#### Acknowledgments

We are particularly indebted to Richard C. Hennemuth, Northeast Fisheries Center, National Fisheries Service, Woods Hole, Massachusetts, for providing advice and information on the foreign fisheries. Mrs. Marjorie Sumner assisted in compilation, typing, and proofreading.

Statistics on domestic commercial landings were compiled from original sources by the senior author under support of a fellowship with the Woodrow Wilson International Center for Scholars, Washington, D. C., in 1971.

### Fishery Landings in the New York Bight Area

New York Bight, usually identified as that region from Montauk Point, Long Island, to Cape May, New Jersey, and out to the edge of the continental shelf (Fig. 1), has been an important fishing ground for at least a century. Great changes have occurred in the fisheries of the Bight during their recorded history. Over this period, the species composition of landings has varied considerably. Despite the recent development of huge foreign fisheries in the area, the total commercial catch, domestic and foreign, from the Bight area in 1974, approximately 197,000 metric tons, was only about 10 percent greater than the reported commercial catch in 1880. The relative proportions of the total catch taken by New York, New Jersey, and foreign commercial fishing fleets, however, have changed greatly.

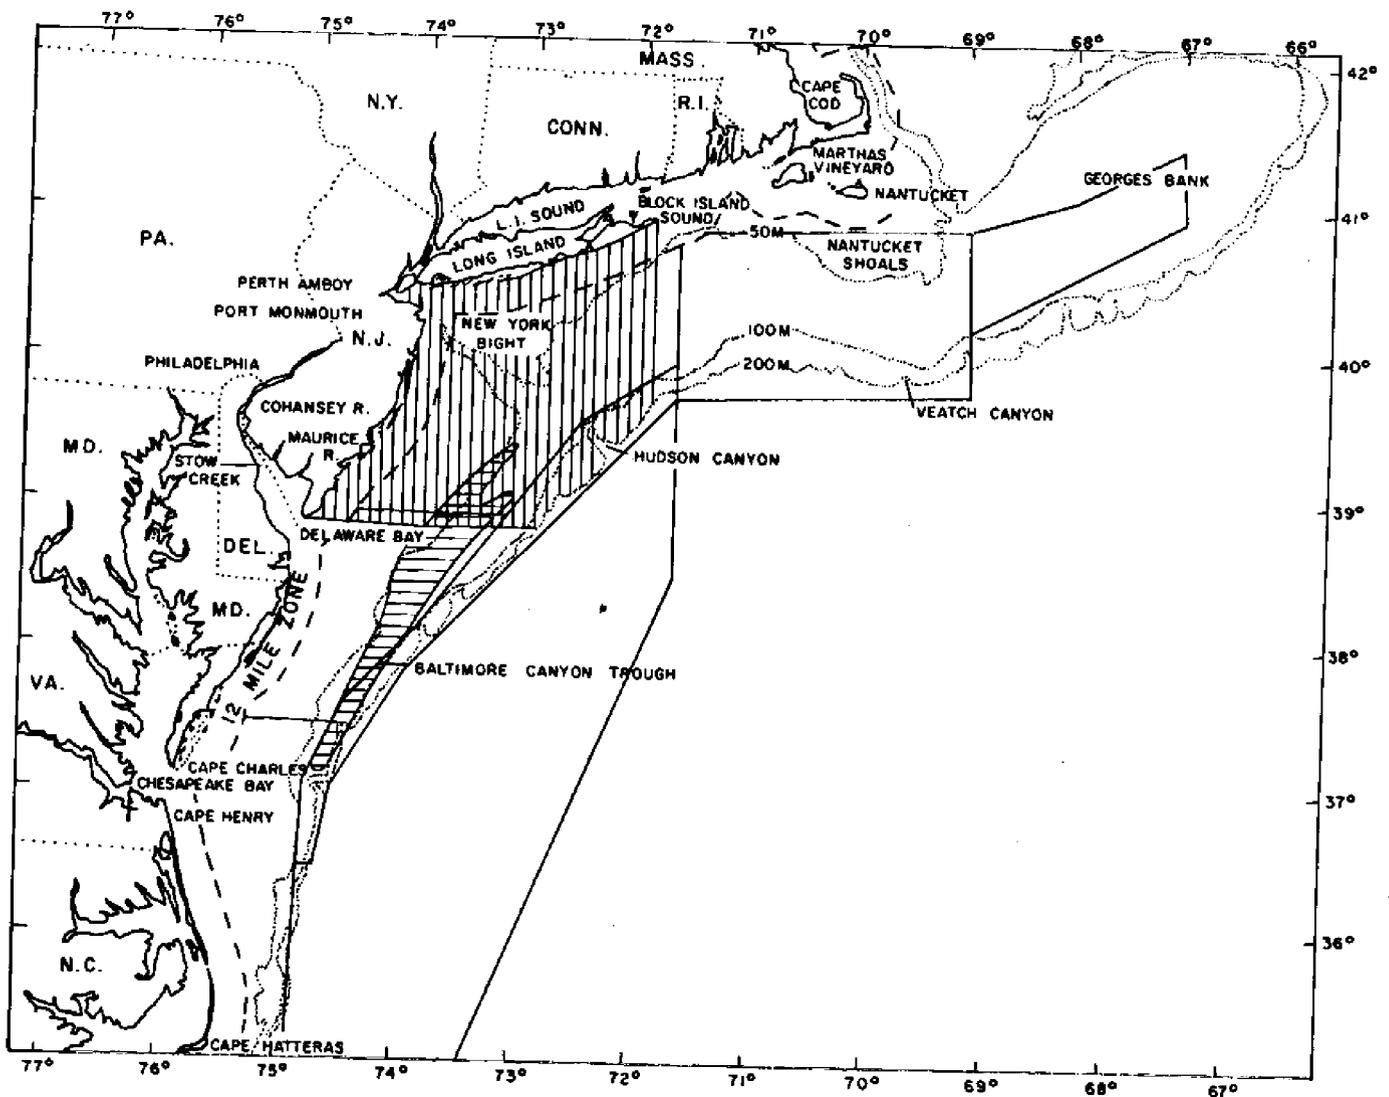

Figure 1.--Middle Atlantic Bight (Cape Cod to Cape Hatteras) showing New York Bight (vertical shading) and the areas designated in bilateral negotiations between the United States and USSR, Poland, and Romania (bounded by solid lines). In these areas fishing may be prohibited during certain seasons, or only specified kinds of gear may be used.

New York Bight is of special interest with respect to environmental quality at the moment because it is one of the most seriously polluted large areas of the marine coastal zone of the United States. The Marine Ecosystems Analysis (MESA) program of the National Marine Fisheries Service has selected this area for immediate and detailed attention, and the area is also of particular interest to the Marine Sciences Research Center of the State University of New York among others.

The purpose of this paper is to present as complete a compilation as possible of available information on fish catches from the New York Bight area. These records are divided into three categories: domestic commercial landings New York and New Jersey, recreational, and foreign catches. In no category is it possible to isolate catches from the Bight alone, as explained later. The migratory habits of many species valuable to domestic fisheries, however, make it useful to include certain catch statistics from the entire Southern New England and Middle Atlantic Bight regions. This was at any rate necessary because records of recreational catches are not available by individual states.

#### New York and New Jersey Commercial Landings

The National Marine Fisheries Service and its predecessor agencies, the Bureau of Commercial Fisheries and others, have collected and published statistics on domestic commercial fishery landings since 1880. Historical summaries of these landings for some major species have been published from time to time in the annual report Fishery Statistics of the United States. These were brought together in a series of publications by major regions (Lyles, 1966a). The regional compilation of interest for this study was for the Middle Atlantic States (Lyles, 1966b), New York, New Jersey, Pennsylvania, and Delaware.

Landings in New York and New Jersey can be considered as having come mostly from New York Bight (Fig. 1). Long Island Sound, more than half of which is New York waters, and Delaware Bay which is shared by New Jersey and Delaware, are outside the bounds of New York Bight, yet they contribute to New York and New Jersey landings. The most important fisheries in these two areas have been molluscan shellfisheries, especially prior to the mid-1950s. New York landings have been subdivided by statistical areas since 1954 in official publications, but New Jersey landings have not (New York Landings, 1954-1969; New Jersey Landings, 1952-1975). Recent landings in New York ports on Long Island Sound therefore can be identified from 1954 to 1969, but the practice of reporting by districts was discontinued in 1970. They have not been large in the period of record, ranging only from about one to five percent of total landings in the State. A history of the fisheries of Long Island Sound was completed recently (Wise, 1975).

The compilation by Lyles (1966b) was quite inadequate for the purposes of this publication. It contains information on only nine individual species of finfish and five species of crustaceans and mollusks. All flounder species were lumped, as were bay and sea scallops. Hard blue crabs were included but not soft crabs. The series of historical catch statistics covering the entire Atlantic coast is even less useful because species were included only if they were of major importance in a particular region. Thus, from these publications alone it is not possible to compare trends in landings by species, state by state, nor is it possible to reconstruct total landings of most species for the Atlantic coast. Many species important in the past but now much less abundant or available are missing, as are all species of intermediate or minor importance. For these reasons it was necessary to return to the original sources for complete data on domestic commercial landings. Most of this compilation was done by the senior author in the summer of 1971 under support of a Fellowship with the Woodrow Wilson International Center for Scholars. For fuller discussions of the commercial and recreational fisheries in the New York Bight area see McHugh (1972, 1974, 1976).

In the period 1880 to 1928 inclusive, statistics were gathered only for twelve years in New York and thirteen in New Jersey. In some years, for example 1892 and 1946, data are available for only

one of the two states. Beginning with 1929 the series is almost unbroken, but no statistics were recorded for New York in 1934, 1936, and 1941, or for New Jersey in 1934, 1936, 1941, and 1946.

The accuracy of statistics prior to 1929 is suspect. Surveys were made infrequently by agents based in Washington, D.C., who usually were not familiar with the fisheries they were surveying and not known to the people in the industry (Power, 1968). To some degree these problems continued to 1940 because the numbers of agents were small and statistical field offices were not established by the federal government until 1940.

Prior to 1942 statistics were gathered principally from interviews with fishermen rather than from records kept by dealers (Power, 1968). A boat captain might find it easy to provide information on his total catch for the year, but if he landed in various ports to reduce running time from seasonal fishing grounds it was difficult to allocate the total catch by species and gear to specific ports of landing. Therefore, up to and including 1940, the entire catch was credited to the principal port of landing. From 1942 on, records were obtained almost entirely from purchase records of dealers, providing more accurate statistics of port of landing, although perhaps less meaningful in terms of where the fish were caught.

The publications New Jersey Landings and New York Landings were started in 1952 and 1954, respectively. New York Landings includes deliveries by domestic fishing vessels to Fulton Market piers in New York City, but "receipts" delivered to Fulton Market by other means, for example by truck, rail, or other land transport, are not included.

Some freshwater species have been included in published domestic marine fishery statistics. When these clearly could not have come from marine or estuarine waters we did not include them here. In response to changing river flows, however, some freshwater species sometimes are carried down into the estuaries, where they may be caught in marine commercial fishing gears. When in doubt, such species, like pike or pickerel, carp, suckers, catfish and bullheads, crappie, sunfish, and black bass (which may have been black sea bass) were included.

Domestic commercial landings are accompanied by figures on landed value. We did not include values here for two reasons. Such figures are of limited usefulness unless they are adjusted to standard dollars, and for obvious reasons sport catches and catches reported by the International Commission for the Northwest Atlantic Fisheries (ICNAF) are recorded only by weight. A study of trends in landed value of the domestic commercial catch is underway and the results will be published later.

#### Recreational Catch Estimates

The only complete estimates of sport fish catches in the New York Bight area are those based on National Surveys of Fishing and Hunting made by the U.S. Bureau of the Census. Four such surveys have been made, in 1960, 1965, 1970, and 1974. Detailed reports on saltwater angling have been published for three of these years (Clark, 1962; Deuel and Clark, 1968; Deuel, 1973), but the results of the 1974 Survey are not yet fully available (Ridgely and Deuel, 1975).

The samples upon which these estimates were based were very small. For instance, in the 1960 survey, 45,000 people were interviewed, of which 1,750 were identified as saltwater sport fishermen, and 92 percent of these anglers provided all the information used in estimating the national sport catch of finfish. For this reason, and because the numbers of anglers interviewed were not always proportional to total population in certain geographical regions, estimates of saltwater recreational catches had to be grouped by areas larger than states.

New York State was included with New England (the North Atlantic Region) in a single series of estimates by species. New Jersey was included with a group of states to the south (the Middle Atlantic Region), including that part of the North Carolina coast north of Cape Hatteras. This makes it difficult to interpret the figures so as to derive estimates for New York Bight waters alone. It is sufficient to say that rough estimates can be deduced by a variety of approximations, such as

knowledge of the distribution and migrations of the major species, relative numbers of each species in the two regions which overlap New York Bight, and from a number of partial sport fishery studies which have been published by scientists in New York and New Jersey state agencies and the federal government. Analysis of all available information on the recreational fisheries of the area is underway (Mohr, 1976).

The Salt-Water Angling Surveys did not include estimates of recreational catches of invertebrates. Practical limitations on surveying also led inevitably to exclusion from the estimates of some minor finfish species (Clark, 1963; Deuel and Clark, 1968; Deuel, 1973). Sport fishermen were asked in each survey to list only those catches taken primarily for recreation and to exclude catches taken for sale; yet it is probable that the catch estimates the Bureau received were overestimated. The interaction of these factors and their effects upon the validity of these estimates are unknown. For these reasons, comparisons of sport and domestic and foreign commercial catches, by species and as a whole, must be done with extreme care.

Estimates of sport catches are, however, probably indicative of trends within the fishery itself. The geographical distribution of those interviewed in each survey was unavoidably uneven. Thus, the accuracy of these estimates probably varies regionally. The reader is referred to the original publications for details of surveying techniques. Further information on recreational fisheries of New York and New Jersey is given by McHugh (1972, 1976), Briggs (1962, 1965a, 1965b, 1968), Buchanan (1972), Poole (1961), and Younger and Zamos (1955). A complete listing of pertinent literature will be given by Mohr (1976).

#### Foreign Catches

ICNAF was established in 1949, and presently is composed of 17 member nations, including the United States and Canada. Figure 2 illustrates the southern part of the region under Commission jurisdiction. The western limit of this area, bounded by the line  $71^{\circ} 40'$  W longitude, runs south through Block Island to  $39^{\circ} 00'$  N latitude, due east of Cape May, New Jersey. The southern boundary runs east to  $42^{\circ} 00'$  W longitude. The eastern boundary is not shown in the figure because virtually all fishing in the area takes place over the continental shelf, bounded by the 200 meter isobath. Catches by foreign fleets from Division 5Z, divided into Subdivision 5Ze (roughly, Georges Bank) and Subdivision 5Zw (Nantucket Shoals), have been included in this report. ICNAF did not separate catches from Division 5Z for these two regions until 1968, and all foreign catches prior to that time have been listed under Division 5Z. Catches listed under this heading after 1967 reflect catches of unknown origin within Division 5Z. Statistics recorded under "Subarea 5 NK" refer to catches made within Subarea 5 which may or may not have been taken in Division 5Z. Foreign catches from this area are likely to affect the abundance of many migratory species in New York Bight. As far as the other Subareas of the Convention Area are concerned, we have assumed that foreign fishing there has had, or will have, negligible effect upon the living resources of New York Bight, and therefore we have not included statistics for ICNAF Subareas 0 to 4 inclusive.

In 1966, ICNAF established Statistical Area 6 (Fig. 2), which includes coastal waters from Block Island to Cape Hatteras. Foreign fleets first began fishing these waters in the early 1960s, and records of these catches begin in 1963. Foreign catches off this section of coast are of great concern to domestic fishermen, commercial and recreational, in the New York Bight area, and in the larger area usually called the Middle Atlantic Bight, which extends from Cape Cod to Cape Hatteras. Subarea 6 has been subdivided into smaller areas, of which Division 6A, from Block Island to Cape May, is of especial interest, as it encompasses New York Bight. Subarea 6 was not subdivided until 1968, and submission by member nations of detailed catch reports from each Division has not been consistent until recently. For this reason, foreign catches from Division 6A, from Subarea 6 as a whole, and from unknown regions of Subarea 6 ("Subarea 6 NK") have been included here. Almost all of the catch, domestic and foreign, from Subarea 6 is taken in the coastal Divisions 6A, 6B, and 6C.

It is probable that much of the foreign catch in Divisions 6B and 6C by other nations and other Atlantic coast states directly influences abundance and availability of many migratory species in New York Bight. With few exceptions fishing in this area takes place over the continental shelf. The edge of the shelf, as marked by the 200 meter isobath, can be considered for practical purposes as the seaward limit of fishing. Hennemuth (1975) stated that fishing actually is conducted to depths of about 400 meters.

It is important to note that the 12 mile limit of fishery jurisdiction is the western boundary of Division 5Z and Subarea 6 for foreign fisheries. For this reason endemic resources such as clams and oyster are not available to foreign fleets. Oceanic mollusks like surf clam are not available to foreign fishermen because they have been declared creatures of the continental shelf and hence are domestic resources under the terms of the 1958 Geneva Convention on the Continental Shelf. Resources such as menhaden, which inhabit waters near shore, are only partially available to foreign exploitation. Some of the major foreign fishing nations have agreed not to conduct specialized fisheries for menhaden, and it seems unlikely that others will seek menhaden deliberately. Since 1970 an increasing number of species of economic importance to the United States have been made less available, to varying degrees, to other nations, as a result of bilateral agreements between the United States and Poland, the USSR, and Romania. These species include silver and red hake, bluefish, menhaden, black sea bass, and scup, among others. Areas closed to foreign fishing in certain seasons, or in which certain kinds of fishing are not to be carried on, are shown in Figure 2. ICNAF also has, since 1972, imposed overall catch quotas and species quotas on foreign

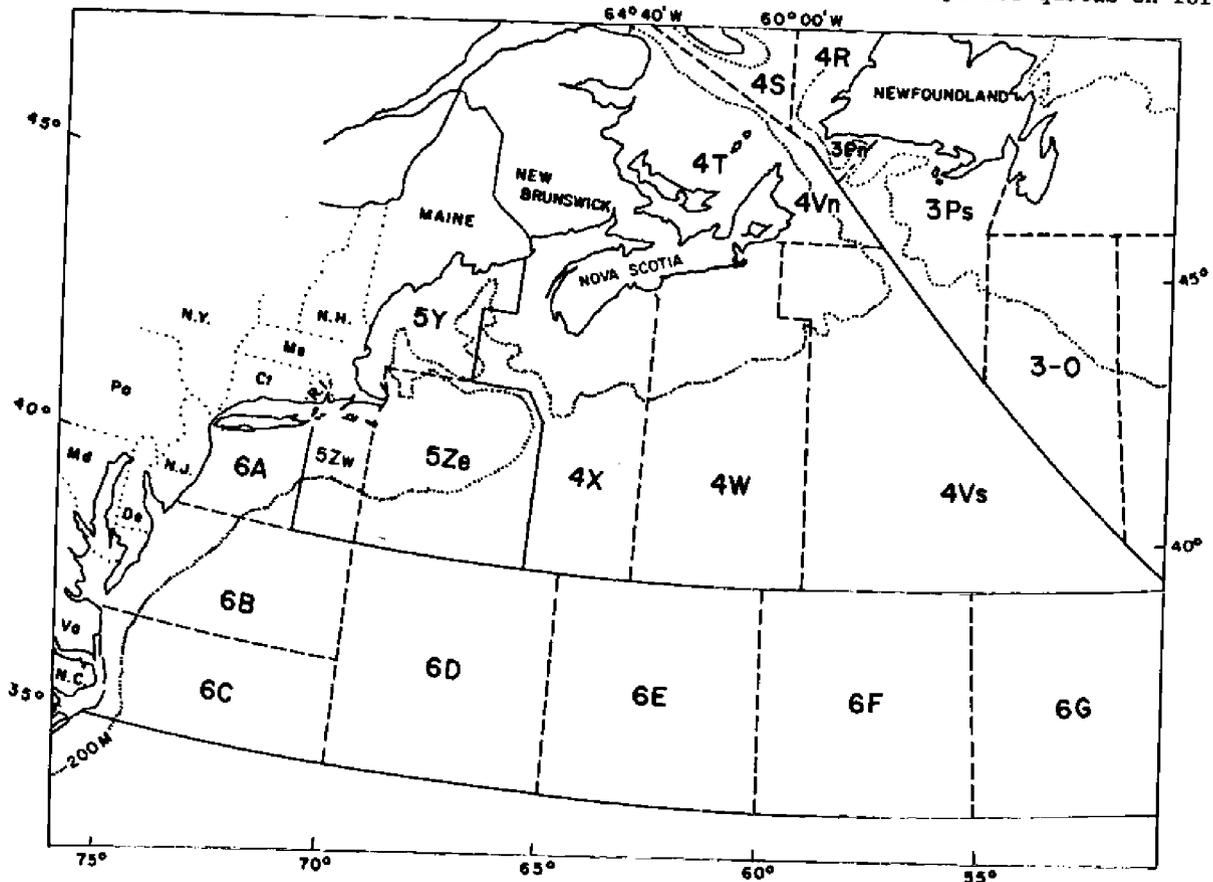

Figure 2.--Regulatory and statistical subareas and divisions established by the International Commission for the Northwest Atlantic Fisheries off the United States coast and part of Canada. The areas of foreign fishing of concern to the New York Bight area are Division 5Z and Subarea 6 and out to the edge of the continental shelf (approximately the 200-meter isobath).

fleets throughout the Convention Area and Subarea 6. In October 1975 a total quota for 1976 of 650,000 metric tons, all species, live weight, was established for ICNAF Subareas 5 and 6 combined. Thus, catches by foreign fleets in Subareas 5 and 6, especially since 1970, should not be interpreted as indicative of species abundance, except in the most general terms. A history of foreign fishing in the New York Bight area was published recently (Williams, 1975).

#### Comparability and Accuracy

Commercial fishery landings in the United States are expressed in two forms. All fishes, crustaceans, and mollusks like squid are given in round weight, sometimes called "live weight," or "nominal catch" by ICNAF, that is, with heads on and not gutted. Molluscan shellfish such as oyster, clams, conchs, and scallops are reported as weight of meats, shells not included, which means that the reported weight for most species is only a small fraction of live weight in the shell. Estimates of the recreational catch, which in the first three surveys omitted invertebrates, are all reported as round weight.

Foreign catch statistics are also reported as nominal catch or round weight, and mollusks are reported with shells included. Thus, United States catches of most molluscan species listed by ICNAF are considerably greater than the weights reported in official United States statistics. Conversion factors are given in Table 1.

Estimates of discards by domestic commercial, recreational, and foreign fishermen are not available.

Species within each category have been listed alphabetically, according to the American Fisheries Society official common name. Sometimes domestic commercial and recreational catch statistics, and ICNAF, have given different common names to the same species. Preferred common names, other common names, and scientific names are listed in Table 2. All weights are given in metric tons, rounded to the nearest ton. Catches of less than half a metric ton have been indicated by an asterisk. Thousands of pounds were converted to metric tons by the factor 0.4536.

United States commercial and recreational landings are estimates, based on partial surveys (see introductions to these sections). Sport catch estimates are based on very small samples, hence have rather wide limits of confidence (Deuel and Clark, 1968; Deuel, 1973). It is possible that sport catches are substantially overestimated (Stroud and Jenkins, 1962; McHugh, 1966; Deuel and Clark, 1968; Deuel, 1973). No comprehensive studies of the reliability of commercial catch estimates have been made to our knowledge. The accuracy of the estimates probably varies state by state, and fishery by fishery, depending on local circumstances. It is generally conceded that commercial catches are underestimated, sometimes substantially, especially in most places along the Atlantic and Gulf of Mexico coasts (Adkins, 1972), although for the New York Bight area this is largely conjecture.

In the New York Bight area comparison of presently available sport and commercial catch estimates should be made with caution. We are reasonably confident, however, that within each series the recorded catches usually are useful indexes of long term trends in abundance. Interpretation of foreign catch statistics as indexes of trends in stock abundance should be done only with extreme caution. Although foreign catches of several species are several orders of magnitude greater than New York and New Jersey commercial landings of these species, and hence perhaps better indicators of stock size, lack of sufficient data, demonstrated overfishing of some stocks and constraints on foreign fisheries imposed by various treaty obligations render these statistics, by themselves, of limited usefulness in estimating stock size. For estimates of standing stock, maximum sustainable yield, and other variables for important fishery species in this region the reader is referred to the Annual Reports of the International Commission for the Northwest Atlantic Fisheries (1951-1975) and a recent paper by Edwards (1975).

TABLE 1.--Factors used by ICNAF to convert U.S. weights of molluscan shellfish meats to live weights

<u>Common name</u>	<u>Scientific name</u>	<u>Conversion factor</u>

Shad, American	Shad, white shad	<u>Alosa sapidissima</u>
gizzard		<u>Dorosoma cepedianum</u>
hickory		<u>Alosa mediocris</u>
Sharks, unclassified		Class Chondrichthyes
grayfish	Smooth and spiny dogfish	Genera <u>Mustelus</u> and <u>Squalus</u>
Sheepshead		<u>Archosargus probatocephalus</u>
Silverside, Atlantic	Spearing	<u>Menidia menidia</u>
tidewater	Whitebait	<u>Menidia beryllina</u>
Skates and rays	Rajafish	Class Chondrichthyes
Smelt, rainbow	Smelts	<u>Osmerus mordax</u>
Snapper, red		<u>Lutjanus</u> spp.
Spot	Lafayette, Cape May goodies	<u>Leiostomus xanthurus</u>
Sturgeon, Atlantic	Common sturgeon	<u>Acipenser oxyrinchus</u>
Suckers		<u>Catostomus</u> spp.
Sunfish		<u>Lepomis</u> spp.
Swordfish	Spearfish, broadbill swordfish	<u>Xiphias gladius</u>
Tarpon		<u>Megalops atlantica</u>

Table 2 (continued)

<u>APS common name</u>	<u>Other common names</u>	<u>Scientific names</u>
Tautog	Blackfish	<u>Tautoga onitis</u>
Tilefish		<u>Lopholatilus chamaeleonticeps</u>
Toadfish, oyster	Oyster toad	<u>Opsanus tau</u>
Tomcod, Atlantic	Tommycod, frost fish	<u>Microgadus tomcod</u>
Tuna, unclassified	Tuna	Family Scombridae
albacore	Albacore	<u>Thunnus alalunga</u>
bluefin	Horse mackerel	<u>Thunnus thynnus thynnus</u>
little tunny	Albacore, false albacore	<u>Euthynnus alleteratus</u>
skipjack		<u>Euthynnus pelamis</u>
yellowfin	Tuna	<u>Thunnus albacares</u>
Wahoo		<u>Acanthocybium solanderi</u>
Weakfish	Gray sea trout, squeteague	<u>Cynoscion regalis</u>
Wolffish, Atlantic	Ocean catfish	<u>Anarhichas lupus</u>
Unclassified fishes:		
not specified	May be any species, including	
for food	some principally used for	
industrial	human food	

Invertebrates and miscellaneous products:

<u>Common names</u>	<u>Scientific names</u>
Bloodworm	Family Glyceridae
Sandworm	<u>Nereis</u> spp.
Crab, blue; blue claw crab; hard crab; soft crab; peelers	<u>Callinectes sapidus</u>
jonah	<u>Cancer borealis</u>
red, deep sea red crab	<u>Geryon quinquegens</u>
rock	<u>Cancer irroratus</u>
horseshoe; king crab	<u>Limulus polyphemus</u>
Lobster, American; northern lobster	<u>Homarus americanus</u>
Shrimp, grass	<u>Palaemonetes vulgaris</u>
sand	<u>Crangon septemspinosus</u>
Clam, hard; hardshell clam	<u>Mercenaria mercenaria</u>
razor	<u>Ensis</u> spp.
soft; softshell clam	<u>Mya arenaria</u>
surf; skimmer	<u>Spisula solidissima</u>
Mussel, blue; sea mussel	<u>Mytilus edulis</u>
ribbed; sea mussel	<u>Modiolus demissus</u>
Scallop, unclassified; bay or sea scallop or both	
bay	<u>Argopecten irradians</u>
sea	<u>Placopecten magellanicus</u>
Oyster, American; Virginia oyster; oyster	<u>Crassostrea virginica</u>
Whelk, channeled; conch	<u>Busycon canaliculatum</u>
knobbed; conch	<u>Busycon carica</u>

Table 2 (concluded)

Common names

Periwinkle  
 Squid, unclassified: May be one or the other, or both species  
     longfinned; squid  
     shortfinned; squid  
 Miscellaneous invertebrates (bait)  
 Terrapin, diamondback  
 Turtles, green  
     hawksbill  
     loggerhead  
     slider  
     snapper

Scientific names

Littorina littorea  
Loligi pealei  
Illex illecebrosus  
  
Malaclemys terrapin  
Chelydra mydas  
Eretmochelys imbricata  
Caretta caretta  
Pseudemys spp.  
Chelydra serpentina

### ICNAF Catch Quotas

For 1975 and 1976 ICNAF established a new system of setting quotas for fishing grounds within Subareas 5 and 6 (Fig. 2). Individual quotas were set for major species and groups of species (first tier quotas) and a total or biomass quota for all species of finfish and squid, including those in the first tier quota, was established (second tier quota). The second tier quota for 1976 was 165,000 metric tons less than the total first tier quota (Table 3). The quotas are further subdivided among nations.

This double-tiered quota system has several advantages. It places strict limits on catches of species for which adequate scientific information is not available to estimate allowable catches. It provides an extra margin of safety for resources in the first tier category, for it means that quotas for some or perhaps all first tier species cannot be reached before all fishing must stop. It makes allowance for incidental catches of species regulated by quota, and it recognizes that the total allowable catch, all species combined, is less than the sum of yields computed species by species. The fishing fleets, if they are to adopt the best fishing strategy, must make serious decisions in advance as to what and where to fish.

Table 3.--ICNAF quota for Subareas 5 and 6 combined in 1976.

Species	Thousands of metric tons
Atlantic mackerel	254
Silver hake	103
Squid	74
Atlantic herring	69
Atlantic cod	43
Red hake	42
Yellowtail flounder	20
Other flounders	20
Pollock	17
Atlantic ocean perch	17
Haddock	6
Other fishes	150
<hr/>	
Total (first tier quota)	815
<hr/>	
Total all species (second tier quota)	650

## The Fishery Conservation and Management Act of 1976

On 13 April 1976 President Ford signed into law HR 200, The Fishery Conservation and Management Act, by which the United States asserted jurisdiction over the living resources out to 200 miles from the coast. This Act, which takes effect on 1 March 1977, will not bring foreign fishing to a halt off United States coasts, as so many people believe. Instead, it will create a licensing system by which foreign fishermen will be permitted to take allowable surplus catches of species or stocks of fish and shellfish which American fishermen are unable or unwilling to take. In the long run this Act may provide opportunities for expansion of United States fisheries and a gradual phasing out of foreign fishing off our shores. If the current Law of the Sea negotiations conclude an International Convention acceptable to the United States, that Convention will supersede the Act.

It is too early as yet to predict the future of the fisheries of the United States continental shelf. Thus, it is sufficient here to call attention to the existence of the Act and its major provisions. Among other things, it sets out United States fishery policy and authority, describes how the Act relates to foreign fishing and existing international agreements, establishes national standards for fishery conservation and management, and provides mechanisms for implementation. The task of the eight Regional Fishery Management Councils to be created under the Act will be complicated and difficult, and their success is by no means assured. The future record of United States fishery landings will be an index of the success of the Act.

\* ICNAF Statistical Bulletins did not record catches of individual species other than cod, haddock, redfish, Atlantic halibut, "flounders" and "shellfish" until 1960. Through 1959 all unidentified catches and all catches of species other than those identified above were recorded under "other groundfish" (1953 - 1956), "pelagic species" (1954), or "all other species" (1954, 1957 - 1959). Beginning in 1960, additional species were added to Statistical Bulletins. The species and species categories listed above in Section 3 were first reported by ICNAF in the following years: 1960 - hakes (unspecified), white hake, silver hake, pollock, American plaice, witch, wolffishes, yellowtail flounder, winter flounder; 1961 - red hake, Greenland halibut (northern turbot), summer flounder, cusk, scup, capelin, sharks (unspecified), Atlantic herring, Atlantic mackerel, Atlantic menhaden, butterfish, swordfish, tunas (unspecified), alewife, sea scallop; 1963 - bluefin tuna, argentine, skipjack tuna; 1964 - ocean pout, skates (unspecified), black sea bass; 1965 - tilefish; 1966 - goosfish, sculpins, searobins, bluefish, American shad; 1967 - roundnose grenadier; 1970 - dogfishes, Atlantic saury; 1971 - American lobster, shrimps, squids, molluscs (unspecified); 1973 - sand lances, rough scad, crabs (unspecified). For a complete list of all species and species categories listed by ICNAF see Statistical Bulletin Volume 24, 1976.

ICNAF Statistical Bulletins did not include the category "other groundfish" in records for 1957 - 1960, 1962, and 1963. The category "pelagic species" was used only in 1954 and included all pelagic species caught that year, except unidentified catches. ICNAF first reported catches of pelagic species individually in 1961, and "unspecified pelagic species" was first listed in 1966, but did not appear in original statistics for 1969 and 1970. "Other species, unspecified" was first recorded in 1966.

Where a series ends before 1974, this means that no catch was recorded for subsequent years.
