistency or otherwise interfere with action taken or planned by another agency; 3) materially alter the budgetary impact of entitlement, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or 4) raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the EO.

The RIR analysis includes a description of management objectives, a description of the fishery, statement of the problem, a description of each alternative considered in the analysis, and an economic analysis of the expected effects of each selected alternative relative to the no action alternative.

3. INITIAL REGULATORY FLEXIBILITY ANALYSIS CONSIDERATIONS AND

REQUIREMENTS

The RFA, 5 U.S.C. 603 et seq., requires government agencies to assess the effects that regulatory alternatives would have on small entities, including small businesses, and to determine ways to minimize those effects. When an agency proposes regulations, the RFA requires the agency to prepare an IRFA that describes the impact on small businesses, non-profit enterprises, local governments, and other small entities and make the IRFA available for public comment. The IRFA is designed to aid the agency in considering all reasonable regulatory alternatives that would minimize the economic impact on affected small entities. Under the RFA, an agency does not have to conduct an IRFA and/or final RFA (FRFA) if an agency can certify that the proposed rule will not have a significant economic impact on a substantial number of small entities. To perform this certification, the agency has to state the basis and purpose of the rule, describe and estimate the number of small entities to which the rule applies, estimate economic impacts on small entities (by entity size and industry), and explain the criteria used to evaluate whether the rule would impose "significant economic impacts."

Under the RFA, the term "small entities" includes small businesses, small organizations, and small governmental jurisdictions.

Small businesses. The Small Business Administration has established size criteria for all major industry sectors in the United States, including fish harvesting and fish processing businesses. A business involved in fish harvesting is a small business if it is independently owned and operated and not dominant in its field of operation (including its affiliates) and if it has combined annual receipts that do not exceed $4.0 million for all its affiliated operations worldwide. A seafood processor is a small business if it is independently owned and operated, not dominant in its field of operation, and employs 500 or fewer persons on a full-time, part-time, temporary, or other basis, at all of its affiliated operations worldwide. A business involved in both the harvesting and processing of seafood products is a small business if it meets the $4.0 million criterion for fish harvesting operations. A wholesale business servicing the fishing industry is a small business if it employs 100 or fewer persons on a full-time, part-time, temporary, or other basis, at all its affiliated operations worldwide. For marinas and charter/party boats, a small business is one with annual receipts that do not exceed $7.0 million.

Small organizations. The RFA defines a small organization as any nonprofit enterprise that is independently owned and operated and is not dominant in its field.

Small governmental jurisdictions. The RFA defines small governmental jurisdictions as governments of cities, counties, towns, townships, villages, school districts, or special districts with populations of less than 50,000.

4. REGULATORY IMPACT REVIEW AND INITIAL REGULATORY FLEXIBILITY ANALYSIS

4.1 Statement of the Problem, Including Reasons for Considering the Proposed Actions

This section summarizes the purpose and need for the proposed actions as discussed in Section 1.2 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS* and Section 1.3 of the *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery DEIS*.

Despite a program completed in 2003 to buy back groundfish limited entry permits and associated vessels, management of the Pacific coast limited entry groundfish trawl fishery is still marked by serious biological, social, and economic concerns similar to those cited in the U.S. Commission on Ocean Policy's 2004 report, *An Ocean Blueprint for the 21st Century*. The trawl fishery is currently viewed as economically unsustainable due to the number of participating vessels (excess capacity), a regulatory approach that constrains efficiency, and the status of certain groundfish stocks, along with the measures in place to protect those stocks.

One major source of concern stems from the management of bycatch, particularly of overfished species. Over the past several years, the groundfish management efforts of the Council have been involved in drafting rebuilding plans for overfished species, minimizing bycatch, and specific management of overfished species.

As highlighted in the following problem statement that the Council sent out for public review in a June 2004 scoping document, these problems with capacity, economic inefficiency, and bycatch management are interconnected with problems related to the ability to achieve OY; the need for a precautionary management approach; and the need for a flexible system that allows for variations and contingencies, long-term and short-term concerns for communities, and safety. The problem statement is presented below:

> As a result of the legal requirement to minimize bycatch of overfished species, considerable harvest opportunity is being forgone in an economically stressed fishery. The west coast groundfish trawl fishery is a multi-species fishery in which fishermen exert varying and limited control of the mix of species in their catch. The optimum yields (OYs) for many overfished species have been set at low levels, placing a major constraint on the industry's ability to fully harvest the available OYs of the more abundant target species that co-occur with the overfished species, wasting economic opportunity. Average discard rates for the fleet are applied to project bycatch of overfished species. These discard rates determine the degree to which managers must constrain the harvest of target species that co-occur with overfished species. These discard rates are developed over a long period of time and do not rapidly respond to changes in fishing behavior by individual vessels or for the fleet as a whole. Under this system, there is little direct incentive for individual vessels to do everything possible to avoid take of species for which there are conservation concerns, such as overfished species. In an economically stressed environment, uncertainties about average

bycatch rates become highly controversial. As a consequence, members of fishing fleets tend to place pressure on managers to be less conservative in their estimates of bycatch. Given all of these factors, in the current system there are uncertainties about the accuracy of bycatch estimation, few incentives for the individual to reduce personal bycatch rates, and an associated loss of economic opportunity related to the harvest of target species.

The current management regime is not responsive to the wide variety of fishing business strategies and operational concerns. For example, historically the Pacific Council has tried to maintain a year-round groundfish fishery. Such a pattern works well for some business strategies in the industry, but there has been substantial comment from fishermen who would prefer to be able to pursue a more seasonal groundfish fishing strategy. The current management system does not have the flexibility to accommodate these disparate interests. Nor does it have the sophistication, information, and ability to make timely responses necessary to react to changes in market, weather, and harvest conditions that occur during the fishing year. The ability to react to changing conditions is a key factor in conducting an efficient fishery in a manner that is safe for the participants.

Fishery stock depletion and economic deterioration of the fishery are concerns for fishing communities. Communities have a vital interest in the short-term and long-term economic viability of the industry, the income and employment opportunities it provides, and the safety of participants in the fishery.

In summary, management of the fishery is challenged with the competing goals of: minimizing bycatch, taking advantage of the available allowable harvests of more abundant stocks, increasing management efficiency, and responding to community interest. "Taking advantage of the available allowable harvests" includes conducting safe and efficient harvest activities in a manner that optimizes net benefits over both the short and long term.

In addition to problems specified in the problem statement, the two DEISs also deal with issues of foregone opportunities, stress within the management system, discard rates, and overfished species.

With respect to allocation of harvest opportunity between sectors of the Pacific Coast groundfish fishery, only long-term fixed allocations for Pacific whiting and sablefish north of 36° N latitude exist. Currently there are established procedures for any species to be formally allocated between commercial open access and limited entry sectors based on catch history for the license limitation allocation period. However, these are rarely implemented due to constraints imposed by management measures designed to rebuild overfished species. Allocating the available harvest of groundfish species and species complexes occurs in the Council process of deciding biennial harvest specifications and management measures; as such, these are considered short-term allocations. Amendment 21 makes a formal allocation between sectors for the majority of groundfish species, and it would, essentially, supersede these preexisting procedures in a single action.

4.2 Description of the Management Objectives and Legal Basis for the Proposed Actions

This section summarizes the management objectives for the proposed actions as discussed in Section 1.2 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS* and Section 1.3 of the *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery DEIS*.

The purpose of the proposed rationalization of the Pacific coast groundfish limited entry trawl fishery is outlined in the following goal and objectives:

Goal: Create and implement a capacity rationalization plan that increases net economic benefits, create individual economic stability, provide for full utilization of the trawl sector allocation, considers environmental impacts, and achieve individual accountability of catch and bycatch.

Objectives: The above goal is supported by the following objectives:

1. Provide a mechanism for total catch accounting.
2. Provide for a viable, profitable, and efficient groundfish fishery.
3. Promote practices that reduce bycatch and discard mortality and minimize ecological impacts.
4. Increase operational flexibility.
5. Minimize adverse effects from an individual fishing quota (IFQ) program on fishing communities and other fisheries to the extent practical.
6. Promote measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.
7. Provide quality product for the consumer.
8. Increase safety in the fishery.

In summary, the trawl rationalization program is intended to increase net economic benefits, create individual economic stability, provide full utilization of the trawl sector allocation, consider environmental impacts, and achieve individual accountability for catch and bycatch.

The purposes of the proposed allocation of harvest opportunity between sectors of the Pacific coast groundfish fishery are as follows:

1. To simplify or streamline future decisions by making formal allocations of specified groundfish stocks and stock complexes. If approved, formal allocations would be fixed and do not have to be decided through every biennial process or developed indirectly through the structure of management measures.
2. To support rationalization of the Pacific coast groundfish limited entry trawl fishery. Long-term, formal allocations of Amendment 21 groundfish species to the limited entry trawl sectors would provide more certainty to these sectors by reducing the risk that these sectors would be closed because of other non-trawl sectors exceeding their allocation. Such certainty will be especially important under the proposed IFQ and harvest co-operative systems proposed under the trawl rationalization program, because it would

make it easier for fishermen to make long-range planning decisions based on the allocation of harvest privileges. In addition, supporting rationalization of the limited entry trawl fishery, which would require individual accountability of catch and bycatch, would improve overall total catch accounting of groundfish species by the group with the largest amounts of groundfish catch, the trawl sector. While allocations could be made biennially to support trawl rationalization, this would be a more difficult and controversial process than making those decisions in advance.

3. To limit the bycatch of Pacific halibut in future limited entry trawl fisheries. The proposed action would place a total catch limit on Pacific halibut with the intent of further minimization of Pacific halibut bycatch in Area 2A trawl fisheries. The action would be consistent with the MSA mandate to minimize bycatch and would provide increased benefits to Area 2A fishermen targeting Pacific halibut.

The introductory paragraphs in Section 1.1 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS* and Section 1.1 of the *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery DEIS* provide information on the legal basis for the proposed actions. The trawl rationalization program would be a limited access privilege program (LAPP) under the MSA, 16 U.S.C. §§ 1851–1891d, as reauthorized in 2007.

4.3 Description of Each Selected Alternative, Including the No-action Alternative

The term "selected alternatives" refers to the alternatives NMFS determined will be analyzed in the RIR and IRFA. The selected alternatives for this RIR and IRFA are the no action alternative and the Council's preferred alternative. The effects of the other action alternatives that were not selected are analyzed in the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS* and *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery DEIS.*

4.3.1 No Action Alternative

The analysis of the no action alternative describes what is likely to occur in the absence of the proposed action. It provides a benchmark against which the incremental effects of the proposed action can be compared. This section summarizes the description of the no action alternative presented in Section 2.1 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS* and Section 2.1.1 of the *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery DEIS.*

Under the no action alternative, the current, primary management tool used to control the Pacific coast groundfish trawl catch—a system of two-month cumulative landing limits for most species and season closures for Pacific whiting—would continue. Only long-term fixed allocations for Pacific whiting and sablefish north of 36° N latitude would exist—all other groundfish species would not be formally allocated between the trawl and non-trawl sectors. Allocating the available harvest of groundfish species and species complexes would occur in the Council process of deciding biennial harvest specifications and management measures and, as such, would be considered short-term allocations.

4.3.2 Preferred Alternative

This section summarizes the description of the preferred alternative presented in Section 2.4 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS* and Section 2.1.6 of the *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery DEIS*.

Table 1 provides an overview of the elements of the trawl rationalization program under the preferred alternative. The existing shoreside whiting and shoreside non-whiting sectors of the Pacific Coast groundfish limited entry trawl fishery would be managed as one sector under a system of IFQs, and the at-sea whiting sectors of the fishery (i.e., catcher-processor sector and mothership sector, which includes motherships and catcher vessels) would be managed under a system of sector-specific harvesting co-ops. The catcher-processor sector would continue to operate under the existing, self-developed co-op program entered into voluntarily by that sector. A distinct set of groundfish species and Pacific halibut would be covered by the rationalization program.

Table 1. Summary of elements under the no action alternative and preferred alternative for trawl rationalization program.

Element	No-action Alternative	Preferred Alternative
Catch Control Tool	two-month cumulative trip limits for non-whiting trawl sector	IFQ program for shoreside whiting and non-whiting trawl sectors (trip limits for non-IFQ species)
	Seasonal management for whiting trawl sector	Harvesting co-operatives for at-sea whiting sector
Initial Allocation and Qualification	None	For shoreside fisheries for use 1994 to 2003 catch history Equal sharing of 1994 to 2003 buyback history in non-catcher-processor sectors (except the incidentally caught overfished species other than canary)
		Rebuilding stocks and halibut allocated on a bycatch rate/pro-rata
		Mothership catcher vessel endorsement and allocation based on 1994 to 2003 catch history; Mothership permit: at least 1,000 mt in two years from 1997 to 2003
Accumulation Limits	None	Shoreside non-whiting sector: 2.7% control limit and 3.2% vessel use limit
		Shoreside whiting sector : 10% control limit and 15% per vessel limit
		Mothership sector: Cannot process more than 45%
		Mothership catcher vessel sector: 20% control limit and 30% usage limit
		Catcher-processor sector: none

Table 2 cont. Summary of elements under the no action alternative and preferred alternative for trawl rationalization program.

Element	No-action Alternative	Preferred Alternative
Grandfather clause	None	None, but entities must divest overage QS at the end of year four
Processor Initial Allocation / Co-op Affiliations	None	Annual mothership declaration requirement
		20% shoreside processor allocation of shoreside whiting
		No processor allocation of non-whiting groundfish
Species Covered	All groundfish	Select groundfish species and Pacific halibut in shoreside sector
		Select groundfish species in at-sea sector; At-sea sector bycatch is allocated at co-op level
Number of Trawl Sectors	Four	Three
Adaptive Management	None	10% QS set aside for shoreside non-whiting groundfish species
Area Management	Trip limits vary by area; main split at $40^0$10' N latitude	None
Carry-over	None	Carryover exists; allowance decreases if OY declines
Permits	Limited Entry, Pacific Whiting Vessel License	Limited entry, mothership permit, catcher-processor endorsement, mothership catcher vessel endorsements

At the start of the IFQ program, quota shares (QS) would initially be allocated to fishery participants based on catch/processing history during a catch history qualification period, 1994 to 2003. After the first two years of the program, shareholders will be free to buy and sell the QS thus distributed. QS represent a proportion, or percent, of the total allowable catch (which is called the optimum yield [OY]in groundfish management) of different groundfish stocks. Each year, these shares are converted from a percent to a quantity by issuing QP based on the OYs/annual catch limits established for the year. The amount of groundfish caught by a limited entry trawl vessel, even if it is subsequently discarded, must be matched by an equivalent quantity of QP. The QP is expended in this way, with the matched amount deducted from the vessel's account.

Harvesters in the shoreside sector would receive all the initial allocation of non-whiting QS (minus any amount held back for the adaptive management program in future years) and 80 percent of whiting QS. Processors in the shoreside sector would receive the remaining 20 percent of whiting QS.

Both QS and QP would be perfectly divisible and tradable. However, to prevent a particular individual, corporation, or other entity from acquiring an excessive QS, accumulation limits

would restrict the amount of QS any single entity may hold or control (the control limit) and the amount of QP that can be placed on a vessel during a given year to cover catch (the vessel limit). These limits would vary between whiting and non-whiting groundfish. For mothership catcher vessels, a usage limit would act similar to a vessel limit. The preferred alternative includes a two-year moratorium on QS sales, followed by a two-year period over which entities receiving an initial allocation of QS in excess of the limits can and must divest their excess QS to any willing receiver.

An adaptive management program that would reserve 10 percent of non-whiting QS for the shoreside sector could be used to address a variety of objectives, such as creating incentives for bycatch reduction and use of habitat-friendly gear, mitigating adverse impacts to processors and fishing communities, and helping second generation fishermen/new entrants. During the first two years of implementation of the preferred alternative, the adaptive management QP would be passed through to QS holders in proportion to their holdings. Allocations of other species' QP under the program would begin in the third year, based on further specification of adaptive management program objectives and mechanisms.

These regulations would modify the existing limited entry permit system and would replace the Pacific whiting vessel license system with a series of endorsements. In 2009, NMFS implemented Amendment 15, which required a Pacific whiting vessel license for any vessel participating in either the shorebased or at-sea whiting fisheries. These licenses were issued to limit the number of vessels in the whiting fishery based on participation history in these fisheries. Under the trawl rationalization program, the Pacific whiting vessel licenses will permanently expire and will be replaced by a new mothership permit and new catcher/processor and mothership catcher vessel endorsements for existing Pacific Coast limited entry permits. [Although the Pacific whiting vessel license restricts what vessels can participate in the whiting fishery, these new endorsements convert the at-sea fisheries into a series of limited entry fisheries with tradable permits and endorsements.]

For the mothership catcher vessels, the years 1994 to 2003 would be used for endorsement qualification, and the best 8 out of 10 years from 1994 to 2003 would be used for catch history assignment. Mothership catcher vessels would be required to declare which co-op they will join before the beginning of the fishing year. They would then be obligated to assign their catch to the associated mothership processor for that fishing season. In any subsequent year, they could change their affiliation without first participating in the non co-op fishery through the pre-season declaration. Provision for a non co-op fishery would still be included in the program structure. Any vessel not wishing to affiliate with a co-op could participate in the non co-op fishery and deliver to any willing mothership processor. Since the catcher-processor sector would continue to operate as a single voluntary co-op, catch history assignment is unnecessary; the co-op would have access to the full sector allocation. Should the catcher-processor co-op fail because, for example, the co-op does not manage harvest such that allocations are repeatedly exceeded, the catcher-processor sector would be managed under a system of IFQs, and an equal amount of QS would be issued to each permit with a catcher-processor endorsement.

Amendment 20 would include a tracking and monitoring program to ensure that all catch (including discards) would be documented and matched against QP. The Council specified that

observers would be required on all vessels, and shoreside monitoring (catch monitors) would be required during all off-loading (100 percent coverage). Compared to status quo monitoring, this would be a monitoring and observer coverage level increase for a large portion of the trawl fleet, particularly nonwhiting shoreside vessels. As a result, more accurate estimates of total mortality would be expected to benefit stock conservation goals, as well as other goals discussed herein.

Amendment 20 would require NMFS-certified, at-sea observers on each vessel. These include shoreside catcher vessels, mothership catcher vessels, mothership processors, and catcher-processors. Because this is a new program, ensuring adequate observer coverage would be particularly important for monitoring the complex suite of allocations. Observers aboard vessels would be required to account adequately for catch and bycatch in the fishery. Among his or her duties, the observer would record fishing effort and estimate total, retained, and discarded catch weight by species; determine species composition of retained and discarded catch (non-whiting vessels) and document the reasons for discard; record interactions and sightings of protected species; take biological samples from tagged fish and discards, and estimate viability of Pacific halibut. Observers would be essential to monitor IBQ in the fishery, including IBQ weighing and discarding.

An increase in observer and catch-monitoring coverage requirements would result in increased costs over the status quo observer program costs. There would be a combined status quo, pay-as-you-go industry funding, and an agency-funded observer and catch monitor system, as required for each sector. The agency has announced its intent, subject to available Federal funding, that participants will initially be responsible for 10 percent of the cost of hiring observers and catch monitors. The industry proportion of the costs of hiring observers and catch monitors will be increased every year so that, by 2014, once the fishery has transitioned to the rationalization program, the industry will be responsible for 100 percent of the cost of hiring the observers and catch monitors. NMFS believes that an incrementally reduced subsidy to industry funding will enhance the observer and catch monitor program's stability, ensure 100 percent observer and catch monitor coverage, and facilitate the industries' successful transition to the new quota system.

Amendment 20 would require that first receivers—shoreside processors and other entities that receive groundfish from IFQ harvesters—sort, weigh, and report all landings of IFQ species under a catch monitoring plan. First receivers will be required to hire NMFS-certified catch monitors to verify all shoreside deliveries of IFQ species; ensure that species are sorted according to Federal species of species group; ensure that the fish are weighed on periodically tested, state-certified scales; and record and submit catch data daily.

To ensure that the QP program goals are met and landings are tracked, first receivers will be required to submit electronic fish tickets using software provided by the Pacific States Marine Fisheries Commission. Further, vessels will be required to continue to use vessel monitoring systems for purposes of indicating location of the vessels and to make declarations. In addition, there are plans to develop and require an electronic vessel logbook, but this component will not be immediately implemented.

To ensure that program goals to track transferrable QS and QP are met, NMFS is also developing

an online accounting system for the tracking and trading of QS by owner and for the tracking, trading, and use of the QP that result from these quota shares by vessels.

The preferred alternative for the proposed allocation of harvest opportunity between sectors of the Pacific coast groundfish fishery is as follows:

- Make long-term, formal allocations of the following species between the non-treaty limited entry trawl sectors and non-treaty, non-trawl sectors: lingcod, Pacific cod, sablefish south of 36^0 N latitude, Pacific ocean perch, widow rockfish, chilipepper rockfish, splitnose rockfish, yellowtail rockfish north of $40^0$10' N latitude, shortspine thornyhead (north and south of $34^0$27' N latitude), longspine thornyhead north of $34^0$27' N latitude, darkblotched rockfish, minor slope rockfish (north and south of $40^0$10' N latitude), Dover sole, English sole, petrale sole, arrowtooth flounder, starry flounder, and Other Flatfish.
- Determine a scheme for an initial shoreside trawl sector allocation to the shoreside whiting and shoreside non-whiting sectors of above species other than darkblotched rockfish, Pacific ocean perch, and widow rockfish, as well as sablefish north of 36^0 N latitude.
- Apportion the limited entry trawl allocation of darkblotched rockfish, Pacific ocean perch, and widow rockfish to the four current trawl sectors (shoreside non-whiting, shoreside whiting, at-sea whiting mothership, and at-sea whiting catcher-processor).
- Consider yield set-asides to accommodate the projected bycatch of above species other than darkblotched rockfish, Pacific ocean perch, and widow rockfish by the two at-sea whiting trawl sectors (motherships and catcher-processors).
- Determine a total catch limit of Pacific halibut in Area 2A trawl fisheries to limit the future bycatch of this prohibited trawl species.

4.4 Description of the Fishery and All Affected Entities, Including the Small Entities to Which the Proposed Actions Apply

This section summarizes stakeholder profiles presented in Chapter 3 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS* and Section 3.4 of the *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery DEIS*.

4.4.1 Description of the Fishery

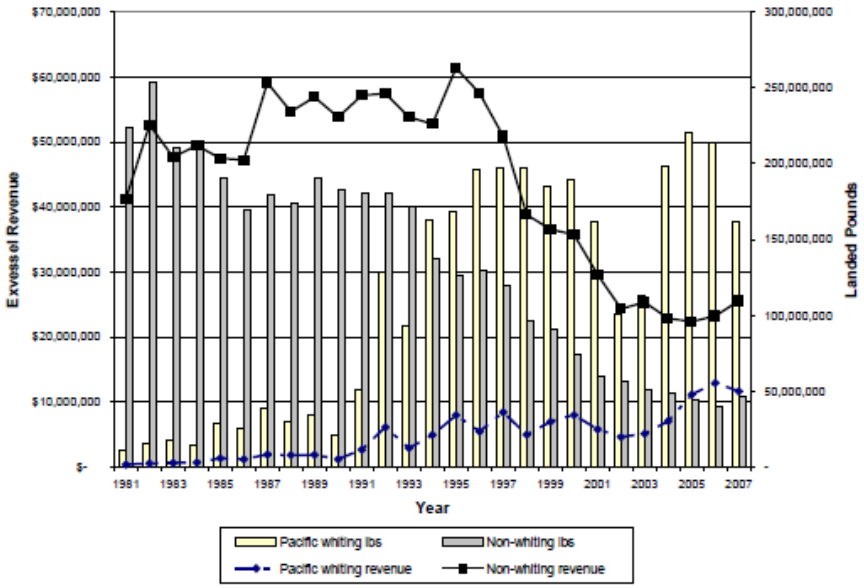
The Pacific Coast groundfish fishery as a whole comprises several different major sectors, defined by fishing gear, species targeted, and regulatory context. In addition to the limited entry trawl fleet, there are open access and the fixed gear fleets. Recreational fishermen also harvest groundfish. For the limited entry trawl fleet, the list of current target species includes flatfish, roundfish, thornyheads, and a few species of rockfish. Primary flatfish target species include petrale sole and Dover sole. Roundfish target species include Pacific whiting, Pacific cod, and sablefish. Some rockfish species, especially Pacific ocean perch and widow rockfish, were important trawl targets until the mid 1990s. However, seven rockfish species are currently declared overfished under the MSA. The need to rebuild these stocks to a healthy size has led to various harvest constraints on groundfish fisheries, and rockfish are generally no longer a target

of these fisheries.

The groundfish trawl fishery is subject to a license limitation program (referred to as limited entry) implemented in 1992. Groundfish fixed-gear fisheries—using longline and pot gear—are managed under a complementary limited entry program. Most of the Pacific coast commercial groundfish harvest occurs in the limited entry fisheries. Some retention of groundfish is allowed without a limited entry permit; these vessels comprise the open access sector. The gears used by the open access sector include longline, vertical hook and line, troll, pot, setnet, trammel net, shrimp and prawn trawl, California halibut trawl, and sea cucumber trawl gears.

The limited entry trawl fishery is divided into two broad sectors: a multispecies trawl fishery, which most often uses bottom trawl gear (hereafter called the non-whiting fishery), and the Pacific whiting fishery, which uses midwater trawl gear. The non-whiting fishery is principally managed through two-month cumulative landing limits along with closed areas to limit overfished species bycatch.[1] Fishery participants target the range of species described above with the exception of Pacific whiting. By weight, the vast majority of trawl vessel groundfish is caught in the Pacific whiting fishery. In contrast, the non-whiting fishery accounts for the majority of limited entry trawl fishery ex-vessel revenues. On average from 2000 to 2005, Pacific whiting accounted for about 75 percent of the quantity of groundfish landed in the limited entry trawl fishery but only 21 percent of the value due to their relatively low ex-vessel price.

Non-whiting trawl vessels deliver their catch to shoreside processors and buyers located along the coasts of Washington, Oregon, and California. They tend to have their homeports located in towns within the same general area where they make deliveries, though there are several cases of vessels delivering to multiple ports during a year. Some Pacific whiting trawl vessels are catcher-processors, which, as their name implies, process their catch on board, while other vessels in this sector deliver their catch to shoreside processors or motherships that receive Pacific whiting for processing, but do not directly harvest the fish.



Over time, landings in the limited entry trawl fishery have fluctuated, especially on a species-specific basis. Pacific whiting has grown in importance, especially in recent years. Through the 1990s, the volume of Pacific whiting landed in the fishery increased. In 2002 and 2003, landings of Pacific whiting declined due to information showing the stock was depleted and the subsequent regulations that restricted harvest in order to rebuild the species. From 2003 to 2007, estimated Pacific whiting ex-vessel revenues averaged about $29 million. In 2008, these participants harvested about 248,000 tons of whiting worth about $63 million in ex-vessel revenues based on shoreside ex-vessel prices of $254 per ton—the highest ex-vessel revenues and prices on record. In comparison, the 2007 fishery harvested about 224,000 tons worth $36 million at an average ex-vessel price of about $160 per ton.

While the Pacific whiting fishery has grown in importance in recent years, harvests in the non-whiting component of the limited entry trawl fishery have declined steadily since the 1980s. Ex-

1 The non-whiting fishery currently uses bottom trawl gear exclusively. However, in the past there have been fisheries targeting widow rockfish and other rockfish species with midwater gear. Due to the need to limit catches of overfished species, these fisheries have been closed. However, once overfished species stocks are rebuilt, the fisheries could reopen.

vessel revenues in the fishery peaked in the mid 1990s at over $60 million. Following the passage of the Sustainable Fisheries Act (1996) and the listing of several species as overfished, harvests became increasingly restricted, and landings and revenues declined steadily until 2002. Since 2002, ex-vessel revenues have stabilized at around $23 to $27 million per year (Figure 1). In 2007, the Council estimates that 159 trawlers landed 94,000 mt of groundfish, earning $37 million in ex-vessel revenues, for an average of $234,000 per vessel.

Figure 1. Shoreside landed pounds and ex-vessel revenue from whiting and non-whiting groundfish caught using trawl gear.

Limited entry trawl vessels make most of their landings in Oregon. During the 2004 to 2006 period, the Oregon ports that received the largest amounts of landed weight and revenue were Newport, Astoria, and Charleston/Coos Bay, Oregon. Eureka, Fort Bragg and Crescent City, California; Brookings, Oregon; and Bellingham Bay, Blaine and Neah Bay, Washington comprise the remaining top 10 largest ports for trawl vessel landings. Non-whiting landings and revenues by non-tribal trawlers in Oregon are significantly larger than the other two states. A detailed description of west coast fishing communities and their economic dependence on the groundfish fishery is found in the *Final Environmental Impact Statement for Biennial Harvest Specifications and Management Measures* (PFMC and NMFS 2009).

Non-whiting trawl vessels deliver their catch from targeted trips to 63 shoreside processing companies located in all three Pacific coast states. Thirty-six to forty-six of these companies received non-whiting groundfish in any one year from 2004 to 2006. There are few major non-whiting groundfish processing centers on the Pacific coast. Only seven cities processed more than 1 percent of coast wide landings, and the largest processing center, Astoria, Oregon, accounted for more than two-thirds of processing activity by weight of landed fish. In 2008, Pacific whiting trawl vessels landed their catch at 16 first receivers located in ports in all three states. Between 8 and 16 of these companies received whiting in any one year from 1997 to 2008. Since processing Pacific whiting requires specialized equipment, most whiting processing plants process whiting only.

Limited entry fixed gear vessels use longline and fish pots (traps) to target groundfish. Limited entry fixed gear vessels principally target sablefish. Limited entry fixed gear vessels may also participate in open access fisheries or in the limited entry trawl fishery. Directed open access vessels use various non-trawl gears to target particular groundfish species or species groups. Longline and hook and line gear are the most common open access gear types used by vessels directly targeting groundfish and are generally used to target sablefish, rockfish, and lingcod. Pot gear is used for targeting sablefish, thornyheads and rockfish. Like the limited entry trawl fleet, limited entry fixed gear vessels and directed open access vessels deliver their catch to ports along the Washington, Oregon, and California coast.

In addition to commercial and tribal participants, state-managed recreational fisheries harvest groundfish. These recreational fisheries are managed by a series of seasons, area closures, and bag limits. Recreational groundfish fisheries occurring off the Pacific coast accounted for about 22 percent of all recreational anglers and 12 percent of trips.

Recreational fishing is an important economic contributor to the Pacific coast in general, and to some communities specifically. The recreational fishing fleet is composed of charter and private vessels. The private fleet typically consists of vessels owned by residents living in or near areas where they fish. The charter boat fleet is a for-hire fleet that plays a large role in the tourism sector of many Pacific coast communities. Opportunities to fish on a charter vessel can be a substantial draw for tourists considering a visit to the coast. The distribution of resident and non-resident ocean anglers among the Pacific coast states in 2000, 2001, and 2002 demonstrates the geographic importance of recreational fishing. Southern California has more than twice the number of resident recreational marine anglers than the next most populous region, Washington State. While most of the recreational anglers are residents of those states where they fish, a significant number of anglers are also non-residents. Oregon had the largest percentage of non-resident ocean anglers in all three years.

About 525 charter boats made up the charter boat fleet in 2005. This is a decrease of almost 30 percent from the 753 charter vessels estimated in the Council's 2005/2006 Groundfish Specifications EIS. Estimates of numbers of private boats are unavailable. Recreational fishing in the open ocean generally declined slightly between 1996 and 2003; however, charter effort decreased while private effort increased during that period. Part of this increase likely resulted from longer salmon seasons associated with increased abundance during the period.

The Makah, Quileute, Hoh, and Quinault Tribes off the Washington coast participate in tribal commercial, ceremonial, and subsistence fisheries for groundfish according to their treaty rights. Participants in the tribal commercial fishery use gear similar to non-tribal commercial fisheries operating off Washington. Groundfish caught in the tribal commercial fishery is typically sold through the same markets as non-tribal commercial groundfish catch. The harvest of the four tribes is taken into account when OYs are established. For a few species (sablefish and whiting, for example) a share of the OYs for groundfish species taken in their fisheries is explicitly allocated. For most species, expected tribal harvest levels are taken into account in setting regulations for other sectors, but there is no allocation to the tribes. For those species allocated to the tribes, and for other species for which expected harvest levels are identified, the tribes

oversee the prosecution of their fisheries separate from the management of other groundfish fishery sectors.

4.4.2 Estimate of the Number of Small Entities to Which the Proposed Action will Apply

The following discussion provides information on the number of small and large businesses that participate in the Amendment 20 Trawl Rationalization Programs. Information from the following sources was reviewed, in addition to information found in the Amendment 20 DEIS, other Council documents, and industry publications (these publications are used to assess size as well as affiliations):

- NMFS NWFSC Survey of Limited Entry Trawlers (ex-vessel revenue estimates)
- NMFS Annual Process Product Survey (employment estimates)
- Pacific States Marine Fisheries Commission Pacific Fishery Information Network—Processor/First Receiver purchases of groundfish from limited entry trawlers (ex-vessel revenues)
- NMFS NWR Ownership Survey (respondents classify themselves as large or small)

The NMFS Northwest Fisheries Science Center surveyed limited entry trawlers that delivered to shoreside plants or to motherships in 2004. [The survey did not include catcher processors or motherships.] These sources paint slightly different but consistent pictures of the size of the participants. The discussion provides two perspectives—one that addresses the entities affected by the intersector allocation decisions of Amendment 21 (all major fishing groups that harvest groundfish) and another that address the groups affected by implementation of the trawl rationalization program (shorebased processors, shorebased trawlers, mothership processors and catcher vessels, and catcher-processors).

Amendment 21 Analysis:

Amendment 20 directly regulates the groundfish trawl, mothership, and catcher-processor fleets and shorebased trawl groundfish processors whereas Amendment 21 affects not only those groups, but the other groundfish fleets—fixed gear and open access because of the allocation rules. These businesses are associated with vessels that either target groundfish or harvest groundfish as bycatch (including vessels that participate in the limited entry (trawl and fixed gear), open access, or charter boat portion of the groundfish fishery), or are associated with processors and buyers of groundfish (including shoreside and at-sea processors). These rules also affect companies that own and fish the limited entry trawl permits and the companies that lease these permits.

NMFS NWR issued 399 limited entry permits at the beginning of 2010. These permits include 177 endorsed for trawl (172 trawl only, 4 trawl and longline, and 1 trawl and trap-pot); 199 endorsed for longline (191 longline only, 4 longline and trap-pot, and 4 trawl and longline); 32 endorsed for trap-pot (27 trap-pot only, 4 longline and trap-pot, and 1 trawl and trap-pot). Of the longline and trap-pot permits, 164 are sablefish endorsed. Of these endorsements, 117 are stacked on 45 vessels. Because not all affected groups operate under the Federal limited entry permit, a review of participation in groundfish fisheries based on actual harvests provides a broader perspective.

Chapter 3 of the DEIS provides the following estimates. In 2007, there were six motherships supplied by 20 mothership catcher vessels with many vessels also delivering shoreside. Nine catcher-processors also fished and processed. About 159 trawlers fished in either the limited entry or open access fisheries. The limited entry fixed gear fleet was composed of 130 hook and line vessels and 20 pot vessels. The open access fleet is composed of several gear types—644 hook and line vessels, 57 net vessels, 180 pot vessels, 151 salmon troll vessels, and 32 trawlers. From 2004 to 2006, there were 63 different first receivers of trawl-caught groundfish. During 2007, 14 first receivers purchased whiting from 37 shorebased trawlers.

Although not directly regulated by these rules, tribal fleets participate in this fishery. According to Chapter 7 of the 0910 Groundfish Specifications EIS, the tribal fleet consists of approximately 66 vessels: longline (52), whiting trawl (4), and non-whiting trawl (10). The 2009 Review of Ocean Salmon Fisheries indicates that there were 465 salmon charterboats. These are presumed to be vessels that also will fish for groundfish. In 2007, 142 vessels were issued halibut licenses. Therefore, this rule affects an estimated 2000 business entities—permit holders, vessels, and first receivers that would be directly regulated by the proposed rule. No small organizations or small governmental jurisdictions would be directly regulated by the proposed actions. Although not directly regulated by this proposed rule, approximately 20 fishing communities that range from small towns to major cities are indirectly affected by this rule because of the potential reduction in the number of first receivers/processors and limited entry trawlers, as well as resulting changes in where fish is landed to be processed. In general, these 2,000 entities are presumed to be small with the exceptions noted below based on various analyses.

Non-Trawl Sectors—The following discussion provides small business estimates for groundfish fishery participants that are affected by Amendment 21's allocation policies, but do not qualify

to participate in Amendment 20's trawl rationalization programs. NMFS has very limited information on the companies associated with the following fleets However, it is expected that these companies (unless these vessels are owned or affiliated with large entities), are most likely to be classified as small companies based on average annual ex-vessel revenues that are far below the $4.0 million level. In 2007, the average limited entry fixed gear hook and line vessel earned $88,000 in groundfish revenues; limited entry fixed gear pot vessels earned about $200,000 in groundfish revenues, and the average open access vessel earned about $7,000 in groundfish revenues. Most of the 1,100 open access vessels target other fisheries. In 2007, salmon trollers averaged $11,000 in salmon revenue per vessel, shrimp trawlers $157 million in shrimp revenues, crab pot vessels $157,000 in crab revenues, and purse seiners $269,900 in coastal pelagic species revenues.

Current revenues for charterboats are unavailable. However, the Pacific States Marine Fisheries Commission surveyed approximately 12 percent of the charter and head boats licensed to operate in California, Oregon, and Washington on their 2000 operations. Vessels were categorized according to the region in which they were home ported: southern California (for homeports from the Mexican border to Point Conception), northern California (for homeports north of Point Conception to the Oregon border), Oregon, and Washington. Vessel size class was defined in terms of vessel length: "small" for lengths of 15 to 30 feet, "medium" for lengths of 31 to 49 feet, and "large" for lengths greater than 49 feet. The estimates of average revenues from all types of recreational activities, including fishing and whale watching charterboat estimates, ranged from $7,000 for small Oregon vessels, $131,000 for medium Washington vessels, $184,000 for large Northern California vessels, and $770,000 for large Southern California vessels, the largest in the coastal fleet. These estimates confirm that that those charterboats most likely to fish for groundfish qualify as small entities.

Amendment 20 Analysis:

NWFSC Survey: During 2004, 116 limited entry trawlers fished on the West Coast, but did not participate in the whiting fishery during 2004. Of these 116 limited entry trawlers, 71 responded to the NWFSC's cost-earnings survey. Among the 71 respondents, the average total revenue from all sources (west coast landings, Alaska landings, at sea deliveries, etc) was $368,271. None of the 71 respondents had revenue exceeding $2,000,000 in 2004. Twenty-six limited entry trawlers fished in the shoreside whiting fishery during 2004 (this figure does not include five limited entry trawlers that had positive whiting landings worth less than $2,500). Of these 26 vessels, the NWFSC received 19 responses to the cost earnings survey. Adding all sources of revenue collected by the cost earnings survey (revenue from landings in locations other than the west coast, at-sea deliveries, and other sources of revenue) to west coast landings revenue reported in PacFIN shows that these 19 vessels had average revenue of $971,871from all sources. Of the 19 survey respondents, the three vessels with the greatest total revenue all earned between $1.7 million and $1.8 million during 2004.

Of the seven limited entry trawl vessels that fished as catcher vessels for motherships in the at-sea whiting fishery and did not have any west coast landings, none had revenue exceeding $4,000,000. These seven vessels had average revenue of $1,624,488 million, and one vessel had revenue of $3.6 million. Of the five limited entry vessels that fished as catcher vessels for

motherships in the at sea whiting fishery and made shoreside whiting landings in 2004, none had revenue over $4 million in 2004. The five vessels had average revenue of $1,554,283 and included three vessels with revenue of $1.7 million to $1.8 million (the same three vessels as noted in the response to the previous question).

Annual Processed Products Survey-Employment Estimates for 2009: This voluntary survey was sent to primary processors and secondary processors in Oregon and Washington, 11 companies of which were primary processors of groundfish. Respondents to this survey, among other things, are to provide monthly estimates of employment. Only one of the shorebased processors reported employing more than 500 employees in any one month. Three of these processors are associated with the same parent company, and, collectively, these companies employ more than 500 employees. Therefore, out of nine companies in Oregon and Washington, seven companies are small and two are large. Catcher-processor and mothership companies were also surveyed. These vessels employ from 100 to 140 employees per vessel.

Chapter 3 of the Amendment 20 DEIS: Processing companies are not necessarily first receivers—they may process fish initially delivered to a buyer who then sells the fish to the processor. The Pacific Fishery Management Council staff indicates that from 2004 to 2006 (Table 3-53 DEIS), 63 shoreside companies received non-whiting. In 2008, 6 companies were first receivers of whiting for a total of 69 companies that received groundfish from 2004 to 2008. Three of these companies have multiple state operations (Table 3-42 DEIS). The companies that receive nonwhiting vary widely in terms of the volume received. Nearly 70 percent, or 44 companies, received fewer than 50 mt during the three-year period (Table 3-45 DEIS). A large proportion of these companies receives but does not process nonwhiting; they include restaurants, wholesalers and retailers, or distributors. Of the remaining 19 companies that received more than 50 mt, only 7 received more than 1,000 mt. One received more than 5,000 mt, and one received more than 20,000 mt. The companies that receive whiting also vary widely in terms of the volume received. Five firms received more than 10,000 mt each during the period, including three with more than 30,000 mt. At the other end of the scale, 4 of the 13 firms received less than 1,000 mt during the period (Table 3-38 DEIS).

PSMFC PacFIN—Small Purchaser Analysis: NMFS reviewed the 2008 and 2009 purchases of limited entry trawl groundfish by first receiver. The results for both years are similar, so only the 2008 results are discussed. In 2008, 75 first receivers purchased limited entry trawl groundfish. There were 36 small purchasers (less than $150,000), 26 medium purchasers (purchases greater than $150,000 but less than $1,000,000), and 13 large purchasers (purchases greater than $1.0 million). When the trawl rationalization program is implemented, to continue buying limited entry trawl groundfish, these purchasers will have to obtain a processor site license that includes requirements to submit electronic fish tickets, provide a catch monitoring plan, and schedule a catch monitor. Assuming that a catch monitor costs $350 per day and assuming that the start-up costs of applying for a license, developing a plan, and obtaining the electronic fish ticket software are an additional $350, the total initial start-up cost is about $700. [Note that, in the first few years, the costs of catch monitors will be subsidized in part by NMFS.] Further assuming that undertaking these steps only makes financial sense if the start-up cost is less than 0.5 percent of the groundfish purchased, than a processing site /first receiver would have to

purchase about $140,000 to break even financially based on these assumptions. Therefore, many of the 36 small purchasers are likely to stop purchasing groundfish from limited entry trawlers as a result of this program. Five of these small purchasers bought less than $10,000 worth of limited entry trawl groundfish. The majority of these small purchasers were not major purchasers of other fish (21 of these small purchasers bought less than $150,000 of fish [groundfish and non-groundfish] in total with 14 of these first receivers, purchasing less than $10,000 in limited entry trawl groundfish). This is not to say that all of these purchasers will go out of business as result of these rules. NMFS does not know how dependent these businesses are on groundfish because the agency does not have data on all sources of income (fishery and non-fishery) of these first receivers. In addition, these companies could make arrangements to purchase fish from another company that has obtained a processing site license or groundfish harvested by fixed gear.

NMFS Ownership Survey: The NMFS Northwest Regional Office is in the final stages of completing a voluntary ownership survey. Respondents to this survey were asked if they consider themselves small businesses or non-profit organizations based on the definitions above. In February 2009, this form was sent to the 177 limited entry permit holders and associated vessels (approximately 150 vessels—not all permits have vessels attached to them.) This form was also sent to the six mothership processors who have Pacific whiting vessel licenses and to the 14 first receiver/shorebased processors who hold 2009 first receiver whiting exempted fishery permits. Thirty-three limited-entry permit holders, thirty-six trawlers, 1 mothership processor, and six shorebased whiting first receivers/processors have yet to respond to this survey. Based on this survey, review of available information on those companies who have yet to respond or on those few companies who responded to the survey but did not respond to the small business question, the following characterization of the industry is provided. The nine limited entry trawl permits that are associated with the catcher-processor vessels are considered large companies. [According to the Pacific Whiting Conservation and Whiting Co-operative website, www.pacificwhiting.org, the catcher-processor fleet is made up of three companies that operate ten vessels. Of these companies, two have wholesale sales from whiting, Pollock, and other products that are at least $500 million—see the *Seafood Business Magazine* discussion below. The remaining company is assumed to be a large business because in addition to the two whiting catcher-processors operate off Alaska along with other company vessels.] Of the remaining 168 limited entry permits, 25 limited entry trawl permits are either owned or closely associated with a large, shorebased processing company or with a non-profit organization that considers itself a large organization. Nine other permit owners indicated that they were large companies. Almost all of these companies are associated with the shorebased and mothership whiting fisheries. The remaining 134 limited entry trawl permits are projected to be held by small companies. Three of the six mothership processors are large companies. There are four large companies within the 14 shorebased whiting first receivers/processors.

Seafood Business Magazine (www.seafoodbusiness.com—archives): In the whiting fishery (at-sea and shoreside), many of the processing companies involved are closely affiliated with the 10 ten seafood suppliers with wholesale sales of ranging from about $500 to $1 billion. These companies tend to be involved with Alaska fisheries, and some have major foreign affiliations. [See "In the can: North America's seafood suppliers grow sales despite fears of an economic

downturn," May 5, 2008; and "Bottom Dollar: The Top 25 North American seafood suppliers had a strong 2008, but the future is in question," June 19, 2009]

Amendment 20 and Amendment 21 Summary Conclusion: NMFS makes the following conclusions based primarily on analyses associated with fish ticket and limited entry permit data, available employment data provided by processors, information on charterboat and tribal fleets, and available industry responses to ongoing surveysd on ownership. Entities were analyzed as to whether they were only affected by the Amendment 21 allocation processes—non-trawl—or if they were affected by both Amendments 20 and 21—(trawl). The non-trawl businesses are associated with the following fleets: limited entry fixed gear (approximately 150 companies), open-access groundfish (1,100), charterboats (465), and the tribal fleet (four tribes with 66 vessels).

Available information on average revenue per vessel suggests that all the entities in this group can be considered small. For the trawl sector, there are 177 trawl vessel permit holders. Nine limited entry trawl permits are associated with the catcher-processing vessels, which are considered large companies. Of the remaining 168 limited entry permits, 25 limited entry trawl permits are either owned or closely associated with a large shorebased processing company or with a non-profit organization that considers itself a large organization. Nine other permit owners indicated that they were large "companies." Almost all of these companies are associated with the shorebased and mothership whiting fisheries. The remaining 134 limited entry trawl permits are projected to be held by small companies. Available information suggests that the at-sea and shorebased processing sectors consists of few large firms, a few moderate-size firms, and a considerable number of small firms. Four of the six mothership processors are large companies. Within the 14 shorebased whiting first receivers/processors, there are four large companies, including, the shorebased whiting receivers, in 2008, 75 first receivers purchased limited entry trawl groundfish. There were 36 small purchasers (less than $150,000), 26 medium purchasers (purchases greater than $150,000 but less than $1,000,000), and 13 large purchasers (purchases greater than $1.0 million). Because of the costs of obtaining a processed processor site license, procuring and scheduling a catch monitor, and installing and using the electronic fish ticket software, these small purchasers will likely opt out of buying groundfish or make arrangements to purchase fish from another company that has obtained a processing site license.

4.5 Economic Analysis of the Expected Effects of Each Selected Alternative Relative to the No-action Alternative, Including the Costs of Compliance for Small Entities

The economic impacts of the selected alternatives are detailed in Chapter 4 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery—Amendment 20 DEIS* (TRAT DEIS) and Chapter 4 of the *Allocation of Harvest Opportunity Between Sectors of the Pacific Coast Groundfish Fishery—Amendment 21 DEIS* (ISADEIS). The allocation of harvest opportunity between sectors under the preferred alternative does not differ significantly from the allocation made biennially under the no action alternative. The primary economic effect of the long-term, formal allocation under the preferred alternative is to provide more certainty in future trawl harvest opportunities, which would enable better business planning for participants in the rationalized fishery.

Expected Effects of Amendment 21—Intersector Allocation

The allocation of harvest opportunity between sectors under the proposed regulation does not differ significantly from the biennial allocation under the no action alternative. The primary economic effect of the long-term, formal allocation under the proposed regulations is to provide more certainty in future trawl harvest opportunities, which would enable better business planning for participants in the rationalized fishery. As described elsewhere, the trawl rationalization program could create an incentive structure and facilitate more comprehensive monitoring to allow bycatch reduction and effective management of the groundfish fisheries. In support of the trawl rationalization program, the main socioeconomic impact of Amendment 21 allocations is longer-term stability for the trawl industry. While the preferred Amendment 21 allocations do not differ significantly from status quo ad hoc allocations made biennially, there is more certainty in future trawl harvest opportunities, which enables better business planning for participants in the rationalized fishery. This is the main purpose for the Amendment 21 actions.

The economic effects of Amendment 21 arise from the impacts on current and future harvests. The need to constrain groundfish harvests to address overfishing has had substantial socioeconomic impacts. The groundfish limited entry trawl sector has experienced a large contraction, spurred in part by a partially federally subsidized vessel and permit buyback program implemented in 2005. This $46 million buyback program was financed by a congressional appropriation of $10 million and an industry loan of $36 million. About 240, groundfish, crab, shrimp permits were retired from state and Federal fisheries—there was a 35 percent reduction in the groundfish trawl permits. To repay the loan, groundfish, shrimp and crab fisheries are subject to landings fees. Follow-on effects of the buyback have been felt in coastal communities where groundfish trawlers comprise a large portion of the local fleet. As the fleet shrinks and ex-vessel revenues decline, income and employment in these communities is affected. Fishery-related businesses in the community may cease operations because of lost business. This can affect non-groundfish fishery sectors that also depend on the services provided by these businesses, such as providing ice and buying fish. An objective to the trawl rationalization program is to mitigate some of these effects by increasing revenues and profits within the trawl sector. However, because further fleet consolidation is expected, the resulting benefits are likely to be unevenly distributed among coastal communities. Some communities may see their groundfish trawler fleet shrink further as the remaining vessels concentrate in a few major ports.

Species subject to Amendment 21's allocations would be lingcod, Pacific cod, sablefish south of 36° N. lat., Pacific ocean perch, widow rockfish, chilipepper rockfish, splitnose rockfish, yellowtail rockfish north of 40° 10' N. lat., shortspine thornyhead (north and south of 34° 27' N. lat.), longspine thornyhead north of 34° 27' N. lat., darkblotched rockfish, minor slope rockfish (north and south of 40° 10' N. lat.), Dover sole, English sole, petrale sole, arrowtooth flounder, starry flounder, and Other Flatfish. While the preferred Amendment 21 allocations of these species do not differ significantly from status quo ad hoc allocations made biennially, there is more certainty in future trawl harvest opportunities, which enables better business planning for participants in the rationalized fishery. This is the main purpose for the Amendment 21 actions.

Amendment 21 would formally allocate a subset of the harvest guideline to the four trawl sectors: SS (whiting and non-whiting), mothership, catcher vessel, and catcher-processor. With to the species subject to Amendment 21's allocations, this would leave the limited entry fixed gear, open access, and recreational fisheries in a pool that would divide the remaining HG (via the biennial specification process). [The open access component of the groundfish fishery consists of fishermen who target groundfish without limited entry permits and fishermen who target non-groundfish fisheries that incidentally catch groundfish.] In general, the allocations are based on catch history from 2003 to 2005 and the recommendations of the Groundfish Allocation Committee. The Council believed that a relatively recent catch period should form the basis for deciding sector allocations since discards during this period were better informed, and current management strategies, such as specification of rockfish conservation areas, are more likely in the near future. However, the Council made modifications for several species. For chilipepper rockfish south of 40º10' N. lat., Amendment 21 contains a higher non-trawl allocation. This is intended to provide greater non-trawl access to this healthy stock off California. Amendment 21 would not allocate longspine thornyhead south of 34° 27' N. lat. to the trawl fishery. Longspine thornyhead are an incidentally caught species south of 34° 27' N. lat., and the available yields are not projected to constrain any of the groundfish fisheries there that incidentally catch these fish. Amendment 21 would allocate a much higher percentage of the available yield of starry flounder to non-trawl sectors (50 percent) than recommended by the Groundfish Allocation Committee. The catch history of starry flounder is highly uncertain, but they are significantly caught in nearshore trawl fisheries and recreational fisheries on the West Coast. The Council thought a 50:50 trawl and non-trawl sharing of the available harvest of starry flounder was the fairest allocation. Amendment 21 includes a higher non-trawl allocation of species in the Other Flatfish complex than recommended by the Groundfish Allocation Committee (10 percent vs. 5 percent). While most of these species are dominant to the trawl fishery, there are some species, such as Pacific sanddabs, that are significantly caught in non-trawl fisheries. The Council believed a higher non-trawl share of the available harvest of Other Flatfish species would better preserve non-trawl fishing opportunities.

Based on ex-vessel revenue projections, Table 4-18 (ISADEIS) shows the potential 2010 yield to trawl and non-trawl (including recreational) sectors under the Amendment 21 alternatives and the potential 2010 value of alternative trawl allocations. Under the no action alternative, the projected ex-vessel value of the trawl allocation is $56 million, while the projected ex-vessel value of the Council's preferred alternative is $54 million—indicating a potential increase to the non-trawl sectors and a potential decrease to the trawl sector.

In addition to the species above, halibut would also be specifically allocated to the trawl fishery. The proposed regulations include a halibut trawl bycatch reduction program in phases to provide sufficient time to establish a baseline of trawl halibut bycatch and to allow harvesters to explore methods (e.g., adjustments to time and/or area fished, gear modifications) to reduce halibut bycatch and bycatch mortality. Pacific halibut cannot currently be retained in any U.S. or Canadian trawl fisheries per the policy of the IPHC. The Council's intent on setting a total catch limit of Pacific halibut in Area 2A trawl fisheries is to limit the bycatch and progressively reduce the bycatch from these limits to provide more benefits to directed halibut fisheries. The program establishes a limit for total Pacific halibut bycatch mortality (legal-size and sublegal fish) by using an IBQ in the trawl fishery. The initial amount for the first two years of the trawl

rationalization program would be calculated by taking 15 percent of the Area 2A total constant exploitation yield (CEY) as set by the International Pacific Halibut Commission (IPHC) for the previous year not to exceed 130,000 lbs per year for total mortality. For example, if the trawl rationalization program went into effect in 2013, the trawl halibut IBQ would be set at 15 percent of the Area 2A CEY adopted for 2012 or 130,000 lbs per year, whichever is less, for 2013 and 2014 (years one and two of the program). Beginning with the third year of implementation, the maximum amount set aside for the trawl rationalization program would be reduced to 100,000 lbs per year for total mortality. This amount may be adjusted downward through the biennial specifications process for future years.

Currently there are no total catch limits of Pacific halibut specified for the west coast trawl fishery. Trawl bycatch of Pacific halibut, therefore, does not limit the trawl fishery. It would apply a halibut bycatch reduction program in phases to provide sufficient time to establish a baseline of trawl halibut bycatch under the new rationalization program and for harvesters to explore methods (e.g., adjustments to time and/or area fished, gear modifications) to reduce both halibut bycatch and bycatch mortality. By limiting the bycatch of Pacific halibut in the limited entry trawl fisheries, Amendment 21 would control bycatch and could provide increased benefits to Washington, Oregon, and California fishermen targeting Pacific halibut. Reducing the trawl limit would also provide more halibut to those who participate in the directed tribal, commercial, and recreational halibut fisheries.

The Council's preferred alternative uses a halibut-abundance-based method for setting the initial trawl allocation by keeping it tied to a percentage of the CEY, but adds a maximum limit on the allocation amount. The initial limit is set at 130,000 lbs, which represents an approximate reduction of 50 percent from the total bycatch estimate provided by the Northwest Fisheries Science Center for the most recent year (2007) If the proposed regulations were applied to the total CEY in 2007 and compared to the actual mortality recorded for 2007, the trawl fishery would find itself about 20,000 lbs short. Similarly, if these regulations were applied in 2008 and 2009, the amount of halibut allocated to the trawl sector would fall short of actual harvests by 204,000 and 161,000 pounds, respectively.

The Council decided to apply the 130,000-pound limit over a four-year period to give the trawl industry more time to learn strategies (and areas) for minimizing their Pacific halibut bycatch. Since this may become the most constraining bycatch species for the rationalized trawl fishery on the northern shelf, this extra adjustment period before the further downward modification of the total catch limit to 100,000 pounds is considered for the fifth year. Additionally, allowing more flexibility for considering a new total catch limit of Pacific halibut in future processes to decide biennial management measures was considered necessary because the limit is lower than the bycatch observed under the WCGOP, and it was unclear how such a stringent limit might affect the fishery. It may turn out that the socioeconomic impacts are too great under these stringent limits, and the Council may ultimately decide to increase the total catch limit. Conversely, the trawl industry may adjust well to these lower limits, and the realized bycatch of Pacific halibut will be lower than the prescribed total limits of 130,000 or 100,000 pounds. In that case, the Council may want to adjust the future total catch limit downward from 100,000 pounds to provide more benefits to Area 2A directed halibut fisheries. In either case, the Council preferred the flexibility of deciding future total catch limits of Pacific halibut in the biennial

specifications and management measures process to avoid a more lengthy and burdensome FMP amendment process for making these decisions. Reducing the maximum limit to 100,000 lbs beginning the third year of the program provides an additional incentive for harvesters to modify their fishing behavior to reduce bycatch and/or bycatch mortality. Information from the Canadian IFQ program indicates that trawl fishermen can voluntarily implement measures to reduce bycatch by avoiding areas known to produce high volumes of halibut, and reduce bycatch mortality by reducing their tow time. Reducing the trawl limit would also provide more halibut to those who participate in the directed tribal, commercial, and recreational halibut fisheries.

If the total CEY from the stock assessment prior to trawl rationalization implementation reflected relatively low abundance (e.g., 640,000 lbs), this would produce an initial trawl allocation of 96,000 lbs. While this is considerably less than what the trawl fishery has caught in previous years, it would also be applied to an exploitation yield lower than what Area 2A has experienced in the past 10 years. This helps ensure that the primary use of halibut is to provide fish for the directed tribal, commercial, and recreational fisheries. If abundance were higher and along the lines of the amounts produced by the 2004 and 2005 assessments (e.g., more than 1 million lbs), the trawl allocation would be capped at 130,000 lbs.

When the Canadian government rationalized its British Columbia groundfish fishery in 1996, an arbitrary cap of 1 million pounds was set for halibut bycatch mortality in that trawl fishery. Halibut bycatch mortality before prior to rationalization was about 1.5 million pounds. The first year of the quota program, halibut bycatch mortality was reduced to about 300,000 pounds. Several factors were the decline of the cod fishery (and a decline in associated halibut bycatch), harvester avoidance behavior, and 100 percent observer coverage, combined with slower fishing practices that allowed the observer to measure every halibut caught and released. Information from the Canadian IFQ program indicates that trawl fishermen can voluntarily implement measures to reduce bycatch by avoiding areas known to produce high volumes of halibut and can reduce bycatch mortality by reducing their tow time (which prevents halibut from being crushed in the trawl cod end).

General Effects of Amendment 21 Trawl Rationalization

The focus of the remaining economic analysis is on the effects of rationalization of the Pacific Coast groundfish limited entry trawl fishery. Below is a summary of the incremental differences (in economic terms) between the proposed action and no action alternative discussed in these draft environmental impact statements. The economic analysis in Chapter 4 of the Amendment 20 FEIS relies predominantly on available fish ticket information (landings and revenues). Section 4.2.1.3 notes the following data limitations:

- Cost and earnings data for individual harvesters are available only for a single year.
- Cost and earnings data for individual processors are unavailable.
- Comprehensive primary data on processed products and product prices are unavailable.
- Final market demand for groundfish products is not well known.
- Data showing the total catch (landings plus discard) of groundfish by individual vessels is unavailable.

Because of the lack of quantitative data, an overall comprehensive model was not feasible. Instead, a set of models designed to focus on specific issues was developed, or are already available. These include the following:

- A model showing the effects of the initial allocation of QS in a trawl IFQ program
- A model assessing the expected amount of fleet consolidation
- A model illustrating the potential for geographic shifts in fishery patterns
- A model illustrating the potential to reduce the catch rate of overfished species and the associated potential for increased target species catch and revenue
- A qualitative comparative advantage model illustrating the potential for regions to be negatively or positively impacted by rationalization
- Available stock assessments showing stock abundance over time under various harvested quantities
- An ecosystem-based model describing the impact on the biological and ecosystem components of the environment resulting from changes in fishing behavior and catch

To illustrate the benefits of the TIQ program, a model projecting the expected amount of fleet consolidation in the shoreside non-whiting fishery was developed. It incorporates the model that illustrates the potential for the fleet to reduce bycatch and potentially increase the amount of target species harvested. This later model is based primarily on bycatch reduction experiences in the Pacific whiting fishery and as carried out in the arrowtooth flounder fishery under an exempted fishing permit. The major conclusions associated with both these models are provided below.

Consolidation under the alternatives will be a key impact mechanism. This model provides projections of consolidation in the fishery and the effects of that consolidation. The model is based on work published by Weninger and Waters (2003).

Ex ante benefit estimates (estimates prior to the action) are obtained by using a two-step methodology. The first step predicts the harvesting practices expected to prevail under an IFQ system. This first step will predict post-QS allocation equilibrium harvesting practices including the folloiwng:

- Groundfish harvest per vessel
- Number of vessels needed to harvest limited entry trawl groundfish catch
- Which vessels remain in the groundfish fishery and which vessels exit
- Nongroundfish harvest per vessel

The model is designed to address the fact that trawlers harvest many species (multiple outputs). It uses fish ticket data and the data from the recently completed West Coast Limited Entry Cost Earnings Survey sponsored by the NMFS Northwest Fisheries Science Center.

Estimates of potential economic benefits are generated based on the predicted harvesting practices from the first step analysis. Because the west coast nonwhiting groundfish fishery is not a derby fishery, it is expected that economic benefits will come through cost reductions and increased access to target species that arise from modifications in fishing behavior (overfished species avoidance). The key output of this analysis is an estimate of post-rationalization equilibrium harvesting cost.

Changes in harvesting costs can arise from three sources. First, the total fixed costs incurred by the groundfish trawl fleet change as the size of the fleet changes. Since many limited entry trawlers incur annual fixed costs of at least $100,000, reductions in fleet size can result in substantial cost savings. In other words, fewer vessels in the fishery will lead to decreased costs through a decrease in annual fixed costs. Second, costs may change as fishery participation changes and participants no longer incur diseconomies of scope (such as the costs of frequently switching gear for participating in multiple fisheries). Third, costs may change as vessels are able to buy and sell quota to take advantage of economies of scale and operate at the minimum point on their long-run average cost curve (i.e., the strategy that minimizes the cost of harvesting).

Using the model developed through this project, it is possible to compare the following:

- Harvesting costs under the current regulatory system
- Harvesting costs under an "unconstrained" IFQ system
- Harvesting costs under an IFQ system where fleet rationalization is constrained through program design features such as quota accumulation caps

The major finding associated with this model and the cost-earnings survey is the following:

> Net revenues for nonwhiting trawl vessels were estimated by Lian, Singh, and Weninger in 2008 (Lian et al. 2008). Estimates of net revenues were generated using a cost earnings survey conducted by the Northwest Fisheries Science Center that collected cost data from trawlers operating in 2004. These cost earnings data were matched with PacFIN fish ticket data to derive estimates of net revenue generated by vessels active in the fishery during 2004.

The major conclusions of Lian, Singh, and Weininger are the following:

> Our results suggest that (with landings held at 2004 levels), the current groundfish fleet (non-whiting component) which consisted of 117 vessels in 2004, will be reduced by roughly 50% to 66% to 40-60 vessels under an IFQ program. The reduction in fleet size implies cost savings of $18- $22 million for the year 2004 (most recent year of the data). Vessels that remain active will, on average, be more cost efficient and will benefit from economies of scale that are currently unexploited under controlled access regulations in the fishery. The cost savings estimates are significant, amounting to 60% of the costs incurred currently, suggesting that IFQ management may be an attractive option for the Pacific Coast

> Groundfish Fishery. We find that mid-sized boats, 60—70 feet in length , are relatively cost efficient and therefore most likely to remain active under the IFQ management of the program; smaller (40-50 feet) and larger vessels (80 feet and above) are likely to leave the fishery. ….(Liann, et al, 2008 page 330)
>
> Our analysis reveals, however, that projected cost savings are sensitive to the design elements of the IFQ program. In particular, we show that restrictions on the total quota that can be harvested by individual vessels, or restrictions on quota trading across vessel length classes, can significantly reduce estimated benefits (cost savings) of switching to IFQs. Our estimates suggest that benefits decline by roughly $3.8 million (18.4%) per year if a 1% cap on quota ownership at the vessel level is imposed, and by as much as $2.14 million (10.4%) per year under restrictions on harvest permit trading across vessel classes. (page 330).
>
> Further calculations provide additional insights on the economic conditions under controlled access regulations. Assuming a 10% annual return to the vessel capital investment, estimates indicate that the 2004 groundfish fleet incurred a total cost of $38.789 million. The PacFIN data indicate fleetwide revenue at roughly $36.275 million in 2004, and, therefore, fleet wide losses of $2.514 million. Based on a lower 5% return to vessel capital, the results suffets that the groundfish fleet merely broke even in 2004; i.e., dockside revenues were offset by the fleet wide harvesting costs….(page 337).
>
> The results suggest a switch from the current controlled access management program to IFQs could yield a significant increase in resource rents in the Pacific Coast Groundfish fishery. For instance, our analysis finds that the 2004 groundfish catch generated zero resource rent. Instead, it could have yielded a substantial positive rent at $13.574 million (page 340).

The Council's analysis draws upon the conclusions of Lian et al., presented below:

> These estimates indicate that the average nonwhiting trawl vessel makes zero economic profit. Simply put, zero economic profit means that there are no profits being generated in the fishery above what would be considered a normal wage plus the costs of operating and maintaining a vessel. While the average vessel makes close to zero economic profit, some vessels do make profits while others may actually lose money and would be better off (financially speaking) leaving the fishery (*Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS,page 128 FEIS*).
>
> Indeed, research by Lian, et al. (2008), indicates the nonwhiting trawl fleet may be overcapitalized by more than 50 percent (*Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*), page 273 FEIS.
>
> Based on results from Lian et al. (2008), harvesters in the nonwhiting sector generate no economic profit from harvest activity. While it is unclear whether

processors generate any economic profit from processing of nonwhiting groundfish, it is clear that if profits exist in the industry, harvesters are not realizing those profits. This suggests that, if profits exist in the harvesting and processing of nonwhiting groundfish, harvesters lack much bargaining power in negotiations over ex-vessel prices with processors (*Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS, page 276*).

In addition to increased revenue being generated in the fishery, the consolidation likely to occur in the nonwhiting sector is expected to lead to substantial cost savings. Cost savings occur because of less capital, but also because the fleet is expected to consolidate toward the most efficient vessels. The fleet reduction and cost efficiency model shows the consolidation that may occur could diminish the number of vessels by 50 to 66 percent, or to a nonwhiting fleet size that is somewhere on the order of 40 to 60 vessels. This predicted cost savings is fairly sensitive to the design elements of the program and is also dependent on the quantity of species harvested. This consolidation is predicted to decrease costs of harvesting nonwhiting groundfish by as much as 60 percent annually (before incorporating the cost of at-sea monitoring). Using information from recent years, this may mean a cost savings of approximately $13.8 million. Imposing accumulation limits can restrict the amount of expected cost savings substantially. Retaining the vessel length endorsement may restrict cost savings by 10 percent, though this may be lower since harvesters can bundle permits and change the length endorsement. If a 1 percent accumulation limit is placed on vessels, cost reductions may be restricted by approximately 20 percent.[2] At-sea monitoring costs add an additional cost burden to vessels that is not currently incurred. If at-sea monitors cost vessels $350 per day, this may tend to reduce the size of the fleet from the 40 to 60 vessels expected and increase the average size of vessels remaining. This is because additional costs of fishing will mean the optimal fleet size is smaller. The average size of vessels in the fleet is increased with a daily observer cost because such costs comprise a larger portion of small vessels costs than that of larger vessels. At-sea observers will also reduce fleet-wide profits. The fleet reduction and cost efficiency model illustrates that at-sea observers may cost the nonwhiting fleet $2.2 million if all vessels in the fishery operate near capacity (*Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS, page 290*).

Section 4.6.2.1, *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS,* describes the major benefits of the trawl rationalization for shorebased non-whiting fishery, excerpted below:

Trawl harvesters in the nonwhiting sector may be substantially affected by the rationalization of the west coast trawl fishery. The individual accountability measures and harvesting privileges associated with the rationalization alternatives are likely to induce substantial changes in the

2 The lowest accumulation limit in the alternatives of 3 percent is not expected to impose cost inefficiencies on the nonwhiting trawl sector so long as prices and available harvest volumes do not decrease.

way vessels prosecute fishing activities. In the nonwhiting trawl fishery, substantial impacts are likely to occur because of the constraining nature of overfished species and the perceived reward that is associated with avoiding those stocks that may come in the form of increased catch of target species, which are currently underutilized because of weak stock management. The bycatch rate change model is used to show the amount of additional target species that can be leveraged as the nonwhiting trawl fleet reduces encounters with overfished species. The output of this model indicates that the fleet may generate severalmillion dollars in additional ex-vessel revenue under a rationalization program compared to Alternative 1 activity if ex-vessel prices remain constant.

Increased profits and fleet consolidation

Some of the expected increase in ex-vessel revenue is likely to occur almost immediately after the fishery is rationalized. However, the fleetwide estimates are best perceived as a longer-term outcome of rationalization that will occur as the fleet modifies gears and fishing location, the flow of quota through the market occurs in a way so that it reaches the more successful vessels, and processing companies find buyers for the potential increase in product quantity. This is likely to be a gradual effect where ex-vessel revenue increases over time before reaching full potential. The length of time it takes for the increased harvest volume to be absorbed by the processing sector may also depend on the number of processing entities harvesters have the opportunity to sell their catch to. The requirement that the entire catch be off-loaded at a single processor restricts—to some degree—the number of processing companies that harvesters deliver to. By relaxing this requirement, harvesters may be able to sell their catch to more than one buyer at a time, and if these buyers have relatively different access to markets, being able to sell catch to more than one buyer will make it more likely that an increase in catch can be absorbed by the market more quickly.

Figure 4-7 illustrates the potential range of ex-vessel revenues in the nonwhiting trawl fishery generated under a rationalization program compared to Alternative 1 if ex-vessel prices remain unchanged. The range of values presented is meant to bracket the range of uncertainty within the model while still providing realistic estimates. The uncertainty presented in this figure does not capture the risk posed by thin market conditions that may be present in an IFQ program because of species with low trawl allocations.

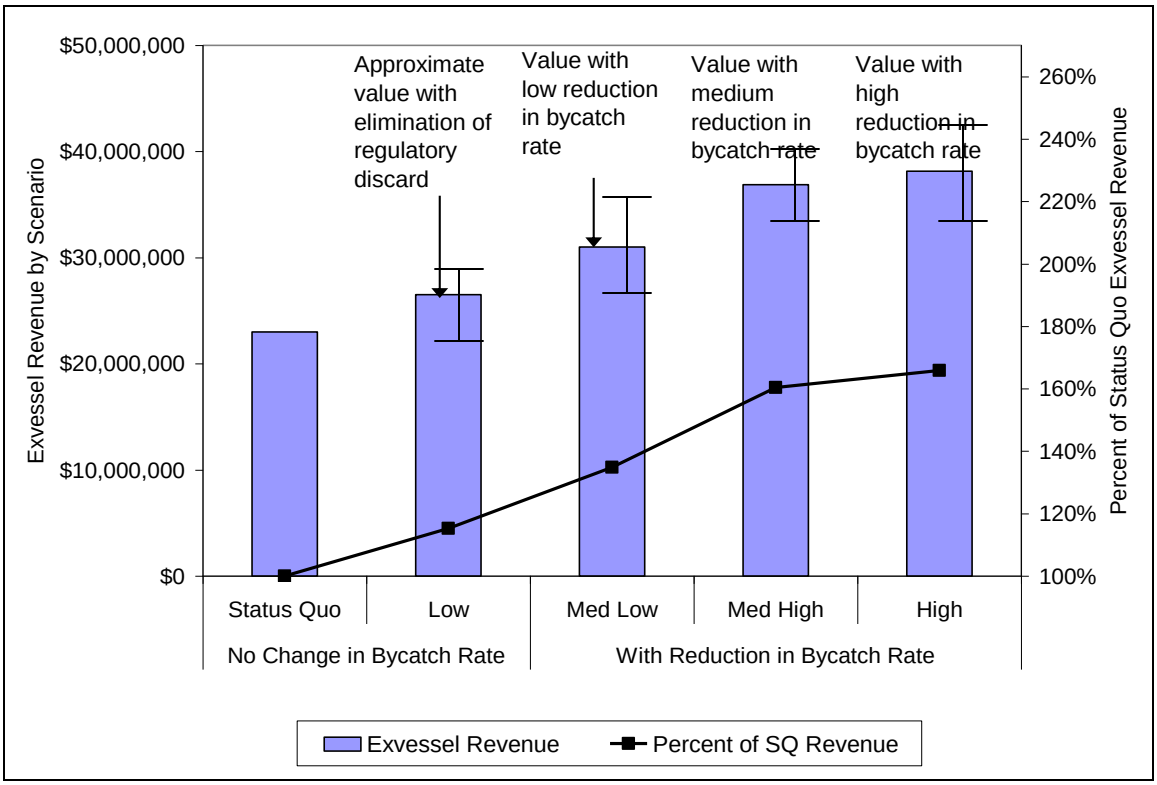


Figure 4.7. Potential ex-vessel revenue in the nonwhiting trawl fishery under rationalization.
Note: Bars are intended to represent uncertainty due to potential variations in ABCs and OYs.

In addition to increased revenue being generated in the fishery, the consolidation likely to occur in the nonwhiting sector is expected to lead to substantial cost savings. Cost savings occur because of less capital, but also because the fleet is expected to consolidate toward the most efficient vessels. The fleet reduction and cost efficiency model shows the consolidation that may occur could diminish the number of vessels by 50 to 66 percent, or to a nonwhiting fleet size that is somewhere on the order of 40 to 60 vessels. This predicted cost savings is fairly sensitive to the design elements of the program and is also dependent on the quantity of species harvested. This consolidation is predicted to decrease costs of harvesting nonwhiting groundfish by as much as 60 percent annually (before incorporating the cost of at-sea monitoring). Using information from recent years, this may mean a cost savings of approximately $13.8 million. Imposing accumulation limits can restrict the amount of expected cost savings substantially. Retaining the vessel length endorsement may restrict cost savings by 10 percent, though this may be lower since harvesters can bundle permits and change the length endorsement. If a 1 percent accumulation limit is placed on vessels, cost reductions may be restricted by approximately 20 percent.3 At-sea monitoring costs add an additional cost burden to vessels that is not currently incurred. If at-sea monitors cost vessels $350 per day, this may tend to reduce the size of the fleet from the 40 to 60 vessels expected and increase the average size of vessels

3 The lowest accumulation limit in the alternatives of three percent is not expected to impose cost inefficiencies on the nonwhiting trawl sector so long as prices and available harvest volumes do not decrease.

remaining. This is because additional costs of fishing will mean the optimal fleet size is smaller. The average size of vessels in the fleet is increased with a daily observer cost because such costs comprise a larger portion of small vessels costs than that of larger vessels. At-sea observers will also reduce fleet-wide profits. The fleet reduction and cost efficiency model illustrates that at-sea observers may cost the nonwhiting fleet $2.2 million if all vessels in the fishery operate near capacity. If some relatively marginal producers remain in the fishery, the cost will be higher. Table 2 illustrates the effect of various factors on profitability.

Table 2. Factors affecting profitability.

Effect of Consolidation	Improves harvesting cost efficiency. May allow the fleet to realize profits of ~$14 to $23 million compared to $0 or less under Alternative 1.
Effect of Accumulation Limits	No effect unless vessel limit is smaller than ~2.5 percent. A 1 percent vessel limit restricts potential cost efficiency by ~20 percent
Effect of Permit Length Endorsement	Restricts cost efficiency by ~10 percent, or imposes costs of ~$1.5 to $3 million[a]
Effect of At-Sea Observers	Increases average vessel size slightly. Decreases fleet size slightly. May reduce profits by ~$2.2 million depending on fee structure.

a) This estimate was modeled based on the idea that QS would be restricted from trading across vessel size classes. That restriction is not part of the options contained in the existing alternatives. Therefore, this estimate does not apply to the existing alternatives for rationalization of the trawl fishery.

Figure 4-8 shows potential fleet-wide profit if all vessels are operating at their most cost effective point. The results in this figure use the fleet-wide revenue estimates shown above in conjunction with the cost-savings and consolidation model. The results show profit under unconstrained cost conditions, profit with a vessel length restriction (i.e., retaining the permit length endorsement), and profit with a vessel length restriction and at-sea observers. Although not shown in the figure, for reference purposes Alternative 1 profits in the fleet are estimated to be between zero and a loss of approximately $2 million annually.

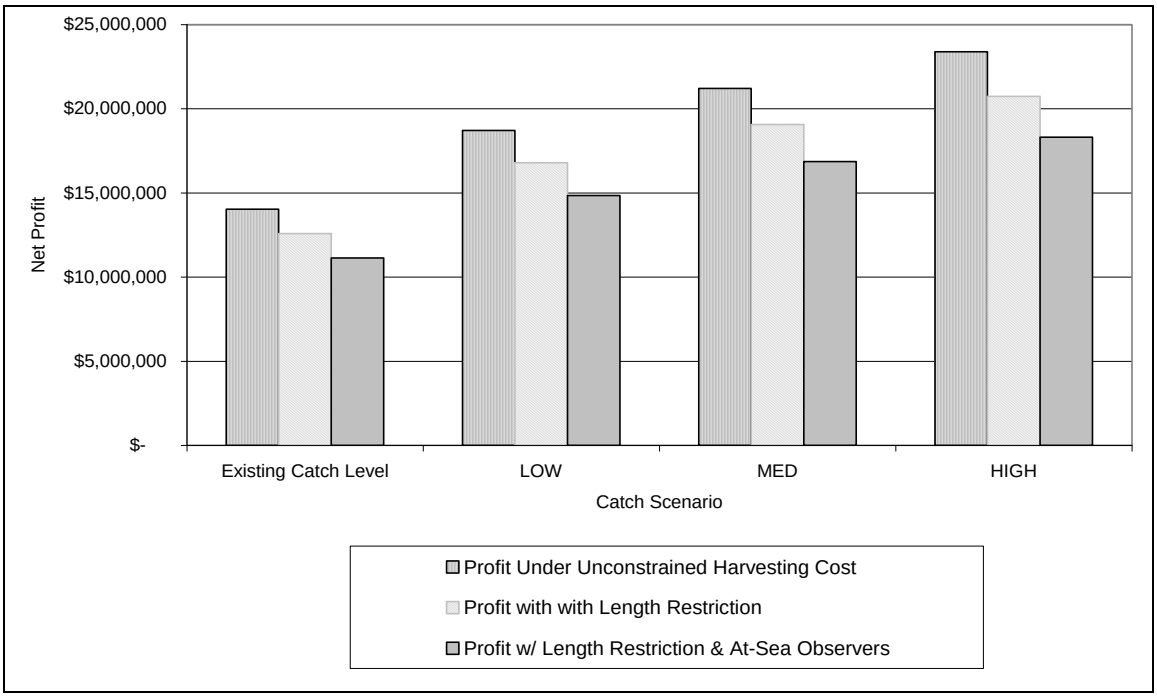

Figure 4-8. Estimated fleetwide profit in a rationalized nonwhiting trawl fishery.

The above information shows that when potential cost savings are combined with the projected increase in gross revenue displayed in Figure 4-7, actual revenues to catcher-vessels and permit holders may increase by several million. Empirical evidence from other programs suggests that consolidation and the associated cost savings could occur quite rapidly after the fishery is rationalized.

The consolidation and cost efficiency model shows that the most efficient vessels for harvesting nonwhiting trawl groundfish are approximately 60 to 70 feet in length. Smaller vessels tend to be limited by the effectiveness of harvest capacity per vessel size while larger vessels tend to operate in an area where costs are increasing more rapidly per scale compared to harvest effectiveness. Vessels that are larger or smaller may find it more profitable to sell QS and leave the fishery rather than remain in the fishery.

Current Status of the Fishery—Changes Since 2004

This discussion is in addition to the information provided in the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. As the "Consolidation" model is based on the fishery, it may be useful to provide current trends in the fishery. [The indicators below are landings, ex-vessel prices, and revenues from PacFIN, fuel prices collected by PSMFC, and U.S. export prices for whiting and sablefish shipped from the Seattle Customs District. PacFIN data include tribal harvests and revenues.]

In 2004, the shorebased non-whiting trawl fishery generated about $30 million in ex-vessel revenues. But according to NWFSC cost estimates, this fishery was at best breaking even or perhaps suffering a loss of up to $2 million.

Since 2004, shorebased non-whiting trawl fisheries have increased their revenues to about $40 million

The increases in shorebased revenues have come from increased landings of flatfish and sablefish and significant increase in sablefish ex-vessel prices. Sablefish now accounts for almost half of the trawl fleet's revenues.

While revenues were increasing so were fuel prices. Fuel costs are about 30 to 40% of the vessels revenues (Table 4-43 DEIS). The average 2005-2009 revenues were about $28 million—22 percent greater than of 2004. The average 2005-2009 fuel price was about $2.81—70% greater than that of 2004. Therefore, it appears that 2009 fishery may not be that much improved over that of 2004.

The indicators below also show the growth in whiting revenues due to increased landings and ex-vessel prices stimulated by high export prices. Note that after reaching a peak in 2008 of $0.11 per lb in 2008, the 2009 price for whiting has fallen to $0.05 per lb in 2009.

Non-whiting Trawl Sector: In summary, ex-vessel revenues for the non-whiting sector of the limited entry trawl fishery are estimated to be approximately $30 to 50 million per year under the preferred alternative compared to $22 to 25 million under the no action alternative. This revenue increase is expected to occur in a rationalized fishery because target species quotas can be more fully utilized. Currently, in the non-whiting sector, cumulative landing limits for target species have to be set lower because the bycatch of overfished species cannot be directly controlled. Introducing accountability at the individual vessel level by means of IFQs provides a strong incentive for bycatch avoidance (because of the actual or implicit cost of quota needed to cover bycatch species) and prevents the bycatch of any one vessel from affecting the harvest opportunity of others. In addition, under the preferred alternative, the non-whiting sector would have control over harvest timing for the whole calendar year. Under the no action alternative, the non-whiting sector would continue to operate under two-month cumulative landing limits, which reduce flexibility within a two-month period (because any difference between actual limits and the period limit cannot be carried over to the next period). Finally, the ability for vessels managed under IFQs to use other types of legal groundfish gear could allow some increases in revenue by targeting higher-value line- or pot-gear-caught fish. This opportunity would mainly relate to sablefish, which are caught in deeper water, rather than nearshore species where state level regulatory constraints apply.

The preferred alternative may also increase ex-vessel revenues of non-whiting trawl harvesters by changing their bargaining power with processors over ex-vessel prices. Under the preferred alternative, the current two-month cumulative limits structure of the non-whiting trawl fishery would be replaced with QS that is available for a year, thereby extending the time horizon harvesters have to negotiate prices with processors without losing available fishing opportunity. The extended period would give harvesters greater latitude to hold out for better prices compared to the no action alternative. However, it should also be noted that these negotiations will also be affected by the availability of target species, as well the availability of bycatch.

Costs for the non-whiting sector of the limited entry trawl fishery are expected to decrease under the preferred alternative because of productivity gains related to fleet consolidation. Productivity gains would be achieved through lower capital requirements and a move to more efficient vessels. Operating costs for the non-whiting sector are predicted to decrease by as much as 60 percent annually. Based on estimates of current costs, this percentage decrease represents a $13.8 million cost reduction relative to the no action alternative.

The accumulation limits considered under the preferred alternative are not expected to introduce cost inefficiencies in the non-whiting sector, provided that current prices and harvest volumes do not decrease. However, the preferred alternative would impose new costs on the non-whiting sector that would not be incurred under the no action alternative. First, a landings fee of up to 3 percent of the ex-vessel value of fish harvested would be assessed under the preferred alternative to recover management costs, such as maintenance of the system of QS accounts. Second, new at-sea observer requirements would be introduced, and vessels would have to pay the costs of complying with these requirements, estimated at $500 a day if independent contractors are hired. The daily observer cost could place a disproportionate adverse economic burden on small businesses because such costs would comprise a larger portion of small vessels costs than that of larger vessels.

The increase in profits that commercial harvesters are expected to experience under the preferred alternative may render them better able to sustain the costs of complying with the new reporting and monitoring requirements. The improved harvesting cost efficiency under the preferred alternative may allow the non-whiting sector to realize profits of $14 million to $23 million compared to zero or less under the no action alternative. In addition, a provision that allows vessels managed under the IFQ program to use other legal gear (gear switching) would allow sablefish allocated to the trawl sector to be sold at a higher price per pound, possibly contributing to increased profits. The imposition of accumulation limits could reduce the expected increase in the profitability of the non-whiting sector by restricting the amount of expected cost savings, and the costs of at-sea observers may reduce profits by about $2.2 million depending on the fee structure. However, the profits earned by the non-whiting sector would still be substantially higher under the preferred alternative than under the no action alternative.

New entrants are likely to face a barrier to entry in the Pacific Coast groundfish limited entry trawl fishery in the form of the cost of acquiring QS (or a co-op share in the case of the at-sea whiting sector). This disadvantages them compared to those entities that receive an initial allocation of harvest privileges. Small entities may be particularly disadvantaged to the degree that they may find it more difficult to finance such quota purchases than larger-scale harvesters. Among the goals the Council identified for the adaptive management program was using the reserved non-whiting QS to facilitate new entry into the fishery. In addition, as a trailing action, the Council identified a framework to allow the establishment and implementation of community fishing associations as part of the adaptive management program. These entities could facilitate entry into the fishery by leasing QS at below market rates, thereby leveling the playing field in terms of costs between initial recipients of QS and new entrants.

Whiting Sector. While the effect of the preferred alternative on revenues and costs in the whiting sector of the limited entry trawl fishery is more difficult to estimate, the lower motivation to "race for fish" due to co-op harvest privileges is expected to result in improved product quality, slower-paced harvest activity, increased yield (which should increase ex-vessel prices), and enhanced flexibility and ability for business planning. The overall effect of these changes would be higher revenues and profits for harvesters in the shoreside and mothership portions of the whiting fishery compared to the no action alternative. Under the preferred alternative, some consolidation may occur in the shoreside and mothership sectors of the Pacific whiting fishery, though the magnitude of consolidation is expected to be less than in the non-whiting sector. The existing catcher-processor co-op would continue under the preferred alternative, with effects on the catcher-processor sector that look similar, or identical, to those of the no action alternative. However, the change from a vessel-restriction under Amendment 15 to the permit-based limit of Amendment 21 will provide additional flexibility that currently does not exist in the whiting fishery.

Trawl Groundfish Processors. The incremental effects of the preferred alternative on buyers and processors of trawl-caught groundfish are detailed Sections 4.9 and 4.10 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. Even though processors may have to pay fishermen higher ex-vessel prices, processors may see cost savings under the preferred alternative to the degree that rationalization allows greater control over the

timing and location of landings. Processors could use current plant capacity more efficiently, because available information suggests that processing facilities are currently underutilized. Fleet consolidation in the non-whiting sector could also provide cost savings for processors if landings occur in fewer locations, thereby reducing the need for facilities and/or transport. The preferred alternative would also impose new costs on processors that would not be incurred under the no action alternative. Processors would be required to pay some or all of the costs of plant monitors, who would verify landings. Similar to at-sea observers, these monitors would be independent contractors rather than direct employees of the processing firm.

In the non-whiting processing industry, harvest volumes may increase because of a decrease in constraining species bycatch and a subsequent increase in underutilized target species catch. This boost in target species catch may increase utilization of processing capital and processing activity. [It should be noted that if bycatch has been underreported under the current system, with 100 percent observer coverage under the new system, the gains in increased target catches may be less than expected.] Consequently, the possibility of capital consolidation in the non-whiting shoreside sector may be lower than in the shoreside whiting sector. However, shifts in the distribution of landings across ports as a result of fleet consolidation, industry agglomeration, and the comparative advantage of ports (a function of bycatch rates in the waters constituting the operational area for the port, differences in infrastructure, and other factors) could lead to consolidation in processing activity at a localized or regional scale and an expansion in processing activity elsewhere. To mitigate harm to adversely impacted shoreside non-whiting processors, the adaptive management provision provides a mechanism to distribute non-whiting QS to processors, thereby ensuring that some processors receive greater landings of groundfish than would otherwise be the case.

As noted above, the preferred alternative may reduce the power of shoreside non-whiting processors to negotiate ex-vessel prices with harvesters. The larger harvest volume due to bycatch avoidance may lower processor average costs, which could offset the negative effects on shoreside non-whiting processors of a shift in bargaining power. In addition, QS could be purchased by processors over the long term, thereby increasing processor's negotiation power. However, the accumulation limits included in the preferred alternative would limit the ability of processors to purchase substantial quantities of QS. Alternatively, the adaptive management provision could be used to allocate QS to shoreside non-whiting processors, thereby providing them additional leverage when negotiating terms with harvesters.

The allocation of 20 percent of the initial shoreside whiting QS to the shoreside processing portion of the whiting fishery would give these processors more influence in negotiations over ex-vessel prices and would tend to offset the gains in bargaining power for harvesters. For example, a processor could use QS to induce a harvester that is short of QP for a Pacific whiting to make deliveries under specified conditions and prices. However, because of a reduction in peak harvest volume, fewer processing companies and/or facilities may be necessary to handle harvest volumes of Pacific whiting, meaning some companies may find themselves without enough product to continue justifying processing operations of Pacific whiting.

The annual co-op declarations under the preferred alternative are expected to give motherships some certainty over delivery volumes from catcher vessels in the upcoming year, but little

leverage in negotiations over prices or profit sharing.

Captains and Crew. The incremental effects of the preferred alternative on the employment and safety of the captains and crew of limited entry trawl vessels are detailed in Section 4.7 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. The fleet consolidation expected to occur under the preferred alternative would result in a decrease in the number of captain and crew jobs; however, those who retain jobs in the fishery are expected to receive higher wages due to higher vessel profit margins. The increased financial ability of vessel owners to invest in safety equipment and conduct vessel maintenance, together with increased vessel operational flexibility, are anticipated to improve safety conditions on board trawl vessels.

Nontrawl Commercial Harvesters and Processors. The incremental effects of the preferred alternative on nontrawl commercial harvesters and processors are detailed in Section 4.8 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. Nontrawl harvesters include those targeting groundfish with other gear types and those that do not target groundfish. Since groundfish are an important part of Pacific coast landings, relatively few processors specialize exclusively in nongroundfish species. The preferred alternative may have a number of spillover effects on these harvesters and processors, including the following:

- Fleet consolidation and increased harvest timing flexibility may allow vessels in the non-whiting sector of the limited entry trawl fishery to be made available for use in nontrawl fisheries, increasing participation in those fisheries and adversely affecting the economic performance of nontrawl harvesters.
- Reduction in trawl catch of Pacific halibut (a prohibited species) allows more catch opportunity in target fisheries, thereby increasing ex-vessel revenues in the directed halibut fisheries.
- Gear switching to target sablefish with fixed gear under trawl quotas could increase competition on fishing grounds, a potential cost increase for nontrawl harvesters.
- If the fleet consolidation expected in the non-whiting sector under rationalization concentrates trawl landings in fewer ports, the loss of fishing-related port infrastructure could increase costs for nontrawl harvesters and processors in those ports.

Recreational Harvesters. The incremental effects of the preferred alternative on recreational harvesters are detailed in Section 4.5.3 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. Fleet consolidation in the non-whiting sector that is expected to occur under the preferred alternative could reduce the availability of fishing-related infrastructure in specific ports. It is, however, unlikely that this reduction would substantially affect the types of services and amenities upon which recreational harvesters depend (e.g., charter operations, boat ramps, bait suppliers, tackle shops) or the quality of the recreational fishing experience.

Fishing Communities. The FEIS describes the status quo of fishing communities as the following :

A summary of major themes presented in public testimony during the 2007-08 groundfish

specification process (PFMC 2006) includes comments on the following:

- The negative cumulative effects of both Federal regulations (such as closed areas, fathom restrictions, season restrictions, and VMS) and nonfederal actions (cable crossings, proposed state restrictions) on fisheries, businesses, and communities
- Crumbling infrastructure (processors, buyers, ice plants, and businesses that support processors closing or consolidating, docks and harbors not being maintained; market infrastructure collapsing);
- Recreational and commercial fishing vessels going out of business or being forced to diversify;
- Fishing-related businesses, such as gear stores, boat repair shops, tackle shops, and fishing equipment manufacturers, and nonfishing-related businesses, such as hotels, restaurants, and car dealerships, feeling the impacts of reduced fishing income, including laying off employees or closing
- Decreasing tax bases due to business closures
- Increasing social tensions in communities, such as psychological impacts, marital tension, divorce and suicide
- Difficulty in making business decisions and planning for the future
- Further dependence on groundfish due to salmon cutbacks

The fleet consolidation that is expected to occur under the preferred alternative, particularly in the non-whiting sector, could have a negative economic effect on some coastal communities where groundfish trawlers are an important component of the local fishing fleet (in terms of local purchases, not necessarily number of vessels). As the fleet size shrinks, the remaining vessels would concentrate in a few major ports. Income and employment in those communities that experience a decline in local fleet size could be adversely affected. Fishery-related businesses in the community may cease operations because of lost business. Smaller, specialized retailers (e.g., ice suppliers, ship chandlers, cold storage facilities, fuel docks) would be especially vulnerable to a decreased demand for fishing-related goods and services inputs. Businesses unrelated to fishing may also feel the impacts of reduced fishing income in the community. Some of these effects would be mitigated by the higher profits expected to be earned by trawl harvesters under the preferred alternative. However, because fleet consolidation is expected, the benefits of increased vessel profitability are likely to be unevenly distributed among coastal communities. Tracking and monitoring costs may affect ports with low landings or intermittent landings, as there may be logistical issues with deploying catch monitors and observers.

The table below summarizes the comparative advantage of non-whiting communities under the preferred alternative. Ports at a disadvantage from consolidation and geographic shift have a relatively inefficient fleet (vessels with a relatively long travel time to fishing grounds, those with relatively unsuccessful operators, costly vessels, and inefficiently sized vessels contribute to the "fleet efficiency" score in the table below), insufficient infrastructure, and are adjacent to fishing grounds with high constraining overfished species abundance ("bycatch dependence" in the table below). The table also includes a positive or negative score for "initial allocation of groundfish," as determined by the initial allocation estimates.

Table 3. Comparative advantage of non-whiting trawl communities under the preferred alternative.

Port	Fleet Efficiency Score	Bycatch Dependent Area Score	Shore-based Infrastructure	Initial Allocation of Groundfish	Score

*Small governmental jurisdiction based on Small Business Administration standard. No small governmental jurisdictions would be directly regulated by the proposed actions.
[†]Community that is "vulnerable" due to a high dependence on fishing activity and/or a relatively low resilience to change.

The adaptive management provision could be used to mitigate adverse impacts to communities, particularly ports with non-whiting processors. Directing the adaptive management quota to specific communities that have demonstrated harm, or a likely harm, could maintain fishing activity in a community that may otherwise stand to lose that activity. In addition, the preferred alternative includes other mechanisms that could mitigate adverse impacts to communities, such as a two-year moratorium on QS transfers, a five-year review that includes a community advisory committee, accumulation limits and a two-year review of some of the limits, the opportunity for communities to receive an initial QS allocation by acquiring a trawl permit, and a trailing action to establish community fishing associations.

The allocation of 20 percent of the initial shoreside whiting QS to the shoreside processing portion of the whiting fishery would give these processors more influence over the location of landings by enticing or directing harvests to existing plants even if the harvesters prefer to fish in other areas. However, consolidation in the processing sector is still expected to occur, and this consolidation of shoreside whiting processors will have an effect on communities.

Communities have been evaluated according to whether they are "dependent," "engaged," "resilient," or "vulnerable." Most studies use the term "dependence" to mean a community's use of a particular resource (for example, whiting or flatfish). "Engagement" is used to describe a community's use of a more general resource (for example, fisheries). The term "resilience" is

used to describe a community's ability to adapt to change. "Vulnerable" areas are communities that are either highly engaged or highly dependent and that have relatively low resilience.

This information is useful for considering impacts to communities in cases where changes in fishing activity have different degrees of impact on a community. In such cases, a moderate change in fishing activity occurring in a vulnerable community may be considered a substantial impact, while a moderate change in fishing activity in a less vulnerable community may be considered relatively inconsequential. The projected effects of the trawl rationalization program on the communities is described in Table 4 (Table 4-71 of the FEIS):

Table 4. Summary of the impacts of rationalization on communities.

Community	General Impacts	Vulnerability	Cumulative Impact Notes
Bellingham	Benefits from initial allocation, allocation of IFQ to processors; but close to high bycatch area.	Vulnerable. Medium dependence and medium resilience.	Long-term decline in natural resources employment, but diversified economy. Population has grown 14% since 2000. Increasing gentrification. Young population.
Anacortes	Not strongly affected by rationalization due to nature of fishery (at-sea catcher-processors)	Not vulnerable.	Long-term decline in natural resources employment. Increasing tourism and retiree destination. Population has grown 14% since 2000. Should benefit from whiting amendments (10 & 15).
Seattle	Not strongly affected by rationalization due to nature of fishery (at-sea whiting), diversity and size of community	Not vulnerable.	Diversified economy with strong fishing infrastructure. Population has grown 5% since 2000. Should benefit from whiting amendments (10 & 15). Increasing gentrification.
Neah Bay	At risk of losing trawl fleet. Receives less than average in initial allocation. May experience reduction in landings if processors are allocated quota.	Extremely vulnerable.	Relatively heavy reliance on natural resource jobs. Impacted by 2008 salmon closures. Near marine sanctuary and wave energy site. Older-than-average population.
Westport	Would receive less than average initial allocation. Processor could benefit from processor QS. Consolidation could remove nonwhiting activity from port.	Vulnerable. Fairly dependent on groundfish fishery, but fairly resilient.	Tourism and natural resources both historically important to economy. Impacted by salmon closure. Luxury boatbuilding, important to economy, could be affected be economic downturn.
Ilwaco	Primarily a whiting port. Receives less than average initial allocation of nonwhiting. Processor could benefit from QS.	Vulnerable. Low dependence on groundfish, but low resilience.	Increasing population (5%). Older-than-average population. Impacted by 2008 salmon closure. Should benefit from whiting amendments (10 & 15).

Table 4 cont. Summary of the impacts of rationalization on communities.

Community	General Impacts	Vulnerability	Cumulative Impact Notes
Astoria/Warrenton	Expected to benefit from rationalization, with large initial allocation and possibly increased harvesting and processing activity.	Astoria is vulnerable; Warrenton is not. Medium to high resilience.	General long-term decline in natural resources employment. Astoria population stable; Warrenton population increasing. Slightly older-than-average population. Impacted by 2008 salmon closures. Should benefit from whiting amendments (10 & 15). Increasing tourism (with accompanying low-paying jobs) and increasing gentrification, especially in Astoria. Some population leaving to find higher-paying jobs.
Newport	Expected to benefit from rationalization, with large initial allocation and possibly increased harvesting and processing activity.	Vulnerable. Very dependent on groundfish fisheries, but also fairly resilient.	General long-term decline in natural resources employment. Active tourist industry and increasing gentrification. Older-than-average population. Slightly increasing population. Impacted by salmon closure. Should benefit from whiting amendments (10 & 15). Wave energy projects have been proposed for nearby waters.
Coos Bay/ Charleston	Expected to benefit from rationalization, with large initial allocation and possibly increased harvesting and processing activity.	Somewhat vulnerable. Dependent on groundfish with medium resilience.	Heavily dependent on natural resource economy. Impacted by salmon closure. Should benefit from whiting amendments (10 & 15). Slight population increase since 2000. Older-than-average population. Large wave energy project proposed for nearby waters.
Brookings	Would benefit slightly from initial allocation. Currently no processors of trawl groundfish; processing could be less likely to move to Brookings under rationalization.	Not vulnerable. Dependent on groundfish, but high resilience.	General long-term decline in natural resources employment. Greatly increasing population (23.8% between 1990-2000, 15.9% between 2000-2007), many retirees. Much older-than-average population. Heavily reliant on recreational fishing. Impacted by 2008 salmon closures.
Crescent City	Would receive lower-than-average initial allocation. Relatively inefficient fleet; however, scores well on bycatch dependency, which could mitigate other factors.	Vulnerable; relatively dependent on groundfish, with medium resilience.	General long-term decline in natural resources employment. Many large rent-paying vessels removed by 2003 trawl buyback. Reliant on tourism. Slightly increasing population. Impacted by salmon closure.

Table 4 cont. Summary of the impacts of rationalization on communities.

Community	General Impacts	Vulnerability	Cumulative Impact Notes
Eureka	Would receive higher-than-average initial allocation. Located in low-bycatch area.	Vulnerable; relatively dependent on groundfish, with medium resilience.	General long-term decline in natural resources employment; reliant on tourism, timber, and fishing. Sixteen groundfish vessels retired through trawl buyback. Decreasing population (3%). Impacted by salmon closure. Four wave energy projects are proposed for nearby state and Federal waters.
Fort Bragg	Would receive higher-than-average initial allocation. Located in low-bycatch area. However, a relatively inefficient fleet.	Vulnerable; relatively dependent on groundfish, with medium resilience.	General long-term decline in natural resources employment (large mill closed in 2002). Decreasing population (3%). Older-than-average population. Impacted by 2008 salmon closure. Increasing gentrification. Three wave energy projects are proposed for nearby state and Federal waters. Several marine protected areas located in nearby waters.
San Francisco	Would receive higher-than-average initial allocation. Strong infrastructure. However, located in a high-bycatch area. May lose some of its relatively inefficient fleet.	Not vulnerable.	Decreasing population (2%). Ongoing gentrification of fishing facilities. Wave energy projects proposed for nearby waters (mainly bay). Impacted by 2008 salmon closure.
Princeton/ Half Moon Bay	Initial allocation may be higher or lower than average, depending on allocation formula. Located near high bycatch area. Relatively inefficient fleet (some vessels may be lost), but strong infrastructure may mitigate these factors.	Not vulnerable.	Historically dependent on tourism; active tourist industry. Slightly increasing population; older-than-average population. Increasing gentrification. Near Monterey Bay Sanctuary and newly designated California MPAs.
Moss Landing	Would receive higher-than-average initial allocation. May experience reduction in landings if processors are allocated quota. Inefficient fleet near high bycatch area.	Vulnerable; somewhat dependent on groundfish, with low resilience.	Historically reliant on sardine and other fisheries. Near Monterey Bay Sanctuary and newly designated MPAs. Affected by 2008 salmon closure.

Table 4 cont. Summary of the impacts of rationalization on communities.

Community	General Impacts	Vulnerability	Cumulative Impact Notes
Morro Bay	Currently no trawlers are trawling out of Morro Bay. Permits bought out by Nature Conservancy. Impossible to predict how efficient fleet may be in future. Would receive less than average initial allocation of QS.	Vulnerable. Medium dependence on groundfish, but highly resilient.	Active tourist industry. Slightly decreasing population. Increasing gentrification. Impacted by salmon closure. Five groundfish vessels participated in buyout. New MPAs located in nearby waters. One wave energy project currently proposed for nearby waters.

One of the key indicators of community health is the unemployment rate. Unfortunately, because many of these communities are small, current unemployment rates cannot be found. However, there are current estimates for the counties in which these communities reside. [The data below are taken from the Local Area Unemployment Statistics, U.S. Department of Labor, Bureau of Labor Statistics Databases –see www.bls.gov .]

These trends show that, relative to 2004, unemployment rates were declining but then increased significantly in 2009, mirroring the general trend in the overall U.S. economy. The implication is that vulnerable communities are becoming more vulnerable.

Tribal Fisheries. The incremental effects of the preferred alternative on treaty tribe harvesters are detailed in Section 4.15 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. Under the preferred alternative, tribal groundfish fisheries are expected to generate at least the same level of ex-vessel revenues and personal income as generated under the no action alternative. Loss of port infrastructure due to harvester and processor consolidation could affect tribal fisheries disproportionately. As shown in Table 4-69 of the FEIS, the port of Neah Bay appears to be at a particular disadvantage under the preferred alternative because of its lack of fleet efficiency, lack of shore-based infrastructure, and the high degree of dependence that vessels in this port have on areas defined as "high bycatch."

Seafood Consumers. The incremental effects on seafood consumers are considered in Section 4.5.4 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. Under the preferred alternative, consumers of groundfish products could benefit from greater availability of target species and new product forms. Given that the current management strategy is focused on a year-round fishery via bimonthly trip limits, there may be little change in the seasonal availability of groundfish products. However, due either to the high bycatches of rockfish species or to high catches of petrale sole preseason, the traditional winter petrale sole fishery has been greatly restricted or closed down as occurred in 2007. These closures affect the availability of petrale sole to the consumer. Under the preferred alternative, closures of major fisheries are unlikely to happen. The major product form for whiting in recent years has been H&G whiting. This product is mainly for the Eastern European markets. The other groundfish products generally have close substitutes available from elsewhere in the global supply chain. For example, seafood processors have testified to the competition from imported tilapia. Therefore, for most consumers of fresh and frozen seafood products, there is probably little difference between the preferred alternative and no action alternative.

Nonconsumptive and Nonuse Values. The incremental effects on nonconsumptive and nonuse values are considered in Section 4.5.5 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery DEIS*. The preferred alternative may reduce bycatch of overfished stocks, which could enhance the value of wildlife viewing experience for nonconsumptive users. Nonuse values are affected by the impact of harvest on the status of fish stocks. To the degree that the preferred alternative is more effective than the no action alternative in constraining trawl sector harvests to levels expected to improve stock status, nonuse values would be enhanced. It was not practicable to monetize theses changes in nonconsumptive and non-market values; however, they are treated qualitatively in order to provide a complete accounting of costs and benefits attributable to the preferred alternative.

Management Agencies. The incremental effects on management agencies were detailed in Section 4.16 of the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery FEIS*. Public expenditures for monitoring and enforcement are expected to increase under the preferred alternative compared to the no action alternative. Some of these costs would be covered by industry directly (at-sea observer and plant monitor costs) or indirectly through a landings fee. At the state and Federal level, the total expenditure is estimated to range from approximately $2.8 million to $5.6 for startup of the program based on fiscal years 2010 and

2011 first quarter expenditures. After a period of transition, annual program costs are expected to be in the neighborhood of about $5.0 million annually.

4.5.2 Summary of Net Benefits to the Nation

Table 5 summarizes the net benefits to the nation under the preferred alternative based on a qualitative and quantitative assessment. Improvements in the economic performance of harvesters in the Pacific Coast groundfish limited entry trawl fishery may be substantial as a result of expected cost efficiencies created by fleet consolidation, increased flexibility in harvest timing, and increase in the harvest of underutilized target species due to incentives to reduce bycatch. Those harvesters who choose to exit the fishery would receive financial compensation from selling their permit or share of the resource. The improvement in the economic performance of processors in the fishery may also be substantial due to increased processing of target species, increased season length and processor consolidation. An initial allocation of QS to shoreside whiting processors is expected to replace the lost capital value potentially occurring among these processors due to a decline in processing demand.

The preferred alternative may also result in a shift in the balance of bargaining strength between harvesters and processors. This shift, in turn, can affect the distribution of efficiency gains. By providing harvesters with a guaranteed harvest opportunity over a longer period compared to the no action alternative, the preferred alternative may change the relative bargaining power between processors and harvesters by giving harvesters greater latitude to hold out for better ex-vessel prices. On the other hand, an initial allocation of whiting QS to whiting processors will tend to enhance their negotiation power with harvesters over prices. In addition, the adaptive management provision provides a mechanism to distribute non-whiting QS to processors, thereby mitigating harm to adversely impacted shoreside non-whiting processors.

Fleet consolidation would result in a decrease in the number of captain and crew jobs; however, those who retain jobs are expected to receive higher wages due to higher vessel profit margins. Increased vessel profits and operational flexibility are anticipated to improve safety conditions onboard trawl vessels. Fleet consolidation may lead to the spillover of excess vessels into nontrawl commercial fisheries that are operationally similar, thereby increasing competition in those fisheries. Fishing communities will be affected differentially, depending on whether fleet and processor consolidation results in a concentration or loss of vessels and commercial infrastructure.

The main socioeconomic impact of the long-term, formal allocations of specified groundfish stocks and stock complexes among sectors of the Pacific Coast groundfish fishery is increased stability for the limited entry trawl fishery. While the allocations under the preferred alternative do not differ significantly from status quo allocations made biennially, there is more certainty in future trawl harvest opportunities, which enables better business planning for participants in the rationalized fishery.

Table 5. Summary of net social benefits of the preferred alternative relative to the no action alternative.

	Qualitative Assessment	Quantitative Assessment
Trawl Harvesters and Processors		
Change in Costs	+/-	~$13.8 million decrease for non-whiting sector due to productivity gains related to fleet consolidation, but at-sea observe requirements will increase costs by ~$2.2 million
Change in Revenues	+	$5-22 million increase in ex-vessel revenues for non-whiting sector
Change in Profitability	+	$14-23 million increase in profits for non-whiting sector, not including at-sea observer costs
Captains and Crew		
Change in Employment and Wages	+/-	
Change in Fishing Vessel Safety	+	
Nontrawl Commercial Harvesters and Processors		
Change in Costs	+	
Change in Revenues	+/-

Change in Values Associated with Healthy Fish Stocks	+	
Management Agencies		
Monitoring and Enforcement Costs	+	$5.0 million for startup of the program, $6.5 million for the first few years of the program, and perhaps falling to $4.0 to $4.5 million

4.6 Description of the Projected Reporting, Recordkeeping, and Other Compliance Requirements of the Proposed Rules

The preferred alternative has reporting, recordkeeping, and other compliance requirements. A tracking and monitoring program would be necessary to ensure that the total catch (including discards) is accurately documented and matched against QP. All vessels in the shoreside non-whiting and whiting sectors would be required to carry at-sea observers to monitor sorting and discarding of the catch and shoreside landings. There would also have to be an electronic system to report bycatch and landings, which may be integrated with the current state fish ticket

(landings reporting) system. Plant monitors would be required to ensure that the electronic fish tickets are accurate.

A new reporting requirement related to the tracking of quota shares and QP in the shoreside sector. Current requirements for motherships, mothership catcher vessels, and catcher-processors would continue to be in effect. However, a new program for the mandatory submission of economic data by both the shoreside and at-sea whiting sectors would be implemented to facilitate monitoring IFQ and co-op program performance.

In addition to the catch reporting and monitoring requirement, the preferred alternative would impose other compliance requirements. A landings fee of up to 3 percent of the ex-vessel value of fish harvested would be assessed to recover costs of management, data collection and analysis, and enforcement activities. Second, new at-sea observer requirements would be introduced, and vessels would have to pay the costs of complying with these requirements, estimated at $350 to $500 a day.

4.7 Identification of Relevant Federal Rules that may Duplicate, Overlap, or Conflict with the Proposed Rules

There are no relevant Federal rules that may duplicate, overlap, or conflict with this action.

4.8 Description of Significant Alternatives to the Proposed Rules

Each IRFA shall also contain a description of any significant alternatives to the proposed rule that accomplish the stated objectives of applicable statutes and that minimize any significant economic impact of the proposed rule on small entities.

There are no significant alternatives to the proposed rule that accomplish the stated objectives of applicable statutes and that minimize any of the significant economic impact of the proposed rule on small entities.

The proposed action includes provisions that would have a beneficial impact on small entities. It would create a management program under which most recent participants in the Pacific Coast groundfish limited entry trawl fishery (many of which are small entities) would be eligible to continue participating in the fishery and under which the fishery itself would experience an increase in economic profitability. Small entities choosing to exit the fishery should receive financial compensation from selling their permit or share of the resource. To prevent a particular individual, corporation, or other entity from acquiring an excessive share of the total harvest privileges in the program, accumulation limits would restrict the amount of harvest privileges that can be held, acquired, or used by individuals and vessels. In addition, for the shoreside sector of the fishery, an adaptive management program would be allocated an amount of harvest privileges that could be used to mitigate any adverse impacts, including impacts on small entities, that might result from the proposed action.

The following is excerpted from "Analysis of Components, Elements, and Options for the Individual Fishing Quota Alternative Trawl Individual Components Analysis, Appendix A to the Pacific Coast Groundfish Limited entry Trawl Fishery Environmental Impact Statement."

Under the MSA, the Council is required to consider entry-level fishermen, small vessel owners, and crewmembers, and in particular the possible allocation of a portion of the annual harvest to individuals falling in those categories. No special provisions have been identified for analysis given that new entry is addressed indirectly by allowing crew, captains and others to acquire QS in small increments.

Section 303A(c)(5)(C) of the MSA requires that in developing a LAPP, the Council do the following:

> Include measures to assist, when necessary and appropriate, entry level and small vessel owner-operators, captains, crew, and fishing communities through set-asides of harvesting allocations, including providing privileges, which may include set asides or allocations of harvesting privileges, or economic assistance in the purchase of quota.[4]

The MSA requires that the Council consider, and, **if appropriate**, provide additional measures to benefit the named groups. The Council has considered these groups and certain other elements of the program have been designed with impacts on these groups in mind, including the following:

1. Allocating based on the history of the permit, allowing new entrants to receive a greater initial allocation than they would if the allocation were based just on their personal history in the fishery (Section A-2.1.1).
2. Including an equal allocation component as part of the initial allocation formula for permits, this will benefit historically smaller producers (Section A-2.1.3).
3. Not including a minimum holding requirement provision, this might be more difficult for smaller vessels to comply with than larger vessels (A-2.2.1).
4. Specifying a broad class of eligible owners, that includes crews and fishing communities (Section A-2.2.3.a).
5. Specifying that the QS/QP be highly divisible so as to facilitate the acquisition of QS/QP in small increments by crewmembers, those that have just entered the fishery, and operators of small vessels (Section A-2.2.3.d).
6. Including provisions for a set-aside, as needed to support an adaptive management program that may be used at some future time to address community concerns or create other incentives to benefit the groups listed in 303A(c)(5)(C) or for other purposes (Section A-3).

The TIQC also debated and reported to the Council options for a loan program and a provision that would allocate shares forfeited through a use-or-lose provision to new entrants. The TIQC did not recommend that the Council adopt the loan program because the rationalization program already has high costs and the program would act as a subsidy that might drive up QS prices.

4 An **Assisted Purchase Program** may be developed to aid in financing quota purchase by small vessel fishermen and first time purchase by entry-level fishermen (MSA – 303A(g)(1)).

The use-or-lose provision was not included as part of the package because of implementation obstacles. The TIQC also noted that providing a central lien registry would facilitate obtaining financing by increasing security in the collateral, reducing risk and therefore lower interest rates. This would benefit new entrants. Such a registry, while required by the MSA, has not been implemented.

Much of the focus in developing the program is on the impacts of those who are currently in the industry and who will benefit from receiving an initial allocation of QS. Those individuals will be in an economically stronger situation. The value of the QS they receive will be a stream of resource-related rents (additional profits). Because of the infusion of wealth provided by the QS, they will likely be in an economically better position to bear the brunt of increasing fuel prices, program costs, and, if it should occur, declines in the available harvest. As holders of the QS, they will also accrue the benefits that occur from factors that increase the value in the fishery.

However, over the long term, the constituents of the commercial fishery who come before the Council will be those who at one time or another have been new entrants. New entrants who choose to own QS will have paid an amount for their QS based on the best projections of future profits after taking into account expected fuel prices and other production costs, including observer costs, expected ex-vessel prices for raw fish, expected harvest levels, and, significantly, the cost of the QS. If it turns out that costs are greater than expected or revenue is less than expected, they will not have the same revenue buffer initial QS recipients have. Under such circumstances, a new entrant may experience below-normal levels of profit, possibly even similar to those seen in the status quo fishery. At the same time, if costs are lower or revenues higher, they will experience a higher than expected return that will not be dissipated by increased competition. Thus, the IFQ program provides some expectation of more stable profits even for second-generation participants that choose to own QS. However, second-generation participants need not necessarily take on the risk of QS ownership.

The need to acquire quota will add to costs for second-generation owners, as compared to those who came before. In addition to paying for the physical capital (vessel, etc.) they will have to acquire QP each year and may choose to do so by making a capital investment in QS (by acquiring QS). By owning their own QS they would control their risk with respect to changing QP prices. However, by holding their own QS they will bear risk and reward from the changing value of the QS asset (increases, if there is a trend toward higher vessel costs or lower revenue, or decreases if conditions move in the other direction). If there were not an IFQ program, entering the fishery would require less of an investment but revenues would likely be lower. Assuming that all extra profits (resource rents) under status quo are dissipated, the fishery would have similar downside risks but less upside potential as compared to a fishery managed with IFQs. Upside potential would be lower under status quo because higher than expected profits would likely be dissipated by increased competition. If a harvester enters the fishery and chooses not to acquire QS, but rather to lease QP, the capital investment will be lower, they will not risk the potential decline in value of the asset they purchase, they will have a more limited benefit from any long-term improvement in economic conditions in the fishery, and, if they are able to be competitive, will fish at a normal profit level through QP they buy during the season or are provided by processors. [Note: a normal profit implies zero economic profit but sufficient profit to compensate for their investment.]

4.9 RIR Significance Questions

The RIR Guidelines require a review of the following four questions. Responses to those issues are provided.

1) Will the rule have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or state, local, or tribal governments or communities?

The proposed action is expected to have a positive effect on the national economy, although it is unlikely to exceed $100 million annually. Economic profit from the non-whiting sector of the Pacific Coast groundfish limited entry trawl fishery is estimated at about $14 million to $23 million, although various proposed measures (accumulation limits, at-sea observers) would reduce this profit somewhat. While similar estimates of changes in profits are not available for the whiting sector, the lower motivation to "race for fish" due to co-op harvest privileges is expected to result in improved product quality, slower-paced harvest activity, increased yield (which should increase ex-vessel prices), and enhanced flexibility and ability for business planning. The overall effect of these changes would be higher revenues and profits for harvesters in the shoreside and mothership portions of the whiting fishery.

Improvements in the economic performance of processors in the Pacific Coast groundfish limited entry trawl fishery may also be substantial due to increased processing of target species, increased season length, and processor consolidation. An initial allocation of QS to shoreside whiting processors is expected to replace the lost capital value potentially occurring among these processors due to a decline in processing demand.

Fleet consolidation would result in a decrease in the number of captain and crew jobs; however, those who retain jobs are expected to receive higher wages due to higher vessel profit margins. Increased vessel profits and operational flexibility are anticipated to improve safety conditions on board trawl vessels. Fleet consolidation may lead to spillover of excess vessels into nontrawl commercial fisheries that are operationally similar, thereby increasing competition in those fisheries. Fishing communities will be affected differentially, depending on whether or not fleet and processor consolidation results in a concentration or loss of vessels and commercial infrastructure.

The main socioeconomic impact of the long-term, formal allocations of specified groundfish stocks and stock complexes between sectors of the Pacific Coast groundfish fishery is increased stability for the limited entry trawl fishery. While the allocations under the proposed action do not differ significantly from status quo allocations made biennially, there is more certainty in future trawl harvest opportunities, which enables better business planning for participants in the rationalized fishery.

The proposed action does not present a risk to long-term productivity. As discussed above, productivity is expected to increase through fleet consolidation and other factors. The gains are expected to continue over the long term.

2) Will the rule create a serious inconsistency or otherwise interfere with action taken or planned by another agency?

No inconsistencies or conflicts with the activities of other agencies have been identified.

3) Will the rule materially alter the budgetary impact of entitlement, grants, user fees, or loan programs or the rights and obligations of recipients thereof?

The MSA (§303A(e) and §304(d)(2) provides that up to 3 percent of the ex-vessel value of fish harvested under a limited access privilege program may be assessed to recover costs of management, data collection and analysis, and enforcement activities. The assessment of such a fee is included as part of the proposed action in order to cover management costs, such as maintenance of the system of quota share accounts. In 2006, the Federal government established a loan program to purchase groundfish limited entry trawl permits and associated vessels and retire them from the fishery to reduce capacity. This buyback program is based on both a grant to subsidize the cost and a loan program whereby remaining fishery participants pay a landings-based fee to retire the upfront cost. The proposed action will not alter this obligation and fishery participants will continue to pay the landings fee.

4) Will the rule raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the EO?

The Council considered various arrangements for obligating catcher vessels participating in co-ops to deliver to certain processors. In particular, the co-op proposal for shoreside whiting vessels included provisions for obligating deliveries that were found to be outside NMFS's legal authority. However, this proposal was not included in the preferred alternative. The co-op program proposed for the mothership sector, which was included in the preferred alternative, was structured in a way to avoid potential legal issues. Otherwise, the proposed action is consistent with the President's priorities as reflected in the NOAA Administrator's emphasis on the use of catch share programs in fishery management.

Attachment 1

Update to the Tracking and Monitoring Costs of the Program

Tracking and Monitoring Program

A key feature of the trawl rationalization program would be a shift from the current catch accounting system for the shoreside sector that uses fleetwide estimates of discards based on an observer sampling system that has 20 percent coverage to an 'individual accountability' system where all catch by shoreside vessels would count against participants' shares, including both retained and discarded catch based on 100 percent observer coverage on vessels and 100 percent compliance monitoring in the plants. Under the current management system, shorebased fishermen fish against bimonthly trip limits and annual fleetwide quotas and have no direct accountability for discards. Under the proposed system, shorebased fishermen would fish against "individual" quotas against which their discards would count. Within the whiting fishery, there will be two major changes. Shoreside whiting vessels will no longer be monitored by cameras as they will be required to have observers. Catcher-vessels that deliver to motherships are currently unmonitored; these vessels, too, will be required to carry observers.

Amendment 20 would include a tracking and monitoring program to ensure that all catch (including discards) would be documented. For shoreside vessels, catch would be matched against QP; for the at-sea co-ops, catch would be matched against sector amounts. The Council specified that observers would be required on all vessels, and shoreside monitoring (catch monitors) would be required during all off-loading (100 percent coverage). Compared to status quo monitoring, this would be a monitoring and observer coverage level increase for a large portion of the trawl fleet, particularly nonwhiting shoreside vessels.

The Council recommended providing NMFS with the flexibility to develop a monitoring program that would achieve the objectives of the QP program. NMFS is working closely with the states and the Council to develop the details of the tracking and monitoring program, as reported by Pacific States Marine Fisheries Commission (PSMFC) at the April 2010 Council meeting. The details of the program will be proposed in the upcoming program components rule. As reported by PSMFC, the following tracking and monitoring components will be addressed.

Amendment 20 would require NMFS-certified, at-sea observers on each vessel. This requirement includes shoreside catcher vessels, mothership catcher vessels, mothership processors, and catcher-processors. Because this is a new program, ensuring adequate observer coverage would be particularly important for monitoring the complex suite of allocations. Observers aboard vessels would be required to adequately account for catch and bycatch in the fishery. Among his or her duties, the observer would record fishing effort and estimate total, retained, and discarded catch weight by species or species group; determine species composition

of retained and discarded catch (non-whiting vessels), and document the reasons for discard; record interactions and sightings of protected species; take biological samples from tagged fish and discards; and estimate viability of Pacific halibut. Observers would be essential to monitor IBQ in the fishery, including IBQ weighing and discarding.

An increase in observer and catch-monitoring coverage requirements would result in increased costs over the status quo observer program costs. There would be a combined status quo, pay-as-you-go industry funding and agency-funded observer and catch monitoring system, as required for each sector. The agency has announced its intent, subject to available Federal funding, that participants initially be responsible for 10 percent of the cost of hiring observers and catch monitors. The industry proportion of the costs of hiring observers and catch monitors will be increased every year so that, by 2014, once the fishery has transitioned to the rationalization program, the industry will be responsible for 100 percent of the cost of hiring the observers and catch monitors. NMFS believes that an incrementally reduced subsidy to industry-funding will enhance the observer and catch monitor program's stability, ensure 100 percent observer and catch monitor coverage, and facilitate the industries' successful transition to the new quota system.

Amendment 20 would require that first receivers—shorebased processors or other entities that receive groundfish from IFQ harvesters sort, weigh, and report all landings of IFQ species under a catch monitoring plan. First receivers will be required to hire NMFS-certified catch monitors to verify all shoreside deliveries of IFQ species, ensure that species are sorted into Federal species groups, ensure that the fish are weighed on state-certified scales that are tested periodically and record and submit catch data daily.

To ensure that the QP program goals are met, and landings are tracked, first receivers will be required to submit electronic fish tickets using software provided by the Pacific States Marine Fisheries Commission. Further, vessels will be required to use VMS to indicate vessel locations and to make declarations. In addition, there are plans to develop and require an electronic vessel logbook, but this component will not be immediately implemented.

To ensure that program goals are met to track transferrable QS and QP, NMFS is also developing an online accounting system for the tracking and trading of QS by owner and for the tracking, trading, and use of the QP that result from these quota shares by vessels.

The agency will collect fees to cover the administrative costs of issuing the quota shares, permit endorsements (one-time fee and annual renewal), and first receiver site licenses (annual). Amendment 20 would allow for assessing cost recovery fees of up to 3 percent of ex-vessel value, consistent with 303A(e) of the MSA. The costs to be recovered would be the agency's costs of management, data collection, analysis, and enforcement activities. The Council will develop the methodology required by 303(A)(e) in a trailing action.

NMFS plans to propose additional program details in a future proposed rule. Such additional details would include program components applicable to IFQ gear switching, observer programs, retention requirements, equipment requirements, catch monitors, catch weighing requirements, coop permits/agreements, first receiver site licenses, quota share accounts, vessel quota pound accounts, further tracking and monitoring components, and economic data collection requirements. In order to encourage more informed public comment, this proposed rule includes a general description of these additional program requirements. NMFS is also planning a future cost-recovery rule based on a recommended methodology yet to be developed by the Pacific Fishery Management Council.

Tracking and Monitoring Costs

The costs of the program can be broken into three categories:

> Agency Implementation Costs (one-time costs to develop the tracking and monitoring programs)
>
> Agency Annual Costs (state and Federal costs associated with running the Program when fully implemented)
>
> Direct Observer and Monitoring Costs (daily costs associated with hiring observers and plant monitors)

These costs are shown in the table below. They are based on converting quarterly estimates developed for the Federal fiscal year budget process. While funds may be received in one quarter, they may not be expended in that quarter. Estimates of agency implementation costs were based on funds received during FY 2010 and first quarter of FY 2011. As programs develop, in some cases using this approach to estimate implementation cost may yield estimates that are too high and in other cases too low. As the fishery progresses and programs adapt, new features will have to be developed, while others will be corrected or phased out. For example, the quota share trading system, while initially developed for 2011, will not be tested until 2013 because the trading in quota shares is prohibited for the first two years. There may also be implementation costs associated with the Adaptive Management Programs or the Community Fshery Association Program. As programs develop, agency costs may increase because of the transition from old programs to new programs where, for a period of time, both programs have to be maintained (see attached figure).

<u>Agency Implementation Costs</u>

These are one-time additional costs to NMFS and the states to implement the program. For managing the program, these include developing the initial issuance processes (historical database development, initial application forms, the appeals processes), permitting processes and development of the shorebased total catch accounts (electronic fish tickets, compliance monitor

reports, and observer discard estimates) and shorebased, vessel accounting systems). Based on review of NMFS Alaska and Northeast Region programs, NMFS estimates that there may be over 100 appeals. States will also incur some implementation costs for upgrading their catch tracking systems to meet the new electronic reporting requirements. The federal enforcement program will have to train new officers and staff and pay their salaries while in training. State enforcement programs will also have to train new officers and staff, but these costs are included in annual costs. Both the NWR and NWFSC will have to expand their monitoring programs and develop the necessary infrastructure (IT, equipment, training, and office space. It may cost more than $12,000 to equip an observer with a laptop, motion-compensated scale, safety gear, and raingear. It costs about $2000 to equip a compliance monitor with gear and a computer. Approximately 100 observers and 60 to 80 plant monitors will have to be equipped and trained for the first year of implementation.

Agency Annual Costs

These are recurring state and federal costs associated with running the program when fully implemented. For the NMFS NWR Management Office, these costs include five positions for managing the permitting processes, quota share accounts, vessel accounts, catch monitoring program, and cost-recovery program. PSMFC and NMFS NWR will continue to expend about $200,000 annually to maintain the IT aspects of electronic fish ticket, total catch databases, quota share, and vessel accounts. States will continue to receive $200,000 each for managing state fish ticket system and for increased port sampling needs. For the Federal enforcement office, these costs fund four positions. For state enforcement, $800,000 is planned to be provided to the three states because of increased enforcement levels. The trawl rationalization program is complex, and there will be a initial need for high enforcement presence. These costs may decline once the program matures, and participants develop better understanding and acceptance of the regulations. These enforcement costs may also decline as a result of the expected consolidation of the fleet. Other costs may change as a better understanding of the roles of compliance monitors, port samplers, and enforcement agents develops, and the roles are revised to avoid duplication or to better complement each other. With respect to the Observer and Economic Data Collection Programs, the Northwest Fisheries Science Center will expend funds associated with about five positions. PSMFC will continue to receive grants for debriefing positions and gear. In addition, contracts for collecting economic data will be developed. The total cost is expected to be approximately $5.0 million by FY 2013. [Note that inflationary effects are taken into consideration.]

Direct Observer and Compliance Monitor Costs—Estimates by Fleet

Observer-Shoreside Non-whiting: In 2008, there were 2,166 actual non-EFP trawl trips. The number of trips has ranged from a high of 3,486 to a low of 2,088 between 2002 and 2008. Therefore, for purposes of analysis, we will assume 2,300 trips. The average trip length has been 3.3 days (trips are usually no longer than five days but range from one to eight days in length).

This yields about 7,600 sea days. The cost of an observer is estimated to be $500 a day based on conversations with the observer providers. Due to the logistical complexities of the west coast groundfish fleet and the high number of unknowns, there is considerable risk for the providers, and they estimate that the cost per sea day at $500 per day. This is higher than in the North Pacific but lower than the $510 estimates associated with the Northeast Region's industry-funded scallop observer program. This estimate leads to a direct annual cost for the shorebased non-whiting fishery of about $3.8 million. Unit costs of observers are a function of the ability to work with the observer providers and make arrangements to lower costs. At the September 2009 Pacific Fishery Management Council meeting, the NWFSC provided information suggesting that if an observer is placed on a monthly stipend under which the observer is expected and guaranteed to work 20 days, the average daily rate of the observer could be lower (Agenda Item E.6.B Supplemental NWFSC Powerpoint September 2009 "Thoughts on Costs").

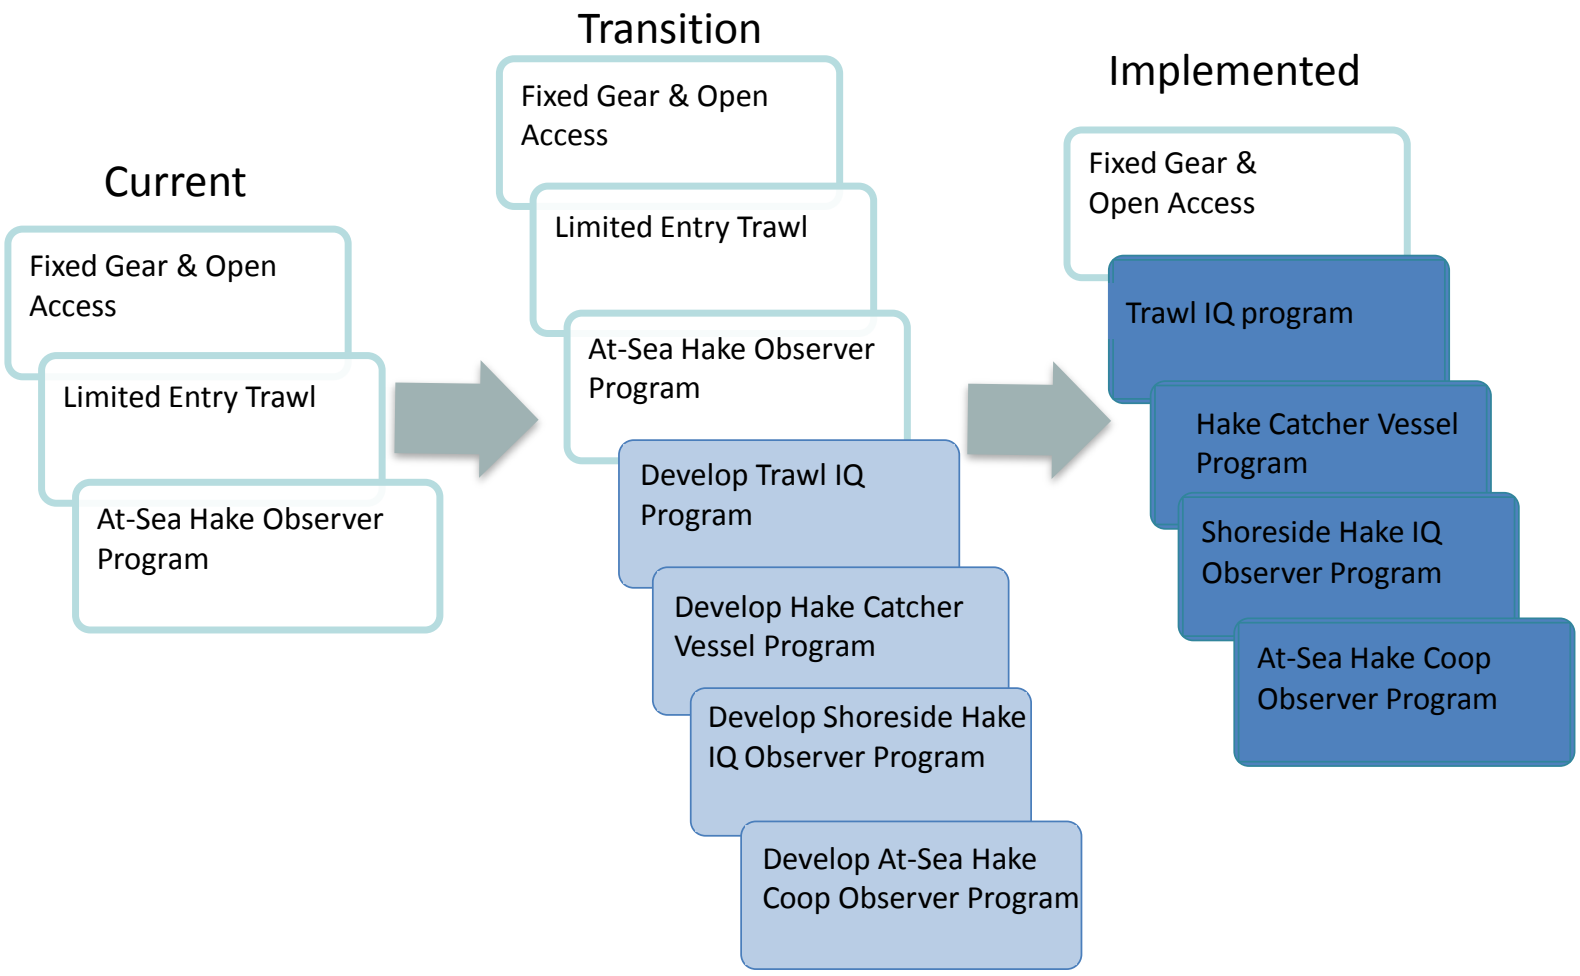
Observer-Shoreside Hake: In 2008, 590 trips were taken. Using this value and $500 as the daily observer cost, the total cost is $295,000.

Observer-Mothership Catcher Vessel: It is estimated that they will fish for 30 sea days. Using 15 participants and 30 sea days each yields 450 total sea days. At $500 per day, this would yield an observer cost of $225,000. If the season were 60 days with
20 participants, at $500 per day for an observer, the total cost would be $600,000

Mothership Processors and Catcher-Processors: The NWFSC estimates the current at-sea costs of observers for both the Mothership and Catcher-Processor fleets is about $600,000.

Catch monitors: For the non-whiting fishery, if there are 7,600 sea days, and the average trip is 3.3 days, then a projected 2,300 trips that will have to be monitored. This implies that if a catch monitor can monitor one trip per day the direct annual compliance monitor cost would be about $800,000 at $350 per day. For the whiting fishery, if there are 14 processors and a 60-day season, there will be 840 processing days and potential cost of $300,000. If the season is 30 days, then the costs would be about $150,000. For approximation purposes, these estimates were rounded up to a total of $1.3 million.

The total of the direct cost observers and compliance monitors for the shoreside component is $5.4 million (observers, shoreside non-whiting, $3.8 million; observer shoreside hake, $300,000; and catch monitors, $1.3 million). The total costs for the observers in the mothership and catcher-processor fishery is about $1.2 million (observer-mothership catcher vessel, $600,000 and mothership processors and catcher-processors, $600,000). The initial grand total of the direct costs of observing and monitoring this fishery is about $6.6 million.



The agency has announced its intent, subject to available Federal funding, that participants would initially be responsible for
10 percent of the cost of hiring observers and catch monitors. The industry proportion of the costs of hiring observers and catch monitors would increase every year so that, by 2014, once the

fishery has transitioned to the rationalization program, the industry would be responsible for 100 percent of the cost of hiring the observers and catch monitors. NMFS believes that an incrementally reduced subsidy to industry funding would enhance the observer and catch monitor program's stability, ensure 100 percent observer and catch monitor coverage, and facilitate the industries' successful transition to the new quota system.

The initial observer and catch monitoring costs projections (shoreside, $5.4 million and at-sea whiting, $1.2 million) do not reflect two cost lowering effects: the effects of consolidation and as the industry increasingly bears the burden of paying for the observer and catch monitors and the ability of the industry to work with observer and compliance monitor providers to reduce costs. It is not unreasonable to expect a 25 percent reduction in costs to a level of $5.0 million annually as a result of these effects.

Observer Program Transition to TRat

RECORD OF DECISION
for the
FINAL ENVIRONMENTAL IMPACT STATEMENT
on
RATIONALIZATION OF THE PACIFIC COAST GROUNDFISH LIMITED ENTRY TRAWL FISHERY

National Marine Fisheries Service
Northwest Region

1 INTRODUCTION

The Final Environmental Impact Statement (FEIS) provides background information and analyzed possible environmental impacts resulting from the proposed action and alternatives. The proposed action is to create a management regime under which the owners of Pacific Coast groundfish fishery limited entry (LE) permits with trawl endorsements are more individually accountable for catch of target and nontarget species harvested by the vessels to which their permits are registered.

The lead agency for this FEIS is the National Marine Fisheries Service, Northwest Region (NMFS Northwest Region). The FEIS was prepared to address regulatory requirements of NMFS, pursuant to National Environmental Policy Act (NEPA), the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the Regulatory Flexibility Act, and Executive Order (EO) 12866. The proposed action requires regulatory approval from NMFS prior to implementation.

The Pacific Fishery Management Council (Council) proposes changes to its *Pacific Coast Groundfish Fishery Management Plan* (FMP) to rationalize Federal management of the Pacific Coast groundfish trawl fishery through Amendment 20. This would be accomplished by implementing a limited access privilege (LAP) program and modifying the approach to controlling bycatch of Pacific halibut in the groundfish trawl fishery. LAPs are a form of output control whereby an individual fisherman, community, or other entity is granted the privilege to catch a specified portion of the total allowable catch (TAC). The proposed action (termed "trawl rationalization") is intended, among other things, to increase economic efficiency within the Pacific coast groundfish trawl fishery and reduce the incidental catch of overfished groundfish and possibly Pacific halibut (often referred to as bycatch and defined as fish that are not kept or sold and are discarded, usually at sea). Implementing the action will involve both changes to the management framework in the FMP and promulgation of implementing regulations.

The two approaches considered for rationalizing the fishery—harvest cooperatives or IFQs—although structurally different, are intended to fulfill the following goal:

> *Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.*

The above goal is supported by the following objectives:

1. Provide a mechanism for total catch accounting.
2. Provide for a viable, profitable, and efficient groundfish fishery.
3. Promote practices that reduce bycatch, discard mortality, and minimize ecological impacts.
4. Increase operational flexibility.
5. Minimize adverse effects from an IFQ program on fishing communities and other fisheries to the extent practical.
6. Promote measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.
7. Provide quality product for the consumer.
8. Increase safety in the fishery.

Amendments 20 to the Pacific Coast Groundfish FMP would establish a trawl rationalization program for a limited entry trawl fishery. The target date for implementation of the trawl rationalization program is January 1, 2011. Due to the complexity and timing of the program NMFS has issued, or is in the process of issuing three separate rulemakings that would implement this program. The final rule that was published in the Federal Register on January 29, 2010, established data reporting and collection requirements that would be used to determine the initial allocations of quota shares for the trawl rationalization program if the program is implemented (75 Federal Register [FR] 4684). The proposed rule was deemed by the Pacific Fishery Management Council (Council) at the April 2010 Council meeting, and contains certain key components that would be necessary to have permits and endorsements issued in time for use in the 2011 fishery and in order to have the 2011 specifications reflect the new allocation scheme. The target date of implementation of these program components is September 2010. The third rule will include additional program details that would, if adopted, complete the trawl rationalization program.

The trawl rationalization program is intended to increase net economic benefits, create individual economic stability, provide full utilization of the trawl sector allocation, consider environmental impacts, and achieve individual accountability of catch and bycatch. The program would consist of: (1) an individual fishing quota (IFQ) program for the shore-based trawl fleet (including whiting and non-whiting sectors); (2) cooperative (coop) programs for the at-sea (whiting only) mothership and catcher-processor trawl fleets; and (3) fixed allocations for limited entry trawl participants.

2 DECISION TO BE MADE

This Record of Decision (ROD) documents the decision made by the NMFS Northwest Region to select the preferred alternatives identified in the *Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery Final Environmental Impact Statement*. This ROD is issued pursuant to the NEPA, the Council on Environmental Quality (CEQ) NEPA regulations at 40 CFR Parts 1500-1508, and NOAA NEPA environmental review procedures in NOAA Administrative Order (NAO) 216-6 Section 6.03 (a) Environmental Review Procedures for Fishery Management Plan actions. This decision is based upon the analyses included within the Final Environmental Impact Statement (FEIS) issued June 25, 2010 (75 FR 36386, June 25, 2010).

3 ALTERNATIVES CONSIDERED

The following is a summary of the alternatives analyzed in the FEIS. The Council and NMFS considered four alternatives for implementing the trawl rationalization program. These are as follows:

- Alternative 1: Status quo management (no action alternative)
- Alternative 2: IFQs for all groundfish trawl sectors
- Alternative 3: IFQs for the nonwhiting sector and cooperatives for all whiting sectors
- Alternative 4: IFQs for a single shore-based sector and co-ops for the whiting at-sea sectors

As part of the impact analysis in the FEIS, which supported Council and NMFS decision making, variations on some alternatives were developed to contrast key program features, which are sub-alternatives denoted by a letter suffix. These are Alternatives 2a, 2b, and 2c and Alternatives 4a and 4b. Alternatives 1 and 3 do not contain sub-alternatives. Alternative 4b is the preferred alternative. With these variations included, six alternatives were evaluated in the EIS. The alternatives are summarized below.

3.1 Alternative 1: Status Quo Management

Under this alternative, most of the elements of the current management regime for the groundfish LE trawl fishery would remain in place.

Every 2 years, the Council establishes harvest limits, called optimum yield (OY), for various species or groups of species. OYs represent an annual quantity of fish that the groundfish fishery as a whole may catch. A few species, such as Pacific whiting and sablefish, have fixed trawl allocations. The FMP defines other allocations between different gears, which, in addition to the whiting and nonwhiting trawl fisheries, include LE fixed-gear, the open access sector, and recreational fisheries in each state. Other allocations are determined through the biennial process to specify harvest limits ([Acceptable biological catch] ABCs, OYs, and harvest guidelines) and management measures. The need to rebuild the seven currently overfished rockfish species means that the OYs for these species are relatively low compared to target species OYs. Due to the multi-species nature of the fishery, these low OYs affect all aspects of groundfish management. The principal management measures for nonwhiting trawl fisheries are as follows:

- Trip limit periods. Two-month cumulative trip limit periods are the primary catch control tool.
- Gear restrictions. Gear restrictions focus on discouraging or prohibiting gear that may be used in rocky habitat, where some overfished species occur. The use of bycatch-reducing trawl nets has also been required in some areas.
- Rockfish conservation areas (RCAs). Closed areas were first implemented in 2003 to keep vessels away from depth ranges where overfished species are more abundant. These closed areas, called RCAs are a coastwide feature of management.
- Essential fish habitat (EFH) conservation areas. These are a set of closed areas to protect bottom habitat from the adverse effects of trawl gear.

Each sector of the Pacific whiting fishery receives an annual allocation, and the fishery is managed under a primary season structure where vessels harvest Pacific whiting until the sector allocation is reached, and the fishery is closed. This is different from the cumulative trip limits used to manage the nonwhiting trawl fisheries. Incidental catch of nonwhiting groundfish species in the Pacific whiting fishery, however,

is managed under the trip limit structure. Season start dates for each whiting sector are set by regulation, and each sector's fishery proceeds until the whiting quota is reached or the fishery is closed.

To allow the Pacific whiting industry to have the opportunity to harvest the full Pacific whiting OY, the nontribal commercial fishery is managed with whiting sector specific bycatch limits for certain overfished species. To date, bycatch limits have been established for darkblotched, canary, and widow rockfish. Regulations provide for the automatic closure of the commercial (nontribal) portion of the Pacific whiting fishery upon attainment of a bycatch limit. This is different from the nonwhiting trawl fishery where harvest availability of target species is often constrained by the projected catch of overfished species.

Incidental take of endangered or threatened salmon runs is another concern for the Pacific whiting fishery. Chinook is the salmon species most likely to be affected because of the spatial/temporal overlap between the Pacific whiting fishery and the distribution of Chinook salmon that could result in incidental take of listed salmon. The season start dates are, in part, meant to prohibit fishing when listed Chinook salmon are most likely to be taken incidentally. NMFS also has the option of closing inshore areas to fishing if too many salmon are caught.

To improve bycatch accounting in the nonwhiting trawl fishery, NMFS implemented the West Coast Groundfish Observer Program (WCGOP) in 2002 for vessels that harvest catch and land the catch on shore. Currently less than 25 percent of nonwhiting trawl fishing trips is monitored by the WCGOP. The primary purpose of the observer coverage is to provide data that can be used to derive catch ratios of nontarget species. Using observer, fish ticket, and logbook data, the fishery is modeled to derive estimates of total catch by species. Due to the delayed availability of fish ticket and logbook data and the time needed to process observer data, the final analysis of estimated total catch by species typically is not finalized until well over 1 year after the fishing year has ended. The At-Sea Hake Observer Program (whiting mothership and catcher-processor sectors) is a seasonal program where the operational costs are shared by NMFS and the vessel owners. Observers are placed on all processing vessels.

3.2 Alternative 2: IFQs for All Groundfish Trawl Sectors

3.2.1 Catch Control Tool

Under this alternative, all groundfish trawl sectors (both whiting and nonwhiting) would be managed with IFQs, which would replace the current two-month cumulative trip limit periods in the nonwhiting fishery and season/quota-based management in the whiting fishery as the primary catch control tool. Three sub-alternatives are evaluated under this alternative (Alternative 2a, 2b, and 2c) to compare and contrast certain key elements of the IFQ program.

3.2.2 Initial Allocation of IFQ and Qualification

At the start of the program quota shares (QSs) must be initially allocated to fishery participants based on catch/processing history during a catch history qualification period, 1994 to 2003. Thereafter, shareholders are free to buy and sell the QSs thus distributed. QSs represent a proportion, or percent, of the Total allowable catch (TAC) (OY) of different groundfish stocks. Each year, these shares are converted from a percent to a quantity by issuing quota pounds (QPs) based on the OYs/annual catch limits (ACL)s established for the year. The amount of groundfish caught by an LE trawl vessel, even if it is subsequently discarded, must be matched by an equivalent quantity of QPs. The QPs are expended in this way, with the matched amount deducted from the vessel's account. Both QSs and QPs are perfectly divisible and tradable.

QSs would be of long duration, so a transfer represents a long-term or permanent divestment. In contrast, QPs must be used within the year for which they are issued (although there is a provision for limited carry-over of unused QPs from one year to the next or QPs issued in the following year to be used in the current year), so QP transfer would not represent a permanent divestment of the harvest privilege, so long as one continues to control the underlying QSs. QS transfers would be prohibited in the first two years of the program so that transfers would only occur once participants fully understand how the program operates, and stable prices have been reached. QPs would still be fully transferable during the first two years.

Eligibility to own QSs/QPs would be defined very broadly; the main requirements are a U.S. citizen must be the owner, and a U.S. documented fishing vessel registered to a groundfish LE trawl permit must be used to harvest groundfish using QPs.

3.2.3 Number of Sectors

Three sectors would be established whereby the two current whiting and nonwhiting shore-based sectors would be combined into a single sector. Participants in this single sector would be free to trade IFQ (QSs or QPs), eliminating any regulatory barrier between targeting whiting and nonwhiting (operational differences among participants may mean that a large degree of specialization in targeting could continue). The whiting mothership and catcher-processor sectors would each be managed separately with their own allocations of catch opportunity and IFQ. IFQ could not be traded among the three sectors.

3.2.4 Accumulation Limits and Grandfather Clause

The maximum number of QSs and QPs an entity may control would be limited, with these limits varying according to the management unit (stock or stock complex). QS limits restrict the amount an individual or entity may control through ownership or other means. QP limits refer to the maximum amount that may be assigned to any one vessel during a given year to cover catch. These vessel limits are twice the control limits to allow several QS holders to work together on a single vessel. These limits are intended to restrict the consolidation of quota holdings by just a few entities. Table 1 summarizes control and vessel limits under the alternatives. This alternative contains a grandfather clause under which initial recipients of QSs who exceed the accumulation limits would be allowed to possess excess QSs up to the amount initially allocated to them.

Table 1. Control limits for QSs, co-op shares, or processing and QP vessel limits under the alternatives.

Alternative	Control Limits: QSs / Co-op Share / Processing					QP Vessel Limit / Co-op Usage Limit				
	NW	SSW	MS	MS(CV)	CP	NW	SSW	MS	MS(CV)	CP
Alternative 1	N/A	N/A		N/A	N/A	N/A	N/A		N/A	N/A
Alternative 2	3%	12%		25%*	60%	6%	25%		50%*	75%
Alternative 3	1.5%	15%†	20%	10%	-	3%	-	-		-
Alternative 4a	2.2%	25%	30%	15%	-	4.4%	12%	-		-
Alternative 4b	2.7%	10%	45%	20%	-	3.2%	15%		30%‡	-

Notes:
NW: Nonwhiting sector; SSW: Shoreside whiting; MS: Whiting Mothership processors; MS(CV): Mothership catcher vessels; CP: catcher-processor whiting.
*Under Alternative 2 the mothership sector would be managed with IFQs, and there would be no distinction as to the type of entity that could hold QSs.
†Under Alternative 3, whiting sectors would be managed with co-ops; shoreside whiting control limit applies to vessels.
‡Catcher vessel usage limit.

3.2.5 Initial Allocation of IFQ to Processors

Under Alternatives 2a and 2b, all of the initial allocation of QSs would go to LE permit holders (harvesters). Under Alternative 2c, shore-based processors would receive 25 percent of the initial allocation of non-groundfish species and 50 percent of the allocation of whiting QSs, and mothership processors would receive 50 percent of the initial allocation of whiting QSs based on their processing history during a qualification period. Catcher-processors both harvest and process fish. For the purposes of initial allocation, they would be considered harvesters.

3.2.6 Species Covered by IFQ

QSs/QPs would be issued for all of the current groundfish management units. Management units are fish stocks, or complexes comprising co-occurring or related stocks, for which an OY (ACL) is established. Table 2 shows the management units for which IFQ would be established. Procedures would be established to reallocate QSs when management units are changed or new ones are added.

Alternative 2 also includes an individual bycatch quota (IBQ) for Pacific halibut. Although functionally equivalent to the IFQ system applied to other species, Pacific halibut are a prohibited species in the groundfish trawl fishery and cannot be retained. Therefore, although accounted for through the IBQ, all halibut must be discarded.

Table 2. Management units considered for IFQ under the alternatives. Overfished species shown in bold.

IFQ Management Units	Flatfish
Roundfish	Dover sole
Lingcod	English sole
Pacific cod	Petrale sole
Pacific whiting	Arrowtooth flounder
Sablefish north of 36° N. latitude	Starry flounder
Sablefish south of 36° N. latitude	Other Flatfish stock complex
Rockfish	**Not Managed With IFQs (Alternative 4b only)**
Pacific ocean perch	Shortbelly rockfish
Widow rockfish	Longspine Thornyhead S. of 34°27'
Canary rockfish	Black Rockfish - coastwide
Chilipepper rockfish	Minor Rockfish North Nearshore complex
Bocaccio	Minor Rockfish South Nearshore complex
Splitnose rockfish	California scorpionfish
Yellowtail rockfish	Cabezon (off CA only)
Shortspine thornyhead north of 34° 27' N. latitude	Kelp Greenling
Shortspine thornyhead south of 34° 27' N. latitude	Other Fish*
Longspine thornyhead north of 34° 27' N. latitude	
Cowcod	
Darkblotched	
Yelloweye	
Minor Rockfish North slope species complex	
Minor Rockfish North shelf species complex	
Minor Rockfish South slope species complex	
Minor Rockfish South shelf species complex	

*Starting in 2009, Longnose skate is managed under its own OY. Because during the time period used to determine initial allocation of QSs, it was managed under the Other Fish complex, however, this species would not be managed with IFQ.

3.2.7 Adaptive Management

Under Alternative 2b each year up to 10 percent of the QSs that would otherwise be distributed to eligible recipients would be set aside for an adaptive management program. This program is meant to address a variety of objectives, ranging from socioeconomic dislocation resulting from implementation of the trawl rationalization program to encouraging innovative fishing methods, for example to reduce bycatch. The Council would decide how much QP would be set aside every two years for adaptive management use as part of the biennial harvest specifications process. The harvest specifications process establishes OYs/ACLs for a two-year period and adjusts management measures so that catches will not exceed these limits.

3.2.8 Area Management

Under Alternative 2, no separate QSs would be created for different latitudinal areas. Area-specific QS is considered under other alternatives because this could prevent substantial geographic redistribution of QS holdings and related impacts to communities. Some stocks are currently managed geographically with separate OYs established for each component; for those stocks, QSs/QPs would be denominated accordingly.

3.2.9 Carryover of Unused QPs between Consecutive Years

Under Alternative 2, unused QPs amounting to 10 percent of the used and unused QPs in the vessel account may be carried over for use in the next year. Similarly, to cover an overage (landings that exceed the amount of QPs held in a vessel account) QPs that may be allocated in the next year may be transferred to the current year, up to 10 percent of the used and unused QPs in the vessel account during the current year.

3.2.10 Tracking and Monitoring

All vessels would be required to carry at-sea observers to monitor sorting and discarding of the catch and shoreside landings. There would also have to be an electronic system to report bycatch and landings, which may be integrated with the current state fish ticket (landings reporting) system. Plant monitors would be employed to ensure that the electronic fish tickets are accurate. NMFS would also administer a system to track QS/QP holdings. Fees would be charged to cover the cost of the tracking system. A comprehensive mandatory monitoring program is expected to require minimal increases in enforcement effort.

3.2.11 Gear Conversion

Once QSs have been distributed, recipients would be free to use them with any legal groundfish gear, which, aside from trawl, principally means bottom longline and fish pots. There is a separate catch opportunity for nontrawl sectors, which would be unaffected by any catches resulting from gear conversion under the IFQ program.

3.3 Alternative 3: IFQs for the Nonwhiting Sector and Cooperatives for all Whiting Sectors

3.3.1 Catch Control Tool

Under this alternative, the nonwhiting sector would be managed with IFQs in a program similar to that described under Alternative 2 (differences are summarized below), while the three whiting sectors would be managed with cooperatives. A separate co-op structure would be used for each of the whiting sectors.

Unlike Alternative 2, there would be four separately managed trawl sectors: shoreside nonwhiting, shoreside whiting, mothership whiting, and catcher-processor whiting.

3.3.2 IFQ Program for the Nonwhiting Sector

Initial Allocation: Under Alternative 3, the initial allocation of QSs would be based on both catch history during the qualification period and an equal allocation of the catch history associated with LE trawl permits that were bought back and retired in 2003 as part of a capacity reduction program. The buyback program is partly funded through a loan to remaining participants, which is being paid back through landing fees. Equal allocation of QSs associated with the buyback permits would result in a more even distribution of QSs among permit holders compared to allocation based on catch history alone.

Allocation of Overfished Species: Unlike Alternative 2 (where all species are allocated based on catch history) under this alternative, a different formula is used for overfished species. These species will still be under rebuilding programs after the projected implementation date of the trawl rationalization program (2011), requiring relatively small OYs. Thus, QSs/QPs for these species could act as a primary constraint on target fisheries to the degree that incidental catch is unavoidable. Furthermore, since regulations prompted a large proportion of overfished species catch to be discarded, landings toward the end of the allocation period (1994 to 2003) do not accurately reflect the actual distribution of historical catch among fishery participants. Therefore, a different formula would be applied to overfished species to allocate QSs. This formula takes into account the amount of target species QSs received by including a proportional component for overfished species QSs. It also factors in areas where fishing occurred, 2003 to 2006, by a vessel associated with an eligible permit in order to account for geographic variation in overfished species bycatch rates. This approach is intended to better balance individual holdings of target and overfished species QSs and take into account the areas where permit holders have fished in the recent past. Provisions may allow QSs to be reallocated once a species is rebuilt, recognizing that the annual OY/ACL could be increased substantially once the rebuilding restrictions are lifted. This formula would be applied to the landings history associated with current permits, which account for 57 percent of the landings history. As with non-overfished species, landings history for overfished species associated with the buyback permits would be divided equally among the current permits.

Accumulation Limits and Grandfather Clause: Under Alternative 3, the nonwhiting sector would be subject to lower accumulation limits in comparison to Alternative 2 (see Table 1). Alternative 3 does not contain a grandfather clause; any potential initial allocation in excess of the accumulation limit would instead be redistributed to those permits below the limits.

Initial Allocation of IFQ to Processors: In Alternative 3, 25 percent of nonwhiting groundfish would be allocated to shoreside processors. This differs from Alternative 2c, because shoreside whiting is not included since that sector would be managed with co-ops. Small amounts of whiting, representing incidental catch by nonwhiting vessels, would be allocated as QSs to the nonwhiting sector permit holders.

Species Covered: Unlike Alternative 2, this alternative does not include a halibut IBQ. Pacific halibut bycatch would be subject to status quo management. Under status quo, the allocation to other fishery sectors in the west coast management area (International Pacific Halibut Commission [IPHC] Area 2A) is determined by reducing the area (TAC) by an amount equal an estimate of the previous year's groundfish trawl sector halibut bycatch. This is an approximate method for accounting for trawl bycatch; if the trawl bycatch in a given year exceeds the amount by which the area TAC was reduced, that is factored into the next stock assessment.

Adaptive Management Program: This alternative would include the adaptive management program described above for Alternative 2b.

Area Management: Under this alternative, QSs/QPs for each management unit would be divided geographically so that area-specific QPs would be needed to cover catches in each area. Two zones would be established, one north and the other south of 40°10' N. latitude.

Carryover of Unused QP: This alternative would not contain the carry-over provision included under Alternative 2.

3.3.3 Cooperatives for the Shore-based and Mothership Pacific Whiting Sectors

Under Alternative 3, the shore-based and mothership whiting sectors would be managed separately but with a co-op structure that is very similar. For that reason, the co-op structure for both sectors is described here, but differences in the co-op rules for the two sectors are pointed out. The catcher-processor sector currently operates under a voluntary co-op. Under Alternative 3, this voluntary structure would continue with modest changes to the management system. The catcher-processor co-op included in this alternative is described in a separate, subsequent section.

The existing allocation of whiting between the shoreside whiting, mothership, and catcher-processor sectors would not change (42, 24, and 34 percent, respectively). No portion of one sector's whiting allocation could be transferred to another sector.

Although Pacific whiting comprises the dominant portion of the catch in this sector, some overfished rockfish do get caught. As discussed above, bycatch caps have been imposed on the whiting fishery. These sector caps would continue to be used under trawl rationalization. Under this alternative, there would be a single cap to cover catch in all three whiting sectors for each overfished species managed this way. These bycatch caps would be established for those overfished species likely to be caught in the whiting fishery: widow, canary, darkblotched rockfish, and Pacific ocean perch (a separate cap for the same species would be applied to the catcher-process sector). In addition, the current endangered species act (ESA)-listed Chinook salmon bycatch management measure, a triggered 100-fathom closure, and an ESA consultation threshold would continue in effect. Status quo management (trip limits) would be used for other bycatch species. In addition, an amount would be deducted from allocations to the trawl sector for these species to account for the expected small amounts of bycatch. Caps on overfished species would be expected to indirectly limit bycatch of these other species.

Motherships and catcher-processors are already subject to full observer coverage, so few changes in the current monitoring program are needed under this alternative. Shore-based whiting vessels must land all their catch, allowing full dockside monitoring. Under this alternative, this full retention requirement would continue, possibly with additional monitoring to better detect at-sea discards.

3.3.3.1 New Permit Requirements

Mothership processor permit: Historically, any vessel with the proper groundfish LE permit could enter this sector as a processor. The Council adopted a stopgap measure to limit participation, which would be replaced by a new mothership permit under this alternative. Permit qualification would be based on whiting processing history.

Shore-based processor permit: Similarly, a new shore-based processor permit would be created under this alternative. Only those processors possessing one of these permits could receive whiting during the first two years of the program. Thereafter, any shore-based processor could receive whiting.

Catcher vessel permit: New, separate LE permit endorsements would be created for catcher vessels participating in either the mothership or shoreside co-op sectors. Qualification for a permit would be based on past participation in the relevant whiting sector.

3.3.3.2 Co-op Formation and Allocation

Each year, catcher vessels would be able to choose to join a co-op or fish in a non-co-op fishery. If a vessel chooses to fish in a co-op, it would have to deliver all of its catch to the processor in its co-op (a mothership or shoreside facility). If a catcher vessel wishes to change its co-op membership, it would have to first fish for a year in the non-co-op fishery before joining the new co-op.

Each co-op that is formed would receive an allocation of the sector's overall whiting allocation, based on the combined catch history associated with each member's LE permit. Although the co-op allocation would be based on particular LE permits' catch history, vessels in the co-op would be able to arrange to have another vessel harvest all or a portion of their catch if they do not want to participate in the fishery.

The non-co-op fishery would receive an allocation based on the collective catch history of vessels that choose not to join a co-op, in a fashion similar to the co-op allocations. However, harvest would be further controlled in the non-co-op fishery through season restrictions. A vessel fishing in the non-co-op fishery would not be obligated to deliver to any one processor.

3.3.3.3 Control Limits

Shoreside and mothership co-ops would be subject to control limits similar to those described for the IFQ program. Shoreside whiting catcher vessel permit holders would be limited in terms of their control of co-op shares (recognizing that one entity could own multiple permits). In the mothership sector, the mothership processors and associated catcher vessels would be limited with respect to how much of the allocation they could process or control through co-op shares. Table 1 summarizes these limits.

3.3.3.4 Co-op Operation

Co-ops are expected to facilitate coordination and cooperation among members with respect to harvest strategy. Although co-op members would be guaranteed catch opportunity equal to the portion of the allocation they brought into the co-op through their catch history, the co-op allocation, in general, is pooled. Members could jointly agree on the specifics of harvesting.

Two or more co-ops could reach an inter-co-op agreement to coordinate harvest strategy and pool whiting and bycatch cap allocations. Various standards for both co-op and inter-co-op contractual agreements

would be established, both to aid NMFS in its fishery management role and to prevent any member from being unduly disadvantaged by co-op participation.

3.3.3.5 Management of the Non Co-op Fishery

For the duration of any given year, a permitted catcher vessel could participate in the non-co-op fishery, but the structure of this sector is intended to encourage co-op participation. Non co-op fishery participants would not have the surety of a buyer that a processor co-op obligation represents and could not easily coordinate fishing strategy in the way they are expected to in co-ops. In essence, it would be expected to function as an Olympic-style fishery with individual vessels competing against one another to catch the largest portion of the allocation.

3.3.3.6 Mothership and Catcher Vessel Quota Limits

As in the IFQ alternative, ownership limits would be imposed so that no single entity can accumulate too large a share of the overall sector allocation, based on the catcher vessel permits they own. Processors would be limited in terms of the share of the particular sector's allocation (mothership or shoreside) they could process.

3.3.4 Catcher-processor Sector Cooperatives

The catcher-processor sector currently operates under a single, voluntary co-op. A permit endorsement would be created to limit participation in the sector. Historically any vessel with the proper groundfish trawl LE permit could participate. The Council adopted a stopgap measure to limit participation, which would be replaced by the catcher-processor cooperative provisions of the trawl rationalization program. There is concern that new entrants could disrupt the current voluntary co-op. Provisions allow for implementing an IFQ program if the current voluntary co-op system were to fail. Few other changes are proposed for this sector under the alternatives.

3.3.5 Adaptive Management Program for Whiting Sectors

An adaptive management program, similar in intent and structure of that described under Alternative 2 would be established for each of the whiting sectors such that only participants in a given sector would be eligible for the adaptive management amounts deducted from each sector's whiting allocation.

3.4 Alternative 4: IFQs for a Single Shore-based Sector and Co-ops for the Whiting At-Sea Sectors

Two sub-alternatives, Alternative 4a and 4b, were considered in the analysis to compare and contrast certain program elements. The Council ultimately chose Alternative 4b as their preferred alternative. Differences between the two sub-alternatives are noted. All common elements are part of the preferred alternative. Council decision making on a preferred alternative occurred over several meetings from June 2008 to June 2009.

3.4.1 Catch Control Tool

Alternative 4 uses IFQs as the management tool for a combined whiting and nonwhiting shoreside sector and cooperatives for the two at-sea whiting sectors.

3.4.2 IFQ Program for the Shoreside Sector

Initial Allocation: In contrast to Alternative 2, where initial allocation is based on catch history alone, under this alternative, the initial allocation of QSs would be based on both catch history during the qualification period and an equal allocation of the catch history associated with buyback permits, as described under Alternative 3. Under Alternative 4a, equal sharing of buyback history would apply to the combined shoreside sector only; co-op shares for catcher vessels in the whiting mothership sector would be based on catch history alone. Under Alternative 4b (the preferred alternative) the equal sharing provision would apply to both the shoreside sector and the mothership sector. Since the catcher-processor sector would continue to operate as a single voluntary co-op, catch history assignment is unnecessary; the co-op has access to the full sector allocation.

Allocation of Overfished Species: Under Alternative 4, overfished species QSs would be distributed according to the area-based formula described above under Alternative 3. However, there are no equal sharing element based buyback permits except for canary rockfish under the preferred alternative (Alternative 4b), while in Alternatives 3 and 4a, IFQ based on buyback permit history is distributed equally for overfished species, as it is for nonoverfished species. This difference in the preferred alternative (Alternative 4b) resulted from a reconsideration adopted by the Council at their November 2009 meeting. Canary rockfish bycatch tends to be episodic and unpredictable and has occurred across a range of target strategies. The Council decided that an allocation formula for canary rockfish that included the equal sharing element (so that every permit gets at least some minimum level of canary rockfish IFQ) would lower the risk of some harvesters being forced out of the fishery because they did not possess, and could not obtain (due to expected high cost), the canary rockfish IFQ needed to cover their bycatch.

Accumulation Limits and Grandfather Clause: Table 1 compares accumulation limits across the alternatives. Alternative 4a contains the grandfather clause allowing QS holdings in excess of accumulation limits based on initial allocation. Alternative 4b (the preferred alternative) does not contain the grandfather clause. Permit holders who would receive QSs in excess of the accumulation limits would have two years to divest their excess QSs to any willing receiver. This would occur in the third and fourth years of the program, since QS transfers are prohibited in the first two years of the program. Any QSs not divested at the end of the fourth year would be forfeited, and the excess QSs would be reallocated to other permit holders below the limit. Before divesture, these quota holders are free to use the QPs derived from their excess QSs. This is meant to smooth the transition for those fishery participants with historically large catches.

Initial Allocation of IFQ to Processors: Under Alternative 4a, 50 percent of shoreside whiting would be allocated to processors based on processing history. Under Alternative 4b (the preferred alternative), 20 percent of shoreside whiting would be allocated to processors.

Species Covered: Alternative 4a does not include a halibut IBQ; Alternative 4b (the preferred alternative) does include a halibut IBQ. Alternative 4b would not use IFQs as the catch control tool for selected management units. Table 2 shows management units that would have IFQs for which separate QSs/QPs would be established and those for which IFQ would not be issued under Alternative 4b. Species for which IFQ is not issued would continue to be managed with current tools, such as cumulative landing limits. Part of the trawl allocation for nonwhiting management unit species taken in the at-sea whiting sectors would be set aside to accommodate catches in those sectors; the remainder would be available for harvest in the shoreside sector.

Adaptive Management Program: Alternative 4a would implement an adaptive management program for the combined shoreside sector reserving 10 percent of the QSs for all species (as in Alternative 2b).

Alternative 4b would implement a program where only nonwhiting species QSs would be reserved. In addition, under Alternative 4b during the first two years of implementation of trawl rationalization the adaptive management QPs would be passed through to QS holders in proportion to their holdings. Allocations of other species QPs under the program would begin in the third year, based on further specification of adaptive management program objectives and mechanisms.

Area Management: As in Alternative 2, there would be no area management provisions under Alternative 4b, except for existing area designations as shown in Table 2. Alternative 4a would have the same area designations described under Alternative 3.

Carryover of Unused QPs: As in Alternative 2, Alternative 4 contains the carry-over provision.

3.4.3 Mothership Sector Cooperative Structure

The mothership cooperative structure proposed under Alternative 4 is identical in most respects to that proposed in Alternative 3, with a few key differences. There are also some important differences between Alternative 4a and 4b. These are summarized below.

Under Alternative 4a, catcher vessels would be obligated to deliver 50 percent of their catch to the processor to which they are tied (compared to all their catch under Alternative 3). They would be free to deliver the remaining 50 percent to any mothership processor willing to receive it. As in Alternative 3, to change their processor affiliation they would have to participate in the non-co-op fishery first. Under Alternative 4b, catcher vessels would declare which co-op they would join before the beginning of the fishing year. They would then be obligated to deliver their catch to the associated mothership processor for that fishing season. In any subsequent year, they could change their affiliation without first participating in the non-co-op fishery through the pre-season declaration. Provision for a non-co-op fishery would still be included in the program structure. Any vessel not wishing to affiliate with a co-op could participate in the non-co-op fishery and deliver to any willing mothership processor.

Control limits for the mothership sector differ among the alternatives as shown in Table 1. In addition, under Alternative 4b, mothership catcher vessels would be subject to a usage limit as well as to a control limit. The usage limit is a limit on the amount any one vessel can catch and deliver to a processor. Since co-op shares would be pooled, and the allocation of catch opportunity among vessels would be decided by co-op members, it would be impossible to track the accumulation of co-op shares on a vessel in the way that QP vessel limits work in the IFQ program. The usage limit is an alternative approach to achieve the same end.

3.4.3 Catcher-processor Sector Cooperatives

The catcher-processor co-op structure would be the same as described for Alternative 3.

3.3.5.1 Adaptive Management Program for At-Sea Whiting Sectors

There would be no adaptive management program for the mothership and catcher-processor whiting sectors.

4 ENVIRONMENTALLY PREFERABLE ALTERNATIVE

NMFS is required by regulation to specify in the ROD "the alternative or alternatives which were considered to be environmentally preferable" (40 CFR 1505.29b)). The environmentally preferred alternative generally means the alternative that causes the least damage to the biological and physical environment; it also means the alternative that best protects, preserves, and enhances historic, cultural, and natural resources.

The environmentally preferred alternative for the trawl rationalization program is the preferred alternative. The comprehensive program addresses the goals and objectives identified early on in the planning process. In particular, it addresses multiple conservation objectives, leading to the conclusion that the preferred alternative is the environmentally preferred alternative. The program is expected to provide a basic management framework that will provide the most benefits to the nation for the public resource, including assigning personal accountability for the fisheries, providing opportunities for bycatch reduction, enhancing stock rebuilding through improved fishery information and full observer coverage, providing opportunities to maximize catch of targeted species while protecting species of concern, improving economic performance, helping to maintain community stability, improving safety, and addressing unforeseen circumstances through an innovative adaptive management provision. In sum, NMFS views trawl rationalization as a program that will help address conservation concerns and take a system that is not economically viable for many and turn it into one that will work for those who remain in the fishery after rationalization.

5 RATIONALE FOR SELECTION OF THE PREFERRED ALTERNATIVE (ALTERNATIVE 4B)

In addition to identifying the environmentally-preferred alternative, CEQ and NEPA implementing regulations require agencies in the ROD to state what decision was made, discuss how the decision was affected by the preferences among alternatives based on relevant factors including economic and technical considerations and agency statutory missions, and whether all practical means to avoid or minimize environmental harm from the alternative selected have been adopted, and if not, why they were not (40 CFR Part 1505.2(a)(b)(c)).

NMFS' rationale in choosing the preferred alternative focused on the need to carefully consider the balance of market power between harvesters and processors, as well as the importance to communities of maintaining processing capabilities along the coast. NMFS believed that an initial allocation of twenty percent of the whiting resource to eligible shoreside processors struck an appropriate compromise among these multiple factors. In addition, NMFS believed that the Adaptive Management Program (AMP) could be used to lessen potential impacts to processors and communities.

The need for a change from status quo is identified in the problem statement. After reviewing status quo and both the beneficial and adverse impacts of six trawl rationalization alternatives, NMFS' judgment was that the advantages of its final preferred alternative for trawl rationalization, Alternative 4b, outweighed the disadvantages.

There are two primary drivers in the problem statement that guided this process: the first is the need to account for, control, and reduce bycatch, and the second is the need to provide for an economically sustainable fishery for the benefit of industry participants and fishery dependent communities. These needs are both reflected in the goal for this action discussed in Section 1.

5.1 Trawl Focus

Foremost, this goal reflects NMFS' understanding that trawl gear is the only gear that can viably harvest much of the groundfish that is economically important to the fishery and it is the only gear that can remove much of the biomass that is available for harvest within conservation constraints. Therefore, the focus is on improving management of the trawl fishery rather than considering direct reallocation of trawl harvest to other gears. While the focus was primarily on improving management of the existing trawl fishery, NMFS' action also provides opportunities for harvest using nontrawl gears through the scope of the program, which allows vessels with trawl permits to switch to nontrawl gears to take their quota in the IFQ program.

5.2 Bycatch Reduction Objective and Observer Coverage

This action responds to the identified need for bycatch control and the need for conservation through its focus on individual accountability for catch and bycatch. At present, total mortality for all species is measured and controlled by monitoring total landings and sampling 20 percent of the trawl trips to estimate bycatch rates (discard rates) that are then applied to landings to develop an estimate of total catch and mortality. With this approach, there is substantially less certainty about total catch and mortality than there are total landings. Further, while agencies are able to regulate total landings in the nonwhiting trawl fishery through two-month cumulative limit periods and influence bycatch rates with catch area restrictions and gear restrictions, they face difficulties in managing for total catch in the nonwhiting portion of the trawl fishery. The current monitoring system was designed to provide fleetwide total catch estimates over the course of a year. It was not intended as a tool for managing individual vessel discards in the nonwhiting trawl fishery or for providing for individual accountability.

The Pacific whiting fisheries monitoring is in place that is intended to manage for total catch. The at-sea fisheries use 100 percent observer coverage on both catcher-processors and motherships and document landings and discards that are occurring in those fisheries. The shoreside whiting fishery is exploring the feasibility of cameras intended to verify full retention of catch on board vessels in that fishery. Through a full retention program, the documentation of total catch of species in that fishery occurs dockside.

NMFS considered achieving individual accountability and improved mortality estimates through full retention rules in the nonwhiting fishery with compliance monitored through video cameras. However, the practicality of using cameras in the nonwhiting fishery is problematic because of the vessels' need to discard debris and prohibited species and the difficulty of monitoring holds for surreptitious catch sorting and discarding.

The other means identified for providing individual accountability for discarding is to require 100 percent observer coverage for vessels participating in the trawl sector. Full observer coverage, combined with a

shift from regulating landings to regulating catch, is a key element of the NMFS' preferred alternative. These elements provide for individual accountability for catch and some incentive for bycatch reduction.

5.3 Link between Bycatch Control and Need for Rationalization

Full at-sea monitoring and the switch from controlling landings to controlling catch would achieve the main conservation related objectives; however, 100 percent observer coverage for the nonwhiting fishery and observers/cameras for whiting catcher vessels would be costly. Even if the observers/cameras were not paid for by industry, there are still costs that a vessel incurs when it has an observer or camera on board. If vessels must pay for the cost of observers, then the burden is substantial, and it moves the fishery away from achieving social and economic objectives. As identified in the problem statement, the fishery is already under substantial economic stress. Imposing large additional costs to carry observers could devastate the fishery unless its overall economic health is also improved. Early on (in its strategic plan and Amendment 18), the Council identified rationalization as a way to improve the economic health of the fishery. Under a perfectly rationalized fishery, capacity would be reduced, and costs would be minimized so that the labor, capital, and other inputs used to capture the fish are no more than is absolutely necessary to fully take the amount that can be harvested while meeting conservation objectives. Thus trawl rationalization is viewed as a necessity for improving the health of the industry. Further, with 100 percent observer coverage, the Council would be able to better monitor total mortality of all groundfish species. Better mortality estimates would improve both stock assessments and the Council's ability to keep catch below the harvest limits developed based on those assessments, substantially contributing to conservation goals. Finally, rationalization based on a system that relies on transferable quotas enhances the incentive to avoid bycatch. Without transferable quota, the incentive is to reduce bycatch only to the point where all targeted species can be harvested. With transferable quotas, fishermen who can lower bycatch rates even further have a potential opportunity to sell their unused quota to others, thus benefiting from reducing their bycatch rate to a level lower than what was necessary for them to take their own available target harvest.

5.4 Choosing Between Status Quo and Trawl Rationalization: Broad-Level Council Concerns and Tradeoffs

The Council considered if there was a potential for achieving some of the goals and objectives through other types of modifications to status quo. The Council considered whether modifications such as extending the duration of the two-month cumulative trip limit periods and a full retention requirement might achieve some of the important objectives. Extension of cumulative limit periods would decrease the Council's opportunity to make inseason adjustments and would be expected to increase the number of vessels taking their full limits. This would move the fishery in the direction of individual permit quotas without generating the degree of benefits expected from a regular IFQ program. However, extending the two-month cumulative trip limit reduces the number of opportunities the Council has for making adjustments to catch limits to stay within allowable catch levels, thus increasing the possibility of exceeding ABCs and OYs established by the Council. Extension of the length of the cumulative limit periods was an option that had been previously considered and rejected by the Council. For the whiting fishery, there is a need to end the derby because of safety and waste issues; however, the bioeconomics of the fishery does not lend itself to management through cumulative limit periods used in the nonwhiting fishery. While Amendment 15 has resolved some of these issues, the trawl rationalization program would implement a longer-term solution. The Council considered maximized retention in the Pacific whiting fishery, and NMFS is currently considering it for approval as regulations to implement Amendment 10 to the Groundfish FMP. Maximized retention for the nonwhiting fishery was considered as a monitoring option under the IFQ program, but was rejected. The Council was not able to identify other ways to

modify status quo that would be as effective as trawl rationalization in moving the fishery toward its most important goals and objectives.

Under status quo, the trawl fishery is viewed as economically unsustainable due to the number of participating vessels, excess capacity, a regulatory approach that constrains efficiency, and the status of certain groundfish stocks along with the measures in place to protect those stocks. Regardless of the deficiencies of status quo, the Council had to determine whether trawl rationalization, would be an improvement over status quo. In particular, the Council debated whether the economic benefits expected from increased harvest and efficiency would be sufficient and occur early enough in the program to help the fishermen handle the increased costs of the program. The broadly held view by Council members was that the potential for improving the economics of the fishery through trawl rationalization was substantial enough to overwhelm the risks and uncertainties. Council members noted that, due to cumulative limit management, the amount of one highly marketable fish species that had gone unharvested in a recent year was nearly enough to alone cover observer program costs, and reported discard rates and wastage were unacceptable. Given the under-harvest of available OYs, the Council believed it was important to the fishermen and the public to provide an opportunity to achieve the OYs and develop markets for additional fish products. Furthermore, the program would provide the fishery an opportunity to increase profits, not just through harvest expansion, but also through a variety of mechanisms leading to cost reductions. For the nonwhiting fishery, an economically healthy fishery would also be expected to result in some improvement in safety. For the whiting fishery, an end to the derby would create substantial safety improvements. In addition to the potential for safety and strong economic benefits, Council members noted the substantial conservation benefits expected from 100 percent monitoring of catch. This would help reduce bycatch and discards and rebuild stocks that are suffering partially because of discards.

While the trawl rationalization program would move the fishery toward some of its most important goals and objectives, in order for the program to realize those benefits, a large amount of consolidation would have to occur, resulting in fewer people employed in the fishery. Council members acknowledged and expressed concern about the expected consolidation and its impacts and noted the need to attend to the potential for disproportionate impacts on some communities. There was also concern that the potential accumulation of wealth under the IFQ program should have corresponding levels of benefit for the nation, and that state implementation costs be addressed. Finally, Council members expressed an interest in maintaining the character of the fleet and a diversified industry. Balancing the need for consolidation to generate adequate levels of benefit with the potential adverse impacts of consolidation was a major challenge. At the same time, status quo (buyback program and cumulative limits) has resulted in consolidation in the fleet and a redistribution of vessels along the coast. Because of the high degree of concern about impacts on communities and maintaining some sharing of benefits (both among harvesters and between harvesters, processors, and others dependent on the fishery) the Council made a number of tradeoffs in the trawl rationalization program that may prevent the program from reaching the full degree of economic efficiency that might otherwise be achievable through rationalization.

In taking this action, the Council acknowledged that work will have to continue to monitor the program and to make adjustments in response to program performance. Even prior to implementation, the Council will continue to work on provisions for Community Fishing Associations and an Adaptive Management Program. While there may be unintended and unanticipated consequences, there will be an opportunity to modify the program through a review process, and a data collection process will be implemented to support that review.

Overall, the Council viewed the trawl rationalization program as addressing many of the difficult, time-consuming management problems it has struggled with under status quo. It is expected to provide a basic management framework that will provide the most benefits to the nation for the public resource, including assigning personal accountability for the fisheries, providing opportunities for bycatch reduction,

enhancing stock rebuilding through improved fishery information and full observer coverage, providing opportunities to maximize catch of targeted species while protecting species of concern, improving economic performance, helping to maintain community stability, improving safety, and addressing unforeseen circumstances through an innovative adaptive management provision. In sum, the Council views trawl rationalization as a program that will help address conservation concerns and take a system that is not economically viable for many and turn it into one that will work for those who remain in the fishery after rationalization.

5.5 Choice between IFQs and Co-ops for Each Trawl Sector

Under an IFQ program, each vessel acquires the quota necessary to prosecute its own fishing strategy, and each vessel is individually responsible to the fishery management agency for complying with the program and covering its harvest with quota. Under a co-op program, an allocation is given to the co-op and the co-op then distributes the allocation to its participating vessels. The co-op agreement and managers determine the amounts each vessel will harvest, and the vessels are responsible to the co-op for complying with the terms of the co-op agreement. In some cases, the allocation received by the co-op is determined by the history associated with each of the permit holders who are members of the co-op. The fishery management agencies do not track the transfer of harvest opportunity among co-op members, nor do they track each vessel's catch against allocations to that vessel. The fishery management agencies hold the co-op as a whole responsible for staying within its limits and the individual vessels responsible for complying with other aspects of the program, such as requirements to carry an observer.

The Council looked at rationalization for the four groundfish trawl sectors: nonwhiting shoreside, whiting shoreside, mothership whiting, and catcher-processor whiting. IFQs were considered for each fishery and co-ops were considered for each of the three whiting sectors.

5.5.1 Choice for the Shoreside Nonwhiting Sector

The whiting fisheries are more homogeneous in terms of fishing strategies, the timing of the fishery, and their geographic distribution. This homogeneity lends itself more to the type of centralized management provided by the co-op.

5.5.2 Choice for the Shoreside Whiting Sector

The shoreside whiting fishery is viewed as having greater homogeneity among participants than the nonwhiting fishery, but less homogeneity than the other whiting fisheries. Representatives of the harvesting and processing sectors reached a compromise agreement and recommended that under an IFQ program there be a 20 percent allocation of whiting QS to processors. This allocation to processors addressed concerns about the effects of trawl rationalization on market power balance between the harvesting and processing sectors. Also contributing to the decision to manage the shoreside whiting sector under IFQs was the opportunity that managing the two sectors together provided for resolving intersector allocation issues between them.

5.5.3 Choice for the Mothership Whiting Sector

For the mothership fishery, the Council had more latitude to consider regulating processors, since processing facilities in this sector are on vessels and, therefore, come under the Council's authority within the MSA. While the Council had authority to limit new entry for processing vessels, NOAA General Counsel advised the Council that absent a strong conservation rationale it would not have the authority to regulate economic relationships between vessels and processors that would otherwise be determined in

the marketplace; i.e., the Council's authority to recommend processor ties was limited. On this basis, the Council developed a processor tie provision that only required a vessel to commit its production to a particular processor for the coming year and did not extend that obligation to any subsequent year. This requirement came about after hearing public testimony indicating that the absence of certainty regarding catcher vessel deliveries in the mothership portion of the Bering Sea pollock fishery nearly led to the bankruptcy of a mothership company engaged in that fishery. The declaration procedure is intended to facilitate some business planning certainty to the mothership for the coming year. Even though the processor tie provision had to be severely weakened, the co-op alternative was still viewed as providing some balance of marketing power between mothership harvesters and processors, because it created an LE system for mothership processors, thereby strengthening their position vis à vis harvesters. The co-op alternative also had the advantage of encouraging vessels to work together and share information about catch rates through the co-op structure. Some savings in administrative costs were also expected because the co-op will track transfers of allocation among vessels, alleviating the need for NMFS to handle that task. Finally, some Council members voiced a preference for supporting industry participants by addressing their issues through co-op efforts and less governmental involvement. Under the IFQ program for the mothership sector, the issue of market power balance might have been addressed through an initial allocation of QS to processors (something like the 20 percent that was given to shoreside processors), but the IFQ program alternative did not include an LE system for mothership processors. Additionally, the IFQ program did not provide the incentive and structure for information sharing about bycatch. Finally, the mothership co-op alternative was originally developed through a consensus between the majority of mothership sector harvester and processor participants, and the participants in that consensus continued to support the co-op alternative, even with the substantially weakened processor tie provision.

Managing the mothership sector under an IFQ program would have provided an opportunity to reduce management costs and allocation controversy by combining the mothership and shore-based sectors under a single IFQ program. However, there were also concerns that vessels participating in the mothership sector might have an economic advantage over the traditional shoreside fleet and that if the catcher vessel fishery (shoreside and mothership catcher vessels) were managed under a single IFQ program the mothership catcher vessels might use that advantage to purchase more QS, redistributing harvest within the fleet and among communities, causing disruption and adverse social consequences.

5.5.4 Choice for the Catcher Processor Whiting Sector

The catcher processor sector of the whiting fishery is already rationalized under a self-developed co-op program, entered into voluntarily by the participants in that fishery. The self-designed program was initially facilitated by (1) a license limitation program, which created a barrier making it very expensive for new catcher-processors to enter the fishery, and (2) the Council's specification of a whiting allocation for the catcher-processor sector. The program was further supported by Amendment 15, which established a Pacific whiting vessel license based on historical participation. Implementation of Amendment 15 prohibits new entrants and, thereby, maintains the current structure and stability of the catcher-processor co-op. The Pacific whiting vessel license was intended to be an interim measure until the Council fully considered trawl rationalization. During the development of the preferred alternative (Alternative 4b), the Council expressed concern that the structure of the co-op could deteriorate, resulting in a derby fishery. Therefore, it specified that in the event the co-op failed the fishery would be managed with an IFQ program and that an equal amount of QS would be issued to each permit with a catcher-processor endorsement.

5.6 Major Decisions in Designing the IFQ Program

With respect to IFQs, the Council considered programs that would manage each trawl sector under a separate IFQ system, one that would manage the shore-based trawl sectors together, but the two at-sea whiting sectors separately, and one that would manage all four trawl sectors under a single program. Under the Council-preferred alternative (Alternative 4b), the Council chose IFQ management for the shore-based whiting sector and the nonwhiting shore-based sectors and recommended managing them together as a single shore-based trawl sector. Managing the shore-based trawl fishery as a single sector is expected to increase the likelihood that available harvest will be fully taken. If the shore-based trawl sector were managed as two separate IFQ programs, the Council would have to allocate nonwhiting species taken incidentally in the whiting fishery to the shore-based whiting sector and nonwhiting trawl sectors. If the incidental catch allocations the Council provided to the shore-based whiting sector were not sufficient to allow the sector to take all of its whiting allocation, there would be no way for the shore-based whiting sector to acquire additional nonwhiting quota to cover its incidental catch, and whiting would go unharvested. At the same time, if the shore-based whiting sector were allocated more than the amount it needed to cover incidental catch, there would be no mechanism to move the excess back to the nonwhiting shore-based trawl fishery for its use, and the excess allocation would go unharvested. By managing the shore-based trawl sectors together under a single IFQ program, there is an increased likelihood that the market place will overcome constraining species issues as quota holders buy and sell quota to whomever can put it to best private use (i.e., to whomever is willing to pay the highest price for it).

Deciding on the groups which would receive an initial QS allocation was another major decision for the Council. One of the primary issues debated extensively was whether to give an initial allocation of QS to processors and, if so, in what amount. During Council discussion, it was noted that the MSA LAP Program provisions in Section 303A(5) require that the Council ensure fair and equitable initial allocations, including consideration of (1) current and historic harvests, (2) employment in the harvesting and processing sectors, (3) investments in and dependence on the fishery, and (4) the current and historical participation of fishing communities.

Congress specifically instructed the Council to fully analyze alternative program designs, including allocation of LAPs to harvest fish to fishermen and processors. Much of the Council's discussion about an allocation to processors revolved around the impact of both status quo and trawl rationalization on market power. It was noted that the U.S. economy relies on competition and on individuals and businesses acting in their own self interest for growth, innovation, price setting, and the allocation of resources. There was a sentiment that government should not interfere in business competition unless it is necessary for the public benefit.

In its preliminary preferred alternative, the Council recommended giving processors 20 percent of the shore-based allocation of QSs for all species except bycatch taken in the shore-based whiting fishery. Council members noted the difficulty of determining the correct percentage for a possible QS allocation to processors. Council members noted that the case for providing QSs to whiting processors seemed to be relatively clear but it was less clear for nonwhiting processors. The 20 percent approach chosen for the preliminary preferred alternative was believed by some to be a fair middle ground for public review and comment.

In its final preferred alternative, after further review of the analysis and public testimony, the Council recommended giving processors 20 percent of the QSs only for shore-based whiting and no QSs for shore-based nonwhiting. In taking this action, Council members expressed their concern that an initial allocation of QSs to nonwhiting processors would add too much to the market power of shore-based nonwhiting processors. Additionally, Council favored providing a 10 percent allocation for adaptive

management. The adaptive management program could be used not only to provide some amount of certainty and security to the larger processors, but also to provide flexibility to tailor a program that would provide some protection to smaller processors. In making its decision, the Council specified its intent that the adaptive management program be constructed in a manner to ensure that the program accomplishes this as one of its objectives.

Consideration was also given to allocating QSs to communities and crew members. However, communities expressed no interest in receiving an initial allocation of QSs. Therefore, the Council developed other mechanisms to address concerns about communities, including, but not limited to, the adaptive management program, a two-year moratorium on QS transfers, a five-year review that includes a community advisory committee, accumulation limits and a two-year review of some of the limits, the opportunity for communities to receive an initial QS allocation by acquiring a trawl permit, and a trailing action on community fishing associations. With respect to crew members, an initial allocation is difficult because there is limited historic information on the identity of crew members who have fished on trawl vessels. It is the Council's hope that by providing highly divisible QSs and ensuring that other elements of the program design facilitate crew ownership of QS, that crew members who want to do so will be able to incrementally accumulate QSs.

5.7 Major Decisions in Designing the Co-op Program

The most important and broadly controversial elements of the mothership co-op program design were the processor tie provisions and LE for mothership processors. These issues were covered above in the discussion of the Council's decision on whether to go with IFQs or co-ops for each of the whiting sectors.

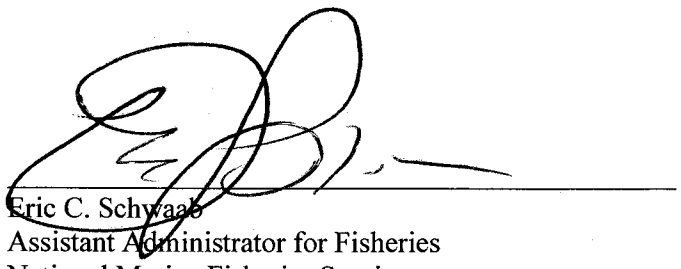
For the catcher-processor co-op program, one of the most controversial design elements was the decision whether the catcher-processor co-op would be issued a permit. When the Council developed its preliminary preferred alternative on this issue, there was extensive debate on the question of whether the catcher-processor co-op would be designated as a LAP program and subject to a 3 percent fee. However, the Council was advised that if it provided an allocation for the co-op and required a co-op permit, then the program would be a LAP program. On this basis, the Council adopted the final preferred alternative in November 2008 and June 2009 which did not to require permits for co-ops. However in reviewing proposed regulations for program implementation and determining them to be necessary and appropriate ("regulatory deeming"), the Council reconsidered. In April 2010, the Council agreed that the regulations should include the co-op permit requirement. NMFS indicated that the Council will participate in subsequent deliberations on formulating cost recovery provisions. Through that process, the Council may determine what aspects of program cost may be attributed to a given fishery sector.

6 COMMENTS RECEIVED ON THE DEIS AND FEIS

A 45-day public comment period on the Draft Environmental Impact Statement (DEIS) commenced on December 4, 2009, as required by the CEQ regulations. NMFS and the Council have received a substantial number of public comments on the trawl rationalization program during Council meetings and during the public comment periods for the DEIS that analyze the impacts of Amendment 20. Some comments have supported the program, while others have criticizes different aspects of the program. Chapter 10 of the FEIS included responses to the comments received on the DEIS. NMFS received two additional public comments on the FEIS during the 30 day cooling off period that concluded on July 26,

2010, similar to comments received on the DEIS, which were addressed in the response to comments included in Chapter 10 of the FEIS.

7 MITIGATION MEASURES AND MONITORING



An EIS must discuss "means to mitigate the adverse environmental impacts" stemming from the proposed action (40 CFR 1502.16(h)), even if the adverse impacts are not by themselves significant. The mitigation measure incorporated into the proposed action and included in the preferred alternative (Alternative 4b) is the adaptive management provision, which annually sets aside up to 10 percent of the QPs in the shore-based IFQ fishery and up to 10 percent of the available aggregate harvest pounds for the Pacific whiting cooperative program. This harvest opportunity would then be allocated by the Council to meet specified objectives, including unforeseen impacts, such as geographic shifts in catch or landings, previously unidentified impacts to participants (e.g., processors), or unexpected barriers to new entry into the fishery.

8 SUMMARY FINDINGS

Through the EIS and the documentation in this ROD, NMFS has considered the objectives of the proposed action and has analyzed a reasonable range of alternatives that adequately address the objectives of the proposed action, and the extent to which the impacts of the action could be mitigated. NMFS has also considered public and agency comment received during the EIS review period. In balancing the projected effects of the various alternatives presented in the EIS and the public interest, NMFS has decided to implement the preferred alterative, Alternative 4B. Consequently, NMFS concludes that the approved alternative provides reasonable, practical and practicable means to avoid, minimize, or compensate for environmental harm from the action.
