Preface

This is the first of a series to present information concerning marine fisheries in North Carolina. An essential background for discussion of the industry and resource is in the statistical data, thus this section is presented initially. The other two major sections focus on the biology and life history of major species and descriptions of the industry in its various aspects.

Through the years inquiries from varied sources have continually requested statistics and other information on differing aspects of fisheries. This material is assembled to meet future requests and hopefully to stimulate a recognition of deficiencies and further needs to provide more detailed data.

The first author is responsible for the statements, comments, and any errors that might be present. The information was gleaned from official figures and great care was taken to be accurate and precise.

A number of persons are to be acknowledged for their assistance in bringing this material together. Doris Oakley and Andrea Midgett assisted in tabulating the figures. Joyce Lewis, Brenda Bright, Linda Waters, Rosemond Baldree, Linda Gillikin and Elaine Spalding and others typed and retyped the numerous tables as additions and corrections were made.

INTRODUCTION

Harvesting of living marine resources on a worldwide scale has continued to increase over the past 20 years. The world catch of fisheries products has increased from 46 billion pounds in 1950 to 83 billion pounds in 1960, and to 153 billion pounds in 1970. Meanwhile production in the United States has remained relatively stable between 4 and 6 billion pounds for this period.

Fisheries resources are renewable and have been freely available. Limits of ultimate or maximum production are not known. Estimates of possible production vary from 3 to 4 to as high as 40 times the present level of nearly 70 million metric tons. Some estimates of potential world production made 20 years ago have been exceeded in recent years. There are biological limits to productivity of most species and intense selective fishing pressure may reduce size and yields of stocks. The irreversible destruction of estuarine habitats and effects of gross pollution would contribute to further reduction of fish populations. Environmental conditions probably have a greater influence on fish populations than fishing activity. A recent statement by Shapley (1972)¹ probably summarizes the state of the situation: "There isn't a technical way of figuring out when a stock will reach the point of a serious decline. The question is how small the breeding stock can be and no one really knows the answer." However, fishermen are readily aware when stocks are reduced or depleted by their small catches, increased cost of operations, and limited profits.

Proper development and management of natural resources is necessary and is generally dependent upon resource administration. Management programs need

¹Shapley, D. 1972. Science, Vol. 178, 1 December 1972, pp. 965-966.

to be structured with consideration of meeting production demands in balance with preservation of natural stocks. Research programs have been in effect, have been expanded, and continue to seek answers toward improvement of stock and yields but still fall far short of the goals and needs.

Any business venture requires an inventory to provide basic information of stock or raw product, volume of production, sales, and costs. In fisheries, a great gap exists in an inventory of raw product or stock on hand, for it is difficult to determine the wild populations of fishes in the ocean with a reliable degree of accuracy. Fishermen still function as "hunters" dependent upon nature and natural production. It becomes necessary then to base an inventory of raw product upon the total catch harvested. Such information is available from fishery statistics, which are historical, but can provide valuable information even with the many existing limitations and shortcomings.

The purpose of this publication is to provide a needed source of information containing fisheries statistics for North Carolina. Through the years, innumerable requests have been received, and continue to the present, for such information. In order to compare information for subsequent years one must consult at least forty-five volumes. Some of these are difficult to obtain and are not readily accessible. A ready reference will save much time and effort and hopefully will prove of value in detecting trends, fluctuations, and focus areas for improved gathering of statistical information.

A brief overview of the world and national production is included in this introduction as a general background. It is not the purpose of this paper to present a detailed summary of the world or national situation.

GENERAL REVIEW

Commercial catch of marine products by continents shows Asia producing from 37 to 44 percent of the total volume over a period of twelve years. Production from Europe amounts to 17 to 20 percent of the total. U.S.S.R. has gradually increased in production from 7 percent in 1960 to 12 percent in 1972. South America produced about 11 percent in 1960, increasing to 17 to 21% from 1964 to 1970 then dropped to 11 percent in 1972, reflecting the fluctuation in the Peruvian fisheries. North and Central America produced from 7 to 8 percent of the total production and Africa accounts for 5 to 6 percent of the total.

In general the continued increase in volume of production by some leading nations can be attributed to improvements in fish harvesting through increased effort and some technological advancements. The marked decrease in volume of production in the Peruvian fisheries is reflected in the total world production and points out the overriding effects of environmental factors which may exert a greater influence upon fish populations than that of fishing activity.

Six nations accounted for approximately 59% of the total world production in 1970. The six leading nations have remained in the same rank in position from 1967 to 1971. For many years the United States ranked second only to Japan in volume of fisheries production. During the years of 1957 to 1959, U.S. was third, then dropped to fifth place in 1960 to 1965 and since 1966 has been in sixth position. The volume and value of fishery landings for 1970 were as follows:

	<u>VOLUME</u> <u>(billion pounds)</u>	<u>VALUE</u> <u>(million dollars)</u>
Peru	27.8	\$ 187
Japan	20.5	2,549
U.S.S.R.	15.9	1,305
China (Mainland)	13.7	1,713
Norway	6.5	197
United States	6.0*	613

*Includes weights of mollusk shells for comparative purposes.

Commercial catch of fisheries products in 1972 show Japan as the leading nation in production and value, for the first time since 1961. Peru dropped to fourth place in volume. The volume and value of landings in 1972 was as follows:

	<u>VOLUME</u> <u>(billion pounds)</u>	<u>VALUE</u> <u>(million dollars)</u>
Japan	22.5	\$ 3,366*
U.S.S.R.	17.1	1,573*
China	16.6	2,171*
Peru	10.5	91
Norway	6.9	235
United States	5.8**	704

*Estimated.

**Includes weights of mollusk shells for comparative purposes.

The main reason for the shift in position was the marked decline in the Peruvian anchovy fishery which decreased from 27,807 million pounds in 1970 to 10,512 million pounds in 1972. This was due to temporary changes in the environmental conditions off the Peruvian coast. Some recovery in the Peruvian fishery is expected with return of environmental stability.

In the species composition of the world catch about 30% comprises the herring-sardine-anchovies group and approximately 15% are of the cod-haddock-hake group.

On a worldwide scale, fish contribute to about 10 percent of the total animal protein intake by humans. The amounts of fisheries products consumed vary in different nations. The annual per capita consumption of fish and shellfish was highest in Iceland at 86.1 pounds; Japan, 70.8 pounds; Malasia, 51.5 pounds; Portugal, 50.7 pounds; Hong Kong, 46.7 pounds; Sweden, 45.1 pounds; compared to 12.2 pounds in the U.S. (data for years 1964-1970).

U. S. Fisheries

Total commercial fishery landings by U. S. fishermen in 1972 were 4.7 billion pounds valued at a record exvessel price (paid to fishermen) of \$703.6 million. In 1973, the commercial harvest was 4.7 billion pounds with a new record value of \$907.4 million. The record volume of landings in U.S. was 5.3 billion pounds in 1962.

Commercial landings in 1972 by coastal regions in the U.S. was greatest along the Atlantic coast, 1,743,757 thousand pounds, 1,584,799 thousand pounds for the Gulf coast, and 853,145 thousand pounds for the Pacific coast (Washington, Oregon, California). The Atlantic coast had an increase of nearly 300 million pounds over 1971, while the Gulf coast had decreased by more than 500 million pounds. Production for the South Atlantic area was 284,168,000 pounds in 1972.

For statistical purposes the U.S. coast is separated into six areas: New England (Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut); Middle Atlantic (New York, New Jersey, Delaware); Chesapeake (Maryland, Virginia); South Atlantic (North Carolina, South Carolina, Georgia, Florida, east coast); Gulf (Florida, west coast, Alabama, Mississippi, Louisiana, Texas); Pacific (California, Oregon, Washington, Alaska); and Hawaii. The Gulf area has been

the leading producer of all the areas, accounting for 30 to 40 percent of the total U.S. production. The Pacific states produce about 25 percent, Chesapeake area about 15 percent, New England area about 10 percent, South Atlantic area about 5 to 6 percent and Middle Atlantic area about 3 percent of the total. The remaining production in U.S. amounting to about 5 percent is from the Great Lakes area, Mississippi River and tributaries, and from Hawaii.

Landings by states showed North Carolina in ninth position in 1971 and 1972 in volume, and 17th in value. Listed below is the rank of 10 states in volume and value for 1972.

	<u>POUNDS</u> <u>(Millions)</u>		<u>DOLLARS</u> <u>(Millions)</u>
1. Louisiana	1,070	1. California	\$91.8
2. Virginia	663	2. Texas	85.0
3. California	639	3. Alaska	80.7
4. Alaska	390	4. Louisiana	71.9
5. Mississippi	260	5. Florida	55.7
6. Massachusetts	248	6. Massachusetts	48.0
7. New Jersey	190	7. Washington	38.4
8. Florida	176	8. Maine	34.8
9. North Carolina	175	9. Virginia	25.9
10. Maine	149	10. Oregon	24.0
		(17. North Carolina	11.8)

Each year some shifting in positions of states for volume and value does occur

The relative positions for 1972 differed from those for 1973 listed below:

	<u>POUNDS</u> <u>(Millions)</u>		<u>DOLLARS</u> <u>(Millions)</u>
1. Louisiana	1,035	1. Alaska	\$162
2. California	669	2. California	102
3. Virginia	631	3. Louisiana	98
4. Alaska	455	4. Texas	91
5. Mississippi	271	5. Florida	64
6. Massachusetts	269	6. Massachusetts	57
7. New Jersey	209	7. Washington	47
8. Florida	174	8. Maine	43
9. Maine	143	9. Virginia	39
10. North Carolina	137	10. Oregon	28
		(16. North Carolina	16)

Landings and values by states since 1961 show that virtually the same states are listed among the ten leading states. Some shifting in positions occurs as shown above. North Carolina, for example, was in sixth position in 1965, in ninth position in 1961 and 1972, and in tenth position in 1973. In position of states listed according to relative value, North Carolina has fluctuated from fourteenth to seventeenth position during the past decade.

Seven species comprised 74.2% of the total volume of landings in U.S. in 1970. These were: menhaden (37.4%), salmon (8.4%), tuna (8.0%), shrimp (7.5%), crabs (5.6%), anchovies (3.9%), and flounders (3.4%). Eight species comprised 76.5% of the total value, shrimp (21.2%), salmon (16.1%), tuna (12.2%), crabs (6.4%), menhaden (5.6%), American lobsters (5.5%), oysters (4.8%), and clams (4.7%).

More than half of the total U.S. landings during the past three years (1971-1973) were for industrial products converted into meal, oil, used as bait and animal food, and fertilizer, thus are indirectly utilized for human consumption. Some meal is even utilized in production of fish from farm ponds and aquaculture. The amount used for industrial products and edible use may fluctuate from year to year. During the years of 1960-1973, landings for human food were greater than that for industrial products in 9 years, while landings for industrial products were greater in 5 years. In 1973, landings for industrial products amounted to 2.4 billion pounds valued at \$91 million dollars, compared to landings of 2.3 billion pounds for human food, valued at \$816 million dollars. A record of 3.3 billion pounds was used for human food in 1950. The record volume for industrial products was 2.8 billion pounds in 1962.

Imports of edible fishery products in U.S. have shown a continual increase over the past decade. In 1960, more than one billion pounds were imported, valued at \$310 million dollars. A new record was set in 1973 when 2.3 billion pounds were imported at a record value of \$1.3 billion dollars. Including the value of non-edible imports, the total value amounted to \$1.5 billion dollars.

The greatest volume of imports of edible products in 1973 were from Asia (792 million pounds) with Japan as the leading nation with 605 million pounds. North American countries exported over 732 million pounds with Canada exporting the greatest quantity (521 million pounds) to U.S.

The major products imported in U.S. were tuna (747 million pounds), fresh and frozen fillets (419 million pounds), blocks and slabs (359 million pounds), and shrimp (203 million pounds). More than 40 countries exported shrimp products to U.S. in 1973.

Exports of U.S. domestic fishery products have shown a gradual increase over the past decade. In 1960, 40 million pounds of edible products were exported. This increased to 239 million pounds by 1973 valued at \$299 million dollars. The U.S. exports represent about ten percent of the volume of total imports and about 23 percent of total value of imports. U.S. fishery products are exported to about 87 nations with the greatest volume in 1973 to Japan (93 million pounds), Canada (40 million pounds), and United Kingdom (43 million pounds).

South Atlantic States

The South Atlantic region comprises the states of North Carolina, South Carolina, Georgia and east coast of Florida. This region produces from 5 to

6 percent of the total volume of domestic landings in U.S. The greatest volume of production for this region was in 1959 when 469 million pounds of fishery products were landed. The most recent published statistics for 1971 show 258 million pounds, lowest volume since 1932, but the highest value on record at \$41.6 million dollars. The 1971 statistics show a decline in production of 22.1 million pounds but an increase of \$11.9 million dollars compared with 1970. The marked gain in value resulted primarily from increased shrimp harvest and is expected to show a greater value increase reflecting the national economic situation.

North Carolina has been the leading state for production among the South Atlantic states since 1880 and the leading state in value from 1880 to 1966. Value of landings in Florida has exceeded North Carolina since 1967. North Carolina has accounted for 65 to 70 percent of the volume of production but in recent years with a decline in the menhaden fishery the percentage has dropped. Florida production has accounted for 16 to 27 percent of its total volume. Listed below are the percentage of volume for each state at five-year intervals since 1950:

	<u>1971</u>			<u>1970</u>			
	<u>%</u>	<u>POUNDS (Million)</u>	<u>DOLLARS (Million)</u>		<u>%</u>	<u>POUNDS (Million)</u>	<u>DOLLARS (Million)</u>

GEO.	5%	19	2	S.C.	5%	15	3
		<u>346</u>	<u>\$16</u>			<u>260</u>	<u>\$20</u>

The greatest volume of landings were fish, ranging from 74 to 81 percent of the total catch, with menhaden comprising from 38 to 65 percent of the total volume. Crabs amounted to 9 to 15 percent of the total volume and shrimp were the next individual species ranging from 7 to 12 percent of the volume. The most valuable species were shrimp which represented from 37 to 50 percent of the total value.

In the past 20 years there has been marked expansion of processing plants, especially in Georgia. Since 1950 Georgia has led the South Atlantic states in value of processed fishery products, until 1971 when Florida surpassed Georgia. In many cases products have been processed from raw products imported from other states or foreign countries. For example, the volume of processed shrimp in Georgia for 1971 was 18.2 million pounds compared to landings of

raw shrimp at 8.8 million pounds. In Florida the total landings of shrimp in 1971 were 3.9 million pounds and the quantity of processed shrimp was 13.3 million pounds. In 1970 the total volume of processed shrimp for east coast Florida and Georgia was 31.5 million pounds which exceeded the total catch of 20.6 million pounds for the four South Atlantic states.

Listed below are values of processed products at 5-year intervals since 1940.

	<u>1971</u>		<u>1970</u>		<u>1965</u>		<u>1960</u>

North Carolina

The greatest volume of fishery products from the four southeastern states has consistently come from North Carolina. A long coastline of about 320 miles along the outer banks enclosing about 2,500 square miles of shallow sounds, bays, tidal creeks, and marshlands affords many habitats utilized by a great variety of fishes and invertebrates. More than 50 species are harvested annually in commercial quantities from the rivers, sounds, and near ocean areas. Perhaps a greater variety of commercial species, many still not utilized to full potential, are found in North Carolina waters than in any other coastal state along the Atlantic seaboard. Some species are endemic to the area, others appear as transients during migratory movements at different seasons of the year, some utilize the shallow waters for nursery areas, feeding, or spawning grounds. The geographical location of the state and proximity of the Gulf Stream, with Cape Hatteras considered as a natural boundary between sub-tropical and cold water species, marks the southern limits of some forms and the northernmost distribution of others. Many methods and types of gear are employed to harvest this resource. Details of the biology and various fisheries will be considered in another section.

A number of tables and compilations of statistical information on fisheries of North Carolina are presented for ready reference to quantities and values of fishery products. These are at the end of the descriptive portion.

Table I is a summary of the quantity and values of total landings for North Carolina from 1880 to 1973. Figures for 1972 and 1973 are preliminary since unclassified species utilized for bait, reduction, and animal food are not included. The record volume was in 1959, corresponding to the record year for menhaden landings. The record value for price received by fishermen for their

catch was in 1973, when nearly \$16 million was recorded, although the volume of catch was the lowest since 1937. It is expected that values for 1974 will be greater than in 1973, to establish a new record.

Tables II through X contain information on individual species landed in commercial quantities. Table II is a listing for each year from 1880 to 1973 of the quantity and value of species landed. In Table III is a summary for individual species for the years that quantities and landings were recorded. Some species, such as black bass, as freshwater species are no longer captured for market. Other species such as mackerel, appear in some years and not in other years. Table IV is a listing of the relative volume and value for individual species landed in excess of 500,000 pounds and in excess of \$100,000. Menhaden has been the leading species in volume since 1902, succeeding alewives which were the largest quantity landed from 1880 to 1897. The species of greatest value was shad in the years from 1880 to 1902, and in 1923, 1928, 1931 and 1932. Menhaden landings were the species of greatest value in the intermittent years from 1918 to 1965, when shrimp brought the highest prices from 1966 through 1973. Table V is a listing of the record year for volume and value for individual species. Sixty-seven species are in the list. New record catches were recorded for 30 species since 1950, and new record values for 44 species since 1950. Table VI has yearly record volumes and values of individual edible species, excluding menhaden, thread herring and alewives. Blue crabs have been the species landed in greatest volume since 1956 with a record catch of 24.6 million pounds in 1964. Shrimp have been the most valuable of edible species since 1945, except for 1958 when blue crabs had a higher value than shrimp.

Table VII is a summary of total landings, landings of edible species, and landings of nonedible species for five selected years, 1956, 1960, 1965, and 1970. The greatest volume of landings has been during November and December when the menhaden fishery was at its peak. In 1970, the month of greatest landings was in June when the local menhaden fishery landings were greater than in other months, reflecting the decline of the coastal menhaden landings. Peaks in landings of edible species are dependent upon abundance of specific forms that may vary from year to year. In general, the blue crab and shrimp fisheries are at a peak during the summer months and are the dominant species landed. More detailed listings of species landed by months is in Table VIII, which contains species landings in excess of 100,000 pounds for each month in 1973 and for the five year average for 1969-1973. Table IX has a list of species generally harvested in all months of the year and those species that occur at seasonal intervals. Table X has a detailed listing of shrimp landings by species, beginning in 1957 when collections of such data were started. Brown shrimp (*Penaeus aztecus*) are usually greatest in number, and white shrimp (*Penaeus setiferus*) show the greatest fluctuations from year to year. Additional information is collected on shrimp landings by species and size, with a breakdown in size groups of 15-20 count, 21-25, 26-30, 31-40, 41-50, 51-67, and 68 and over.

Tables XI through XVI contain information on persons, vessels, boats, units of gear, and catch by gear in North Carolina fisheries. Table XI shows a gradual decline in number of persons in fisheries from the early 1950's to the present, a decline of nearly 3,000 persons. The number of vessels showed a marked increase from 1945 to 1950 when the number nearly doubled. At this time an active interest in trawler construction developed and larger vessels were being used in the shrimp and fish trawl fisheries. In Table XII is a listing of units of gear used in

various fisheries. The number of various types of gear has shifted over the years reflecting some changes in fisheries in the sounds and rivers. Marked declines in number of gill nets, haul seines and pound nets are noted. A dramatic increase in number crab pots with the beginning of this type of gear used in 1952 to the present, from 1,200 crab pots to over 30,000 in 1966. The increase in number of otter trawls beginning in 1950 reflects the shift to more fishing effort in the near shore and ocean areas. Table XIII contains a summary of catch by gear for different types of units used in 1971. Table XIV is a list of volume and value of total catch by gear in relative rank of importance for five year intervals from 1887 to 1970. Table XV contains the total catch for each unit of gear and the values of the catch for years that information was available. Table XVI is a listing of catch and value of major species by various types of gear used in harvesting these specific forms.

Tables XVII through XIX contain information on catch by counties and districts. Table XVII is a listing of total catch and value by districts in North Carolina. The statistical information, beginning in 1967, has been reported for these districts comprising several counties. The central district which includes Carteret County is the leading district. In Table XVIII is a summary of landings for each county at five year intervals from 1945 to 1965. Carteret County has been the leading county in landings since 1897. Brunswick County has been the second leading county, primarily from the volume of menhaden and thread herring caught for industrial purposes. Table XIX contains detailed information on volume of landings and values of products for each county where commercial production has been reported since 1889. Figure 1 shows the location of each county in eastern North Carolina. Commercial catches have been reported from 33 counties over the past years. This has been reduced to 18 counties at present.

FISHERIES STATISTICS

Statistics are essential and needed to determine and evaluate the magnitude of the varied coastal fishery resources. Effective management and development of both commercial and sports fisheries requires biological and statistical information. The available statistics have much to be desired in completeness but gradual improvements have been made.

Federal and state agencies collect data in an attempt to present accurate statistics for each year using methods that would be comparable over a period of years between states and regions. Data are collected on the number of persons engaged, plants, vessels and boats, type and quantity of gear used in capture, volume and value of each species captured, and the quantity and value of processed fishery products. Trained field personnel collect information from central locations, interviews with vessel captains, dealers, and processors. Many state agencies cooperate with federal agencies in collection and publication of current monthly and annual data. The federal agency conducts necessary surveys to make the data comparable with those from various states, assembles, analyzes, and publishes fishery statistics. Considerable improvement has been made in recent years in local and special surveys to provide detailed information on daily landings, grounds from which fish are captured, variety and size of certain species landed, number of fishing trips, time spent fishing, and other information.

Need and Value of Statistics

Some of the needs and application of statistical information are briefly outlined below.

Accurate statistics, in addition to biological information, are needed to provide proper tools for management. An evaluation of the status of the resource requires information on species involved, size groups, locations of populations, and quantities removed from specific areas.

Information on harvesting of species by selective methods and gear is of value in determining the species and sizes desired for economic implications with proper concern for future abundance through regulation.

Information on quantity, quality, and variety of species harvested with projections of potential abundance is of value to prospective industries, development of new products, and expansion of processing and bulk handling facilities.

Allocation of funds for specific fisheries programs, such as PL88-309, are based on statistical data of landings and processed products. The importance of accurate and complete information is obvious and of considerable significance.

The relationship of the fisheries industry to other industries based on natural resources in the total U. S. economy cannot be determined without necessary comparisons in terms of labor, investments, economic impact and other important factors. Long range planning is not possible without adequate statistics.

Limitations of Available Statistics

In past years lack of funds limited the coverage of areas with considerable gaps existing between years. The historical statistics have gaps of 5, 6, and 10 years when no surveys were made in North Carolina. The series are not continuous before 1950 and the use of interpolations or extrapolations

can be misleading and erroneous, particularly since wide fluctuations often occur from year to year. Some basic trends can be determined even with the existing gaps. Supplemental information from state tax receipts from fishery products have often shown wide discrepancies between state and federal figures so attempts to bridge some missing years with such figures would not resolve the problem.

The available statistics do not specifically indicate abundance of particular species. In some years landings were low for a species but this was due to market demand or weather conditions. At times a particular species was present in abundance but prices received by fishermen were too low for profitable endeavor or economic factors prohibited processing of marginal sized fish resulting in cessation of fishing. Adverse weather conditions have often reduced fishing activity, thus reflecting decreased landings due to reduced effort and not to availability of the resource.

Information is lacking on specific areas of fishing effort. Landings have been reported by counties but this indicates in which county the catch was unloaded. Such fishery products might represent capture from areas within boundaries of several counties or a combination of landings from the sounds, from the ocean, or from the open ocean beyond the territorial limits of the state. Shrimps caught in Pamlico Sound within boundaries of Pamlico, Hyde, and Dare counties might be landed in and reported for Carteret County. Croakers, sea trout, flounders, and other species caught in the ocean off the Currituck or Dare county coast are often landed in Pamlico and Carteret counties.

A problem exists in earlier records when one cannot determine different species of the same group. At least three species of flounders are combined

in the reported landings. This is true in many species of fish such as king whiting, sea basses, and others. Early records of shrimp combined the three species. In recent years the shrimp figures have been improved to report species and sizes. At times two species of scallops, one caught in the sounds and the other in the ocean, were not separated. This has been true in the case of two species of hard clams.

Among the deficiencies existing in the statistical information are: indications of number of fish or sizes of individuals; catch per boat or vessel; catch from specific locations or areas; size of gear used by individual boats; amounts of fishery products taken for home use; amounts of fishery products sold directly from vessel operators to consumers.

The first comprehensive statistical survey for North Carolina was made in 1880. At varying intervals of years partial or complete surveys have been made. Federal statistics are available for North Carolina for the years: 1880, 1887-1890, 1897, 1902, 1908, 1918, 1923, 1927-1932, 1934, 1936-1940, 1945, 1950 to date. There are some references for specific fisheries in other years. In order to compare information for subsequent years, it is necessary to consult at least forty-five volumes. Some of these are difficult to obtain and not readily accessible. Publications by federal agencies containing information for North Carolina are listed below.

Recreational Fisheries

Statistical information related to marine fisheries has been directed primarily toward the commercial activities. Detailed statistics on marine recreational fisheries catch have been lacking and unavailable except for special studies or surveys. In recent years some information has been forthcoming at 5-year intervals beginning with a national survey of fishing and hunting in 1955 by the U.S. Department of Interior. Salt-water angling surveys have been made for 1960 and 1965 by the Department of Interior and for 1970 by the U.S. Department of Commerce.

It is appropriate and necessary to include some comments on the marine recreational fisheries since substantial quantities of fish are caught in sport activities. Although the sport and recreational activities are considered as pursuit for pleasure, the economic impact and income producing contributions to the coastal regions are of considerable magnitude. There is a critical need for information on a comparable basis with the commercial data if effective management and development procedures are to be inaugurated. In general the same resource is utilized by both segments and the impact on stocks of many species cannot be determined with accuracy if significant amounts are being harvested which are not accounted for and for which reliable data are not available.

Recreational use of marine fisheries resources has rapidly increased over the past 20 years. Surveys show the total number of fishermen increased from 4.5 million in 1955 to 9.4 million in 1970. The largest number is along the Atlantic coast (2.3 million in 1955, 5.0 million in 1970). The Gulf of Mexico area increased from 1.0 million fishermen in 1955 to 2.2 million in 1970 and

the Pacific coast had 1.1 million in 1955, increasing to 2.1 million in 1970.

The quantity of fishfish caught has increased from 1.38 billion pounds caught in 1960 to 1.58 billion pounds in 1970. The Atlantic coast had an estimated catch of 917.6 million pounds in 1970, the Gulf coast had 485.7 million pounds, and the Pacific coast had 173.4 million pounds.

In comparison, the total commercial finfish landings for U.S. in 1970, excluding menhaden and anchovies amounted to 1.88 billion pounds and the recreational catch was 1.58 billion pounds.

The available information on sports fisheries does contain many omissions, particularly in the exclusion of marine invertebrates such as shrimp, crabs, oysters, clams and other forms caught for personal use and pleasure. Weight estimates of some fishes contain errors in sampling and responses, and often include fish caught but not brought ashore.

The statistical regions for recreational catch data differ from those used for gathering commercial data. The regions for sports fisheries are defined as: North Atlantic (Maine to New York)

Middle Atlantic (New Jersey to Cape Hatteras, N. C.)

South Atlantic (Cape Hatteras, N. C. to Florida Keys, included)

East Gulf of Mexico (Florida Keys to Mississippi River delta,
included)

West Gulf of Mexico (Mississippi River delta to Mexico border)

South Pacific (Mexican border to Point Conception, California)

North Pacific (Point Conception, California to Washington,
including Alaska)

The Gulf of Mexico region, including east and west regions, showed an estimated catch of 485.7 million pounds in 1970. The South Atlantic region had 403.9 million pounds; North Atlantic - 267.4 million pounds; Middle Atlantic - 246.2 million pounds; South Pacific - 94.2 million pounds; and North Pacific - 79.2 million pounds.

In the South Atlantic region the reported recreational catch of 403.9 million pounds in 1970 exceeded the commercial catch of finfish of 209.3 million pounds, which included 152.9 million pounds of menhaden, herring and alewives. Some comparisons of individual species landed in 1970 show quantities caught by sport fishermen far exceeding commercial landings. The table below contains comparisons of several species utilized by both commercial and recreational fishermen. The comparisons are interesting and some may question the magnitude of the recreational figures but these are results of surveys made.

A confusing issue for many years has been the misleading comparisons made in presenting the values of recreational and commercial fisheries. Total expenditures for recreational fisheries were \$799.6 million in 1965, increasing to \$1.2 billion in 1970. The price received for finfish by U.S. commercial fishermen was \$241.1 million in 1965 and \$326.9 million in 1970.

The recreational expenditures include cost of travel, lodging, meals, equipment, bait, and various other incidentals. The commercial figures used represent the price paid to fishermen for fish landed. If equitable comparisons are to be made the value of commercial fisheries should include operating costs of fuel and oil, gear purchased, repairs and maintenance,

capital investment in vessels and equipment, and other incidentals included in the recreational totals.

South Atlantic Region - 1970

Species	Commercial Landings (million pounds)	Recreational Catch (million pounds)
Croakers	(886,000)	5.9
Drum, black	(144,000)	12.1
Drum, red	(157,000)	13.3
Flounders	3.3	8.9
Grunts	(51,000)	25.9
Mackerel, king	4.3	34.9
Mackerel, Spanish	3.6	14.6
Porgies	(575,000)	24.0
Sea Bass	2.0	12.3
Seatrout, gray	2.7	-
Seatrout, spotted	1.1	25.0
Snappers	1.1	26.5
Spot	3.3	9.8
Striped Bass	2.3	(189,000)

Definitions and Explanations of Terms, Measures and Procedures

There are differing interpretations of descriptive terms used by the industry and in statistical publications. From the types of inquiries continually received from individuals associated in fisheries, and other interested persons, it is evident that many have a vague concept of, do not understand meanings of, or are not aware of commonly used terms. In many cases definitions of size, grades, and measures are vague, nebulous, ill-defined, and frequently vary with market demand. There is a need for an official definition of many terms and measures. Statistical publications usually include a glossary of terms at the end of the tables and footnotes of explanation to many tables. Reference should be made to these for the many terms since it is not proposed to repeat the listings but to supplement and include additional notes. The following definitions are selected from statistical digests of Fishery Statistics of the United States.

OPERATING UNITS:

Persons employed, and craft and gear used in fisheries.

PERSONS:

Commercial fisherman - an individual who derives income from catching and selling living resources taken from fresh or salt-water bodies of water.

Regular fisherman - an individual who receives more than half of his annual income from fishing activities.

Casual fisherman - an individual who receives less than half of his annual income from fishing activities.

Full-time commercial fisherman - an individual who spends 50% or more of his working year in commercial fishing activities.

Part-time commercial fisherman - an individual who spends less than 50% of his working year in commercial fishing activities.

CRAFT:

Boat, motor - a motor driven commercial fishing craft with capacity of less than 5 net tons.

Boat, other - a commercial fishing craft not powered by a motor, may be row or sail, having a capacity of less than 5 net tons.

Vessel - a commercial fishing craft having a capacity of 5 net tons or more. Usually documented by the U. S. Coast Guard and with an official number assigned.

FISH:

Include all species belonging to the class Pisces, and includes sharks, skates, and rays.

SHELLFISH:

Aquatic invertebrates (animals without backbones) having a shell. Included under this classification are all other forms not listed under "fish", such as turtles, frogs, sponges, seaweed, worms, sea urchins, etc.

CRUSTACEANS :

Group of animals with jointed appendages belonging to class Crustacea, included under shellfish. Commercial forms include shrimps, crabs, lobsters, crayfishes, etc.

MOLLUSKS :

A diverse group of soft-bodied animals with or without a heavy outer calcareous shell, included under shellfish. Commercial forms include oysters, clams, scallops, mussels, conchs, snails, squid, octopus, etc.

EXVESSEL PRICE:

Price received by a fisherman for products captured or harvested and landed at the dock.

WHOLESALE (FISH) PRICE:

Price charged by manufacturers and other producers for sale of fish and other products generally in large quantities.

RETAIL (FISH) PRICE:

Price of fish and other products sold to the final consumer by food and specialty stores or markets.

PER CAPITA CONSUMPTION:

Consumption of edible fishery products in the United States divided by the total civilian population.

PER CAPITA UTILIZATION:

Utilization of all fishery products, edible and non-edible, in the United States, divided by the total population of the United States.

INDUSTRIAL FISHERY PRODUCTS:

Products manufactured from fish, shellfish and other aquatic plants and animals which are not directly consumed by humans - such as fish meal, fish oils, condensed fish solubles, shark and other animal skins, products from sea weeds, shells, etc.

PROCESSED FISHERY PRODUCTS:

Fish, shellfish, and other aquatic plants and animal products preserved by canning, freezing, cooking, dehydrating, freezing, salting, pasturizing, adding other chemical substances, and other commercial processes.

FISH MEAL:

A ground, dried product made from fish or shellfish by cooking raw fish or shellfish with steam and pressing the material to obtain solids which are dried.

FISH OIL:

Oil processed from body (body oil) or liver (liver oil) of fish. Usually a byproduct of fish meal production.

FISH SOLUBLES:

A product extracted from residual press liquor (called "stick water") after solids are removed for drying fish meal and the oil extracted by centrifuging. Residue is generally condensed to 50% solids and marketed as "condensed fish solubles".

ROUND (LIVE) WEIGHT:

Complete or full weight of fish, shellfish and other products taken from the water as caught. In the case of mollusks only the weight of meats is included, excluding the shell weight.

Following are some general remarks on grading measures, and various practices in handling certain groups and species prior to marketing.

OYSTERS:

Capacity of U. S. Standard bushel for oysters is 2,150.42 cubic inches. State bushels for oysters vary from 2,148.4 cu. in. or -0.1% of the U. S. Standard bushel in Louisiana to 5,343.9 cu. in., or +148.5% greater than U. S. Standard bushel in Georgia.

The North Carolina state bushel was defined by statute as 2,801.9 cu. in. or 30.3% greater than U. S. Standard bushel. In recent years the state bushel measure was changed by Statute 113-129 to conform to the U. S. Standard bushel of a dry measure containing 2,150.42 cubic inches.

Data collected as bushels is converted to pounds of meats according to average yields per bushel. The yields vary from year to year and in different seasons. The table of conversion factors lists the pounds per bushel for each year since 1930. Prior to 1930 a yield of 7 pounds per bushel was used for each year for each state.

Oyster data collected as gallons of shucked meats is converted to pounds of meats by multiplying by 8.75 pounds per gallon.

Four general classifications of shucked oysters according to size have been in use by the industry. These vary with different packers in different seasons. The Food and Drug Administration adopted the following size grades effective in January, 1947.

The classifications are:

<u>Counts or Extra Large</u>	= not more than 160 oysters per gallon not more than 44 oysters per quart.
<u>Extra Selects or Large</u>	= more than 160 but not more than 210 oysters per gallon more than 36 but not more than 58 oysters per quart.
<u>Selects or Medium</u>	= from 211 to 300 oysters per gallon from 46 to 83 oysters per quart.
<u>Standards or Small</u>	= from 301 to 500 oysters per gallon from 68 to 138 oysters per quart.
<u>Standards or Very Small</u>	= over 500 oysters per gallon more than 112 oysters per quart.

In North Carolina most shucking houses have generally graded oysters into two sizes, standards and selects.

<u>Oyster Spat</u>	= small oysters, generally less than one-inch in length, attached to various materials.
<u>Oyster Cultch</u>	= material of various nature, such as shells, fossil rock, cement coated substances, etc. Scattered on bottom or suspended in the water for purpose of providing material for attachment of larval oysters in the swimming stage.
<u>Seed Oysters</u>	= small oysters, ranging in size from a fraction of an inch to nearly market size of 2 1/2 to 3 inches, used for planting purposes.

HARD CLAMS:

Uniformity in marketing hard clams in the shell has been lacking in the past, varying in different states and according to market demand.

In North Carolina a bushel of hard clams in past years was considered as 100 pounds. In recent years the weight was 90 pounds per bushel. Generally fishermen gathering clams are paid for their harvest by a determined price per pound.

Size grades were by count with about 600 clams per 90 pound bushel classed as little necks and about 350 clams per 90 pound bushel as cherrystones. Large clams with count of less than 200 to 250 clams per bushel were graded as chowders. An intermediate size of 250 to 350 clams per bushel were often sold as mediums. Counts often varied depending upon market demand and at times sold by a given number per "bag". Subgrades such as "large cherrystones" or "large littlenecks" and other gradations have often been used when market prices were at a premium. The smaller size clams bring the highest prices.

"Seed" clams frequently sold for planting purposes in bags per 1000 count consisted of clams too small for half-shell or raw trade.

The Atlantic States Marine Fisheries Commission proposed to establish a uniform measure for marketing clams. At a meeting in October, 1969, the Commission passed Resolution 7 recommending adoption by all states in which hard clams are harvested of the following standard measures:

A unit measure determining a bushel in pounds to be a minimum of 75 pounds per bushel.

Little necks = not less than 450 clams per 75 pounds.

Cherrystones = not less than 250 clams per 75 pounds.

Chowders = less than 250 clams per 75 pounds.

Data collected as bushels of clams (U. S. Standard Bushel) is converted to pounds of meats by multiplying 8.75 pounds per bushel.

Data collected as gallons of shucked clam meats is converted to pounds of shucked meats by multiplying by 8.75 pounds per gallon.

SHRIMP:

Shrimp landings are reported as heads-on (round) weight or the total weight of shrimp. The first step in processing is to remove the "heads" (cephalothorax) which are discarded or utilized for industrial products, i.e. conversion to meal, for trout farms, mink food, or other non-human use. The remaining "tails" are graded for market according to number per pound. Thus, 26-30 count shrimp is interpreted as not less than 26 nor more than 30 individual shrimp per pound. In recent years use of grading machines have facilitated a better uniformity in graded shrimp for market resulting in higher prices for the product. The larger size shrimp bring the higher prices.

BLUE CRABS:

Hard crabs are usually sold to processing firms by fishermen at a determined price per pound of total weight of crabs. Crab meat is removed after steam cooking and separated into three categories: backfin or lump, flake, and claw. Backfin or lump brings the highest price, about \$1 to \$1.25 more than flake per pound. Flake generally averages about 10 cents per pound above claw meat. At times grade variations may appear on the market as jumbo-lump, and lump-flake mixed.

Proposed U. S. Standards for grades of cooked blue crab meat (April, 1971) set forth five categories as follows:

- Lump = meat from body portion next to back fin appendage. Lumps weighing at least 1/15 oz. per portion.
- Jumbo Lump = meat from body portion next to back fin appendage. Lumps weighing at least 1/7 oz. per portion.
- Flake = meat from body portion containing no lumps.
- Lump-Flake Mixed = mixture of lumps and flakes with lumps weighing at least 1/15 oz. per portion.
- Claw = meat from claw.
- Formed Products = minced or comminuted meat pressed or formed into larger pieces to simulate lump or jumbo lump.

Additional criteria have been proposed for grading various quality factors which include appearance, texture, amount of shell fragments, extraneous matter, etc.

Soft crabs are sold per dozen individuals. These are crabs that have been removed from floats or pens as soon after having shed the outer shell as possible, before the new outer shell has hardened.

Peeler or shedder crabs are crabs recognized by the fishermen by color changes, indicating that moulting or shedding will soon take place. These are sorted and sold to dealers that have floats for the purpose of gathering soft crabs.

FISH:

Fish are landed and sold in round or whole weight by fishermen. Dealers market whole fish usually according to size which consists of count or individuals per box or designated gross weight. A wood fish

box commonly used by fish dealers to ship fish in the round, had outside dimensions of 14 inches wide, 14 inches deep, and 32 inches long. In recent years coated cardboard containers have been in use.

In general three sizes are in practice, such as small, medium and large. With certain species there may be differing grade names such as large flounders called jumbo, or small gray trout designated as pan trout.

The number of individuals per size is flexible, fluctuates with market demand, and varies with species. Size grades for spot and croakers, for example, approximate the following:

Small = an average of 250 individuals per box.

Medium = average of about 220 individuals per box.

Large = an average of 170-180 individuals per box.

Size grades for gray trout may be as follows:

Pan or small = from 190 to 260 per box.

Medium or round = about 115 to 200 per box. Individuals from 3/4 to 1 pound.

Large = about 60 to 80 per box.

Jumbo size grade for flounders consist of individual fish weighing 3 to 4 pounds and up. Smaller individuals are graded as selects, 2 to 3 pounds, and mediums, 1 to 2 pounds per fish.

The measure for buying and selling menhaden for manufacture into fish meal and oil within North Carolina is defined by Statute 113-186 as a container of 22,000 cubic inches for 1000 fish.

1929	7.0	8.0	6.0	3.0	3.0	

Prior to 1930, oysters were converted from bushels to pounds by factor of 7; Hard Clams, 8.0; Bay Scallops, 6.0; Soft and Hard Crabs, 3.0.

Yields from private and public oyster areas varies each year during fall and spring months. In 1970, private, fall = 4.78#; private, spring = 5.32; public, fall = 4.60; public, spring = 5.15.

Sea Scallops = 6.0 lbs/US standard bushel

Rangia = 8.1 lbs/US standard bushel

Oysters, Clams, Scallops = 8.75 lbs./gallon

Blue Crabs = pounds converted to live crabs by multiplying by 7.14

Alewives = 2/5 of 1 lb. - 1 fish (1928)

Menhaden = 1 fish = 3/5 of 1 lb. (1928)

Shrimp = pounds of heads-off shrimp converted to heads-on weight by multiplying brown shrimp by 1.61, pink shrimp by 1.60, white shrimp by 1.54. Headed shrimp (tails) represent 62.1% for brown shrimp; 62.5% for pink shrimp, and 64.9% for white shrimp of total weight.

Names of Fishes and Other Forms Used in Statistical Tables

Fishes and other forms that make up the commercial catch are listed in the statistical digests and former publications by their common names. When one attempts to distinguish some species over a period of years considerable confusion may result. For throughout the geographical range of a single species there may be several names for the same species, the same common name for several species, or for a particular group of closely related species. It is apparent that confusion and misunderstanding would develop. One might paraphrase a common expression to say, "a flounder by any other name is still a flounder," but it remains to determine which flounder is listed in the tables. In many cases it is not possible to separate species in the reports for closely related forms are combined under a single name. Some species are not easily separated except by those experienced in handling these, and since there are no market advantages in separating such closely related forms, it would be of little value to do this for general use.

Scientific names of fishes and other animals are accurate and Latinized so the same name is used throughout the world. These are established and determined by the International Rules of Zoological Nomenclature. The purpose of the international decisions is to establish a uniformity of names so each scientist, or any one else, will know exactly what forms others are studying or discussing and to avoid language barriers. Precision is supposedly insured for no two species of animals can have the same name.

Although scientific names are universal in use and are the most accurate means of designating species, these names do change and will continue

to change with advancing knowledge. A few examples will illustrate such changes. In earlier years, striped bass, or rockfish, were known scientifically as Roccus lineatus which was changed to Roccus saxatilis and in recent years to Morone saxatilis. The bay scallop has had several name changes, Pecten irradians, Chlamys irradians, Aequipecten irradians, and currently is known as Argopecten irradians concentricus.

In regard to common names there are many examples of numerous local names for a single species. Hard clams (Mercenaria mercenaria) are called quahaugs, quahogs, round clams, bullnose, little necks, cherrystones, and chowders. Spot (Leiostomus xanthurus) are known as chub, goody, Lafayette, roach, jimmy, Norfolk spot, King William spot, and masooka.

Any attempt to insist upon a strict use of scientific names for general public use would be cumbersome and futile. The difficulty of pronouncing names and understanding which species is involved would probably create greater confusion and frustration. Scientific names will continue to change and should be left to those engaged in scientific endeavors. The difficulty with common names can be resolved and settled through arbitrary agreement by democratic means. The American Fisheries Society has now published a third list of accepted names of fishes of the United States and Canada in an attempt toward uniformity and avoiding confusion in the use of common names. There were 570 entries in the 1948 list, 1852 species in the 1960 list, and 2131 names in the 1970 edition.

In the December 17, 1973 issue of the Federal Register (38FR34682) the Director of the National Marine Fisheries Service, NOAA, U. S. Department of Commerce, expressed the view that an urgent need exists for the clarification and refinement of policy and procedures of naming fish, shellfish,

and their products for the purposes of marketing and labeling. Among the reasons for this need were:

1. Thousands of marine food species have accurate scientific names but are known by various common names in different locations resulting in consumer confusion and marketing difficulties.
2. There is an increasing interest in underutilized fishing resources which have not been marketed and for which no common names exist that are familiar to consumers.
3. Many nutritious species have objectionable common or local names which are aesthetically undesirable and severely limit marketing ability.
4. New techniques for processing resulting in new fishery products present a need for names and precedents for naming which do not exist.
5. Consumer protection is needed in truthful labeling, product identification and aesthetic labeling.

The continuing efforts of the American Fisheries Society and the National Marine Fisheries Service will hopefully eliminate much future confusion over use of common names.

In this review of fisheries statistics for North Carolina the common names used in the statistical reports are listed with the current scientific name and a list of other common names that are in use or have been used. Former scientific names are included in brackets under the present accepted name. An asterisk has been used to indicate specific common names according to the list of common names in the third edition (1970) of Special Publication No. 6 of the American Fisheries Society. No official listing of common names of commercial forms other than fishes is known at this time.

() Less than 500 pounds or 500 dollars

+ F.A.W.S. Statistical Digest #44 lists sharks for N.C. under table-catch by states - none under catch by gear, and reverse for sheepshead, figures presumed for sheepshead.

* Catch by gear show 81,500 pounds (\$5,685) for grouper, 204,300 pounds (\$14,256) for Harvestfish, 20,000 pounds (\$1,380) for grouper under catch by otter trawls presumed to be harvestfish.

Croaker	148,678	Oysters	101,153
Mullet	132,874		
King Whiting	116,606		

TABLE IX

LIST OF SPECIES HARVESTED BY SEASON

SPECIES HARVESTED ALL MONTHS

Bluefish	Gray Trout
Butterfish	Spotted Trout
Carp	Red Snapper
Catfish	Spot
Croaker	Striped Bass
Black Drum	Sturgeon
Red Drum	White Perch
Eels	Yellow Perch
Flounders	Crabs
Groupers	Clams, Hard
King Whiting	Sea Bass
Menhaden	Sheepshead
Mullet	Calico Scallops
Pigfish	Squid
Scup or Porgy	Clams, Rangia

Winter-Spring Months
Nov. (Dec. to Apr.) May

Alewives
 Hickory Shad
 Shad
 Swellfish
 Oysters
 Sand Perch
 Bay Scallops

Summer-Fall Months
May (June to October) Nov.

Cobia
 King Mackerel
 Thread Herring
 Pompano
 Harvestfish
 Spanish Mackerel
 Shrimp
