Additional Mitigation Measure C1. Vessel and aircraft avoidance (by 0.8 km [0.5 miles]) of concentrations of groups of ice seals.

Applicable Activities: All activities that occur during the open-water season (i.e. 2D/3D seismic surveys including in-ice seismic, CSEM surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities)

Purpose: To increase the distance between oil and gas related vessel and aircraft operations and marine mammals therefore decreasing the likelihood of causing disturbance or energetic stress to the marine mammals; to decrease the potential for collisions with marine mammals; and to decrease the likelihood of separating marine mammals that are resting or traveling in close proximity.

Science, Support for Reduction of Impacts, and Likelihood of Effectiveness: Numerous studies have indicated an inverse relationship between distance to a vessel/ aircraft and the likelihood that ice seals, walrus or polar bears will be stressed or disturbed by the vessel/ aircraft (see Brueggeman et al. 1989, 1990, 1991, Salter 1972, Anderson and Aars 2008, Amstrup 1993 and others). Additional studies have indicated that reducing speed, avoiding separating conspecifics and giving a wide berth to marine mammals decreases the potential for collisions (see Silber et al. 2010, Thompson et al. 2010, Weinrich et al. 2010, and others).

This measure would require all vessels to slow down, steer around if possible, and not approach ice seals within 0.8 km (0.5 mi). It is not clear how much practical effect this would have on ice seals even if it is assumed that similar requirements would apply as they do for walrus groups in USFWS LOAs. Ice seals are difficult to see at 0.8 km (0.5 mi) under many weather/sea conditions and they can swim much faster than most exploration vessels so there may be very few cases when a vessel might detect and then successfully maintain a 0.8 km (0.5 mi) safety buffer approaching groups of ice seals. In addition, the great majority of seals observed during aerial surveys in the Chukchi Sea have been single animals rather than recognizable groups (Thomas et al. 2010). This measure may marginally reduce disturbance for ice seals but would probably only be effective for faster vessels if they had PSOs on board.

History of Implementation: This measure has been included pursuant to USFWS LOAs but not previously by NMFS.

Practicability: Not likely difficult to implement. These measures have been required through the USFWS LOA process for a number of years, and operators appear to be following them.

Recommendation: Based on likely reduction in adverse impacts and apparent ease of implementation, this measure should become standard.

Walrus – Additional Mitigation Measure C1 is intended to provide extra protection for groups of ice seals. All of the elements relating to walrus are identical to what would be required under a USFWS LOA so this measure would make no practical difference to walrus.

Polar Bears – Additional Mitigation Measure C1 is intended to provide extra protection for groups of ice seals. All of the elements relating to polar bears are identical to what would be required under a USFWS LOA so this measure would make no practical difference to polar bears.

Additional Mitigation Measure C2. Specified shipping or transit routes to avoid important habitat in areas where marine mammals may occur in high densities.

Applicable Activities: All involving vessel use

Purpose: To minimize the potential for disturbance impacts from repeated overflights or vessel trips when multiple back and forth trips are required to complete operations.

Science, Support for Reduction of Impacts, and Likelihood of Effectiveness: Slowing vessel speeds and using standard shipping lanes and flight paths is a long established method used to decrease the spatial footprint of activities, in this case, to avoid impacting marine mammal concentration areas such as established pinniped haul outs; see Salter 1972, Gales et al 2003, Laist et al 2001, Marine Mammal Commission Report to Congress 2007, Kruse 1997, Lawler 2005, Maier 1998 and others. These designated shipping routes would likely focus on avoiding some of the areas identified above as important for bowheads, belugas, and subsistence hunting. Of note, five Alaska Native Organizations recently came together to form the Arctic Marine Mammal Coalition, which concluded that, unless effectively managed, increasing ship traffic in Arctic waters has the potential to have adverse impacts on marine mammals and their subsistence uses.

This measure would require exploration vessels to use unspecified designated shipping lanes while in transit to avoid concentrations of marine mammals. A designated route could result in decreased disturbance to animals in those important habitats. However, as seismic activities often cover wide regions, particularly for the 2D non-lease sale areas, designated transit routes may be difficult to establish. As long as routes are the same year to year, it would potentially be easier for vessels to avoid these areas, although it may result in increased transit time for some.

Practicability: This mitigation measure is likely feasible; it has been successfully implemented for similar operations (for example, Northstar resupply trips). However, clear proposed routes have not been identified and additionally, less routine activities, such as new seasonal drilling or seismic operations will require further explanation as to how standard routes would be implemented.

Recommendation: This sort of mitigation measure is well-supported by current scientific literature, and specific transit routes have been successfully implemented without apparent conflicts with safe operations in the past. However, because these areas have not been clearly delineated, it will be important to evaluate them on a case by case basis before requiring.

***Walrus* –** This additional mitigation measure requires shipping routes to avoid high densities of marine mammals, including walrus. This measure is also identical to what would be required under a USFWS LOA to protect groups of walrus.

***Polar Bears* –** Additional Mitigation Measure C2 requires shipping routes to avoid high densities of marine mammals. Because polar bears typically do not occur in "concentrations" in open water, it is not apparent that this measure would have any practicable effect on polar bears.

Additional Mitigation Measure C3. Requirements to ensure reduced, limited, or zero discharge of any or all of the specific discharge streams identified with potential impacts to marine mammals or marine mammal prey or habitat.

Applicable Activities: Exploratory drilling activities

Purpose: To decrease potential impacts to marine mammals, and marine mammal prey species through habitat degradation. For example, benthic prey species in the immediate vicinity of a drill site could be smothered or crushed by cuttings, affected by increased suspended sediments, salinity or temperature. The spatial scale and duration of effects would depend upon the depth of the well, amount of discharges and dispersion rates (Section 4.5.1.5.1 and 4.5.2.1) but would likely be small, for example, the extent of the depositional footprint from a previous drill site in the Beaufort Sea was on the order of 30 m (98 ft).

This mitigation measure would also mitigate adverse impacts to subsistence uses and hunts of marine mammals, as discharges raise concerns by Native hunters of food tainting and a reduced willingness to eat animals that have been exposed to oil and gas exploration activity discharges.

Science, Support for Reduction of Impacts, and Likely Effectiveness: See analysis in Section 4.5.1.5.1 and 4.5.2.1 of the EIS. BOEM studies to date in the Chukchi Sea and Beaufort Sea of past exploration wells indicate some increases in contaminants from cuttings in some cases, impacts to benthic invertebrates, fish larvae, fish eggs and possibly other lower trophic organisms in the immediate well site vicinity are likely in the short term. To date, this loss of prey and prey habitat has been limited to relatively small areas and has not been linked to decreases in benthic feeding mammals, such as walrus, bearded seals, or gray whales. Additionally, it is unclear whether moving the cuttings to another area may create a problem there.

History of Implementation: Shell voluntarily included this measure in their proposed action in the Beaufort Sea in 2012; however, neither NMFS nor BOEM have otherwise required this measure previously.

Practicability: This measure is expensive to implement. However, in the Beaufort Sea, Shell voluntarily included this measure during the 2012 season, indicating that it may be practicable in some instances.

Recommendation: Recommend further study and evaluation before large scale implementation. Since two exploration drilling operations were conducted in 2012, only one of which removed cuttings, this presents a good opportunity to conduct follow up studies at both sites. No exploratory drilling programs are proposed for the 2013 open water season.

***Walrus* –** This additional mitigation measure reduces discharge of potentially harmful substances. This measure would require reduced discharges of various waste streams from exploration vessels, drilling rigs, and facilities. No reduction levels are specified but, to the extent that any substances with potentially adverse effects on walrus or their prey could be kept out of the marine environment, this measure could reduce adverse effects on walrus by reducing the risk of injury/mortality and habitat changes.

***Polar Bears* –**

This additional mitigation measure reduces discharge of potentially harmful substances. This measure would require reduced discharges of various waste streams from exploration vessels, drilling rigs, and facilities. No reduction levels are specified but, to the extent that any substances with potentially adverse effects on polar bears or their prey could be kept out of the marine environment, this measure could reduce adverse effects on polar bears by reducing the risk of injury/mortality and habitat changes.

Additional Mitigation Measure C4. Operators are required to recycle drilling muds.

Applicable Activities: Exploratory drilling

Purpose: Reduce contaminant waste streams into the environment and potential impacts to habitat and benthic prey

Science, Support for Reduction of Impacts, and Likely Effectiveness*:* See analysis in Section 4.5.1.5.1 and 4.5.2.1 of the EIS, and Boesch and Rabelais 1987, Neff 2002, Neff 2008, Cranford et al 1999, and others. Although water based drilling muds currently used are less toxic than earlier industry standards, scientific research continues to evaluate the long term effects at drill sites of muds, cuttings and other discharges. These measures would be expected to result in potentially reduced impacts on food sources and habitat of bowhead whales on a localized scale where the discharge activity may occur. The level at which these additional mitigation measures would reduce impacts to bowhead whales is, however, unknown (extent would be dependent on volume of discharge). Also of note, this measure removes one source of potential impacts from the waste stream; however, particulate matter from cuttings may have a higher impact (disruption of feeding, respiration or burial), see Hyland et al. (2003).

History of Implementation: This measure has not previously been required by BOEM or NMFS.

Practicability: Operators could incur additional costs with implementation of this measure; however, companies typically already attempt to re-use drilling muds to the degree possible.

Recommendation: This measure is already mostly standard for industry operators, but could be reinforced through inclusion in MMPA authorizations.

***Walrus* –** This additional mitigation measure requires recycling of drilling muds and other waste reduction measures and is very similar to Additional C3. To the extent that any substances with potentially adverse effects on walrus or their prey could be kept out of the marine environment, this measure could reduce adverse effects on walrus by reducing the risk of injury/mortality and habitat changes.

***Polar Bears* –** Additional Mitigation Measure C4 requires recycling of drilling muds and other waste reduction measures. This mitigation measure is very similar to Additional Mitigation Measure C3. To the extent that any substances with potentially adverse effects on polar bears or their prey could be kept out of the marine environment, this measure could reduce adverse effects.

Additional Mitigation Measure C5. Use trained seal-lair sniffing dogs for areas with water deeper than 3 m (9.8 ft) depth contour to locate seal structures under snow in the work area and camp site before initiation of activities. Seal lairs are to be avoided by a distance of 152 m (500 ft).

Applicable Activities: On-ice seismic surveys

Purpose: The purpose of this measure is to avoid disturbance or injury of ice seals.

Science, Support for Reduction of Impacts, and Likely Effectiveness*:* Use of trained dogs greatly improves the ability to detect ice seals under the snow and ice. It is not clear how many seals may be affected but this measure would definitely reduce the risk of disturbing/injuring ice seals in their lairs from close distances. If proposed on-ice surveys were in known ice seal concentration areas, this measure could reduce disturbance impacts for substantial numbers of seals.

Practicability: The logistics of securing the services of trained dogs and their handlers should be fairly straightforward as this technique has been in use for decades. However, there are a limited number of dogs that are trained specifically for these purposes. Therefore, it might be difficult to implement if there are no dogs available that are well enough trained to be used.

History of Implementation: NMFS has required this measure in past IHAs issued for on-ice seismic surveys in the Beaufort Sea.

Recommendation: This measure should likely be included as a standard measure in IHAs.

Additional Mitigation Measure C6. Use trained seal-lair sniffing dogs to survey the ice road and establish a route where no seal structures are present.

Applicable Activities: On-ice seismic surveys

Purpose: The purpose of this measure is to avoid disturbance or injury of ice seals.

Science, Support for Reduction of Impacts, and Likely Effectiveness*:* Use of trained dogs greatly improves the ability to detect ice seals under the snow and ice. It is not clear how many seals may be affected but this measure would definitely reduce the risk of disturbing/injuring ice seals in their lairs from close distances. If proposed on-ice surveys were in known ice seal concentration areas, this measure could reduce disturbance impacts for substantial numbers of seals.

Practicability: The logistics of securing the services of trained dogs and their handlers should be fairly straightforward as this technique has been in use for decades. However, there are a limited number of dogs that are trained specifically for these purposes. Therefore, it might be difficult to implement if there are no dogs available that are well enough trained to be used.

History of Implementation: NMFS has required this measure in past IHAs issued for on-ice seismic surveys in the Beaufort Sea.

Recommendation: This measure should likely be included as a standard measure in IHAs.

4.5.2.4.16.1 Additional Mitigation Measures Summary for Marine Mammals

Additional mitigation measures that may possibly be incorporated into future authorizations and that could mitigate potential adverse impacts on marine mammals are discussed above. Efficacy and practicability of these measures are discussed to the extent possible, given the varying degrees of current availability and use. The information and analyses provided here will serve as tools in NMFS' and BOEM's future MMPA and OCS Lands Act decision-making regarding whether to require these measures pursuant to specific projects.

A few of the measures, such as sound source verification, have been implemented in recent years. Others, such as acoustic and imaging technologies to enhance detectability of marine mammals during poor visibility conditions have been used with limited success for mitigation and monitoring but still need improvement. Augmenting visual observations by PSOs with acoustic detection could improve detectability of marine mammals at sufficient distances to avoid disturbance and auditory injury at a higher rate than is possible with visual observations alone—once the technology is available and effective for use in Arctic waters. Measures to mitigate impacts to subsistence harvests through time/area closures or to reduce or eliminate discharges would reduce adverse effects to bowhead whales and their habitat, respectively.

Most of the additional mitigation measures considered in this section would have very limited potential to reduce adverse effects on polar bears and ice seals except for Additional Measures C5 and C6. These measures could improve detection of seal lairs on ice and therefore reduce the risk of injury or mortality from on-ice surveys. The temporal/spatial restrictions on exploration activities in the Hanna Shoal area could reduce adverse impacts to Pacific walrus, especially at times when the ice pack was nearby. However, given the mitigation measures that would be required by USFWS LOAs and the standard and additional mitigation measures required by NMFS, the effects on Pacific walrus would still likely be low in magnitude, distributed over a wide geographic area, and temporary in duration.

4.5.2.5 Terrestrial Mammals

There are approximately 30 species of terrestrial mammals within the vicinity of the EIS project area (Table 3.2-5). Based on the proposed action for this EIS, only caribou are expected to be potentially affected during critical periods of their life cycle; therefore, this analysis will focus only on caribou. Four caribou herds utilize habitats along Alaska's Arctic coast: the Western Arctic; the Porcupine; the Central Arctic; and the Teshekpuk herds (ADFG 2010a). Please refer to Section 3.2.5.1 for information regarding caribou distribution, abundance, reproduction, and life history.

The oil and gas exploration activities proposed in Alternative 2 that could affect caribou is one exploratory drilling program in the Beaufort Sea and one exploratory drilling program in the Chukchi Sea per year, as they require aircraft support for crew changes. Aircraft fly overs in support of exploration activities could result in disturbance to caribou while occupying preferred habitats or following preferred migration routes. The other possible effects that may occur as a result of oil and gas exploration would be disturbances caused by additional human activities (air or ground) in the EIS project area, due to the overall increase in human population due to support crews living in the North Slope area.

4.5.2.5.1 Direct and Indirect Effects

Behavioral Disturbance

Aircraft used for crew changes can either be helicopters or fixed wing aircraft. Caribou respond to flyovers and nearby landings in a variety of ways depending on the degree of their habituation, weather conditions, sex and age composition of the herd, and the aircraft itself (Calef et al. 1976, Horejsi 1981). The type of aircraft, altitude, airspeed and frequency of flyovers all play a role on the caribou's reaction. Disturbance of caribou is an important consideration because it can cause immediate physical injury or death by animals fleeing the disturbance, can result in increased expenditures of energy, or changes in the physiological condition of the animals, which reduces their rates of survival and reproduction, and can result in long-term changes in behavior, especially the traditional us of calving areas and insect relief areas (Calef et al. 1976). There is a higher likelihood of a behavioral disturbance along the Beaufort Sea coast where the Central and Teshekpuk herds use the area for calving and insect relief. There are no habitats along the Chukchi Sea that are recognized as caribou calving habitat; however, the Western Arctic Herd uses coastal areas and alpine ridges in the Brooks Range for insect relief.

Injury and Mortality

Another anticipated effect of oil and gas exploration is an increase in vehicle traffic from support crews. Vehicle strikes could also cause injury to caribou or even mortality.

There is the potential for terrestrial mammals to be exposed to small, accidental fuel spills of less than 50 bbl (see Section 4.2.7). Small fuel spills, discharges, and any air/water quality effects would be extremely small, if detectable at all, along the Alaskan coast, and vessel traffic will be far offshore, preventing any noise or other activities from having effects on terrestrial mammal resources. Therefore, negligible effects are anticipated for terrestrial mammals from small fuel spills.

Habitat Alterations

It is possible that road construction, as well as pipeline construction, will not only destroy vegetation within the footprint of the road but could also result in a reduction of habitat use within the adjacent areas. Cameron et al. (1992) found that calving caribou were displaced outward after construction of the Milne Point road system, resulting in underutilization of habitats adjacent to roads and overutilization elsewhere effectively diminishing the capacity of the area to support caribou.

4.5.2.5.2 Conclusion

The direct and indirect effect of oil and gas exploration activities on caribou resulting from implementation of Alternative 2 would be medium intensity, temporary to long term duration, local extent, and the context would be common. Therefore, the summary impact level of Alternative 2 on caribou would be considered minor.

4.5.2.6 Time/Area Closure Locations

The analysis of the direct and indirect effects associated with time/area closures can be found in Sections 4.5.2.4 (Marine Mammals), 4.5.2.3 (Marine and Coastal Birds) and 4.5.3.2 (Subsistence).

4.5.2.7 Mitigation Measures for the Biological Environment—Non-Marine Mammal Resources

Standard Mitigation Measures are outlined in Section 2.4.10 and Additional Mitigation Measures are outlined in Section 2.4.11, and both are described in detail in Appendix A. Requirements for implementation depend on type, time, and location of activities and co-occurrence of multiple activities. A combination of mitigation measures could be required for any one ITA. While the ultimate goal of the mitigation measures is to reduce impacts to marine mammals or subsistence hunts of marine mammals, there is the potential for some reduction of impacts to other biological resources. These standard and additional mitigation measures are evaluated within the context of those more targeted resources (i.e. marine mammals and subsistence uses) and are not repeated here.

4.5.3 Social Environment

4.5.3.1 Socioeconomics

The following discussion of direct and indirect effects of Alternative 2 evaluates effects on public revenues and expenditures, employment and personal income, demographic characteristics, and demand on social organizations and institutions.

The level of impacts on socioeconomics will be based on levels of intensity, duration, geographic extent, and context, identified in Table 4.4-1 (Alternative 1).

4.5.3.1.1 Direct and Indirect Effects

Public Revenue and Expenditures

Under Alternative 2, the following are categories of revenue generation (under the current tax system):

> **Federal Revenue**: None. Federal lease payments were already made in advance of the proposed activities. The likelihood of exploration resulting in production cannot be predicted, but the potential for generating future revenue would not be foregone under this alternative.
>
> **State Revenue**: None. Lease payments were already generated in advance of the proposed activities; there are no facilities proposed that would generate property tax; and no production activity that would generate production revenue or corporate income tax. The likelihood of exploration resulting in production cannot be predicted, but the potential for generating future revenue would not be foregone under this alternative.
>
> **Local Revenue**: Sales or Special Taxes would be generated from the purchase of goods and services in the communities where crew and support services are stationed. No new property taxes would be generated other than potential rental fees. A general economic contribution related to the purchase of goods and services, aside from taxes and employment, would occur in all communities that serve some staging purpose.

A detailed list of communities that could receive local revenue from the proposed action alternatives can be found in Table 4.5-22. Table 3.3-1 lists costal communities’ tax regimes. Only cities with sales or special (bed, tobacco, alcohol, or gaming) taxes would generate local revenue from the stationing of crew, support, logistics, or supplies for survey/exploration vessels. This includes Barrow, Nome, and Unalaska/Dutch Harbor.

Table 4.5-22 Potential Revenue Sources Under Alternative 2

Alternative 2 (Activity Level 1)	Support/Crew Changes[1]	Owner	New Public Revenue from Services[2]
Up to four 2D/3D seismic surveys in the Beaufort Sea per year including One in-ice towed-streamer 2D (using icebreaker)	West Dock or Oliktok Dock near Prudhoe. Air support out of Prudhoe or Barrow.	Up to 3 in federal waters; one survey in state waters (nearshore)	Prudhoe Bay & **Barrow**
Up to three 2D/3D seismic surveys in the Chukchi Sea per year including One in-ice towed-streamer 2D (using icebreaker)	Nome or possibly Barrow & Wainwright	Federal waters, not associated with leases	**Nome** or **Barrow** & Wainwright
Up to three site clearance and high resolution shallow hazards survey programs in the Beaufort	West Dock or Oliktok only once per year	Federal & state active leases	Prudhoe Bay
Up to three site clearance and high resolution shallow hazards survey programs in the Chukchi per year	Wainwright or Nome only once per year	Federal active leases	Wainwright or **Nome**
One exploratory drilling program in the Beaufort per year	Unalaska/Dutch Harbor then Prudhoe Bay. Helicopter resupply and marine monitoring from Barrow	Federal active leases; drilling in state leases from land	**Unalaska/Dutch Harbor**, Prudhoe Bay & **Barrow**
One exploratory drilling program in the Chukchi per year	Unalaska/Dutch Harbor then Wainwright. Helicopter resupply and marine monitoring from Wainwright or Barrow	Federal active leases	**Unalaska/Dutch Harbor**, Wainwright & **Barrow**

Notes:

1) Search & Rescue is coordinated by the Coast Guard and the nearest vessels are deployed. Typically, resources are available out of Barrow and Deadhorse. Coast Guard does not typically reimburse for the cost of these efforts (Majors 2011).
2) Communities that implement sales or special taxes are in **bold**; these communities could capture revenue associated with goods and services.

The establishment of Communications Centers (Com Centers) could generate a small amount of property tax revenue for the City or Borough if it resulted in construction of new facilities. The Com Centers are associated with Standard Mitigation D2:

- D2 – Establishment and utilization of Communication Centers in subsistence communities to address potential interference with marine mammal hunts on a real-time basis throughout the season.

Employment & Personal Income

Under Alternative 2, there would be a limited number of (direct) new local hire employment opportunities associated with the standard mitigation measure D2, associated with jobs:

- A3 – Protected Species Observers (PSOs) required on all seismic source vessels, ice breakers, and support (chase) vessels when required.
- A6 – PSOs required on all drill ships and ice management vessels.

The standard mitigation measures could create a limited number of (direct) new local hire employment opportunities associated with the PSO program, Subsistence Advisor (SA) program, Com Centers program, and Oil Spill Response (see Section 2.3.4 for more details). Employment activities associated with crew positions on vessels and the administration of the seismic, drilling, and survey activities are very specialized and would likely draw from a pool of workers statewide or the Lower 48. All new employment opportunities would draw regionally or nationally for qualified individuals. Table 4.5-23 outlines communities that may see larger numbers of local hire opportunities.

Table 4.5-23 Employment Opportunities Associated with the Standard Mitigation Measures

Required Standard Mitigation	Details	Communities Likely to Experience Higher Employment and New Revenue from Support Services
Protected Species Observers	Details on maximum seasonal part-time employment in Table 4.5-24	Prudhoe Bay, Barrow, Kaktovik, Nuiqsut, Wainwright
Oil Spill Response	Use of Village Response Team members trained in Hazwoper	Seasonal employment opportunities in all coastal villages
Subsistence Advisors	Not available	Prudhoe Bay, Barrow, Kaktovik, Nuiqsut, Wainwright
Communications Center	Staff hired to man radio transmissions from survey vessels, aircraft, and whaling crews in subsistence communities. Unclear whether collaboration between Plan holders would occur.	Seasonal employment opportunities in all coastal villages

Notes: Details about the required standard mitigation measures can be found in Chapter 2.

IHAs require biologically-trained, on-site individuals to be onboard vessels approved in advance by NMFS. Table 4.5-24 demonstrates a hypothetical quantity of PSOs hired under Alternative 2. The total workforce in the NSB, NAB and City of Nome is 12,461. Therefore, the maximum number of new seasonal, part-time positions (200) would represent less than two percent of new employment opportunities. Approximately half of the observers employed seasonally in the Arctic today are local hire, so it is more likely that around 100 new seasonal, part-time positions would be created.

Table 4.5-24 Maximum PSO Positions Under Alternative 2[1]

	Alternative 2 (Annual Activity Level 1)	Vessels Deployed (PSOs required)[2]	Aerial Observers	PSOs/survey	Total PSOs
Beaufort Sea	**Four 2D/3D seismic surveys**	Source (5) 2 chase/monitoring and/or icebreaker (3 each)	4	15	60
	Three site clearance and high resolution shallow hazards survey programs	Source (5)	4	9	27
	One exploratory drilling program	Drilling rig (5) 2 ice management (3 each) 3 other various (2 each)	4	21	21
Chukchi Sea	**Three 2D/3D seismic**	See Beaufort examples	4	15	45
	Three site clearance and high resolution shallow hazards survey programs		4	9	27
	One exploratory drilling		4	21	21
			TOTAL per year	**88**	**201**

	Alternative 2 (Annual Activity Level 1)	Vessels Deployed (PSOs required)[2]	Aerial Observers	PSOs/survey	Total PSOs

Notes:

1) Assumes all positions are unique; one PSO would not be hired for multiple surveys.
2) Numbers based on (Funk 2011) and (NMFS 2009 IHA permit)

Aside from the positions described in the mitigation measures, it is unclear whether direct full-time employment benefits would materialize locally from the Action Alternatives. Companies like Shell and BPXA have committed to hiring local residents. Historically, few village residents have been employed despite industries' efforts of training programs and recruitment (MMS 2002). The NSB is actively advocating for the employment of Iñupiat people, but still sees room for improvement by the industry to train unskilled laborers (MMS 2002).

In general, employment and associated personal income increases would be at a relatively low level in exploration; they usually peak during development activities (MMS 2007a). The indirect employment opportunities associated with Alternative 2 are shore-based, including: transport of equipment, room and board of survey/seismic crews, and administration of permits to conduct the surveys. Native Corporations and private entities may capitalize on these opportunities.

Demographic Characteristics

Alternative 2 would not have a direct or indirect contribution to demographics in the EIS project area communities. The seismic, site clearance, on-ice, and exploratory drilling activities are seasonal and short-term in nature. If workers associated with the surveys and programs do not already live in the EIS project area, they would not relocate permanently.

Social Organizations & Institutions

The implementation of Alternative 2 would result in relatively small revenues to Municipal Governments, primarily in sales and special taxes, and employment and service contracts with Regional and Village Corporations. In the communities where crew changes occur or vessels are based, there could be short-term, seasonal demand on institutions and social services for Barrow, Wainwright, Nome and Unalaska/Dutch Harbor.

If a deflection or disturbance of subsistence resources occurs as a result of Alternative 2 (see Section 4.4.3.2), the activities of non-profit organizations (see Table 3.3-6 in Section 3) could be impacted in order to coordinate adaptive strategies regarding potential economic and social implications of reduced harvest of subsistence resources. The Conflict Avoidance Agreement (CAA), Communication Centers, and Plans of Cooperation (POC) are mechanisms currently used for communication, cooperation, and conflict avoidance between industry and local groups like the AEWC. These are described more in Section 2.3.4 and evaluated in Chapter 5.

4.5.3.1.2 Conclusion

Based on the criteria identified in Table 4.4-1 (under Alternative 1), the magnitude of the socioeconomic impact is positive, but low, because total personal income and local employment rates are not increased by more than five percent. Revenues to the NSB would also not exceed five percent of their annual operating budgets. Standard mitigation measures could reduce interference between industry and subsistence activities and associated social impacts.

The duration of the socioeconomic impacts is temporary because it is not year-round. However, the activity is scheduled to occur over a fixed number of years. The positive economic impacts of the activity are statewide and even national. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat. The summary impact level for Socioeconomics under Alternative 2 is minor.

4.5.3.2 Subsistence

4.5.3.2.1 Direct and Indirect Effects

The level of impacts on subsistence resources will be based on levels of intensity, duration, geographic extent, and context, as shown in Table 4.5-25.

Table 4.5-25 Impact Levels for Effects on Subsistence

Impact Component	Effects Summary		
Magnitude or Intensity	**Low**: No noticeable impact to subsistence use patterns	**Medium**: Minimal spatiotemporal overlap of activities with subsistence hunts; effects able to be mitigated	**High**: Large-scale overlap of activities with subsistence hunts; adverse effects on success of hunts
Duration	**Temporary**: Effects last only a few days; hunters able to obtain species within a few days after impact	**Interim**: Effects last a few weeks to a month; hunters have to wait 1-2 weeks before can attempt hunts again	**Long-term**: Effects last at least an entire hunting season; hunters may not be successful that season for a given species
Geographic Extent	**Local**: Effects realized by a single community	**Regional**: Effects realized by two or more communities	**State-wide**: Effects realized throughout the EIS project area and may extend beyond the EIS project area
Context	**Common**: Affects only locally abundant subsistence resources or little changes in harvest and sharing practices	**Important**: Affects subsistence resources/ access/ or harvest and sharing practices within the region	**Unique**: Affects subsistence resources/ access/ or harvest and sharing practices beyond the region

As a result of activities under Alternative 2, disturbance and displacement of subsistence resources could occur and would be considered a direct impact from the activities. The following sources of disturbance may result in displacement of resources or changes in behavior such that the subsistence resources move away from coastal waters and become less readily available to subsistence hunters:

- Offshore noise from seismic and high resolution shallow hazard surveys and exploratory drilling;
- Offshore and nearshore noise from helicopter and fixed wing aircraft overflights;
- Increased levels of vessel traffic (including their noise contribution) associated with activities offshore and while transiting through nearshore areas;
- Ice management and icebreaking activities;
- Noise and vehicle movement from on-ice seismic surveys; and
- Permitted discharges.

These sources of disturbance have distinct characteristics in their effects on marine mammal and other important subsistence resource species. In the next six sections, the literature on each of these types of disturbance is reviewed in relation to the distinctive impacts on particular species. Traditional knowledge observations from subsistence users and communities are offered alongside the summary from the scientific literature. This review forms the foundation for analysis in later sections of the intensity, duration, extent, and context for estimated impacts to subsistence uses of the major species.

Table 4.5-26 describes the different subsistence hunts that occur within the EIS project area by resource, where these subsistence hunts occur, the seasons of occurrence and the potential for overlapping with proposed activities of Alternatives 2 through 6. Detailed information regarding the seasonal cycles of subsistence resources and harvest patterns is described in Section 3.3.2.

Table 4.5-26 Description of Subsistence Hunts by Resource

Community	Bowhead whales	Beluga Whales	Seals	Walrus	Polar Bear	Fish	Marine and Coastal Birds	Caribou	Potential to overlap with proposed activities (Alternatives 2 through 6)
Kaktovik	Fall – August to October about 20 miles off the coastline.	August to November - (opportunistically harvested with bowhead whaling and sealing in the fall) about 20 miles off the coastline.	Year round – peaks during whaling season. Occurs along coastline Kaktovik to Prudhoe Bay area. Northeastern Camden Bay and Point Griffin in the summer months.	June and July if present nearshore waters.	Year round along coastline - though not as common June, July and August.	Freshwater fish harvested January to mid-June and August through December at Hula Hula River, Kongakut River and into the Brooks Range. Marine fish July to November along the coast. Point Griffin, Kaktovik Lagoon, Camden Bay to Jago Spit in summer and the Canning Delta. Canning and Kuparuk rivers in the fall.	Harvested year round. Waterfowl arrive with open water in late spring and early summer months at Camden Bay and on barrier islands.	January to May and late summer/early fall months (September) if present. Inland fall and winter hunting occurs at the Hula Hula River and into the Brooks Range. Along the coast during summer hunting occurs when caribou are present at Point Griffin, Canning River, and Konganevik Point in the summer months.	Under Standard Mitigation Measure D1 proposed activities could not occur from Aug 25 until after bowhead harvest/quota is reached. Standard Mitigation Measure D2 establishes communication centers. Summer and early fall marine mammal harvests (seals, walrus, polar bears), marine and coastal bird, and caribou hunting could be impacted by aircraft overflights. Flight paths could originate from the Prudhoe Bay area to where offshore seismic survey activities and drilling operations are located but would be limited by altitude restrictions of Standard Mitigation Measure D3. Nearshore summer and late fall seal, walrus, marine and coastal bird hunting could be impacted by nearshore vessel traffic. One on-ice survey could occur at the same time that seals and polar bear are harvested during the winter.
Nuiqsut	Base for fall whaling is at Cross Island which is 90 – 100 miles from the community. Whaling occurs August to October. Most intense periods of whaling begin in mid-September and occur along the coast as far east as the Canning River.	Opportunistically harvested during bowhead whaling activity and sealing in the fall) from August to October.	Hunts occur at Cross Island, Thetis Island and the barrier islands. Seals are taken on the sea ice during March through May. During summer, ringed and spotted seals are hunted near the Colville River to Ocean Point. During the fall (August to October) hunts occur near the Colville Delta and along the coast from Cape Halkett to Foggy Island.	Hunted in June and July if present nearshore waters.	Occasionally taken during bowhead whaling hunt. And occasionally taken on coast late October through March.	Fishing occurs from Nuiqsut east to the Sagavanirktok River, south to the middle Colville, west to Teshekpuk Lake, and along the coast to Pitt Point to the mouth of the Canning River. In June whitefish are taken in the Colville River. Summer fishing occurs farther up the Colville River and on Fish Creek. Summer coastal fishing occurs for whitefish and cisco. Fall and summer fish camps are on the Colville River and at Fish Creek.	Harvest is year round. Hunting occurs from Nuiqsut east to the Sagavanirktok River, south to the middle Colville, west to Teshekpuk Lake, and along the coast to Pitt Point to the mouth of the Canning River. Ducks in fall are taken while whaling offshore.	Caribou harvest is year round. Hunting occurs from Nuiqsut east to the Sagavanirktok River, south to the middle Colville, west to Teshekpuk Lake, and along the coast to Pitt Point to the mouth of the Canning River. Caribou hunting is the primary activity in late summer. Some hunting in the area of Fish Creek during the winter.	Under Standard Mitigation Measure D1 proposed activities could not occur from Aug 25 until after bowhead harvest/quota is reached. Standard Mitigation Measure D2 establishes communication centers. Summer and early fall marine mammal harvests (seals, walrus, polar bears), marine and coastal bird, and caribou hunting could be impacted by aircraft overflights. Flight paths could originate from the Prudhoe Bay area to where offshore seismic survey activities and drilling operations are located but would be limited by altitude restrictions of Standard Mitigation Measure D3. Nearshore summer and late fall marine mammal harvests (seals, walrus, polar bears), marine and coastal bird hunting could be impacted by nearshore vessel traffic. One on-ice survey could occur at the same time that seals and polar bear are harvested during the winter.
Barrow	Spring whaling April through June is based from camps on the ice shelf northwest of the community and occurs west and east of Point Barrow. Hunting area is almost as far as Smith Bay to the east and as far as Skull Cliff to the west where there is an area of overlap with Wainwright whaling areas. Fall whaling occurs east or northeast of Cape Simpson on Smith Bay from August to October in an area that extends 16 km (10 mi) west of	The spring hunt for beluga whale occurs from April to June in the spring leads between Point Barrow and Skull Cliff. Later in the spring, whalers in Barrow hunt belugas in open water around the barrier islands off Elson Lagoon.	Seal hunting areas range from Peard Bay to Pitt Point in spring and summer months and winter. In the spring bearded seals may become available offshore west and north of Point Barrow in April. In June hunting camps are set up along the coast southwest to Peard Bay. Bearded seal hunts in the summer are conducted west of Barrow or from Pigniq. Ringed seals are hunted along the coast in the fall.	Walrus hunt areas range from west of Barrow and southwestward to Peard Bay. In April walrus may be hunted offshore west and north of Point Barrow. During summer to early fall, (June to September) hunts occur from west of Barrow southwestward to Peard Bay.	Hunts occur October to June if present at areas ranging west of Barrow southwestward to Peard Bay.	Fishing occurs April through early November. Fish are harvested in local rivers and lakes and in Elson Lagoon and west of Point Barrow during spring and summer. Historic site of Pulayaaq on the Meade River is used for summer fishing. During fall fishing occurs inland at such historic places as Iviksuk on the Inaru River and Nauyalik on the Meade River.	Hunting occurs primarily in the spring and fall. Historic site of Pulayaaq on the Meade River for taking waterfowl in the spring, Pulayatchiaq is also noted as a current and historical area for and spring waterfowl. By June, duck hunting camps are set up along the coast southwest to Peard Bay including the historic site of Pigniq, north of Barrow. In the fall duck hunting can continue into September at Pigniq.	Caribou hunting occurs year round. Historic site of Pulayaaq on the Meade River is used for trapping in late winter. Pulayatchiaq is also noted as a current and historical area for trapping. Majority of caribou hunting occurs by boat during the summer and fall months along the nearshore coast and inland along rivers.	Standard Mitigation Measure D2 establishes communication centers. Summer and early fall marine mammal harvests (seals, walrus, polar bears), marine and coastal bird, and caribou hunting could be impacted by aircraft overflights. Flight paths could originate from the Prudhoe Bay area and Barrow to where offshore seismic survey activities and drilling operations are located but would be limited by altitude restrictions of Standard Mitigation Measure D3.

Community	Bowhead whales	Beluga Whales	Seals	Walrus	Polar Bear	Fish	Marine and Coastal Birds	Caribou	Potential to overlap with proposed activities (Alternatives 2 through 6)
	Barrow to 48 km (30 mi) north of Barrow, and southeast 48 km (30 mi) off Cooper Island with an eastern boundary on the east side of Dease Inlet. Occasionally, the hunt extends east as far as Smith Bay and Cape Halkett or Harrison Bay. October is preferred month to hunt.								Nearshore summer and late fall harvests for seals, walrus, marine and coastal bird hunting could be impacted by nearshore vessel traffic. One on-ice survey could occur at the same time that seals and polar bear are harvested during the winter.
Wainwright	Spring – In April, these whales are taken in open leads in the offshore ice as they pass close to shore near Point Belcher and Icy Cape. Whalers travel up the coast as far as Peard Bay to hunt bowheads in the spring. Whaling camps are sometimes located 10 to 15 mi (16 to 24 km) from shore. Whales are taken from April through to August. Fall whaling recently resumed in 2010.	The beluga whale hunt takes place in the spring lead system from April to June in the ice along leads or driven into inlets in summer and harvested. Belugas are hunted from late June through mid-July and sometimes later into the summer.	Bearded and harbor seals are harvested from spring through fall. Ringed seals, however, are hunted during the spring in open leads. Bearded seals are hunted in early summer southwest of the community. Spotted seals harvested in the late summer early fall.	Walrus may be taken in spring but most are taken in the summer (July and August) from drifting ice floes near Wainwright and along the coast to Peard Bay. From August to September at local haul-outs, with the main area being from Milliktagvik north to Point Franklin. Icy Cape is a known walrus haulout location.	Polar bear subsistence hunts occur in the fall and winter (October through February) around Icy Cape, at the headland from Point Belcher to Point Franklin, and at Seahorse Island.	Kuk River and Kuk River estuary is an area where fishing occurs. Smelt fishing is done in January through March in the Kuk Lagoon. In general fishing occurs year round. During midsummer, nets are set up in front of the community for salmon, trout, and whitefish. Fall fishing along the Kuk, Ivisaruk, and Avalik rivers.	Migratory waterfowl harvest occurs along the coast and along rivers beginning in late April and early May. Waterfowl are harvested in early summer until nesting and some egg collecting occurs along Kasegaluk Lagoon or Seahorse Island. Fall harvests are at Icy Cape and Point Belcher.	Caribou are harvested year round. Caribou migrate to the coast during summer and are harvested from Icy Cape to Peard Bay and along major rivers beginning in late August and into the fall.	Proposed offshore activities would not overlap with bowhead whale and beluga whale harvests. Standard Mitigation Measure D2 establishes communication centers. Air traffic originating from a Wainwright shorebase, could traverse routes reported as beluga subsistence use areas by hunters from Wainwright, Point Lay, and Point Hope. These communities harvest belugas primarily in the spring, and the majority of harvest would have occurred prior to the commencement of seismic and high resolution shallow hazard surveys and exploratory drilling operations. Summer and early fall marine mammal harvests (seals, walrus, polar bears), marine and coastal bird, and caribou hunting could be impacted by aircraft overflights. Flight paths could originate from Barrow and Wainwright to where offshore seismic survey activities and drilling operations are located but would be limited by altitude restrictions of Standard Mitigation Measure D3. Nearshore summer and late fall marine mammal harvests (seals, walrus, polar bears), marine and coastal bird hunting could be impacted by nearshore vessel traffic.
Point Lay	Spring bowhead hunting resumed in 2009 in open leads.	Hunts occur from late June through mid-July herding them from the south to the shallows inside Kasegaluk Lagoon. Hunters are most familiar with beluga whale harvest in the area between Omalik Lagoon and Point Lay, although hunts can be as far north as Icy Cape. Summer harvest is from the middle of June to the middle of July. The summer hunting area is concentrated in Naokak and Kukpowruk Passes south of Point Lay. If the July beluga hunt is unsuccessful, Point Lay hunters y travel as far north as Utukok Pass and as far south as Cape Beaufort in search of beluga whales.	Ringed and bearded seals are available year-round. Ringed and bearded seals are hunted 20 miles (32 km) and 30 miles (48 km) north of Point Lay, respectively, with bearded seals concentrated in the Solivik Island area and up to three miles north off the island. Bearded seals are also hunted from south of Point Lay to the southern end of Kasegaluk Lagoon. Spotted seals are hunted mostly in the fall.	Summer walrus hunt occurs near Icy Cape. In June, the walrus migrate north past Point Lay, and the community conducts their annual hunt. Walrus are hunted from late May to late August along the entire length of Kasegaluk Lagoon, south of Icy Cape, and as far as 20 mi (32 km) offshore.	Polar bears hunted from September to April along the coast with the hunting area rarely extending more than two miles offshore.	May through October. Summer months fishing occurs near river mouths (except Kokolik), at ocean passes, in Kasegaluk Lagoon, and at Sitkik Point. The season lasts from early July to late September. The nets are moved about 15 miles up the Kukpowruk River in September for grayling fishing.	Icy Cape area used for hunting waterfowl. Migratory waterfowl and eggs are harvested during May and June at coastal sites and along inland rivers. Eggs are harvested at the islands in Kasegaluk Lagoon and along the barrier islands. Fall hunting near icy Cape.	Hunted year round. Caribou hunting areas in the western Brooks Range in the southeast corner of the NPR-A are used by Point Lay and Wainwright hunters. In the summer hunted near as they move toward the coast or in the Amatusuk and Kiklupiklak hills. Also taken along the coast and around Icy Cape. Fall hunting from late August to October at inland locations.	Proposed offshore activities would not overlap with bowhead whale and beluga whale harvests. Standard Mitigation Measure D2 establishes communication centers. Air traffic originating from a Wainwright shorebase, could traverse routes reported as beluga subsistence use areas by hunters from Wainwright, Point Lay, and Point Hope. These communities harvest belugas primarily in the spring, and the majority of harvest would have occurred prior to the commencement of seismic and high resolution shallow hazard surveys and exploratory drilling operations. Summer and early fall seals, walrus, marine and coastal bird, and caribou hunting could be impacted by aircraft overflights. Flight paths could originate from Wainwright to where offshore seismic survey activities and drilling operations are located but would be limited by altitude restrictions of Standard Mitigation Measure D3.

Community	Bowhead whales	Beluga Whales	Seals	Walrus	Polar Bear	Fish	Marine and Coastal Birds	Caribou	Potential to overlap with proposed activities (Alternatives 2 through 6)
									Vessels would not be expected to be present in seal subsistence harvest areas during the summer and fall months. Polar bears are unlikely to be present at times when vessels would be transiting through their habitat during the open water season.
Point Hope	Spring whaling occurs from the time the offshore leads form in the ice in late March or early April until June. Bowhead whales are hunted from March to June from whaling camps along the ice edge south and southeast of Point Hope when pack-ice lead is rarely more than 10-11 km (6-7 mi) offshore.	Spring - belugas are usually taken from late March through June in offshore leads. In summer whaling also occurs again in July, and some may be taken with nets from the beach areas. The second beluga hunt occurs later in the summer from July to August. During this second hunt, residents hunt beluga whales in the open water near the southern shore of Point Hope close to the beaches, as well as north of Point Hope as far as Cape Dyer.	Hunted year round. Main sealing season begins along the south shores of the peninsula after whaling has concluded in the late spring.	Spring – hunts are in south shore leads from May to July along the southern shore from Point Hope to Akoviknak Lagoon.	Hunting takes place from January to April and occasionally from October to January. Hunting occurs in the area south of Point Hope as far out as 16 km (10 mi) from shore.	Summer marine fishing for char and salmon is conducted with beach seines and nets along the north and south shores, and lagoons. Summer salmon and grayling are caught at the mouth of the Kukpuk River and at other fishing areas along the river. About three fourths of the total fish harvest is obtained in the fall at the Kukpuk River. Fishing is combined with caribou and moose hunting up to the mouth of the Ipewik River. Cod are harvested in the fall on the beaches.	Spring - Early migratory birds passing through the area are also harvested. The area of subsistence activities includes extensive sea ice usage along the north coast and around Point Hope north toward Cape Thompson. Inland areas along the Kukpuk and Ipewik rivers are used. Summer - Bird nesting sites at Cape Thompson and Cape Lisburne are visited by boat to collect eggs and harvest birds. Fall - harvests are along the south shore inland to an area beyond the Kukpuk River and part of the north coast.	Hunted year round. Summer - Caribou are harvested at several places inland along the coast, including the Kukpuk River area or towards the Pitmegea River. Fall - Caribou are hunted along the Kukpuk River and at coastal and inland areas around Cape Thompson.	Proposed offshore activities would not overlap with spring bowhead whale and beluga whale harvests. Standard Mitigation Measure D2 establishes communication centers. Air traffic originating from a Wainwright shorebase, could traverse routes reported as beluga subsistence use areas by hunters from Wainwright, Point Lay, and Point Hope. However, the majority of harvest would have occurred prior to the commencement of seismic and high resolution shallow hazard surveys and exploratory drilling operations. Summer and early fall marine mammal harvests (seals, walrus, polar bears), marine and coastal bird, and caribou hunting could be impacted by aircraft overflights. Flight paths could originate from Wainwright to where offshore seismic survey activities and drilling operations are located but would be limited by altitude restrictions of Standard Mitigation Measure D3. Vessels would not be expected to be present in seal subsistence harvest areas during the summer and fall months. Polar bears are unlikely to be present at times when vessels would be transiting through their habitat during the open water season.
Kivalina	Spring – Whalers participate on Point Hope crews.	Beluga whales may occur in the open leads along the coast as early as January and February due to the presence of a persistent polynya. North Kivalina coastline is used for beluga whales during spring and summer.	Winter, ringed seals and bearded seals are harvested on open leads. Spring and summer, Cape Krusenstern is an important use area for residents of Kivalina, Noatak, and Kotzebue when spring sealing takes place in the open leads. North Kivalina coastline is used for hunting ringed, bearded, and spotted seal during the spring. Summer – spotted seals along barrier island beaches and north Kivalina coast.	Spring – hunting occurs along the north Kivalina coast.	Polar bears are hunted in the spring along the north Kivalina coast.	Year round. Winter - Kivalina Lagoon is a subsistence use area that provides overwintering habitat for fish and serves as a migration pathway for anadromous fish bound for the Wulik and Kivalina Rivers. Summer - The Upper Kivalina River and its tributary streams are used for fishing.	The north Kivalina coast is an important resource use area where waterfowl hunting occurs during the spring and later in the fall. Fall - Cape Krusenstern area is used by waterfowl during fall migration.	Year round. Winter - Caribou winter use areas harvest occurs are along the north Kivalina coast and the Upper Kivalina River and its tributary streams. Summer - The Upper Kivalina River and its tributary streams are used for hunting.	Proposed offshore activities would not overlap with spring bowhead whale and beluga whale harvests. Standard Mitigation Measure D2 establishes communication centers. Summer and early fall marine mammal harvest (seals,) marine and coastal bird, and caribou hunting could be impacted by aircraft overflights. Flight paths would be limited by altitude restrictions of Standard Mitigation Measure D3. Vessels would not be expected to be present in seal subsistence harvest areas during the summer and fall months. Polar bears and walrus are unlikely to be present at times when vessels would be transiting through their habitat during the open water season.

Community	Bowhead whales	Beluga Whales	Seals	Walrus	Polar Bear	Fish	Marine and Coastal Birds	Caribou	Potential to overlap with proposed activities (Alternatives 2 through 6)
Kotzebue	Spring – Whalers participate on Point Hope crews.	Spring – beluga harvest near Sisoalik Spit. Summer (June and July) at Eschscholtz Bay and the Elephant Point/Choris Peninsula area.	Spring – ringed seals near Sisoalik Spit. Summer – spotted seal hunting at Eschscholtz Bay and the Elephant Point/Choris Peninsula area.	Rarely harvested.	Rarely harvested.	Kobuk/Selawik Lakes are used year round for subsistence activities by residents of several communities mainly for sheefish hooking. Spring –harvest near Sisoalik Spit. The Kobuk River Delta is another important year-round subsistence use area.	Spring - Waterfowl hunting occurs in Paul's Slough and throughout the delta area. The Sisoalik Spit area is heavily used from June to freezeup (mid-September). Year round - The Kobuk River Delta. Summer – egg gathering at Eschscholtz Bay and the Elephant Point/Choris Peninsula area. Fall - hunting occurs in fall in the Kobuk River Delta and near the Omar River.	Winter - The lower North Fork River and all of the Omar River drainage receives heavy some years use by wintering caribou. The valleys of the Omar and North Forks Rivers provide north/south migration corridors for caribou moving to calving and summering areas in the spring and returning to winter range in the fall.	Proposed offshore activities would not occur offshore of Kotzebue. Flight paths and vessel traffic would not occur from Kotzebue to areas where offshore seismic survey activities and drilling operations are located.

Effects of Seismic and High Resolution Shallow Hazard Surveys and Exploratory Drilling Disturbance to Subsistence Resources

Bowhead Whales

The potential effects of noise from seismic and high resolution shallow hazard surveys and exploratory drilling on bowhead whales, which may result in changes in migration patterns or adverse effects on the bowhead population health and productivity is of great concern to the Iñupiat people due to possible effects on their culture. During seismic and high resolution shallow hazard surveys and exploratory drilling, noise is transmitted through the water and air from acoustic sound sources, helicopter and fixed-winged aircraft traffic, support-vessel traffic, and ice management activities. Section 4.5.2.4 (Marine Mammals) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect marine mammals are primarily those associated with noise exposure, possibly ship strikes and habitat degradation.

As discussed previously in this EIS (Section 4.5.2.4.9), noise from oil and gas exploration activities has been shown in certain instances to displace bowhead whales from certain habitat areas in the EIS proposed project area. Should displacement occur and cause bowhead whales to migrate in areas too far offshore to be readily available to subsistence users, this may be considered an adverse direct impact to the bowhead subsistence hunt. Whaling crews would be required to travel greater distances from shore, which would mean spending more money on gas, additional travel time, and potentially putting crews at greater risk for adverse weather in order to intercept eastward and westward migrating whales (depending upon the time of year of the activity). Hunting at greater distances from shore also means longer distances to tow a whale to shore, following a successful harvest, during which time the meat can spoil. Braund and Moorehead (1995) report that whaling crews rarely pursue whales beyond 80 km (50 mi) from shore.

Another effect as described by hunters is that whales behave differently in the presence of sound in a manner that in turn makes them more difficult to harpoon. Traditional knowledge indicates that bowhead whales become increasingly "skittish" or "spooked" in the presence of seismic noise. Whales are more wary around the hunters and tend to expose a much smaller portion of their back when surfacing (which makes harvesting more difficult). Additionally, Alaska Natives report that bowheads exhibit angry behaviors in the presence of seismic, such as tail-slapping, which translate to danger for nearby subsistence harvesters (NMFS 2006). As described by Tom Albert, former Iñupiat Senior Scientist for the NSB, who related that: *"When a captain came in to talk to me, I knew he was going to say that the whales are displaced [by noise] farther than you scientists think they are. But some of them would also talk about 'spookiness'; when the whales were displaced out there and when the whaler would get near them, they were harder to approach and harder to catch"* (MMS, 1997).

Edward Nukapigak at the Nuiqsut Public Scoping meeting for this EIS on March 11, 2010 remarked that vessel presence also effects bowhead whales: *"with all the interference, with all these vessels we have, it's difficult for us to harvest our quota because all those whales are being spooked, skittish, and hard to approach because they have been harassed from the east by these vessels that are traveling from east to west going to West Dock, maybe possibly further west."*

Iñupiat hunters have for many years stated that bowhead and beluga whales can detect sounds at greater distances than can be measured by scientific instrumentation and methodology. Of great concern to residents of the EIS project area is that the increased levels of noise as a result of seismic and high resolution shallow hazard surveys and exploratory drilling could disrupt the normal migration routes of subsistence resources – in particular the bowhead whale, beluga whale, bearded seal, and walrus. At the Arctic Seismic Synthesis and Mitigating Measures Workshop held in March 1997 by MMS in Barrow, Alaska, with subsistence whalers from the communities of Barrow, Nuiqsut, and Kaktovik, whalers agreed on the following statement concerning the "zone of influence" from seismic-survey noise: *"Factual experience of subsistence whalers testify that pods of migrating bowhead whales will begin to* *divert from their migratory path at distances of 35 miles from an active seismic operation and are displaced from their normal migratory path by as much as 30 miles* (MMS 1997)*."*

The AEWC has commented extensively on the issue of noise impacts to bowhead whales, beluga whales, and other marine mammals: *"As has been documented time and time again, bowhead whales, beluga whales and other marine mammals react to very low levels of underwater noise. Studies conducted by Richardson and others, as have been discuss[ed] in the 2008 Arctic Regional Biological Opinion, document bowhead whale deflection when received sound levels are at or perhaps lower than 120 dB. More recently, we understand that monitoring activities from Shell's seismic activity in the Beaufort during 2007 and 2008 demonstrate that call detection rates drop significantly during airgun operation. Disruption of communication and migration patterns certainly meets the definition of "harassment" under the MMPA and therefore must be regulated by NMFS"* – Harry Brower, representing the AEWC, in written comments on this EIS dated April 9, 2010.

"Our observations, proven correct time and again by scientific research, are that bowhead whales change their behavior when industrial activity is taking place in their usual habitat. Because of these changes in behavior, the whales become less available or completely unavailable to our hunters during the time the activity is occurring, due both to noise disturbance and to pollution in the water. We also are very concerned that some habitats might be abandoned altogether if industrial activity increases or if it is undertaken in a way that creates ongoing disturbance" - Harry Brower, representing the AEWC, in written comments on this EIS dated April 9, 2010.

"If you put a drill ship there at Sivulliq Prospect, the whales are going to start migrating further north. I guarantee you that. They're not going to come in inside the islands. They're going to go up north and go around the drill ship. Then we have to travel 30-plus miles out to try and scout and harvest a whale. Just like one of our elders, one of our whaling elders mentioned earlier, that due to interference, they had travel 30-plus miles out. By the time the whale was harvested, the wind has already picked up. You have no ice out there to protect the swells" – Edward Nukapigak at the Nuiqsut Public Scoping meeting for this EIS on March 11, 2010.

"Barrow whalers and Nuiqsut whalers have encountered "unacceptable levels" of disturbance from industrial activities in these waters, where whales were harvested far from ideal locations. The result was putting the Iñupiat hunters in a greater danger by deflecting the whales as far as 30 miles off course; some boat[s] have succumbed to storms and greater wave actions and sunk; in some cases, individuals lost their lives. The harvest of the whale, therefore, was spoiled, after a 12-hour tow or more; the whale gasifies its internal organs and contaminates the meat, and the whale at this point cannot be eaten. This is a direct impact to feeding the indigenous Iñupiat people of the Arctic. In Barrow alone, it takes a minimum of 10 whales to feed the community for a day, for the season's events. Our culture is surrounded by the whale" - Gordon Brower, as stated in the Arctic Multiple-Sale EIS (MMS 2008) on November 1, 2008.

These direct impacts could result in whalers having to travel further offshore to hunt and an increase in the number of days it takes for whalers to be successful. As subsistence activities and wage economics are highly interdependent, the cost of expenditures for whaling activities could rise in terms of fuel costs and potential for loss of wages (time taken away from regular jobs) if increased time was spent away from work while engaged in subsistence resources harvest activities. Direct effects could also result in a limited sharing of resources and in turn affects the quality of life, which can be summarized as:

"[talking about environmental justice] It has to do with sharing. If Point Lay catches a beluga whale, that beluga whale is shared with people as far away as Anchorage, Kotzebue, Nuiqsut; it just goes all over the place. So if we get 30 belugas, I wouldn't be surprised if that showed up in 30 villages. So when something affects Point Lay, little old Point Lay in the middle of north nowhere, it's felt in Anchorage in some way, in some fashion. So yes, if there is something big that happens offshore at Point Lay and it contaminates, say, our lagoon system, we're not catching the belugas anymore, people in the whole state

of Alaska are going to feel that" - Bill Tracey at Point Lay Public Scoping Meeting for this EIS February 22, 2010.

"Even if the impact on the whales from noise during construction is low as expected, the sociocultural impact of the community is likely to be high. They are -- they are the single most important animal in the North Slope sociocultural system. Iñupiat whaling is a proud tradition that involves ceremonies, dancing, singing, visiting, and cooperation between communities in sharing of food" - Thomas Napageak at the April 19, 1990 public hearing in Nuiqsut on the Beaufort Sea Planning Area Oil and Gas Lease Sale 124.

For the spring bowhead hunt in the Chukchi Sea, the impacts of disturbance could be limited by mitigation measures. Seismic and high resolution shallow hazard surveys and exploratory drilling operations may not occur until the spring bowhead whale hunts of Wainwright, Point Lay, and Point Hope are completed in the Chukchi Sea. In addition, shutdown of exploration activities in the Chukchi Sea for Wainwright, Point Lay, and Point Hope bowhead whale hunts would be based on real-time reporting of whale presence and hunting activity rather than a fixed date. Subsistence hunters in the Chukchi Sea have a limited hunting range. These whalers prefer to take whales close to shore to avoid hauling a harvested whale over long distances during which time the whale can spoil. Subsistence hunters in the Chukchi Sea during the fall will pursue bowhead whales as far as 80 km (50 mi) from the coast in small, fiberglass boats (Comstock 2011). Subsistence whaling is unlikely to occur in areas far offshore in the Chukchi Sea where it is assumed that seismic and high resolution shallow hazard surveys and exploratory drilling operations would occur in the Chukchi Sea during the late summer and fall months where these communities are not actively whaling. However, Wainwright whalers have expressed concerns that offshore oil and gas activities have disrupted previous spring migrations (Quakenbush and Huntington 2010). Wainwright whalers are concerned that increases in the levels of oil and gas activities in the Beaufort Sea could push southward migrating whales away from the eastern coast of the Chukchi Sea where they become inaccessible to hunters during the fall (Quakenbush and Huntington 2010).

In regard to the fall bowhead hunt (largely in the Beaufort Sea), mitigation measures require that seismic surveys and drilling operations would be limited in time and space during the fall bowhead whale migration. Mitigation is intended to reduce negative impacts occurring to subsistence hunting. Limitations of when activity can occur in the Beaufort Sea would continue at least until strike quotas have been filled by the coastal communities. Bowhead whaling at Barrow could continue into October. Standard and additional mitigation measures analyzed in this EIS could require shutdown of exploration activities in the Beaufort Sea for the Nuiqsut (Cross Island), Kaktovik, and Barrow bowhead whale hunts based on real-time reporting of whale presence and hunting activity rather than a fixed date. Short- and long-term effects on the Beaufort Sea subsistence hunts are expected to range from no impact to negligible impacts if the mitigation is applied.

Any impacts of seismic and high resolution shallow hazard surveys and exploratory drilling noise that do affect bowhead whales are expected to result in some temporary deviation in migratory path in the vicinity of the disturbance. However, the level of the response may depend on whether the whales are feeding, aggregated, or spread out and responses could range from apparent tolerance to interrupted communication, minor displacement or avoidance of an area (Section 4.5.2.4.9) Depending on where the disturbance activity occurred relative to the geography of the area the whales could move closer to the coastline or move offshore. Noises in shallow waters are more amplified and could result in bowhead whales moving further offshore. Local knowledge and comments by whaling captains indicate that subsistence whalers perceive deflection of bowhead whales as likely, resulting in the need to travel further for successful hunts. Disturbance effects are not expected to rise to the level of impacts on a population, such that the bowhead resource declines with long term impacts to subsistence harvest. The impact of disturbance to subsistence hunters is estimated to be of low intensity and temporary duration, i.e. for the duration of the seismic surveys and exploratory drilling activities offshore. These effects involve a resource that is unique in context, due to its importance as a key subsistence resource. Direct impacts that do occur would be considered of low intensity, limited in extent to a local area, temporary in duration but unique in context. Bowhead whales are an essential subsistence resource for Iñupiat of the Arctic coast and Yupiit Eskimo of the Bering Strait southward, which places them in the context of being a unique resource. The summary impact to subsistence harvest from disturbance of bowhead whales could be minor.

No effects from on-ice surveys are expected on bowhead subsistence hunts as those activities generally occur outside of the time frame of bowhead hunting. There is the potential for some late season on-ice surveys to occur during part of the spring bowhead whale hunt. However, the on-ice surveys would only occur in the Beaufort Sea, east of Point Barrow. Nuiqsut and Kaktovik do not conduct spring bowhead whale hunts. In the Beaufort Sea, Barrow is the only community to conduct such a hunt. Therefore, impacts from on-ice seismic surveys in the Beaufort Sea are anticipated to have either no effect or negligible impacts on bowhead subsistence harvests.

Beluga Whales

Section 4.5.2.4.10 (Beluga Whales) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect beluga whales. Beluga whales are reported by the Northwestern Alaska communities, including Point Lay, Point Hope, and Kivalina, to be especially sensitive to noise and motors. Huntington et al. (1999) reported that beluga whales avoid anthropogenic noise, although a certain degree of habituation occurs, mostly for noises that are constant.

As noted by the Alaska Beluga Whale Committee (in comments by Willie Goodwin at the public scoping meeting for this EIS on February 18, 2010): *"Now, in the belugas that we tag or the research that we've done, we know that the belugas are sensitive to noise, any noise. And I am concerned about that, because until we know exactly when they had their young, any kind of noise would cause stress in the female beluga and may abort their young beluga, or the mother may just not want to nurse it. So there's some involvement that noise affects the belugas, and we are concerned about that."*

In the Chukchi Sea, beluga whales could be displaced from or could avoid the vicinity of seismic and high resolution shallow hazard surveys and exploratory drilling operations in July through October during their spring and fall migrations. This would have the potential to impact and disrupt some communal beluga subsistence hunts (mostly Point Lay which heavily depends on this resource) by disturbing and altering the course of these migrating whales. Some of the early season industry activities could overlap in time with the Point Lay beluga hunt. This could make belugas more difficult to herd into the lagoons for the harvest (as is the practice in Point Lay). The impacts would be minimized or avoided given the mitigation measures considered and analyzed in this EIS. As mitigated, the effects of disturbance would be considered to be of low intensity and temporary duration, occurring for the duration of the activities offshore, and affecting a resource that is important in context. These impacts would not be expected to rise to the level of impacts on a population level that would have long term impacts to subsistence harvest. Beluga whales are an essential subsistence resource for some Iñupiat and Yupik Eskimo communities of the Arctic coast. The summary impact to subsistence harvest from disturbance of belugas could be minor.

Seals

Bearded, ringed, and spotted seals comprise a large portion of subsistence harvest and could be affected by seismic and high resolution shallow hazard surveys, including on-ice seismic surveys and exploratory drilling activities. Section 4.5.2.4.12 (Ice Seals) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect these seals.

Observations by subsistence hunters have contradicted conclusions that seals are not disturbed: *"Point Hope is having hard time catching seals. There was a little seismic operation that went on in the Arctic a* *few years back, and our seals haven't come back yet"* – Earl Kingik, Point Hope: at the 2011 Open Water Meeting in Anchorage, AK, March 7, 2011.

As a result of the short duration of the proposed activities and in consideration of the observed effects of offshore drilling on seals, measureable population level changes are not expected to seals. The short-term exposures of seals to airgun sounds are not expected to result in any long-term negative consequences for the individuals or their populations. In a study of subsistence hunting in Barrow, Nuiqsut, and Katktovik, Braund and Associates (2010) found that while ringed and bearded seals can be hunted year-round, there tends to be a peak in July. Additionally, while most of the identified hunting areas in the study were closer to shore, some hunters travelled between 32.2 and 40.3 km (20 and 25 mi) offshore to hunt seals, with the mouth of the Colville River and Thetis Island shown as popular seal hunting grounds (Braund and Associates 2010). While there is some potential for temporal overlap at the beginning of the open water season with seismic surveys and exploratory drilling activities, interactions are expected to be limited in duration. Activities within the lease areas far offshore that are likely to be explored would have no impact on subsistence hunting for seals. Therefore, the summary impact of these activities on seal subsistence harvests is expected to be negligible, taking into account the standard mitigation measures.

Pacific Walrus

Effects to walrus could occur during the summer months if seismic and high resolution shallow hazard surveys and exploratory drilling operations were conducted when walrus are present. Section 4.5.2.4.13 (Pacific Walrus) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect walrus. Should walrus leave or abandon areas where they could be harvested by subsistence hunters, then subsistence harvest patterns would be affected.

Impacts of disturbance to walrus are expected to be limited as far as the resource becoming unavailable for subsistence harvest. As a result, the intensity of the impact is low, temporary in duration, local in extent, and affecting a resource that is common in context. The summary impacts of disturbance to subsistence harvest of walrus are negligible.

Polar Bears

Section 4.5.2.4.14 (Polar bears) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect polar bears. Seismic and high resolution shallow hazard surveys and exploratory drilling activities are likely to occur in areas offshore and in open water areas where polar bears are not expected to be present, and subsistence harvest is not likely to be affected. For 2D/3D seismic surveys, high resolution shallow hazard surveys and exploratory drilling activities the summary rating regarding the subsistence harvest of polar bears is no impact.

Fish

Disturbance from sound generated by seismic and high resolution shallow hazard surveys and exploratory drilling activities could result in the temporary avoidance of the vicinity of these sound sources by fish. Mortality of fish or other population level effects are not anticipated. Subsistence fishing tends to occur in harvest areas located closer to shore and not in areas where seismic and high resolution shallow hazard surveys and exploratory drilling would affect subsistence activities. As a result there are no anticipated effects of disturbance to subsistence fishing.

Subsistence fishing has not been observed to occur in the areas likely to be subject to seismic and high resolution shallow hazard surveys and exploratory drilling activities. The sounds generated by seismic and high resolution shallow hazard surveys and exploratory drilling activities and their associated support vessels could result in temporary avoidance of the vicinity of these sound sources by fish but would not result in adult fish mortality or other population effects.

Fishing by residents of the Beaufort Sea communities occurs at inland fish camps and in nearshore areas along the beaches and would be unaffected by seismic and high resolution shallow hazard surveys and exploratory drilling activities. Fishing by residents of the Chukchi Sea communities occurs in the lagoons and inland along rivers in areas that are not expected to be affected by seismic and high resolution shallow hazard surveys and exploratory drilling activities. Offshore areas anticipated to be explored would be in locations that are not used in subsistence fishing harvest. No impact is expected.

Marine and Coastal Birds

No effects from seismic and high resolution shallow hazard surveys and exploratory drilling are expected to occur to the subsistence harvest of birds because of the distance of such activities from the coastlines of both seas. Subsistence harvest of birds and egg gathering occurs throughout the spring, summer, and fall, at inland areas and near coastal waters. The spring bird harvest is often at the same time as marine mammals hunts when seismic and high resolution shallow hazard surveys and exploratory drilling activities would not be occurring. The Nuiqsut eider hunt occurs in the OCS in association with seal hunting, peaking in July (Braund and Associates 2010). There is the potential for some overlap between oil and gas exploration activities and this hunt.

Subsistence bird harvest and egg gathering has not been observed to occur in the areas likely to be subject to seismic and high resolution shallow hazard surveys and exploratory drilling activities. The sounds that would be generated by these activities and their associated support vessels could result in temporary avoidance of the vicinity of these sound sources by birds. However, direct mortality or other population-level effects are not expected to result.

Bird harvest and egg gathering by residents of the Beaufort and Chukchi sea communities occurs in the lagoons and along the coast line, as well as some minimal hunts in the OCS, and could be expected to be unaffected by seismic and high resolution shallow hazard surveys and exploratory drilling activities. Most offshore areas, especially in the Chukchi Sea, anticipated to be explored would be in locations that are not used in subsistence bird harvest and egg gathering harvest. Therefore only negligible impacts would be anticipated.

Caribou

No effects from 2D/3D seismic and high resolution shallow hazard surveys and exploratory drilling activities are expected on caribou. Caribou are an important source (by percent of harvest) of meat for village residents. Offshore seismic and high resolution shallow hazard surveys and exploratory drilling activities are not likely to have any effect on land mammals, including caribou, in consideration of the distance of such activities from the coastlines of both seas.

Offshore 2D/3D seismic and high resolution shallow hazard surveys and exploratory drilling activities are not likely to have any impact from disturbance in consideration of the distance of such activities from the coastlines of both seas.

Effects of Aircraft Overflights to Subsistence Resources

Bowhead Whales

Bowhead whales have been observed to be less responsive to aircraft in comparison to vessel traffic. Information on the impacts of aircraft sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.1.4 and Section 4.5.2.4.9 (Bowhead Whales) of this EIS.

The sound emitted by aircraft overflights potentially could cause some disruption to bowhead whale harvest, but aircraft overflights as mitigated are not expected to make bowhead whales unavailable to (or more difficult to harvest by) subsistence hunters. Whales could be expected to temporarily deflect from overflights, but mitigation measures analyzed in and contemplated by this EIS would limit the probability and consequence of this impact. It is expected that helicopters servicing offshore seismic and high resolution shallow hazard surveys and exploratory drilling operations could traverse areas utilized by subsistence whalers during fall whaling in the Beaufort Sea and limited areas of the Chukchi Sea. Flight paths could originate from the Prudhoe Bay area, Barrow and Wainwright shorebases to areas where offshore seismic activity and exploratory drilling operations are located. Flight path and altitude restrictions are expected to reduce to a low level any such potential impacts.

If bowhead whales were affected by aircraft overflights, it is unlikely that large numbers or a large whaling area would be affected, so the impact would be considered low in intensity and temporary in duration. Effects of the impact would be local, affecting a resource that is important in context. The summary impact is considered minor.

Beluga Whales

Beluga whales are reported to be sensitive and to exhibit short-term behavioral responses to the presence of helicopter and fixed wing overflights. Information on the impacts of aircraft sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.10 (Beluga Whales) of this EIS.

Aircraft traffic transiting the Beaufort and Chukchi seas out to support vessels, and traffic between the shorebase and offshore drilling locations as part of activities under Alternative 2, would have the potential to disturb and alter the course of these migrating whales. In turn, this could make belugas more difficult to herd into the lagoons and harvest as belugas have previously been observed to react to helicopter overflights. The effects of this disturbance would be considered to be of low intensity though temporary in duration and occur for the duration of the overflights but would not be expected to have effects on a population level. The impacts would be minimized or avoided under the standard mitigation measures, such as mandatory flight elevations and offset distances in Mitigation Measure D1. Additional Mitigation Measure B1 would impose further area specific limitations on the areas where aircraft disturbance could potentially occur.

It is unlikely that helicopter traffic from Barrow to offshore areas would traverse routes where belugas are commonly harvested. For helicopter flights originating from a Wainwright shorebase, the routes could traverse reported beluga subsistence use areas by hunters from Wainwright, Point Lay, and Point Hope. These communities harvest belugas primarily in the spring, and the majority of harvest would have occurred prior to the commencement of seismic and high resolution shallow hazard surveys and exploratory drilling operations. The spring/early summer beluga hunts in Wainwright, Point Lay, Point Hope and Kivalina and Kotzebue would occur in the months prior to the start of offshore exploration activities in the Chukchi Sea. Some summer beluga hunting could be impacted by aircraft overflights, though mitigation measures are expected to lessen the extent of disturbance, which would be considered low in intensity, temporary in duration, and localized to a very specific area along the helicopter flight path affecting a locally important resource. Mitigation measures are expected to minimize or altogether avoid impacts to beluga whales and their subsistence harvest. The summary impact to subsistence harvest from aircraft disturbance of belugas could be minor.

Seals

Information on the impacts of aircraft sounds to seals associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.12 (Ice Seals) of this EIS.

The sound emitted by aircraft overflights could cause disruption to subsistence seal harvest, but aircraft overflights as mitigated are not expected to make seals unavailable to subsistence hunters. The assumed aircraft overflights associated with seismic survey activities and exploratory drilling would occur during the open-water season after seals have pupped and molted, fast ice has melted away, and flowing ice has retreated north. The standard mitigation measures of this EIS, including D1 on mandatory elevations and offset distances, would minimize or avoid impacts to seal subsistence harvests. At present, air traffic currently exists along the coastal areas of the Beaufort and Chukchi sea communities (Section 3.3.7). An increase in the levels of helicopter traffic between the expected support shorebases (Barrow, Deadhorse and potentially Wainwright) and the offshore drilling locations would be limited due to the small number of flights and the altitude at which flights occur. The spring/early summer seal hunts in Nuiqsut, Barrow, Wainwright, Point Lay, Point Hope, Kivalina and Kotzebue would occur in the months prior to the start of offshore exploration activities in the Beaufort and Chukchi seas. However, there is some potential for overlap with the hunts in July and August.

Aircraft overflights are unlikely to have an adverse effect on seal availability for subsistence harvest. Impacts that did occur would be considered low in intensity and temporary in duration. Effects of the impact would be local and affecting resources that are common in context. The summary impact is considered negligible.

Pacific Walrus

Walrus could react to aircraft overflights by stampeding into the water when they become disturbed while ashore at haul out sites. During a stampede the calves would be the most vulnerable to trampling mortality. Brueggeman (et al. 1990) observed reactions of walrus to aircraft at an altitude of 305 m (1,000 ft) over the pack ice and at 152 m (500 ft) over land and reported that walrus hauled out on land or ice were more sensitive to overflights (Brueggeman et al. 1990). The implications to subsistence hunters could be that repeated overflights cause disturbance at haul outs sites and limit the availability of this resources for harvest. Information on the impacts of aircraft sounds to Pacific Walrus associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.13 (Pacific Walrus) of this EIS.

Limited numbers of walrus are likely to be present in the central and eastern Beaufort Sea. In the Chukchi Sea walrus would not be expected to haul out in large concentrations during the open water period when seismic and high resolution shallow hazard surveys and exploratory drilling would occur. Instances where walrus occur near these presumed activities would be infrequent.

The mitigation measures analyzed in and contemplated by this EIS, including restricting aircraft to above 457 m (1,500 ft), unless the aircraft is engaged in marine mammal monitoring, approaching, landing or taking off and conducting regular aerial and vessel monitoring surveys, would minimize or avoid impacts to walrus and subsistence harvests of this species. At present, air traffic transits the coastal areas of the Beaufort and Chukchi seas between the communities. An increase in the levels of helicopter traffic between the expected support shorebases (Barrow, Deadhorse and potentially Wainwright) and the offshore drilling locations would be have limited impacts due to the small number of flights and the altitude at which flights occur. This is unlikely to affect the walrus hunting in the Chukchi communities, which occurs primarily in the spring and summer.

Aircraft overflights are unlikely to have an adverse effect on walrus availability for subsistence harvest. Impacts that would occur would be considered low intensity and temporary in duration. The impact would be local in extent, affecting resources that are common in context. The summary impact is considered negligible.

Polar Bears

The responses of polar bears exposed to aircraft overflights are likely to be that a bear initially moves away but then resume their natural habits. Polar bears have not been observed to remain in open water areas over which aircraft overflights occur. Polar bears would be most affected by helicopter and fixed wing aircraft overflights during the months when they are nearest to the shore or unable to access the offshore ice pack. Information on the impacts of aircraft sounds to polar bears associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.14 (Polar bears) of this EIS.

In response to seismic and high resolution shallow hazard surveys and exploratory drilling, polar bears may display avoidance behavior resulting in short-term and localized effects, which could reduce the availability of this resource for subsistence harvest. These behavioral responses to disturbance from aircraft would be expected to be brief and not expected to rise to the level of long-term impacts to individuals or adverse impacts at the population level. Mitigation measure D1 on mandatory flight elevations and offset distances, would be anticipated to reduce the likelihood of impacts to polar bears. Aircraft overflights and helicopter routes could be planned to avoid areas of known polar bear dens.

After mitigation is taken into account, aircraft overflights are unlikely to have an adverse effect on polar bear availability for subsistence harvest. Any unintended impact that did occur would be infrequent and would be considered of low intensity and temporary in duration. Effects of the impact would be local, affecting a resource that is important in context. The summary impact is considered minor.

Fish

No direct or indirect impacts to fish from aircraft overflights are expected. Aircraft traffic would have no impact on the availability of subsistence fish resources. However subsistence hunters may view increased aircraft traffic from seismic and high resolution shallow hazard surveys and exploratory drilling activities as disruptive within harvest areas. The mitigation measures would reduce the likelihood of this perceived disturbance. It would be expected that regular helicopter overflights to support offshore operations would occur through a limited area that overlaps with known fishing areas of Wainwright and Barrow subsistence users. However, no impacts are expected to subsistence fish resources or to subsistence fishing activities because of the required flight altitudes over these areas. Limited aircraft traffic is expected over the Point Hope, Kivalina, or Kotzebue subsistence fish harvest areas. However these areas would be further away from the normal air traffic routes for flights related to exploration activities offshore in the Chukchi Sea and no impacts are expected to subsistence fish resources or to subsistence fishing activities in those areas. Nuiqsut fish hunts are conducted in rivers and at the mouths of the rivers with hunts for Arctic Cisco and burbot peaking in months when open water activities do not occur (Braund and Associates 2010). Although Nuiqsut and Kaktovik fish for several species in July and August, Nuiqsut hunts occur in the rivers, and fishing by Kaktovik hunters is conducted both inland and along the coast. Increased air traffic in the coastal areas could occur during the life of various oil and gas activities but is not anticipated to impact the availability of subsistence fish resources to subsistence users in these communities.

Marine and Coastal Birds

Repeated disturbance from aircraft overflights could prevent staging birds from acquiring or maintaining sufficient nutrients for later migration. Colonies of nesting birds in coastal waters would be the most susceptible to disturbance from repeated aircraft overflights. In the Chukchi Sea, the areas where potential disturbances of marine birds could occur in large numbers include Kasegaluk Lagoon, Peard Bay, and Ledyard Bay all of which are heavily used for molting or staging. Repeated disturbances could result in displacement of small numbers of birds from preferred habitat and induce stress to birds that would then result in birds becoming unavailable for subsistence harvest and egg gathering activities. Information on the impacts to marine and coastal birds from of aircraft sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.3 (Marine and Coastal Birds) of this EIS.

Helicopter traffic between the shorebase and offshore drilling locations and fixed wing aircraft traffic between the shorebase and regional hub airports could potentially disturb birds and therefore subsistence hunts for birds during the summer and fall. The mitigation measures analyzed in and contemplated by this EIS would reduce the likelihood of impacts to marine and coastal birds by restricting aircraft to above 457 m (1,500 ft). Aircraft overflights and helicopter routes could be planned to avoid areas of known bird subsistence harvest areas.

Birds are considered an important food source available during a limited seasonal window and there could be a perception that repeated disturbances could threaten subsistence harvests. The probability of disturbance and displacement of birds occurring within subsistence harvest areas is considered low.

Impacts that did occur to subsistence hunting and egg collecting would be of low intensity and temporary duration. Impacts would be local and affect resources that are common and /or important in context. The summary impact is considered to be minor.

Caribou

Effects to caribou could range from no response or running away from the noise of aircraft overhead. Caribou are present along the nearshore coasts in the summer and have been observed at beach habitats where they congregate to minimize harassment by insects. Subsistence hunting for caribou is conducted along the coastal areas in summer time, using boats for access, and this practice could be affected if long term disruption of caribou habitat causes displacement from a normal harvest area.

Subsistence hunters may view increased aircraft traffic as disruptive and as intruding on their traditional subsistence areas. Hunters have noted that caribou may avoid areas in which they can see and hear aircraft traffic: *"The amount of noise from the activities from these seismic -- from seismic work and by travel that they'll be doing by sea and by air will have a negative impact on our community, because I believe it will scare the caribou away"* – Carla Sims Kayotuk at the Public Scoping Meeting for this EIS on March 3, 2010.

In the Arctic Multiple-Sale EIS (MMS 2008), Nuiqsut residents noted that aircraft have diverted subsistence resources away from areas where hunters were actively pursuing them, directly interfering with harvests or causing harvests to fail. Nuiqsut subsistence hunters report that on-shore seismic activity displaces game, especially caribou, wolves and wolverine from the area being surveyed.

At present, air traffic exists along the coastal areas of the Beaufort and Chukchi sea communities. An increase in the levels of helicopter traffic between the expected support shorebases (Barrow, Deadhorse and potentially Wainwright) and the offshore drilling locations would be limited due to the small number of flights and the altitude at which flights occur. It is likely that there would be a limited disturbance to caribou or to caribou subsistence hunting from helicopter traffic on the coast as the helicopters travel offshore from the shorebases. Thus only small proportions of available subsistence hunting areas would be affected.

The impacts to subsistence hunters would be considered of low intensity and temporary in duration. Effects of the impact would be local and affecting a resource that is common in context. Subsistence hunters could perceive increased levels of aircraft traffic as disruptive and intrusive in subsistence areas, resulting in hunters avoiding affected areas.

Aircraft overflights are unlikely to have an adverse effect on caribou availability for subsistence harvest. Impacts that did occur would be considered of low intensity and temporary duration. The impact would be local in extent, affecting a resource that is common in context. The summary impact is considered negligible.

Effects of Vessel Traffic to Subsistence Resources

Bowhead Whales

Information on the impacts of vessel sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.1 (Bowhead Whales) of this EIS. Bowhead whales have been observed to avoid approaching marine vessels. Reactions have been noted to be less severe when marine vessels are slow moving and do not approach these whales in a direct path (NMFS 2008). Bowhead whales have been reported to respond by swimming rapidly away from approaching vessels with avoidance responses beginning when a vessel rapidly approaches from 1 to 4 km (0.62 to 2.5 mi) away. When vessels approach bowheads, their behavior changes, and they may alter surface time and dive patterns. It has been noted that vessel disturbance can disrupt activities and social groups (Richardson and Malme 1993). Bowhead whales have been reported to avoid marine vessels, altering their behavior during migration to avoid the area(s) within a few miles of vessel activity.

Changes in behavior, such as swimming speed and orientation, respiration rate, and surface-dive cycles, could be temporary and last only minutes or hours. As a result of vessel disturbance, whales could scatter and become less readily available for subsistence whaling activities for a limited period of time.

These types of observations have been reported by whalers. As voiced by Thomas Brower, Sr. on October 1, 2008 in the Arctic Multiple Sale document (MMS 2008): *"The whales are very sensitive to noise and water pollution. In the spring whale hunt, the whaling crews are very careful about noise. In my crew, and in other crews I observe, the actual spring whaling is done by rowing small boats, usually made from bearded sealskins. We keep our snow machines well away from the edge of the ice so that the machine sound will not scare the whales. In the fall, we have to go as much as 65 miles out to sea to look for whales. I have adapted my boat's motor to have the absolute minimum amount of noise, but I still observe that whales are panicked by the sound when I am as much as 3 miles away from them. I observe that in the fall migration, the bowheads travel in pods of 60 to 120 whales. When they hear the sound of the motor, the whales scatter in groups of 8 to 10, and they scatter in every direction)."*

"We were impacted, us whalers were impacted out there, but in -- within the last 10 years, I observed, I was impacted along with all our whalers here, impacted by vessels that were out there. And it costs us to not harvest our whale" – Carl Brower at the Nuiqsut Public Scoping Meeting for this EIS on March 11, 2010.

In addition vessel traffic (barge traffic) presently occurring in subsistence harvest areas, but unassociated with seismic and high resolution shallow hazard surveys and exploratory drilling, has been observed to affect subsistence hunting: *"Because I know when you go to Nuiqsut, you'll hear a lot of this other, you know, entities that's disturbing the hunt…. And then Crowley [a barge company delivering fuel] was the one that disturbed Nuiqsut's hunt"* - Thomas Nukapigak at the Point Lay Public Scoping Meeting for this EIS on February 22, 2010.

Vessels for seismic and high resolution shallow hazard surveys and exploratory drilling and their associated support vessels typically do not enter the Chukchi Sea until after July 1 when most of the spring bowhead migration is complete. Moreover an additional mitigation measure considers vessels not entering the Chukchi Sea until July 15. During the fall migration, vessel activity in the Beaufort Sea associated with seismic and high resolution shallow hazard surveys and exploratory drilling and their associated support vessels would not be present in the areas near Cross Island and Kaktovik from August 25 until after fall whaling is completed by Kaktovik and Nuiqsut subsistence whalers.

The mitigation measures would also protect subsistence harvest of bowhead whales by requiring vessels to reduce speed within 274 m (900 ft) and avoid separating members from a group of whales from one another. Additionally, vessels would be required to avoid multiple course changes when within 274 m (900 ft) of bowhead whales and other marine mammals. During periods of poor weather, vessels would be required to reduce their speed to 10 knots while underway in order to avoid strikes or collisions with bowhead whales and other marine mammals.

A limited number of late migrating spring and fall bowhead whales could encounter seismic and high resolution shallow hazard surveys and exploratory drilling activities. However the mitigation measures would limit impacts from vessel traffic to late migrating bowhead whales and subsistence hunting. Impacts to subsistence hunting are likely to be of low intensity, temporary to interim in duration, local in extent, and affecting a resource that is important in context. The summary impact could be considered minor.

Beluga Whales

Information on the impacts of vessel sounds to beluga whales associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.10 (Beluga Whales) of this EIS. Vessel traffic that causes whales to avoid subsistence harvest areas could result in them being unavailable for harvest – particularly for the Chukchi Sea communities, such as Point Lay, which harvest beluga whale intensively.

A limited number of late migrating spring beluga whales could encounter vessels during seismic and high resolution shallow hazard surveys and exploratory drilling activities and operations. The impact of disruption to beluga whales from vessel traffic could result in temporary deflection of beluga whales from subsistence harvest areas and impact the success of these hunts. Vessels typically do not begin transiting through the Bering Straits into the Beaufort and Chukchi seas for seismic and high resolution shallow hazard surveys and exploratory drilling until July 1 after the majority of the spring beluga hunting is completed in the Chukchi Sea villages. However, some villages, such Point Lay and Kotzebue, may continue hunting belugas into mid-July. An additional mitigation measure contemplates no vessel transit into the Chukchi Sea before July 15. The impact to late migrating beluga whales that do encounter vessels would be of low intensity, temporary to interim duration, local extent, and affecting a resource that is locally important in terms of the context. The summary impact could be considered minor.

Seals

Information on the impacts of vessel sounds to seals associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.12 (Ice Seals) of this EIS. Upon exposure to vessel noise, seals may show avoidance of vessels transiting through an area. Avoidance of vessels transiting through areas of subsistence hunting could make seals less available for subsistence harvest. Seals could be displaced or may avoid areas where vessels are transiting as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities. However as a result of the mitigation measures for vessels transiting into the Beaufort and Chukchi seas for seismic and high resolution shallow hazard surveys and exploratory drilling and their associated support vessels, no unmitigable adverse impacts to seals and subsistence hunting activities are expected. Subsistence hunts for seals occur in nearshore coastal areas away from areas likely to be transited by vessels. Although there is the potential for some spatial and temporal overlap, the impact to subsistence seal harvest would be of low intensity, temporary duration, local extent, and affecting resources that are common in context. The summary impact could be considered negligible to minor.

Pacific Walrus

Information on the impacts of vessel sounds to Pacific Walrus associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.13 (Pacific Walrus) of this EIS. Effects to walrus from approaching vessel traffic may cause them to flee haulout locations and to avoid moving vessels that pass within less than a mile (or less than 1.6 km) (Richardson et al. 1995). However, walrus may also exit the water or approach vessels out of curiosity. Walrus that avoid vessel traffic may affect subsistence harvest by becoming less readily available for subsistence harvest.

Walrus could be displaced or avoid areas where vessels are transiting as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities, By applying mitigation measures to vessels transiting into the Beaufort and Chukchi seas for these activities and their associated support vessels, no unmitigable adverse impacts to walrus and subsistence hunting activities would be expected. Subsistence walrus hunts would occur in nearshore coastal areas away from areas likely to be transited by vessels. In areas where walrus subsistence hunting occurs in the summer, as in Wainwright, vessels associated with these activities could be present in offshore subsistence harvest areas. The impact to subsistence walrus harvests would be of low intensity, temporary duration, local extent, and affecting a resource that is important in terms of the context. The summary impact could be considered negligible to minor.

Polar Bears

Reactions and responses to vessel traffic could range from walking, running, or swimming away to no response at all (Richardson et al. 1995). Polar bears are unlikely to be present at times when vessels would be transiting through their habitat during the open water season.

It would be unlikely that polar bears would be present in open-water areas where seismic and high resolution shallow hazard surveys and exploratory drilling activities would occur, as polar bears would most likely be in active ice zones during the late summer and early fall. Subsistence hunting for polar bears in nearshore areas during the spring and winter months would not be occurring when these proposed activities are being conducted. Under the mitigation measures for vessels transiting into the Beaufort and Chukchi seas for these activities, no unmitigable adverse impacts to polar bears or subsistence hunting practices would be expected. The impact to subsistence harvest of polar bears is considered of low intensity, temporary duration, local extent, and affecting a resource that is unique in context, due to listing under the ESA. The summary impact could be considered negligible, and in some areas, no effect is anticipated.

Fish

Vessel traffic is not expected to affect subsistence fishing harvests. While fish may avoid a vessel transiting through an area, the disturbance would be expected to affect a very small portion of populations. Effects to subsistence fishing are likely below measurable thresholds.

Few impacts to subsistence fishing are anticipated as a result of vessel traffic associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities. Vessels would likely be transiting areas that are offshore and removed from subsistence harvest areas. Crew and supply vessels transiting to or from a coastal community may pass through local subsistence fishing areas. Any impact that did result would be expected to occur for only the length of time the vessel is potentially transiting through a nearshore area where subsistence fishing is occurring. The impact to subsistence harvest of fish is considered of low intensity, temporary duration, local extent, and affecting resources that are common in context. The impact could be considered negligible in terms of the levels of subsistence fishing and sharing of the resource that would be affected.

Marine and Coastal Birds

In response to the presence of vessels, birds may flush from marine and coastal areas where they are foraging or resting. Birds in coastal areas that are engaged in breeding, brood rearing, or foraging in preferred habitat areas in the lagoons are less likely to be affected and displaced by vessels transiting farther offshore. The presence of vessels may also affect some species more than others. The risk for collision and strikes increases as more vessels transit through the nearshore waters where birds are expected to be present in higher numbers. Some species could be attracted to the presence of vessels. If birds were continually displaced from subsistence harvest areas, the levels of harvest could be affected. The effects of vessel traffic to marine and coastal birds are described in Section 4.5.2.3.

Vessel traffic would be expected to potentially cause temporary disruption and displacement of some foraging and resting birds. However, this displacement and disturbance would be limited to the flushing of birds away from vessels transiting through the areas in which the birds were present. Vessel passage closer to nearshore waters would likely cause higher levels of impacts and disturbance to subsistence hunters if birds were flushed and lower productivity results in reduced availability of the resource. However, the disturbance potentially caused from offshore vessel traffic should be short term, occurring only as long as the activity takes place, and affecting only localized areas. The impact from disturbance from vessel traffic is not anticipated to result in bird mortality, so this activity would not be expected to affect birds on a population scale. Only minimal overlap with bird hunting in the region is expected, as few communities hunt birds further offshore. Nuiqsut does conduct some bird hunting in the Beaufort Sea OCS. The impacts to subsistence hunting and egg gathering are likely to be of low intensity, temporary duration, local extent, and affecting resources that are common in terms of context. The summary impact could be considered negligible.

Caribou

No anticipated effects of vessel traffic to caribou and other land mammals that are harvested for subsistence purposes are expected. Vessel traffic would occur offshore, and vessels coming into nearshore areas would be expected to arrive at ports or docks that are already established and not located in subsistence harvest areas. Therefore, no measurable effects to subsistence hunting of caribou are anticipated from vessel traffic.

Given the distance offshore that vessels will transit relative to subsistence harvest areas, it is unlikely that adverse impacts would occur to caribou and other land mammals or would make them unavailable for harvest. Vessels would only come to established dock and port facilities for lightering or offloading supplies and personnel. Disturbances at onshore areas from vessel traffic noise associated with approaching vessels could cause caribou to avoid these areas. However vessels would be approaching established areas where caribou and land mammals would not be expected to be present in large enough numbers to impact subsistence harvests. The impacts to subsistence hunting are likely to be of low intensity, temporary duration, local extent, and affecting a resource that is common in context. The summary impact could be considered negligible.

Effects of Disturbance from Icebreaking and Ice Management

Section 4.5.2.4 describes the effects of icebreaking and ice management on marine mammals. Disturbance from icebreaking activities to marine mammal subsistence resources would depend upon the time of year that the activity occurs. Active icebreaking involved with seismic survey plans could occur from October to December when bowhead whales, beluga whales and seal harvests are not as concentrated. Icebreaking could be associated with seismic survey plans that extend into the late open water season late fall to early winter (October to December) when daylight is very limited to nonexistent and visibility is reduced.

Ice management activities would introduce less noise into the marine environment than full on icebreaking (Section 4.5.2.4). Ice management would be associated with exploratory drilling operations in the summer and open water season and involve the use of smaller support vessels around the drill rig/ship to ensure the safety of the operation. Towards the end of the drilling season (i.e. late October), there is a greater chance of ice occurring in the drilling area. Icebreaking would only occur if the floe posed a risk to the drilling unit and needs to occur to safely cease operations and remove the equipment. Icebreaking would not be conducted for the express purpose to continue operations late in the season. The ice management vessels typically consist of an icebreaker and an anchor handler, as well as an auxiliary ice management vessel.

Bowhead Whales

As discussed in Section 4.5.2.4.9 the additional sound from icebreaking that accompanies seismic activity could cause temporary avoidance of bowhead whales from areas where the vessels are operating and potentially cause temporary deflection of the migration corridor (NMFS 2010c). Some operators have recently proposed to conduct seismic surveys during the in-ice or shoulder season (i.e. October through December). These surveys would require the use of an icebreaker to go ahead of the seismic survey vessel. The mitigation measures limit the time frame in which these activities occur. Surveys utilizing icebreakers could cause avoidance and displacement over a larger radius with the additional noise input from the icebreaking activities, and limited daylight and poor visibility would make it harder for onboard observers to visually observe whales and other marine mammals. The majority of these types of in-ice surveys requiring icebreaking would occur after the completion of fall bowhead harvests in the Beaufort and Chukchi seas.

Bowhead whales would be expected to avoid areas where icebreaking is occurring as a response to the noise generated by this activity. This could affect subsistence harvest by making the whales divert from normal migratory paths and thus become less readily available for harvest. The avoidance by the whales of icebreaking activity may be only temporary but could still have an effect on availability for harvest. It may make it necessary for whaling crews to travel further offshore to be successful or result in a hunt being unsuccessful and/or whales spoiling before being processed. However, many (but not all) of the icebreaking activities are anticipated to occur during times when there is no bowhead hunting. The likelihood of interaction diminishes by late October as most bowhead whales will have migrated out of the Beaufort Sea. The period of time over which icebreaking for seismic surveys could overlap with bowhead whales being present and subsistence whaling in the Beaufort Sea is short and seismic surveys and exploratory drilling could not occur until after fall whaling is complete for Nuiqsut and Kaktovik. In the event that icebreaking does cause bowhead whales to avoid an area, the impact to subsistence resources is expected to be low in intensity, short term in duration, local in extent, and affecting a resource that is unique in context. This would be considered a minor summary impact.

The majority of seismic and high resolution shallow hazard surveys and exploratory drilling activities would be expected to occur during the open water season (i.e. July through November) when seismic and high resolution shallow hazard surveys and exploratory drilling vessels would not encounter large amounts of sea ice. However ice management may be necessary during late fall or early winter when industry may still be engaged in seismic and high resolution shallow hazard surveys and exploratory drilling activities in order to protect equipment, vessels, and infrastructure. The mitigation measures limit the time frame in which these activities that may require ice management could occur. The majority of these types of surveys and exploratory drilling operations would occur after the completion of fall bowhead harvests in the Beaufort and Chukchi seas. As a result, the likelihood of impacts to subsistence harvest as a result of ice management activities is reduced and unlikely to adversely affect subsistence harvest of bowhead whales. In the event that ice management does cause bowhead whales to avoid an area, the impact to subsistence resources is expected to be low in intensity, temporary to interim in duration, local in extent, and affecting a resource that is important in context. This would be considered a minor summary impact.

Beluga Whales

Beluga whales are reported to be extremely sensitive to icebreaking (Section 4.5.2.4.10). Effects of icebreaking and ice management may cause belugas to avoid the vicinity of the activity. Therefore, if such activities were to occur in nearshore areas, the availability of this resource to subsistence hunters could be reduced.

Subsistence hunters have expressed concerns that belugas will "remember" the impacts of icebreaking and avoid specific areas where the impact occurred in subsequent years:

"…evidence of beluga being affected by noise. I have evidence but it is anecdotal. In 1989, Red Dog became operational. Before the port was built, every summer a beluga was harvested in July. Since 1989, Kivalina has never gotten whales in July since then" - Inoke Adams Jr., Kivalina Open Water Meeting in Anchorage on March 7, 2011.

Mitigation measures are expected to minimize and potentially avoid impacts on beluga whales so that no unmitigable adverse impacts occur to the subsistence harvest of beluga whales (i.e. subsistence users are able to conduct hunts that meet subsistence needs). There is a low probability that impacts could occur to subsistence users from late season activities. Some operators have recently proposed to conduct seismic surveys requiring icebreaking during the in-ice or shoulder season (i.e. October through December). These surveys would require the use of an icebreaker to go ahead of the seismic survey vessel. The mitigation measures limit the time frame in which these activities occur. Surveys utilizing icebreakers could cause avoidance and displacement over a larger radius with the additional noise input from the icebreaking activities, and limited daylight and poor visibility would make it harder for onboard observers to visually whales and other marine mammals. The majority of these types of in-ice surveys requiring icebreaking would occur after the completion of harvests in the Beaufort and Chukchi seas. Therefore, no effect is anticipated.

Ice management activities could be necessary as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities when ice is encountered in the late fall early winter months of exploration drilling operations. Ice management would be limited to areas where industry is actively drilling. Ice management activities would be conducted far removed from areas typically used as hunting grounds in the Chukchi Sea. No impacts are anticipated for beluga subsistence hunts in the Beaufort Sea, as beluga hunting is conducted opportunistically during the fall bowhead hunt. Mitigation measures would prohibit seismic and high resolution shallow hazard surveys and exploratory drilling activities (and associated ice management) from occurring during this time.

Seals

Icebreaking could be associated with seismic survey plans that extend into the late open water season late fall to early winter (October to December) when daylight is very limited or absent and visibility is reduced making seals more difficult to spot. At this time of year sealing efforts for subsistence are not a concentrated or intensive activity. Icebreakers could potentially collide with seals hauled out on the ice (Section 4.5.2.4.12). The probability of icebreakers colliding with seals and having lethal effects on populations of seal is low. Seals are more likely to avoid areas where icebreaking is occurring. If large numbers were to be killed by collisions with icebreakers or to avoid areas important for subsistence hunting, then levels of seal harvest could be affected. In the event that icebreaking causes seals to avoid an area, the impact to subsistence harvest is expected to be low in intensity, short term in duration, and local in extent, and affecting resources that are common to important in context. This would be considered a negligible summary impact.

Ice management activities could be necessary as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities and would occur in the offshore waters during the open water season after sea ice has retreated and melted. Activities under Alternative 2 would occur after pupping and molting seasons for all ice seals end, so there would be few seals expected in the area where the proposed activities would be occurring. Subsistence harvest of seals would not be expected to occur in areas of active ice management offshore. The mitigation measures are expected to avoid and minimize impacts on seals and in turn on subsistence harvesting so that no unmitigable adverse impacts occur. In the event that ice management causes seals to avoid an area, the impact to subsistence resources and subsistence users is expected to be low in intensity, temporary in duration, and local in extent, and affecting resources that are common in context. This would be considered a negligible summary impact.

Pacific Walrus

Icebreaking activities could cause walrus to avoid the areas where these activities would be occurring (Section 4.5.2.4.13). Walrus that are hauled out or feeding when icebreaking is occurring could be affected by avoiding the area. In areas where subsistence hunting occurs for walrus, avoidance of the area could lead to reduced availability of this resource to hunters and reduced harvests. Given the dispersed distribution of walrus on the ice and the short time period and limited geographic extent of icebreaking activities authorized under Alternative 2, it is unlikely that many walrus would be affected in the Chukchi Sea and unlikely that any would be affected in the Beaufort Sea. Such disturbance would be temporary as the icebreaker moved through an area and the ice reformed relatively quickly. In the event that icebreaking does cause walrus to avoid a subsistence use area and reduces the success of harvest, the impact to subsistence resources is expected to be low in intensity, short term in duration, local in extent, and affecting a resource that is important in context. This would be considered a negligible summary impact to subsistence harvest of walrus.

Ice management activities, and associated vessel traffic, would not likely be conducted in offshore waters that are subsistence use areas for this species. Mitigation measures are expected to avoid and minimize impacts on walrus subsistence harvest so that no unmitigable adverse impacts occur. There is a low probability that impacts could occur to subsistence users. In the event that ice management activities cause walrus to avoid a subsistence use area and reduce the success of the harvest, the impact to subsistence is expected to be low in intensity, short term in duration, local in extent, and affecting a resource that is important in context. This would be considered a negligible summary impact to subsistence harvest of walrus.

Polar Bears

In response to the presence of icebreakers and icebreaking activities, polar bears may flee from the noise at the sight of icebreakers or be drawn to them. Icebreaking and ice management would likely occur when polar bears are on pack ice. In areas of polar bear subsistence hunting, avoidance of the area could lead to a reduced availability of this resource to hunters and reduced harvest.

Icebreaking could be necessary as part of late season survey activities. Given the dispersed distribution of bears on the ice and the short time period and limited geographic extent of icebreaking activities, it is unlikely that more than a few bears would be affected in either sea and such disturbance would be temporary to both the bears and their ice seal prey (Section 4.5.2.4.14). There is a low probability that impacts could occur to subsistence users, if late season icebreaking causes polar bears to avoid a subsistence use area and reduces the success of harvest. However, the impact to subsistence resources is expected to be low in intensity, short term in duration, local in extent, and affecting a resource that is unique in context, due to listing under the ESA. This would be considered a minor summary impact.

Polar bears are unlikely to be present in the areas where seismic and high resolution shallow hazard surveys and exploratory drilling activities would occur during the open water season. Ice management activities would be conducted in offshore waters that are not subsistence use areas for polar bear harvest. The mitigation measures are expected to minimize and potentially avoid impacts on polar bear harvest so that no unmitigable adverse impacts occur. While there is a low probability that impacts could occur to subsistence users, if ice management does cause polar bears to avoid a subsistence use area and reduces the success of harvest the impact to subsistence resources is expected to be low in intensity, short term in duration, local in extent, and affecting a resource that is unique in context, due to listing under the ESA. This would be considered a minor summary impact based on the unique context of this species under this analysis.

Fishing

Icebreaking and ice management are not expected to affect subsistence fishing. Any effects to fish from icebreaking and ice management would be limited to avoidance in the area near the active ice management vessels during ice management activities. Avoidance would be expected to last only minutes, and no impacts to subsistence fishing would be likely.

Ice breaking and ice management activities would likely occur in areas that are offshore and removed from subsistence fish harvest areas. The impacts to the subsistence harvest of fish would be considered to have no effect.

Marine and coastal birds

Effects of icebreaking and ice management could have similar effects to marine and coastal birds as the vessel traffic and cause birds present to flush or avoid the area where the activity is occurring. Birds could avoid or be attracted to the activity. Avoidance of the area could lead to a lesser availability of birds for subsistence hunters and lower rates of harvest.

Icebreaking and ice management would not be expected to occur in areas of critical bird habitat and other areas of high bird concentrations. Icebreaking and ice management activities are not anticipated to impact the availability or distribution of birds and bird eggs for subsistence harvest. These activities would likely occur in areas that are offshore and removed from subsistence bird harvest areas. The impacts to subsistence harvests of bird and egg gathering are considered of low intensity, temporary duration, local extent, and affecting resources that are common in context. The summary impact could be considered negligible.

Caribou

Icebreaking and ice management activities would occur offshore and would not be expected to affect caribou, a terrestrial mammal. Therefore, no measurable effects to subsistence hunting of caribou are anticipated from icebreaking or ice management activity.

No impacts are anticipated to occur to caribou or caribou subsistence harvests from icebreaking and ice management for offshore seismic and high resolution shallow hazard surveys and exploratory drilling. Due to the distance of such activities from the coastlines of both seas, no impacts on the terrestrial habitat of caribou or on the availability of caribou for subsistence harvests would be expected.

Effects of noise and vehicle movement from on-ice seismic surveys

Bowhead Whales

The on-ice seismic survey that could occur in the Beaufort Sea would take place at a time of the year when bowhead whales are not present. Therefore, no impacts to bowhead whale subsistence harvest from on-ice seismic surveys are expected to occur.

Beluga Whales

The on-ice seismic survey that could occur in the Beaufort Sea would take place at a time of the year when beluga whales are not present. Therefore, no impacts to beluga whale subsistence harvest from on-ice seismic surveys are expected to occur.

Seals

Section 4.5.2.4.12 (Ice Seals) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect seals. One on-ice seismic survey could be permitted in the Beaufort Sea under Alternative 2, but mitigation measures to limit adverse effects to seals and subsistence harvests could be applied. Subsistence harvest areas for ringed and bearded seals by Nuiqsut and Barrow hunters extend through the area east of Point Barrow where one on-ice survey could occur at the same time that seals are in their lairs during the winter. As a result of on-ice seismic survey activities seals could become displaced from their lairs and would then be unavailable for harvest or could become more difficult to harvest for the duration of the industry on-ice activity. Any impacts to seal subsistence harvests would be characterized as a low intensity, limited to a local area, temporary in duration, and affecting a resource that is common in context. The summary impact is considered negligible.

Pacific Walrus

The on-ice seismic survey that could occur in the Beaufort Sea would take place at a time of the year when walrus are not present. Therefore, no impacts to walrus subsistence harvest from on-ice seismic surveys are expected to occur.

Polar bears

Section 4.5.2.4.14 (Polar bears) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect polar bears. There is the potential for one on-ice seismic survey to occur in the Beaufort Sea, east of Point Barrow during January through May. Impacts to polar bear subsistence hunts in the Beaufort Sea communities could be affected as polar bears could become displaced from the on-ice survey area or disturbed while denning. Direct impacts that do occur would be considered of low intensity, limited in extent to a local area, temporary in duration but unique in context. Therefore, impacts from on-ice seismic surveys in the Beaufort Sea are anticipated to have minor impacts on polar bear subsistence harvests.

Fishing

Noise and vehicle movement from on-ice seismic surveys are not expected to affect subsistence fishing. Any effects to fish from noise and vehicle movement during on-ice seismic surveys would be limited to avoidance in the area near the activities. Avoidance would be expected to last only minutes, and no impacts to subsistence fishing would be likely. On –ice seismic activity would occur in a marine area that is removed from subsistence fish harvest areas during the winter and early spring when marine subsistence fishing is not occurring in the Beaufort Sea communities. No impacts to marine subsistence fishing are anticipated.

Marine and Coastal Birds

The on-ice seismic survey that could occur in the Beaufort Sea would take place at a time of the year when marine and coastal birds are not present in large numbers on the coast. The likelihood of disturbance to marine and coastal birds resulting in lost opportunity for subsistence harvest would be of low intensity, temporary, local in extent and common in context. Therefore the impact is considered negligible.

Caribou

The on-ice seismic survey that could occur in the Beaufort Sea would take place at a time of the year when caribou are not present in large numbers on the coast. The likelihood of disturbance to caribou resulting in lost opportunity for subsistence harvest would be of low intensity, temporary, local in extent and common in context. Therefore the impact is considered negligible.

Effects from Permitted Discharges

The effects of permitted discharges (including bilge and ballast water, non-contact cooling water, desalination wastes, domestic and sanitary wastes, excess cement slurry, and deck drainage) to marine waters could affect marine mammals and fish. These species may respond by avoiding the areas in the vicinities of the discharge. Drill cuttings and mud discharges may displace marine mammals and fish from a short distance from each drilling location. Fish eggs and larvae could be destroyed, but it is unlikely that population-level effects would occur or that the discharges would limit the availability of these resources to subsistence hunters. These measurable effects on benthic communities have the potential to impact fish resource, particularly benthic feeders. However, scientific evidence suggests that drilling discharges and cuttings have minor effects on adult fish health (Hurley and Ellis 2004) (See Section 4.5.2.2.).

Concerns of contaminants occurring in Arctic subsistence resources – in particular bowhead whales - as a result of industrial pollution, long distance vectors for transport and deposition in Arctic environments, and high rates of persistence were summarized by NMFS (2008). NMFS noted: *"Bowhead whale subsistence foods have been analyzed for their levels of contaminants, including PCBs, DDTs, OCs, and chlordanes and heavy metals. These contaminant levels varied with gender, length/age, and season, but were generally relatively low compared to other marine mammals. Reports by the Arctic Monitoring and Assessment Programme (AMAP) identified levels of contamination meriting closer public health attention in some parts of the Arctic, through generally not in Alaska (AMAP, 2002, 2003). At the same time, public health officials recognize that the loss of subsistence foods would have far-reaching consequences throughout the sociocultural system of small, predominantly indigenous communities."* NMFS (2008) concluded that *"the documented contaminant levels in bowhead whales in Alaska do not represent a threat to the health of subsistence users at current levels. Given the low levels of risk, public health officials conclude that the nutritional decline from loss of subsistence foods, like bowhead whale meat and blubber, would be far more adverse."* There is an important perception among subsistence hunters that contamination of these subsistence resources could result from the action alternatives. Hunters may harvest "perceived" affected resources in lesser amounts and in turn harvest other terrestrial mammal species or freshwater fish at higher levels. Section 4.5.3.3 describes the direct impacts of environmental contaminants to subsistence resources and implications and perceptions of these effects to public health.

Permitted discharges would be required to be conducted under the conditions and limitations of the required NPDES General Permits. The impacts of a major oil spill are discussed in Section 4.10.6.15 and 4.10.7.15. Permitted discharge could be mitigated by Additional Mitigation Measures C3 and C4, which would place requirements and limitations on the levels of discharge and discharge streams that could affect marine mammal habitat, marine mammals, and eventually the diets of subsistence users.

These mitigation measures may not alleviate the perception that a small oil spill or regulated wastewater discharge might contaminate subsistence resources. There is a perception the foods could become contaminated by discharges and/or small fuels spills, resulting in impacts to human health from consumption of the resources.

"Our whaling captains have always observed that the whales will shy away from human smells. In the spring, we have to be very careful with our cooking when we're camping on the ice during the spring. The whales can pick up the smells of our cooking or even making coffee. It's the same for discharges into the water. We are taught from a young age never to dump anything into the water during whaling. If we do, we won't see the whales. We also worry about the health effects of trying to eat marine mammals that have migrated through areas of waste discharge. We eat our marine mammals right out of the ocean and we can't be feeding our people waste from drilling operations" – Harry Brower, pers. comm., March 12, 2013.

"Near Cross Island, we have observed the whales deflecting around discharges into the water. During the 1980s, we saw this at times when we could also see cuttings floating on the water. At these times, the whales were diverted over 30 miles north from shore. That is why, under our Conflict Avoidance Agreement, we now ask the companies not to discharge any drilling muds or cuttings or other waste into the waters of the near-shore Beaufort Sea, where the whales migrate in the fall time. The whales will deflect away from the areas where waste is being dumped and it makes it harder for our hunters to find them. Shell has agreed to zero discharge under the CAA because of this" - Isaac Nukapigak, pers. comm., March 12, 2013.

The likelihood of subsistence resources occurring in the vicinity of the likely areas where drilling and/or any associated discharge or minor spills could occur is low as these activities would occur at a time when subsistence hunts are not occurring in areas that are offshore and removed from known hunting areas. In addition, fuel transfers are not expected during transit between the Beaufort and Chukchi seas. The direct impact of drill cuttings and mud discharges may displace marine mammals and fish a short distance from each drilling location. The impacts to subsistence users would be of low intensity, temporary to interim duration, local to regional extent, and affecting resources that are common to important in context.

4.5.3.2.2 Conclusion

Impacts of Disturbance from Seismic and High Resolution Shallow Hazard Surveys and Exploratory Drilling Activities to Subsistence Resources

The noise produced by the proposed seismic surveys, high resolution shallow hazards surveys, and exploratory drilling with standard mitigation measures that could be applied in order to minimize or avoid any adverse effects on all marine mammals and other subsistence resources, and other additional mitigation measures will be evaluated here and potentially required in MMPA ITAs. In consideration of the standard and additional mitigation measures, seismic surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling are not expected to disturb or disrupt subsistence activities at a level that would make resources unavailable for harvest or significantly alter the existing levels of harvest.

There may be rare instances where subsistence activities are interrupted. Only then would there be a direct impact from disturbance/disruption of or to the resource being harvested. Subsistence harvest patterns tend to be adaptive, and in the case of bowhead whaling, crews are likely to travel farther on longer trips to achieve harvest goals. Bowhead whales are such a highly productive food resource that in the communities highly reliant on this species, a major decline in bowhead harvest could not be replaced by other subsistence species but could potentially be replaced by sharing with other communities that were able to conduct successful bowhead whale hunts. Apart from the special case of bowhead whale harvests, subsistence harvest composition shows inter-annual variation, and shortfalls in some species are replaced by increased harvests of others, so that overall annual production meets harvest targets. (For a recent quantitative demonstration of variation in subsistence fish harvests in the neighboring Northwest Arctic, see Magdanz et al. 2011).

By implementing mitigation measures, the impacts from disruption of subsistence harvest would be low in intensity and temporary in duration. Impacts would be local to regional in extent and would affect resources that range from common to important in context. For instance, the loss of opportunity for a community to successfully harvest its full quota of bowhead whales for one season if the whales were deflected and hunters had a harder time reaching the whales as a result of seismic and high resolution shallow hazard surveys and exploratory drilling activities this would be a direct impact of the activity. Additional effort to harvest bowhead whales or reduced harvests would be considered an impact that is medium in intensity, interim to long-term in duration, local to regional in extent (in view of sharing practices), and affecting a resource that is important in context. As a result, this summary impact would be considered moderate. Mitigation measures evaluated in relation to this alternative are considered effective in reducing impacts on subsistence resources to the lower levels noted above. The summary impact of Alternative 2 in regard to disturbance to other subsistence resources is considered negligible to minor, depending on the species. The summary impact to belugas is considered minor. The summary impact to seal and walrus harvest are considered negligible. No impacts of disturbance are anticipated to subsistence harvests of polar bear, fish, marine and coastal birds, and caribou.

Impacts of Disturbance from Aircraft Overflights to Subsistence Resources

Increased aircraft traffic associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities could cause subsistence resources some temporary behavioral disturbance and possibly deflection away from the sound source by terrestrial or marine mammals. The level of the disturbance would depend on the size of the aircraft and repeated exposure or displacement. However mitigation measures regarding minimum altitudes and offset distances would reduce these effects.

Aircraft overflights are unlikely to have an adverse effect on subsistence harvests. Impacts that did occur would be considered low in intensity but temporary in duration. Effects of the impact would be local and affecting resources that are common to important in context. The summary impact of Alternative 2 in regard to impacts of air traffic to subsistence resources is considered negligible to minor depending on the species. The summary impact to bowhead whales is considered minor. The summary impact to belugas is considered minor. The summary impact to seal and walrus harvest are considered negligible. The summary impacts to polar bears, marine and coastal birds and caribou are considered minor. No impacts of disturbance are anticipated to subsistence harvests of fish.

Impact of Vessel Traffic to Subsistence Resources

The summary impact of vessel traffic on subsistence harvest of bowhead and beluga whales is expected to be minor to moderate. The summary impact to subsistence harvest from vessel traffic on seals and walrus is considered negligible to minor. The summary impact to subsistence harvest of polar bears is considered minor. Negligible summary impacts to subsistence harvest of fish, bird hunting and egg gathering, and caribou hunting are expected as a result of vessel traffic.

Impacts of Icebreaking and Ice Management on Subsistence Resources

Summary impacts to bowhead whales, beluga whales, and polar bears from icebreaking and ice-management activities are expected to be minor. Summary impacts to seals, walrus, fish, and bird hunting and egg gathering from icebreaking are expected to be negligible. No impacts to caribou or caribou hunting are expected.

Impact of On-ice Seismic Surveys to Subsistence Resources

No impacts are anticipated subsistence harvests of bowhead whales, beluga whales, Pacific walrus, and fishing as a result of the on ice seismic survey. Summary impacts to seals, marine and coastal birds and caribou are expected to be would be negligible. The summary impacts to polar bears could be minor.

Indirect Impact to Subsistence Resources from Permitted Discharges

The impacts to subsistence users would be of low intensity, short term duration, local extent, and affecting resources that are common to unique in context. Therefore the summary impact to subsistence resources, activities, and subsistence users would be minor, though the perception of the impact could be moderate.

Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of all oil and gas exploration activities on subsistence resources resulting from implementation of Alternative 2 would be of low intensity, temporary to interim in duration, local to regional in extent, and the context would be common to important. Therefore the summary impact level of Alternative 2 on subsistence resources and harvests would be considered to range from negligible to minor depending upon the specific subsistence resource affected and source of disturbance.

4.5.3.2.3 Standard Mitigation Measures for Subsistence

In order to analyze likely impacts to subsistence uses arising from the seismic survey and high resolution shallow hazard surveys and exploratory drilling activities under Alternative 2, it is also necessary to identify those mitigation measures that offset potential impacts. The sections that follow examine standard mitigation measures that were designed to mitigate impacts to subsistence hunting and would be required pursuant to all applicable activities under this alternative. Of note, the Marine Mammal section contains more standard mitigation measures that are intended to reduce impacts to multiple species (e.g., bowheads, belugas, and ice seals), and those measures would indirectly reduce impacts to subsistence uses.

D1. Shutdown of exploration activities occurring in specific areas of the Beaufort Sea corresponding to the start and conclusion of the fall bowhead whale hunts in Nuiqsut (Cross Island) and Kaktovik beginning on August 25.

Applicable Activities: 2D/3D seismic, including in-ice, surveys, CSEM surveys, site clearance and high resolution shallow hazards surveys, exploratory drilling activities, and all associated support vessels

Purpose: This mitigation measure applies to the communities of Kaktovik and Nuiqsut to ensure no unmitigable adverse impacts occur to the subsistence harvest of bowhead whales for these two communities.

Science, Support of Reduction of Impacts, and Likely Effectiveness: This mitigation measure would require seasonal restrictions (shutdown) on activities occurring in specific areas of the Beaufort Sea corresponding to the start and conclusion of the fall bowhead whale hunts conducted at Cross Island by Nuiqsut whalers and by Kaktovik whalers. Operators would shut down their activities on August 25 and would not resume until the fall bowhead hunts were concluded for both of these communities.

As a result of the restrictions incorporated into this mitigation measure, industry activity would not occur until after the fall bowhead hunt is considered closed (i.e. when the village Whaling Captains'

Association declares the hunt ended or the village quota has been exhausted, as announced by the village Whaling Captains' Association or the AEWC). During the fall migration, only those whales that have not yet migrated westward of Kaktovik and Nuiqsut would be affected by noise disturbance and possible deflection from proposed activities. As vessels associated with activities transit the area beginning August 10 to August 25, industry participants will communicate and collaborate with AEWC on any planned vessel movement in and around Kaktovik and Cross Island to avoid impacts to the whale hunt. Whalers have reported that spooked/skittish whales become less available during the whaling season, and this mitigation measure would limit the potential for disturbance to occur. This mitigation measure may be reduce impacts to subsistence whalers at Barrow as it would limit the potential for disruption of whales as they pass Kaktovik and Nuiqsut, and, therefore, whales would be assumed to be following their normal migratory paths towards Barrow. This measure has been successfully implemented by industry operators for several years in the Beaufort Sea.

However as indicated by residents of these communities, conflicts can still exist with impacts on the success of the bowhead hunt: *"When there was a rig on the east side of Barrow, Point Barrow, in the fall, and I was there, and as a whaler for the community of Barrow. And when the rig was there, there was no whales within that area, so we had to go further out because the whales had been diverted to further out. The same thing is going to happen within our waters in the Chukchi Sea because they are experiencing that before here. They have to go further out"* Jimmy Oyagak at Nuiqsut Public Scoping meeting for this EIS on March 11, 2010.

Fenton Rexford, then President of Kaktovik Iñupiat Corporation (KIC), in a community meeting on August 14, 1996 stated that during exploratory drilling in Canadian offshore waters: *"We were not successful or had a very hard time in catching our whale when there was activity with the single steel drilling caisson, the drilling rig off Canada. And it diverted [bowhead whales] way offshore; made it very difficult for our whalers to get our quota."*

Carl Brower noted at the Nuiqsut Public Scoping meeting for this EIS on March 11, 2010: *"We were harassed by how many vessels and let us catch half our quota. And last year was a -- we barely saw whales. Most of the whales were up north, and we -- the whales we saw that were close to the island, we saw one, two a day, where we usually see, in one day, each boat chasing their own whale. So that's my question, what do you have to [do to] mitigate [disturbance to] a whale?"*

Innupiat hunters report that this measure is critical for reducing adverse impacts of industry activity on their subsistence hunts.

History of Implementation: Limitation of activities in these areas and times has been consistently required for years during exploration activities in the Beaufort Sea.

Practicability: Although cessation of exploration activities around the particular subsistence hunting activities does incur some cost to industry and increases risk when requiring drilling operations to shut down and move off site into the middle of drilling a well, industry has worked with the various communities along the Beaufort and Chukchi seas to establish communication centers during the open water season to avoid conflicts and have also include design measures in programs to move activities from one area to another to avoid conflicts.

Recommendation: Based on the importance of implementing this measure to ensure no unmitigable adverse impact to subsistence uses, it makes sense to continue requiring this measure of industry operators.

D2. Establishment and utilization of Communication Centers in subsistence communities to address potential interference with marine mammal hunts on a real-time basis throughout the season.

Applicable Activities: 2D/3D seismic, including in-ice, surveys, CSEM surveys, site clearance and high resolution shallow hazards surveys, exploratory drilling activities, and all associated support vessels

Purpose: Mitigation Measure D2 requires the establishment and utilization of Communication Centers in subsistence communities to address potential interference with marine mammal hunts on a real-time basis throughout the season. This measure also would allow for the potential implementation of other proposed mitigation measures that require real-time communication between hunters and industry operations.

Science, Support of Reduction of Impacts, and Likely Effectiveness: In order to be effective, it is necessary that industry and the affected communities both participate and implement the steps that would be taken to cooperate with one another. The Plan of Cooperation (POC) required by this mitigation measure would identify and document potential conflicts and associated mitigation measures that would be taken to minimize any adverse effects on the availability of marine mammals for subsistence use. To be effective, the POC must be a dynamic document which will be updated to incorporate new requirements for effective communications and consultation with the communities. The effectiveness of Mitigation Measure D2 is a subject of debate among some of the affected communities. Concerns have been expressed that the communication centers are not working as effectively in avoiding interference with subsistence hunters as had been expected.

As reported by one commenter: *"And for years now we've had a lot of impacts. We've run into a lot of vessels sometimes. Our boats are small, we're in the ice pack, and we have an ice breaker coming at us, we've had those incidents where we -- you know, we couldn't get to them on the radio…We have Badami right there that they have fuel runs, barge runs that are hauling fuel or hauling material when its barging season is open. And I've seen a lot of deflection, you know, because I'm tracking with GPS, their GPS when they're giving me coordinates. And I keep -- I get coordinates every six hours from industry, and sometimes we say, no, don't go, we have activity there. But still they go because it's their time and money that they're talking about when they have to have these resupply runs to their vessels out there. That causes impact, and it's recorded"* – Dora Leavitt at the Nuiqsut Public Scoping March 11, 2010 for this EIS.

Willie Goodwin, representing the Alaska Beluga Whale Committee made comments at the Kotzebue Public Scoping Meeting for this EIS on February 18, 2010: *"I think you should require that any seismic work or any other work that's going to be done by the oil industry, you should require them to have MMOs, marine mammal observers. At the very least, to be able to not harm the marine mammals or their migration."*

Dora Leavitt remarked at Nuiqsut Public Scoping meeting for this EIS on March 11, 2010: *"I know that they [industry] - and they now use marine mammal observers, but they don't have them in each vessel. They have them in the -- maybe the main supply or whatever vessel. And then you have all these runners, the resupply runners that go on their own with no observers. So, you know, they [industry] need more marine mammal observers."*

Innupiat hunters report that this measure is critical for reducing adverse impacts of industry activity on their subsistence hunts.

History of Implementation: Industry operators have been required to set up and run communication centers for many years.

Practicability: Past success indicates that this measure is practicable.

Recommendation: Based on the importance of implementing this measure to ensure no unmitigable adverse impact to subsistence uses, it makes sense to continue requiring this measure of industry operators.

D3. Required flight altitudes and paths for all support aircraft in areas where subsistence occurs, except during take-off, landing, and emergency situations.

Applicable Activities: 2D/3D seismic, including in-ice, surveys, CSEM surveys, site clearance and high resolution shallow hazards surveys, exploratory drilling activities, and all associated support vessels

Purpose: This mitigation measure is intended to ensure no unmitigable adverse impacts occur to subsistence users from the anticipated increases in levels of aircraft overflights during seismic and high resolution shallow hazard surveys and exploratory drilling operations.

Science, Support of Reduction of Impacts, and Likely Effectiveness: This mitigation measure applies to the communities of Kaktovik, Nuiqsut, Barrow, Wainwright, Point Lay, Point Hope, and Kivalina to ensure no unmitigable adverse impact to subsistence uses occur to the subsistence harvest of whales and seals for these seven communities. Mitigation Measure D3 sets forth the flight altitudes and paths (offset distances) for all support aircraft in areas where subsistence occurs, except during take-off, landing, and emergency situations.

Implementation of this mitigation measure requires that vessels and aircraft avoid concentrations or groups of whales. Operators shall, at all times, conduct their activities at a maximum distance from such concentrations of whales.

Subsistence users have commented on the importance of aircraft altitude restrictions: *"Require aircraft to maintain a 1,000 ft minimum altitude when flying over marine mammals observed on or near the surface"* - Alex Whiting and Linda Joule - Written comments representing Native Village of Kotzebue February 26, 2010.

Inclement weather may occasionally cause brief instances when aircraft are operated at altitudes below 305 m (1,000 ft) and short term impacts to subsistence resources and users would then occur.

The complete removal of potential sources of aircraft disturbance to marine mammals during any subsistence uses (with exceptions noted above), is expected to reduce potential adverse impacts on subsistence uses from industry activities. Innupiat hunters report that this measure is critical for reducing adverse impacts of industry activity on their subsistence hunts.

History of Implementation: Limitation of aircraft activity in the vicinity of the hunts has been consistently required for years during exploration activities in the Beaufort Sea.

Practicability: Although limitation of air activity around the particular subsistence hunting activities does incur some cost to industry, industry has worked with the various communities along the Beaufort and Chukchi seas to establish communication centers during the open water season to avoid conflicts and have also include design measures in programs to move activities from one area to another to avoid conflicts.

Recommendation: Based on the importance of implementing this measure to ensure no unmitigable adverse impact to subsistence uses, it makes sense to continue requiring this measure of industry operators.

Walrus – This mitigation measure applies to all open-water exploration activities and is intended to ensure no unmitigable adverse impacts to the availability of marine mammals (particularly bowhead whales) for subsistence uses. This mitigation measure is similar to B1, but, as it specifically concerns the reduction of potential conflicts with subsistence hunting of bowhead whales, it is more limited in time and areas of implementation and would not likely be an effective mitigation measures for walrus.

***Polar Bears* –** This mitigation measure applies to all open-water exploration activities and is intended to ensure no unmitigable adverse impacts to the availability of marine mammals (particularly bowhead whales) for subsistence uses. This mitigation measure is similar to B1, but, as it specifically concerns the reduction of potential conflicts with subsistence hunting of whales, it is more limited in time and areas of implementation and would not likely be an effective mitigation measures for polar bears.

4.5.3.2.4 Standard Mitigation Measures Summary for Subsistence

In general, the Standard Mitigation Measures discussed above would avoid or reduce the disturbance of marine mammals and other resource harvests for subsistence purposes, or would avoid or reduce interference with subsistence activities. Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources resulting from implementation of Alternative 2 would be of low intensity, temporary in duration, local to regional in extent, and the context would be common to important. Therefore the summary impact level of Alternative 2 on subsistence resources and harvests would be considered to range from negligible to minor depending upon the specific subsistence resource affected and source of disturbance.

4.5.3.2.5 Additional Mitigation Measures for Subsistence

Additional mitigation measures are outlined in Section 2.4.11 and described in detail in Appendix A. These measures may, or may not, be incorporated in future permits and authorizations, depending on the specific activity and the analysis conducted pursuant to the MMPA and the OCS Lands Act. See Sections 2.4.2 and 4.3 for an explanation of how specific measures would be chosen for inclusion in any future permits or authorizations. The following are applicable to mitigating effects of oil and gas exploration activities on marine mammals.

Of note, the Marine Mammal section contains more additional mitigation measures that are intended to reduce impacts to multiple species (e.g., bowheads, belugas, and ice seals), and those measures, if required and implemented, would indirectly reduce impacts to subsistence uses.

Additional Mitigation Measure B1. Temporal/spatial limitations to minimize impacts in particular important habitats, including Kaktovik, Barrow Canyon, Hanna Shoal, the shelf break of the Beaufort Sea, and Kasegaluk Lagoon, and Ledyard Bay Critical Habitat Unit.

Section 4.5.2.4.16 contains the full analysis for this mitigation measure. As noted in that section, this additional mitigation measure would also help to reduce impacts to the following hunts: the fall bowhead whale hunt by the community of Kaktovik; the fall bowhead whale hunt by the communities of Barrow and Wainwright; and the late spring/early summer beluga hunt by the community of Point Lay. Additionally, adverse impacts to some subsistence sealing would also potentially be reduced.

Additional Mitigation Measure D1. No transit of exploration vessels into the Chukchi Sea prior to July 15 or until the beluga hunt is completed at Point Lay. Any vessel transiting through the Chukchi Sea for the purpose of conducting geophysical work in the Chukchi Sea should remain at least 8 km (5 mi) offshore during transit except for emergencies or human/navigation safety. Actual geophysical operations shall not be conducted within 96.5 km (60 mi) of any point on the Chukchi Sea coast. Oil and gas exploration operators would need to communicate with local hunters to ascertain the hunting end date.

Applicable Activities: 2D/3D seismic surveys, including in-ice seismic, CSEM surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities, and associated support vessels

Purpose: The purpose of the mitigation measure is to minimize conflict with the beluga whale hunt at Point Lay and Wainwright. It would also reduce disturbance from vessels on bowhead whales migrating east in that time frame, although most bowhead whales have already migrated past these areas by July.

Science, Support for Reduction of Impacts, and Likely Effectiveness*:* The science behind the mitigation measure is contained in Section 4.5.2.4.10, Beluga Whales, of the EIS. Deflection due to noise and vessel presence could cause whales to avoid subsistence harvest areas, which could make the whales less available for harvest.

The potential effectiveness of the mitigation measure is not well known. The discussion in Section 4.5.3.2 , Subsistence, indicates that most of the beluga hunt occurs from late June to mid-July inside Kasegaluk Lagoon or other inshore locations inside the barrier islands. As such, the prohibition against conducting geophysical activity within 96.5 km (60 mi) of the Chukchi Sea coast seems somewhat excessive in order to prevent interference with the subsistence hunt at Point Lay, which occurs at nearshore locations. However, there is some concern amongst subsistence hunters that belugas that may be disturbed by operations offshore may not enter into the nearshore areas, thus reducing the number of animals available for the hunt.

BOEM lease stipulation 7 and the standard requirement placed in G&G permits based on the FWS BO prohibits transit of exploration vessels and seismic activity in the LBCHU, which will keep those vessels outside of the harvest area. However, the concern still remains about affecting belugas farther offshore.

History of Implementation: NMFS required a similar measure in IHAs until 2008. However, this measure has not been required in recent years.

Practicability: Limiting entrance into the Chukchi Sea until after July 15 could shorten exploration periods during the open water period in both the Beaufort and Chukchi seas by preventing activity and staging prior to this time. Operators often begin entering the Chukchi Sea around July 1 (or as soon thereafter as ice conditions allow) so as to be at the activity location a few days or one week later (depending on site location).

Recommendation: This measure should be revised to require operators to ensure all vessel traffic remains at least 8 km (5 mi) offshore when transiting through the Chukchi Sea prior to July 15.

Additional Mitigation Measure D2. Vessels transiting east of Bullen Point to the Canadian border should remain at least 8 km (5 mi) offshore during transit along the coast, except for emergencies or human/navigation safety.

Applicable Activities: All exploration activities

Purpose: The purpose for which the mitigation measure is intended is to avoid conflict with the subsistence hunt in the nearshore region, but would also reduce the potential for vessel disturbance to marine mammal subsistence resources hunted near Nuiqsut and Kaktovik.

Science, Support for Reduction of Impacts, and Likely Effectiveness*:* Subsistence mapping of Nuiqsut, Kaktovik, and Barrow (MMS OCS Study 2009-003) and described in the Draft EIS indicates most intense use in in the nearshore area of the coast, although not all the area described in the mitigation measure is intensely used. The measure would likely be effective in preventing use conflicts.

History of Implementation: NMFS has not required this measure in the past.

Practicability: Operators could incur costs and lost survey time associated with altering transit routes farther offshore. However, operators have shown that routes can be altered in the Chukchi Sea to remain farther offshore.

Recommendation: This sort of mitigation measure is supported by current scientific literature, and specific transit routes have been successfully implemented without apparent conflicts with safe operations in the past. However, because specific transit routes in this particular area have not been required previously, it will be important to evaluate this measure on a case by case basis before requiring.

Additional Mitigation Measure D3. Shutdown of exploration activities in the Beaufort Sea for the Nuiqsut (Cross Island) and Kaktovik bowhead whale hunts based on real-time reporting of whale presence and hunting activity rather than a fixed date.

Applicable Activities: All exploration activities

Purpose: The purpose for the mitigation measure is to avoid conflict with the subsistence hunt and give both the hunters and operators flexibility in when they stop activities in the vicinity of Nuiqsut and Kaktovik. As the hunters commence whaling activities, the exploration activity would move out of the area. Therefore, there would be fewer disturbances to bowhead whales from exploration activities, but whaling activities also result in disturbance to the animals.

Science, Support for Reduction of Impacts, and Likely Effectiveness: Subsistence mapping of Kaktovik and Nuiqsut bowhead use areas (MMS OCS Study 2009-003, Map 64 and 65 and 113 and 144, respectively) indicates overall and most intense use areas. As the hunters commenced whaling activities, they would communicate with industry vessels via the designated communication protocols and the exploration activity would move out of the area. Therefore, there would be less chance that the industry activities would either disturb bowhead whales or otherwise interfere with the bowhead hunt. As noted earlier in this EIS, cessation of activities at the time of a whale hunt reduces the potential for conflicts between hunters and operators and also reduces impacts to the animals.

History of Implementation: NMFS has not required this measure in the past.

Practicability: Although industry could incur costs associated with shutting down operations, basing closures on real time reporting could lead to shorter closure periods and reduced survey down time. Specific protocols for real-time communication would need to be determined in order for this measure to be practicable.

Recommendation: If measures for real-time communication to shutdown activities can be determined, this measure could replace Standard Mitigation Measure D1.

Additional Mitigation Measure D4. Shutdown of exploration activities in the Beaufort Sea for the Barrow bowhead whale hunts from Pitt Point on the east side of Smith Bay to a location about half way between Barrow and Peard Bay from September 15 to the close of the fall bowhead whale hunt in Barrow.

Applicable Activities: All exploration activities

Purpose: The purpose for the mitigation measure is to avoid conflict with the subsistence hunt and give both the hunters and companies certainty regarding when they stop activities in the vicinity of Barrow. On the date indicated, the exploration activity would move out of the area. Therefore, there would be less disturbance to bowhead whales from exploration activities.

Science, Support for Reduction of Impacts, and Likely Effectiveness: As noted in other parts of this document, cessation of activities has the potential to reduce impacts on marine mammals and therefore to reduce the potential for interference with subsistence hunts of marine mammals. However, the geographic area in this measure does not correspond to the historic overall use area or the most important high use area for fall bowhead whale hunting by crews in Barrow. Data indicate that the hunting grounds do not extend to the west side of Smith Bay or to Peard Bay. The measure has the potential to be effective, as it replicates agreed to conditions for exploration activities by some oil and gas operators. However, the overall areal extent of the measure is not supported by available information on subsistence use areas.

History of Implementation: NMFS required a similar measure in past IHAs. However, this measure has not been required in recent years.

Practicability: Although industry could incur costs associated with shutting down operations, shutdowns for subsistence activities in the Beaufort Sea have proven practicable in the past.

Recommendation: NMFS recommends that if this measure is to be included in future ITAs, the geographic extent should be re-defined to more closely match with current fall whaling areas. Additionally, this measure may benefit from real-time communication instead of a fixed date, allowing for flexibility in the shutdown date. This measure would be assessed on a case-by-case basis, with spatiotemporal overalap of the activity playing a key role in whether or not it would be included in an authorization.

Additional Mitigation Measure D5. Shutdown of exploration activities in the Chukchi Sea for the Barrow (the area circumscribed from the mouth of Tuapaktushak Creek due north to the coastal zone boundary, to Cape Halkett due east to the coastal zone boundary) and Wainwright (the area circumscribed from Point Franklin due north to the coastal zone boundary, to the Kuk River mouth due west to the coastal zone boundary) bowhead whale hunts based on real-time reporting of whale presence and hunting activity rather than a fixed date.

Applicable Activities: All exploration activities

Purpose: The purpose for the mitigation measure is to avoid conflict with the subsistence hunt and give both the hunters and companies flexibility in when they stop activities in the vicinity of Barrow. As the hunters commence whaling activities, the exploration activity would move out of the area. Therefore, there would be fewer disturbances to bowhead whales from exploration activities, but whaling activities also result in disturbance to the animals. The purpose for the mitigation measure is to avoid conflict with the subsistence hunt and give both the hunters and companies flexibility in when they stop activities in the vicinity of Barrow. As the hunters commence whaling activities, the exploration activity would move out of the area. Therefore, there would be fewer disturbances to bowhead whales from exploration activities, but whaling activities also result in disturbance to the animals.

Science, Support for Reduction of Impacts, and Likely Effectiveness*:* The potential effectiveness of the mitigation measure is low, as it does not correspond to areas where most intense bowhead whaling takes place. However, any reduction in activity has the potential to reduce overall impacts.

History of Implementation: NMFS has not required this measure in the past.

Practicability: Although industry could incur costs associated with shutting down operations, shutdowns for subsistence activities in the Beaufort Sea have proven practicable in the past.

Recommendation: This measure should be removed and changed to reflect current fall whaling areas by the communities of Barrow and Wainwright in the Chukchi Sea.

Additional Mitigation Measure D6. Shutdown of exploration activities in the Chukchi Sea for the Point Hope and Point Lay bowhead whale hunts based on real-time reporting of whale presence and hunting activity rather than a fixed date.

Applicable Activities: All exploration activities

Purpose: The purpose for the mitigation measure is to avoid conflict with the subsistence hunt and give both the hunters and companies certainty in when they stop activities in the vicinity of Point Hope and Point Lay.

Science, Support for Reduction of Impacts, and Likely Effectiveness: The science behind the measure is not clear. Exploration generally cannot begin in the Chukchi Sea until the ice has retreated, which is well after the completion of the spring whale hunts in the communities. Successful fall whaling in these communities is not historically undertaken from these communities. Hunters from Point Lay and Point Hope typically travel to Barrow or other communities that conduct fall bowhead whale hunts. Distance of the coastal buffer does not appear to correspond to reported use areas. Point Lay subsistence activities are currently "buffered" by BOEM Lease Stipulation 7, and requirements for exclusion of vessel traffic related to BOEM permitted and authorized activities in the FWS BO effectively curtails exploration activities from occurring within the LBCHU. It is not clear how effective the measure will be.

History of Implementation: NMFS has not required this measure in the past.

Practicability: Although industry could incur costs associated with shutting down operations, shutdowns for subsistence activities have proven practicable in other parts of the U.S. Arctic in the past.

Recommendation: This measure is not recommended for inclusion.

Additional Mitigation Measure D7. Transit restrictions into the Chukchi Sea modified to allow offshore travel under certain conditions (e.g. 32 km [20 mi] from the coast) if beluga whale, fall bowhead whale (Barrow and Wainwright), and other marine mammal hunts would not be affected.

Applicable Activities: All exploration activities

Purpose: The purpose for the mitigation measure is to avoid conflict with the subsistence hunts in Barrow and the Chukchi Sea communities.

Science, Support for Reduction of Impacts, and Likely Effectiveness*:* The science behind the mitigation measure is contained in Section 4.5.3.2, Subsistence, of the Draft EIS. Deflection due to noise and vessel presence could cause whales to avoid subsistence harvest areas, which would make the whales unavailable for harvest. Discussion indicates that not all marine mammals have pronounced avoidance behaviors or are hunted during the period in which transits would take place.

The potential effectiveness of the mitigation measure is marginal. As the discussion in Section 4.5.3.2 , Subsistence, indicates, most of the beluga hunt occurs from late June to mid-July inside Kasegaluk Lagoon or other inshore locations inside the barrier islands. The terminology "travel under certain conditions" is vague as it defines neither the type of travel nor the conditions. The distance of 32 km (20 mi) appears to be arbitrary, with no definitive basis identified in the analysis.

History of Implementation: NMFS has not required this measure in the past.

Practicability: While oil and gas operators have shown that they are able to abide by transit distances from shore in the past, the reason for this measure is unclear.

Recommendation: This measure is not recommended for inclusion.

Additional Mitigation Measure D8. For exploratory drilling operations in the Beaufort Sea west of Cross Island, no drilling equipment or related vessels used for at-sea oil and gas operations shall be

moved onsite at any location outside the barrier islands west of Cross Island until the close of the bowhead whale hunt in Barrow.

Applicable Activities: Exploratory drilling activities

Purpose: The purpose for the mitigation measure is to avoid conflict with the Barrow subsistence hunt.

Science, Support for Reduction of Impacts, and Likely Effectiveness: As noted earlier in this EIS, ceasing activities prior to and during a subsistence hunt reduces impacts to the individual animals and also elimates the possibility of interference between the hunters and the operators. The measure would likely be effective at reducing or eliminating the potential for interference with the hunt. Equipment would need to be moved to a location agreed upon with the affected subsistence users to ensure that the "stand-by" location does not create impacts to the hunters.

History of Implementation: NMFS has not required this measure in the past.

Practicability: While the oil and gas operators have shown that they are able to conduct temporary shutdowns for subsistence hunts, there are extra costs that are incurred. Additionally, this measure does not specify if activities could occur up until a specific time prior to the hunt.

Recommendation: This measure needs to be better defined before it is considered for inclusion.

Collectively, Additional Mitigation Measures D1 through D8 could be required for issuance in ITAs (as described in Sections 2.4.2 and 4.3) and are intended to reduce impacts to marine mammal subsistence users in the various communities. The efficacy of previous similar mitigation measures is described by subsistence hunters who have reported the following observations:

> *On the Chukchi we have a big wide buffer, a 25-mile wide buffer zone that goes way down -- all the way down near Point Hope. That's there for us. That's -- we're the ones that's taking the impact. I mean all these years we've been asking, ever since the lease sales start occurring, to protect our subsistence whales. And so far up today that we haven't received a buffer [near Cross Island]* - Thomas Napageak Jr. Nuiqsut Public Scoping Meeting on March 11, 2010.

4.5.3.2.6 Additional Mitigation Measures Conclusion for Subsistence

The additional mitigation measures considered in this section would have the potential to further reduce the potential of adverse effects on subsistence resources. Given the standard and additional mitigation measures the effects on subsistence resources would likely be considered low intensity, temporary in duration, local to regional in extent, and the context would be common to important. Therefore the summary impact level of Alternative 2 on subsistence resources and harvests with additional mitigation measures applied would be considered to range from negligible to minor depending upon the specific subsistence resource affected and source of disturbance.

4.5.3.3 Public Health

The level of impacts on public health and safety will be based on levels of intensity, duration, geographic extent, and context, as shown in Table 4.5-27.

Table 4.5-27 Impact Levels for Effects on Public Health and Safety

Impact Component	Effects Summary		
Magnitude or Intensity	**Low**: Affects one health indicator in a single community	**Medium**: Affects multiple communities or multiple health indicators in a single community	**High**: Affects multiple health indicators in multiple communities throughout the region
Duration	**Temporary**: Changes in health indicators last for less than one year	**Long-term**: Changes in health indicators extend up to several years	**Permanent**: Changes in health indicators persist after actions that caused the impacts cease
Geographic Extent	**Local**: Affects individuals in a single community	**Regional**: Affects two or more communities in the EIS project area	**State-wide**: Affects communities throughout the EIS project area
Context	**Common**: Affects communities that are not minority or low-income	**Important**: Not Applicable	**Unique**: Affects minority or low-income communities

4.5.3.3.1 Direct and Indirect Effects

This section describes the direct and indirect effects of Alternative 2 on six important pathways that may affect the health and well-being of the people who live in the study area:

- Diet and nutrition;
- Contamination;
- Safety;
- Acculturative stress;
- Economic impacts; and
- Health care services.

Figure 4.5-2 summarizes the complex relationships between the environmental and social factors that could be impacted by the action alternatives and the factors that comprise health and well-being in the affected communities.

Diet and Nutrition

Changes in diet and nutrition are common potential effects of oil and gas exploration activities where there are populations that rely on subsistence resources. These changes can lead to a number of important public health outcomes.

For indigenous populations, a traditional diet has been shown to be strongly protective against chronic diseases. The traditional diet in Alaska is associated with reduced risk of chronic diseases such as diabetes, high blood pressure, high cholesterol, heart disease, stroke, depression and arthritis (Chan et al. 2006, Dewailly et al. 2001, Dewailly et al. 2002, Din et al. 2004, ADHSS 2005, Murphy et al. 1995, Ebbesson et al. 2007, Reynolds et al. 2006, Murphy et al. 1995, Adler et al. 1994, Adler et al. 1996, Ebbesson et al. 1999).

Decreasing intake from subsistence diets is usually associated with an increased reliance on store-bought foods. Some studies have shown that the nutritional value of store-food available in rural Alaskan villages tends to be low (high in saturated fat, sugar and salt), and that the cost of buying nutrition-dense food (such as fruits, vegetables and whole grains) is often prohibitively expensive (Bersamin and Luick 2006). The result is that when subsistence resources become unavailable and people rely more heavily on store-bought foods to replace traditional sources, the nutritional value of the diet decreases, and the risk of developing problems such as diabetes increases (Murphy et al. 1997, Young et al. 1992, Bjerregaard et al. 2004). Therefore, any change away from a subsistence diet is likely to cause an increase in metabolic disorders such as obesity, heart disease, and diabetes.

Food insecurity is another potential outcome associated with a shift away from subsistence diets. Food insecurity refers to an inability to secure sufficient healthy food for a family. Studies of food insecurity and health have found a variety of detrimental health impacts including overweight/obesity, poor psychological functioning among children, poor cardiovascular health outcomes, and lower physical and mental health ratings (Olson 1999, Stuff et al. 2004, Seligman et al. 2010). The high cost of store-bought food, the costs associated with harvesting of subsistence resources, and the year-to-year variation in subsistence resource availability is all implicated in high rates of food insecurity in many northern indigenous populations.

As described in Section 3.3.3.5, the reliance on subsistence foods is very high in the NSB. In the 2010 NSB census, between 44 and 67 percent of households indicated that they get at least half of their meals from subsistence sources, and virtually all Iñupiat households reported relying on subsistence resources to some extent (Circumpolar Research Associates 2010). As described in Section 4.5.3.2 (Subsistence), in Kotzebue and Kivalina an estimated 78 to 95 percent of households actually harvest subsistence foods and 100 percent of households use subsistence foods. As described in Chapter 3, rates of obesity, diabetes and heart disease–all outcomes associated with dietary changes towards less-healthy foods—have been rising rapidly in the study area over the last several decades. This combination of a high reliance on subsistence foods and metabolic changes in the population means that changes to the availability or quality of subsistence resources could have severe detrimental impacts on nutritional health outcomes and food insecurity for the local population. A compensating factor is that the wide variety of traditional food sources has provided most communities with the ability to adapt to transient changes in availability of single species. This has historically helped temper the dietary and nutritional impact of year-to-year variability in the success of the hunt.

Summary

Activity levels pursuant to Alternative 2 are not expected to have a significant impact on the numbers of marine mammals harvested in any community in the study area, as discussed in Section 4.5.3.2. Although dispersion of some animals may result in greater travel time and cost, the overall availability and subsequent consumption levels of traditional foods is not expected to change. Therefore, changes in diet and health outcomes resulting from decreased subsistence availability are not anticipated.

The potential for diet and nutrition to be affected via increased income to hunters is discussed below under *Economic Impacts*. The potential for diet and nutrition to be affected via perceived safety of subsistence foods is discussed below under *Contamination*.

Contamination

Offshore oil and gas activity has the potential to produce a number of environmental contaminants that may be harmful to human health. These include polycyclic aromatic hydrocarbons (PAHs) such as benzene, toluene, ethylbenzene, and xylene, and heavy metals such as arsenic, lead, cadmium and mercury. Chronic exposure to these substances can increase the risk of cancer and may have other effects on the respiratory, pulmonary, gastrointestinal, renal, or dermatologic systems (ATSDR 2009).

Whether any health effects manifest from exposure to environmental contaminants depends on several factors, including the nature of the contaminant, the amount and duration of exposure, and the sensitivity of the person who comes in contact with the contaminant. In the case of the NSB and NAB communities, exposure could occur through the consumption of contaminated subsistence food sources.

A number of studies have examined the current contaminant load in marine mammal species used for subsistence purposes in the North Slope communities, including bowhead whales, beluga whales, seals, walrus and polar bear. The range of contaminants examined has included polychlorinated biphenyls (PCBs); dichlorodiphenyltrichloroethane (DDT); heavy metals; organochlorines, including chlordanes; and PAHs.

Elevated levels of contaminants were found in several of these species (Becker 2000). However, the levels found in subsistence foods in the North Slope area appear at present to be generally low compared with other Arctic areas (NSB 2006). Bowhead whales in particular appear to have contaminant levels lower than those found in other whale species (USDC 2008). The current levels of contaminants in subsistence foods in the North Slope area are lower than what would trigger public health concern (NSB 2006) and "do not represent a threat to the health of subsistence users at current levels" (USDC 2008, Wetzel et al. 2008).

Aside from actual exposure to environmental contamination, the *perception* of exposure to contamination is also linked with known health consequences. Perception of contamination causes stress and anxiety about the safety of subsistence foods and avoidance of subsistence food sources (CEAA 2010, Loring et al. 2010), which may result in changes in nutrition-related diseases. It is important to note that these health results arise regardless of whether or not there is any "real" contamination at a level that could induce toxicological effects in humans; the effects are linked to the perception of contamination, rather than to measured levels.

However, many Iñupiat residents of the NSB have reported that they are concerned that current and/or future oil and gas activities could increase contaminant loads of subsistence foods to a level that would threaten human health (Poppel et al. 2007). Concerns center around accidental oil spills, persistent leaks, and poor waste management practices. In a recent survey, 44 percent of Iñupiat village residents outside of Barrow reported concern that fish and animals may be unsafe to eat (Poppel et al. 2007). Residents have also indicated that they believe that established contaminant thresholds developed by regulatory bodies do not take into consideration the large amounts of fish or game consumed by the Iñupiat but rather were developed based on the consumption levels of the general population (BLM 2005).

Summary

Current levels of contamination in subsistence food sources are low. As described in Section 4.5.3.2, the permitted discharges associated with Alternative 2 are likely to result in only a minor change in the availability of subsistence resources, although the predicted contaminant load of marine mammals, fish, and seabirds is not discussed. Except in the event of a very large oil spill (discussed in Section 4.10), there are likely to be only negligible to minor health effects from contamination of food sources as a result of the activities associated with Alternative 2.

However, even at the current low levels of contaminants, perception of contamination is widespread in the EIS project area. The level and nature of the activity specified under Alternative 2 may add to this perception. Although any anticipated change in risk perception will likely be below the threshold required to see measurable changes in health outcomes, ongoing oil and gas exploration activity has the potential to reduce confidence in subsistence resources and subsequent consumption. The potential for these impacts is addressed in the cumulative impact assessment in Section 4.10.

Acculturative Stress

Acculturation is a commonly used concept to describe the psychological and cultural impacts of rapid modernization and loss of tradition. Studies have found rapid cultural change to be linked to a wide variety of health outcomes, ranging from impaired mental health and social pathology (such as substance abuse, violence and suicide) to cardiovascular disease and diabetes (Curtis et al. 2005, Bjerregaard 2001, Shephard and Rode 1996). While acculturation can affect any population experiencing rapid change, it is a particularly common problem in indigenous populations, including the Iñupiat, other Arctic populations such as the Inuit, and aboriginal populations in Australia (Inuit Tapirisat of Canada 2000, Smylie 2009).

The specific health impacts of acculturation in the Iñupiat are well documented; for example, the shift away from a nutrient-rich traditional diet and towards store bought and western foods is associated with cardiovascular risk and obesity (Curtis et al. 2005). Similarly, the transition from a traditional to a wage economy and lifestyle may play a role in cardiovascular disease and diabetes in part due to the associated decrease in physical activity (Murphy et al. 1992, Ebbesson et al. 1998, Jørgensen et al. 2002). However, equally if not more important is the loss of the sociocultural value of subsistence: traditional foods are highly valued among circumpolar populations, as they are considered to be “healthy and provide strength, warmth and energy in ways that store-bought food do not” (Arctic Climate Impact Assessment 2004). Subsistence foods contribute to cultural identity, tradition, and social cohesion. The enjoyment of traditional foods is seen to be of equal cultural value to speaking the native language (Kleivan 1996, Searles 2002).

Identity and involvement in cultural activities provide numerous benefits to Alaska Natives: improved self-esteem (Zimmerman et al. 1996); enhanced resiliency in harsh life circumstances (Belcourt-Dittloff 2006, Walters and Simoni 2002); and diminished feelings of historical loss (Whitbeck et al. 2004). Participation in American Indian traditional activities has been found to be protective against substance use problems and risk (Herman-Stahl et al. 2002, Lysne 2002, Winterowd et al. 2005) and suicide attempts (Garroutte et al. 2003, Lester 1999). Evidence suggests that focusing on culture to promote health and prevent disease in Arctic communities may provide value (Curtis et al. 2005); indeed, health promotion professionals often promote traditional culture as a population health intervention.

The importance of Iñupiat participation in subsistence activities and consumption of subsistence foods extends beyond their nutritional and dietary importance: the hunt and consumption of subsistence foods involve cultural, traditional, and spiritual activities that involve the entire community. Of particular importance among subsistence activities is the bowhead whale hunt. The Iñupiat have hunted the bowhead whale for over 2,000 years (Stoker and Krupnik 1993), and the whale hunt continues as a cornerstone of diet, social organization, and cultural survival (Brower et al. 1998, Michie 1979).

Oil and gas exploration in the Arctic, and the rapid modernization associated with the development of this resource, has led to many of these symptoms being observed in the NSB and similar communities (Ahtuangaruak 2003, BLM 2004). In *Gift of the Whale*, Bill Hess highlights an unsuccessful bowhead hunt in 1982 (Hess 1999). The news that no whales had been caught for the season was “greeted with frustration and anger”, whereas during years with a good hunt, social problems were described to virtually disappear. These sentiments, and the resulting social pathologies, are shared by this public testimony:

> *We had seismic activity in Camden Bay that caused us to lose two whaling boats. We did not harvest whale two seasons in a row. We went without whale those winters. Those were the deepest, darkest winters I faced as a community health aide. We saw an increase to the social ills, we saw domestic violence, we saw drug and alcohol abuse, we saw all the bad things that come when we are not able to maintain our traditional life activities.* (BLM 2004)

In the NSB, whaling is seen as a “physical, emotional, and spiritual experience” which provides self-confidence and unites the communities (Brower et al. 1998). A report analyzing potential restrictions on the bowhead hunt described that the bowhead hunt held particular importance to this culture and found that where societal changes had weakened cultural ties, particularly in younger Iñupiat, whaling had "revitalized interest in traditional culture" among this age group (Hankins 1990). Traditional skills are passed on to younger generations, and traditional social structure and the Iñupiat cultural identity are reinforced (Worl 1979, Braund and Associates 1997). The whale hunt is "one of the greatest concentrations of community-wide effort and time" (USDC 2008). Most of the village is involved in some part of the whale hunt, and the proceeds are shared and enjoyed in feasts and celebrations. Where in many aspects of Iñupiat life cultural changes have taken place at the expense of tradition, the whale hunt remains "key to the survival of [Iñupiat] culture" (Brower et al. 1998).

Although acculturative stress is a concern among the Iñupiat, the strength of traditional culture and local institutions, and in particular the value and stability of the bowhead hunt, provide a strongly protective effect against the health impacts of acculturation.

Summary

The communities that will be most impacted by industrial activity (crew changes and staging for offshore exploration) are Deadhorse and Barrow. Deadhorse is an enclave development specifically built for industrial use. Consequently, increased activity in Deadhorse associated with Alternative 2 will have no impact on health as a result of acculturative stress. Similarly, Barrow is accustomed to a transient and non-indigenous workforce and a wage economy. The small increase in activity level associated with Alternative 2 is unlikely to result in a significant change in acculturative stress in Barrow and will not cause measurable changes in health in the community.

The use of Wainwright as a staging site for activity within the Chukchi Sea is likely to result in some acculturative stress, given the community's smaller size and more traditional nature. It is unlikely, however, that this stress will be great enough to cause measurable health impacts.

The greatest risk to the Iñupiat with regard to the health impacts of acculturative stress would arise from a major and persistent decline in the success of the bowhead hunt in any single community. This is not an anticipated result of the activity levels associated with Alternative 2, and, thus, the anticipated health impacts remain negligible.

Safety

In indigenous populations in Alaska and across North America the rate of accidents and trauma is very high (ANTHC 2008; Day et al. 2006). This is particularly true in the Arctic populations of Alaska and Canada and is reflected in the statistics for hospitalizations and deaths from injuries (McAninch 2010). A large part of this burden is a result of the risks inherent to subsistence activities in an often hostile environment. Not surprisingly, the indigenous people of the Arctic have a strong concern for safety.

For the Iñupiat, harvesting of marine mammals requires travel in small open boats in the Beaufort and Chukchi seas, camping at the edge of shorefast ice, and travel by snow machines and sleds across sea ice. Local history provides numerous examples of both fatal accidents and near misses, the details of which are recounted and dissected to provide warnings and lessons for other hunters. Weather and ice conditions are constant topics of discussion. Traditional knowledge provides the base for interpretation of current conditions and risks and allows for adaptation and responses to help mitigate or avoid the dangers associated with subsistence activities.

Some hunters are concerned that safety has already been compromised by climate change and offshore exploration activity. Shorefast ice is less predictable in recent years (George C. 2011) and may be associated with an increased risk of break-offs (USDC 2008). Anecdotal reports suggest that hunters believe that offshore seismic activity has already caused deflection of whales from their migratory paths, requiring them to travel further to successfully complete an open water hunt. This could lead to a greater risk of hazardous open water incidents. For example, unfavorable weather conditions could suddenly arise while a crew is far offshore.

Icebreaking activity could result in the isolation of hunting groups or weakening of ice for those traveling over the sea ice to hunting areas (Brubaker et al. 2011). *Changes in ice quality secondary to icebreaker travel would most likely impact communities during the early winter hunts for seals and polar bears. Icebreaking activity close to shore or to and from staging areas is of particular concern as it has the highest likelihood to intersect travel routes of local hunters.*

Injury and trauma will continue to be a significant public health concern, tempered primarily by the strong local search and rescue capacity, traditional knowledge and communication between hunters.

Summary

The main contributor to public safety impacts arising from Alternative 2 is the potential for water and ice safety issues during hunts. Water safety will be compromised should the dispersion of marine mammals occur, which will result in longer and riskier travel for subsistence activities.

Open water hunts for bowhead in the fall (occurring in Barrow, Kaktovik, Nuiqsut, and Wainwright) are likely to carry the greatest risk, along with greater travel for hunters in Point Lay if beluga are significantly dispersed from the lagoons.

The primary concern with regard to ice safety is if icebreaking activities were to result in disruption of sea access for winter hunting. Early winter hunting for seals and polar bears in areas of icebreaking could cause some increased risk, particularly during travel to and from hunting grounds. The limited amount of icebreaking activity and the separation of icebreaking from traditional hunting will minimize this risk, and the overall risk can be classified as minor. Additionally, the use of Com Centers will reduce this risk.

Economic Impacts

Industrial development often impacts population health through changes to the economic environment. Income and employment are fundamental determinants of health (Cox et al. 2004). Increased income directly or indirectly resulting from oil and gas activity has the potential to reduce impacts to health in affected communities by raising the standard of living, reducing stress, and providing opportunities for personal growth and social relationships (ACPH 1999). Income and employment may also strengthen community and cultural ties by providing money to fund subsistence activities, the health effects of which are described above. Conversely, low income increases risk of low birth weight babies, injuries, violence, most cancers, and chronic conditions (Yen and Syme 1999), and unemployment is associated with increased stress, depression, and anxiety, which are known contributors to cardiovascular disease (Doyle et al. 2005).

However, income and employment can also result in increased prevalence of social pathologies in some populations, including substance abuse, assault, domestic violence, as well as unintentional and intentional injuries. Fraternization of high-wage migratory workers with the local communities also has a tendency to increase rates of sexually transmitted infections in small communities (Goldenberg et al. 2008).

At present, most industrial activity in the study area has followed a model of enclave development with transient workers housed in camps in Deadhorse. Barrow provides most government and service jobs and has a mixed economy with a combination of wage employment and subsistence activities. Outside of Barrow, most communities have a fairly traditional economy; although some communities have expressed a desire to see an increase in investment and jobs.

Although the rate of sexually transmitted infections in the NSB is high, the current focus on enclave development and isolation of most communities from transient workers is likely protective against exacerbation of these rates. Additionally, some Alaskan data support the argument that with strong social and political systems, income can be channeled to provide positive influences for a community, such as increased access to health care and educational opportunities (Haley 2004).

Summary

The economic benefits resulting from Alternative 2 are not great enough to anticipate measurable changes in health status at either the individual or community level and should be classified as negligible. Similarly, the adverse impacts of increased cash in a community (typically manifesting as the social pathologies described in Chapter 3) are not anticipated to result from the activity levels of Alternative 2.

The presence of transient workers in Wainwright may result in some increase in alcohol and drug use or sexually transmitted infections if transit times through the community are prolonged and fraternization with locals is allowed.

Health Care Services

Resource development projects around the world have demonstrated the potential for increased demand on local health and social services when workers migrate to an area or when the local burden of disease changes (Utzinger et al. 2004, Calain 2008, Barron et al. 2010). An influx of resource development workers into an area can strain local health resources for trauma, injuries, and illness. Resource development projects may also directly or indirectly cause the increase of certain conditions, including alcohol/drug-related issues, social pathology and increased rates of infectious disease (Utzinger et al. 2004, Goldenberg et al. 2008, Barron et al. 2010). If this increased demand exceeds the capacity of local services, then community health may be affected by reduced access to, and quality of, available health and social services (Calain 2008, Barron et al. 2010). However, resource development projects in some instances can improve local service provision in remote communities by providing additional tax revenue to local government (Calain 2008, Barron et al. 2010).

Outside of Barrow, healthcare provision in NSB communities is limited and has little capacity to deal with increased demand. Daily care and emergency services are provided by Health Care Aides, and patients must either travel to see a physician or wait for a regularly scheduled physician visit. Acute injuries and trauma require local stabilization and air transfer to Barrow. These villages have little to no capacity to respond to increased demand or medical incidents. Barrow, which acts as the referral center for the NSB communities, has more adaptability and ability to respond should increase demand or an emergency occur (ASNA 2010). Search and rescue capacity, based out of Barrow, is strong.

Summary

Tax revenues from increased exploration activity in Alternative 2 may bolster the provision of health care services in the NSB; however, the impact would be negligible and would not be expected to result in any measurable change in population health outcomes. Acute care and search and rescue capacity in Barrow will be able to absorb any increase in demand that could be expected to result from illness and injury related to activity levels in Alternative 2.

Staging of crews in Wainwright could stress the limited resources of the local clinic, particularly if transit times through the community are prolonged, thereby potentially allowing for the spread of infectious disease. However, the most common way in which oil and gas crews interact with local health care facilities is as a result of injury, and the centralization of search and rescue operations in Barrow will minimize the impact on Wainwright's health care facilities.

4.5.3.3.2 Conclusion

The following table summarizes the public health and safety effects of Alternative 2. The definitions and rationale for each of the five criteria used can be found in Section 4.1.3 of this document.

Table 4.5-28 Summary of Effects on Public Health and Safety from Alternative 2

Impact Criterion	Effects Summary
Magnitude or intensity	Low: above background conditions, but within normal variation of human health conditions
Duration	Permanent: changes in health indicators persist after actions that caused the impacts cease
Geographic Extent	Regional: affects two or more communities in the EIS project area
Context	Unique: affects minority or low-income communities

Both potential beneficial and adverse impacts are anticipated as a result of Alternative 2. Possible changes could occur to health outcomes such as chronic disease and trauma and many of the pathways relate to traditional practices and subsistence activities. However, there is a very low likelihood of these health outcomes arising, and effects are unlikely to be large enough cause a measurable change in health outcomes. The magnitude or intensity of effects is estimated to be low: above background conditions, but small and within both the natural variation and adaptive ability of the local population. If health changes do occur, the duration of changes may be permanent, and multiple communities could be affected.

4.5.3.4 Cultural Resources

This section describes potential impacts to cultural resources from each of the alternatives described in Chapter 2. The information presented below has been derived from a review of records on file with the Alaska Office of History and Archeology, which document previously recorded archaeological sites and the results of previous archaeological inventory efforts conducted within the vicinity of the EIS project area. These records largely concern on-shore resources. An appropriate level of investigation, including intensive on-shore and offshore surveys; evaluations of all resources potentially eligible for listing on the National Register of Historic Places; assessments of adverse effects; and applicable mitigation of identified impacts, would be completed before any potentially destructive activities could begin.

Activities associated with lease operations (exploratory drilling and site clearance high resolution seismic surveys) will only occur on active leases, along potential pipeline corridors, and on leases acquired in future lease sales (both federal and state). Seismic surveys not specifically associated with a lease (i.e. 2D and 3D surveys) would occur over large areas within the EIS project area, and could occur either on- or off-lease. Active State of Alaska leases occur in the Beaufort Sea from the coastline out to three nautical miles, except in the areas of Harrison Bay and Smith Bay, which are considered historical bays thus extending the area beyond three nautical miles from the coastline. Most of the State's active leases are concentrated between Harrison Bay and Bullen Point. There are currently no State of Alaska leases in the Chukchi Sea. As of May 2011, the State has 360,435 acres on 189 leases in the Beaufort Sea. Exploratory activities (drilling and seismic surveys) could occur in any of these active state leases. The State of Alaska plans to conduct area-wide lease sales in the Beaufort Sea annually through 2017 (ADNR 2013), potentially adding new areas where exploratory activities could occur. Industry activities on State of Alaska Beaufort Sea leases in the recent past have largely been concentrated offshore between Harrison Bay and Bullen Point.

Exploratory activities will include 2D and 3D seismic surveys, site clearance and high resolution shallow hazards survey, on-ice seismic surveys in the Beaufort Sea, exploratory drilling located in offshore portions of the Beaufort Sea, and exploratory drilling in the Chukchi Sea.

Seismic surveys and clearance and hazards surveys are conducted using towed arrays, in-ice arrays, and ocean-bottom cable (OBC) or ocean bottom node (OBN) seismic surveys. OBC and OBN surveys are used primarily to acquire seismic data in transition zones where water is too shallow for a towed marine streamer seismic survey vessel and too deep to have grounded ice in the winter. An OBC operation begins by laying cables off the back of a layout boat, using cable lengths of 4 to 6 km (2.5 to 3.7 mi) but occasionally up to 12 km (7.5 mi). Seismic-survey receivers (a combination of both hydrophones and vertical-motion geophones) are attached to the cable in intervals of 12 to 50 m (39 to 164 ft). Multiple cables are laid on the seafloor parallel to each other, with a cable spacing of between hundreds of meters to several kilometers, depending on the geophysical objective of the seismic survey. When the cable is in place, a vessel towing the source array passes over the cables with the source being activated every 25 m (82 ft). The source array may be a single or dual array of multiple airguns, which is similar to the 3D marine seismic survey. Laying an array of cables on the seabed could potentially adversely affect surface cultural resources, if any exist in that location.

Towed arrays or in-ice arrays demonstrate little or no potential to damage offshore archaeological resources. OBC and OBN seismic surveys could potentially impact both prehistoric and historic archaeological resources, because the cables or receivers are placed on the seafloor instead of towed behind a survey vessel.

Three principal forms of exploratory drilling platforms are currently used in offshore exploration: artificial or natural islands; bottom-founded structures; and floating vessels. Exploratory wells are generally drilled vertically to simplify well design and maximize benefits from subsurface data collection (i.e. well logs, cores). Directional wells (any well that is not vertical) may be drilled if a suitable surface location cannot be used or if there is a subsurface anomaly that should be avoided. Like seafloor seismic surveys, exploratory drilling potentially could impact both prehistoric and historic archaeological resources.

The level of impacts on cultural resources will be based on levels of intensity, duration, geographic extent, and context, as shown in Table 4.5-29.

Table 4.5-29 Impact Levels for Effects on Cultural Resources

Impact Component	Effects Summary		
Magnitude or Intensity	**Low**: Disturbances in cultural resources may not be measurable or noticeable	**Medium**: Noticeable disturbances in cultural resources	**High**: Acute or obvious disturbance in cultural resources
Duration	**Temporary**: Disturbances in cultural resources last less than one year	**Long-term**: Disturbances in cultural resources extend up to several years	**Permanent**: Disturbances in cultural resources persist after actions that caused the impacts cease
Geographic Extent	**Local**: Affects cultural resources only locally	**Regional**: Affects cultural resources on a regional scale	**State-wide**: Affects cultural resources beyond a regional scale
Context	**Common**: Affects usual or ordinary resources; not depleted or protected by legislation	**Important**: Affects depleted resources within the locality or region or resources protected by legislation	**Unique**: Affects unique resources or resources protected by legislation

4.5.3.4.1 Direct and Indirect Effects

Nearly all potential direct physical impacts to cultural resources would occur during the exploratory and construction phases of project activities. Cables for towing seismic arrays on the seafloor would disturb cultural resources on the surface of the seafloor, and any coring could affect buried archaeological sites (including geomorphological features) and palaentological resources. There could also be impacts resulting from ground-disturbing activities that encounter additional cultural materials that, based on previous archaeological studies, were either thought to occur only at the surface (on-shore resources) or were previously undetected because they were completely buried (onshore and offshore resources). Improved access to remote on-shore areas could also increase the likelihood of looting or other damage to archaeological properties during the construction and operation phases of the project. Another impact that could occur from construction of on-shore project facilities would be visual intrusion effects to potential traditional cultural properties.

Direct effects to archaeological resources include those activities that physically impact the condition or integrity of the resource. Sea-floor based seismic activities and exploratory drilling could directly affect submerged prehistoric sites or historic vessels on the seafloor.

Indirect effects to offshore resources are unlikely, given that impacts would likely result during the exploratory phase of the project. Previously undiscovered resources, however, could be inadvertently damaged during this phase of the project. On-shore resources are more susceptible to indirect effects and can include inadvertent damage, looting caused by the introduction of increased access and local activity; and visual impacts to historic or traditional cultural properties.

4.5.3.4.2 Conclusion

Compliance with existing federal, state, and local archaeological regulations and policies and the application of 30 CFR 550.194 regarding the protection of archaeological resources and 30 CFR 551.6 (a)(5) regarding G&G Explorations of the Outer Continental Shelf and the provision to avoid disturbing archaeological resources, will reduce or eliminate most impacts to archaeological resources. Therefore, no impacts or only negligible impacts to archaeological resources are anticipated. To ensure compliance, prior to exploratory drilling of a well, lessees may be required to conduct surveys to detect archaeological resources. Lessees may also be required to conduct analyses and/or provide reports if proposed activities are of the type that have the potential to cause effects on historic properties. These surveys may be collected over portions of individual lease blocks or several contiguous lease blocks depending on the likelihood that historic or prehistoric resources may be present. These surveys would typically need to be completed at least one season in advance of a drilling operation. Alternatively, since it is difficult to assess effects in the absence of information, federal agencies may request archaeological reports of contiguous seismic areas or post-seismic archaeological reports rather than completion of a survey in advance of a drilling operation. Companies may also use high resolution geophysical equipment to survey off-lease areas for possible subsea pipeline routes. As a result of these studies, many submerged archaeological resources can be identified prior to seafloor disturbing activities and resources can be avoided.

Direct and indirect impacts to cultural resources resulting from the implementation of Alternative 2 would be low-intensity and long-term in duration, but in a very localized area and affecting resources that are common in context. Therefore, the summary impact level of Alternative 2 on cultural resources would be considered negligible.

4.5.3.5 Land and Water Ownership, Use, and Management

The level of impacts on land and water ownership, use, and management will be based on levels of intensity, duration, geographic extent, and context, identified in Table 4.4-2 (Alternative 1).

4.5.3.5.1 Direct and Indirect Effects Land and Water Ownership

Federal Ownership

Because federal processes involved in seismic exploration and exploratory drilling (see Section 2.3.1) utilize leases and do not result in any change in existing leasing rights or the sale or transfer of any federal land or waters, no direct or indirect change in underlying land or water ownership is anticipated. This includes federal waters (from 3 to 200 nm), the Arctic National Wildlife Refuge (ANWR), the National Petroleum Reserve-Alaska (NPR-A), Alaska Maritime National Wildlife Refuge, and Cape Krusenstern National Monument. Additional conditions may be attached to federal exploration activity authorizations and permits to avoid or mitigate adverse effects.

State Ownership

Because state processes involved in seismic exploration and exploratory drilling (see Section 2.3.1) utilize leases and do not result in any change in existing leasing rights, or the sale or transfer of any state land or waters, no direct or indirect change in underlying land or water ownership is anticipated. This includes state waters (shore to the 3 nm limit), state lands, and state selected lands. State land selections have already been established, and their conveyance is not influenced by the implementation of this project alternative.

Private Ownership

Because the project does not involve any ANCSA corporation lands or Alaska Native allotments, no direct change in land ownership is expected. Support activities are anticipated to use existing facilities or new facilities built on private lands; however, no foreseeable indirect effects on land ownership will result. This private ownership includes Native corporation lands (village and regional [with some selections still under the ownership of the federal government]), and Native allotments. Alaska Native Corporation land selections have already been established, and their conveyance is not influenced by the implementation of this project alternative.

Borough and other Municipal Lands

Because the project does not involve or facilitate the sale or transfer of borough or municipal lands, no direct change in underlying municipal land or water ownership is expected. Likewise, since support activities are anticipated to use existing facilities or new facilities constructed on private lands, no foreseeable indirect effects on land ownership will result. This includes lands owned by the NSB and the NAB. No change in ownership is anticipated for any other municipal lands. Municipal land selections have already been established, and their conveyance is not influenced by the implementation of this project.

4.5.3.5.2 Conclusion

Based on Table 4.4-2, and the analysis provided above, the impacts on land and water ownership under Alternative 2 are described as follows. The magnitude of ownership impacts would be low because no changes in land or water ownership will result from this action. The duration of impact would be temporary because no changes in ownership or development rights will occur. The extent of impacts would be local, occurring only in the activity area and involving no ownership change. The context of impact would be common because the federal waters affected have no special, rare, or unique ownership characteristics. In total, the direct and indirect impacts on land ownership are considered to be negligible;

they would be low intensity, temporary, localized, and result in no change of ownership or development rights.

4.5.3.5.3 Direct and Indirect Effects of Land and Water Use

Recreation

Recreation occurs at generally low levels of use in the EIS project area. Key recreational activities include wildlife viewing and sightseeing from the air. Because seismic exploration is already occurring in the EIS project area, use conflicts would be low, given the low level of recreation activity and existing exploration activities. Direct and indirect impacts on recreation are discussed in detail in Section 4.7.3.7.

Subsistence

Subsistence, which refers to harvest activities involving hunting, fishing, trapping, and gathering as a way of life, is a wide-spread land use throughout the EIS project area. Some seismic activities are already occurring in the EIS project area, utilizing standard mitigations described in Appendix A. Utilization of standard and additional mitigation would reduce the potential land conflicts with subsistence use, and would be considered low. Direct and indirect impacts on subsistence are discussed in detail in Section 4.7.3.2.

Industrial

Under Alternative 2, there is the potential for an increase in crew change and survey preparation activity in some areas as a result of increased ship traffic. If activity under this alternative requires the construction of new facilities such as a dock, warehouse, airstrip or other industrial facilities, zoning may change to accommodate the change in land use, and this is a direct impact. If a smaller community, such as Wainwright where no infrastructure yet exists, requires such construction, impacts would be considered more intense than in an area where such infrastructure is already found, such as Deadhorse, and depending on perspective, beneficial or adverse. Potential impacts would be low to medium, depending on the location. If activities under this alternative do not require new facilities or infrastructure or if only existing facilities are used, no direct impact is expected.

Residential

There is the potential for an increase in the number of crew members and support staff in some areas as a result of the increase in ship traffic. Despite this, residential land use would not be affected because the activities under Alternative 2 are temporary and would not result in any new permanent residents needing housing.

Mining

This alternative would increase offshore exploratory and seismic activity; however the levels or extent of mining operations is not influenced by seismic exploration and would not result in any road construction or other infrastructure that would open new areas to mining. For this reason no direct or indirect impacts are expected to affect mining in the EIS project area.

Protected Natural Lands

An increase in seismic exploration activity under Alternative 2 would have no expected direct or indirect impacts on critical habitat, wilderness areas, or other land used for ecological reasons; the land use is removed from areas of offshore seismic activity and exploratory drilling. The primary potential for land use conflict would be associated with marine vessel and air traffic associated with crew changes and other support activities. Any seismic and exploration activities as part of this alternative would be compatible with current protected land uses and compliant with the way they are currently managed.

Transportation

Under Alternative 2, an increase in aircraft and vessel traffic along the North Slope is expected to and from the North Slope to transport people and supplies to support the survey vessels. If new docks and airstrips are needed to accommodate this increase, rezonings to industrial uses may result, as mentioned above. This increase in air and transportation use would occur primarily in areas that are currently being used for support activities such as Barrow, Deadhorse, Nome, and Dutch Harbor, and would constitute a minor increase in existing use. However, increase in transportation activity in Wainwright could constitute a moderate increase. No new roads or railroad lines are expected to be built under this alternative; therefore no changes are expected in land use to accommodate expanded land transportation systems.

Commercial

Under Alternative 2, an increase in seismic exploration would increase commercial activity associated with support activities. However, potential impacts to commercial land use are expected to be low because it will be temporary in nature, and no new facilities are likely to be built as a result of the project, with the possible exception of Wainwright. See Socioeconomic Section 4.5.3.1 for further discussion on employment opportunities under this alternative.

4.5.3.5.4 Conclusion

Based on Table 4.4-2 and the analysis provided above, the impacts of land and water use caused by Alternative 2 are described as follows. The magnitude of impact would be high where activity occurs in areas of little to no previous activity (such as Wainwright), and the magnitude of impact would be low where activity occurs in areas where previous activity is common (Prudhoe Bay, Barrow, Nome, Dutch Harbor). The duration of impact would be temporary because an increase in aircraft and shipping traffic would last only for that survey season, although the impact could be permanent if construction of a new facility or infrastructure to accommodate shipping traffic were built in Wainwright. The extent of impacts would be local because any changes in land use as a result of this alternative would be limited geographically to the communities that would support the survey vessels. The context of impact would be common because the areas of land and water use affected are extensively available and have no special, rare, or unique characteristics identified. In summary, the direct and indirect effects of Alternative 2 on land and water use would be moderate because of the possibility for high intensity impact and long term structures in smaller communities.

4.5.3.5.5 Direct and Indirect Effects of Land and Water Management

Federal Lands and Water Management

BOEM has awarded leases in the Beaufort and Chukchi seas for the purpose of exploring for and developing petroleum resources in the federal OCS. The level of exploration activity in federal water under this alternative is consistent with management of the OCS. Currently, the U.S. Fish and Wildlife Service is updating the Comprehensive Conservation Plan for the Arctic National Wildlife Refuge, with a final revised plan expected to be released during the summer of 2012 (USFWS 2011b), and the Bureau of Land Management is updating the Integrated Activity Plan/Environmental Impact Analysis for the National Petroleum Reserve-Alaska, with the first draft scheduled for early 2012 (BLM 2011). Because seismic surveys, exploratory drilling and leasing activities have been ongoing in the Beaufort and Chukchi seas for over 30 years, their occurrence is already well established and not newly introduced by this project. Consequently, they are already part of the existing regulatory environment known in the area. However, both documents are in draft form, and there is a chance that the information generated in this EIS could result in additional mitigation measures affecting the management of exploratory drilling activities in the Records of Decision of those documents. Based on this, no inconsistencies or changes in federal land or water management are anticipated to result from this alternative, including federal waters (from 3 to 200 nm), Alaska Maritime National Wildlife Refuge, National Petroleum Reserve-Alaska, and Cape Krusenstern National Monument.

State Lands and Waters Management

The state prepares Best Interest Findings before allowing seismic exploration activities on state lands and waters, and each proposed activity must demonstrate individual consistency with state management policies before permits are issued on state lands or waters. Permitted exploration activities are consistent with the management of state waters. Therefore, no inconsistencies or changes in state land or waters management is anticipated as a result of this alternative. This includes state waters (shore to the 3 nautical mile limit), Area Plans, and lands subject to oil and gas lease sales.

Borough and other Municipal Lands

While the level of exploration activity may increase under this alternative, no change in underlying land or water management is anticipated as a result of this project. This includes community planning, and the NSB and NAB comprehensive plans. The NSB Zoning ordinance (Title 19.70), in particular, includes policies related to offshore development and coastal management. However, compliance with local land management regulations within state and federal waters is undertaken on a voluntary basis. As indicated in Section 3.3.6 Coastal Management, the Alaska Coastal Management Program was not reauthorized by the State legislature and is no longer in effect. The NSB and NAB may recommend mitigation measures and permit/authorization conditions in response to new land based projects proposed within its jurisdiction.

4.5.3.5.6 Conclusion

Based on Table 4.4-2 and the analysis provided above, the impacts on land and water management caused by Alternative 2 are described as follows. The magnitude of impact would be low because the action is consistent with existing management plans, subject to conditions of approval. The duration of impact would be temporary because project activities are short term in duration and would not result in long-term conflicts with management plans. The extent of impacts would be local because proposed activities would not involve management plans beyond the localized areas of exploration and support activities. The context of impact would be common because the areas of land and water affected are extensively available and have no special, rare or unique characteristics identified in an adopted management plan. In total, the direct and indirect impacts of Alternative 2 on land and water management would be negligible because they are low intensity, would be temporary in nature, local, and common.

4.5.3.6 Transportation

The direct and indirect impacts for transportation are described by mode. Activity levels under Alternative 2 for seismic exploration and exploratory drilling in the EIS project area would increase, thereby influencing air, surface, and marine traffic.

The level of impacts on transportation will be based on levels of intensity, duration, geographic extent, and context, as shown in Table 4.5-30.

Table 4.5-30 Impact Levels for Effects on Transportation

Impact Component	Effects Summary		
Magnitude or Intensity	**Low**: change in transportation volume may not be measurable or noticeable	**Medium**: Noticeable change in transportation volume	**High**: Acute or obvious change in transportation volume
Duration	**Temporary**: Changes in transportation volume last less than one year	**Long-term**: Changes in transportation volume extend up to several years	**Permanent**: Changes in transportation volume persist after actions that caused the impacts cease
Geographic Extent	**Local**: Affects transportation volume only locally	**Regional**: Affects transportation volume on a regional scale	**State-wide**: Affects transportation volume beyond a regional scale
Context	**Common**: Affects usual or ordinary transportation opportunities and constraints	**Important**: Affects transportation opportunities and constraints within the locality or region protected by legislation	**Unique**: Affects unique transportation opportunities and constraints

4.5.3.6.1 Direct and Indirect Effects

Air Transportation

The levels of commercial and private aircraft transportation that currently exist within the coastal communities of the project area and the Prudhoe Bay area (including Deadhorse) are likely to continue at existing levels, as described in Section 3.3.7. Air traffic would increase, as associated with the programs listed in Table 2.4 in Chapter 2. The level and pattern of increase would be affected by the number of source and support vessels, the types of sound sources used, time periods when the activity could occur, number of days of active operations, and size of the program activity area. Increased levels of air traffic activity could require construction of new airstrips or hangars/warehouses or modifications to existing facilities.

Exploratory drilling located in offshore portions of the Beaufort Sea would likely occur initially in areas offshore of Camden Bay in the eastern portion of the Beaufort Sea during the initial year of this EIS's analysis window. For Beaufort Sea operations, it is expected that support flights would originate in Barrow, Deadhorse, or Prudhoe Bay. Helicopters stationed at Barrow would provide emergency or search and rescue support (SAR), as needed. Exploratory drilling in the Beaufort Sea is assumed to include the use of helicopters (4 to 12 air operations per week) to provide support for crew changes, provision resupply, and SAR operations for each drilling program. Fixed winged aircraft operating daily out of Barrow or Deadhorse would support marine mammal monitoring and scientific investigations.

Exploratory drilling in the Chukchi Sea would likely occur initially in areas on federal leases for which exploration plans have recently been submitted or expected to be submitted during the timeframe of this EIS, and where there have been recent requests to authorize ancillary activities. For surveys in the Chukchi Sea, air support operations would occur primarily out of Nome but could also occur out of Wainwright and/or Barrow. Exploratory drilling in the Chukchi Sea is assumed to require up to 24 air operations per week, for transit from Wainwright or Barrow to each of the drilling sites. For emergencies, SAR helicopters would operate out of Barrow.

The increased levels of air traffic that result from activities under Alternative 2 are considered to be a direct impact to existing local and regional transportation. Air travel that is necessary to support seismic surveys and exploration drilling programs would be required to comply with the required mitigation measures in order to conduct aerial monitoring for marine mammals and provide flights in support of crew changes, expansion of shore based infrastructure, and for littering supplies to offshore support vessels.

Aircraft overflights associated with oil and gas seismic surveys and exploratory activities would occur in the nearshore areas of the Beaufort and Chukchi seas. Aircraft traffic associated with seismic surveys and exploratory drilling would likely be limited to an area where infrastructure for air traffic/commercial travel already exists (i.e. Prudhoe Bay, Barrow and potentially Wainwright). The levels of aircraft using Prudhoe Bay, Barrow, and Wainwright shore based infrastructure may increase for short durations while offshore seismic survey and exploratory drilling operations are occurring. A limited fleet of industry support aircraft would use existing airport infrastructure and is unlikely to interrupt the patterns of existing air traffic or strain the capacity of existing carriers within the region. It is possible but unlikely that increased aircraft use would require construction of new infrastructure.

Subsistence users have noted that aircraft overflights can disturb subsistence resources making it more difficult for hunters to obtain these resources. Aircraft disturbance in caribou migratory pathways from industry operations and recreational hunters (tourism) near the coast has been observed:

> *We have a lot of air traffic, not just from the oil companies but from tourist stuff going on. Hunters traveling along the coast, too, so we we're having to deal with that on top of the helicopters and stuff doing their routes to Point Thompson already. They're flying in the same migration -- or the times as the migration of the caribou and stuff, and I'd just really hate to see more of it happen because I think it's going to -- the cumulative impact is going to have a great negative impact on our community.* - Carla Sims Kayotuk at the Kaktovik Public Scoping Meeting for this EIS, March 12, 2010.

> *These are our only times during the summer [on calm days] that we have access to hunting caribou that go down to the coast. If activity, support activity, such as aircraft or helicopters or other support activities are near the coast -- and we have many people that can make oral statements that during the summer when they're getting close to caribou, either a small plane or helicopter show up and drive the caribou further inland.* - Fenton Rexford, representing Native Village of Kaktovik at the Kaktovik Public Scoping Meeting for this EIS, March 12, 2010.

Surface Transportation

Increased use of airstrips and docks by aircraft and vessels under Alternative 2 would require ground support to transfer passengers and supplies, refuel aircraft and vessels, or provide other support that would increase vehicle traffic on local roadways. Additionally, increased use of aviation and vessel fuel could result in overland shipments of fuel via trucks on ice roads or by Rolligons.

The on-ice seismic survey that would be permitted under this alternative would likely require the construction of ice roads for surface transportation. Transportation of supplies and crews would occur via winter ice roads and are expected to originate from the Prudhoe Bay area. Therefore, there would be no direct or indirect impact from aircraft overflights in the winter. Construction of ice roads and equipment traveling the roads could disturb marine mammals during January to May exploration activities.

Marine Transportation

The levels of local marine vessel traffic are expected to continue at their present rate, as described in Section 3.3.7. This includes localized small vessel, tug, and barge traffic between the communities located near the Beaufort and Chukchi seas. Vessel traffic in nearshore coastal waterways encompasses sealift and tug/barge traffic to and from the Prudhoe Bay area, and through the eastern Beaufort Sea towards Canada. Activities proposed under Alternative 2 would result in an increase in the present levels of vessel traffic in the nearshore waters and in the offshore areas of the Beaufort and Chukchi seas.

It is assumed that marine-based support for 2D/3D seismic surveys, shallow hazard surveys, and support vessel traffic would increase, and Beaufort Sea operations would originate from the West Dock area, or Oliktok Dock near Prudhoe Bay. For 2D/3D seismic surveys in the Chukchi Sea, vessel-support operations, including crew changes, would occur primarily out of Nome, and possibly Barrow or Wainwright as well. Increased vessel activity could result in the need for new or improved docks and other marine related infrastructure along the coast.

Chase/monitoring vessels would provide transport for crew changes and resupply, as well as for acoustic study and marine mammal monitoring support. They would also assist in ice management operations if required. These vessels would not introduce sounds into the water beyond those associated with standard vessel operations. These activities could occur several times during a season, involving transit to onshore support areas.

Vessel traffic associated with exploratory drilling in offshore portions of the Beaufort Sea would likely occur initially in areas offshore of Camden Bay in the eastern portion of the Beaufort Sea during the initial year of this EIS' analysis window. Table 2.4 (Chapter 2) outlines specifics associated with these activities. Assumptions of increased vessel traffic related to exploratory drilling in the Beaufort Sea are as follows:

- For each exploratory drilling program, a drillship or conical drilling unit (CDS) with up to 11 support vessels would be deployed that would be used for ice management, anchor handling, oil spill response, refueling, resupply, and servicing the drilling operations. The ice management vessels will consist of an icebreaker and anchor handler.
- At the start of the program, the drillship or CDS and support vessels would transit the Bering Strait into the Chukchi Sea, and then transit further on to the Beaufort Sea drill site(s). Vessels could transit from marine bases in the Canadian Beaufort Sea (e.g. Tuktoyaktuk) or Russian Arctic.
- Timing of operations would commence on or after approximately July 1 and typically end by early November.
- Drilling could occur on multiple drill sites per drilling program per year with the analysis assumption being up to three wells drilled per program per year.
- Resupply vessels would operate from both Dutch Harbor (using ocean going vessels) and West Dock at Prudhoe Bay using a coastwise qualified vessel. Ten resupply trips per drilling program are estimated.
- At the end of the drilling season, the drillship or CDS (under tow) and associated support vessels will exit the area by traveling west into and through the Chukchi Sea. As an alternative, the CDS, if used, could be towed to the Canadian Beaufort for the winter.

Under Alternative 2 the exploratory drilling programs in the Chukchi Sea would likely occur initially in areas on federal leases for which exploration plans have recently been submitted and where there have been recent requests to approve ancillary activities. Table 2.4 (Chapter 2) outlines specifics associated with these activities. Assumptions for vessels associated with the exploratory drilling in the Chukchi Sea would include:

- For each exploratory drilling program, a drillship or jackup rig with six to eight support vessels would be deployed. Support vessels would be used for ice management, anchor handling, oil spill response, refueling, resupply, and servicing the drilling operations. The ice management vessels would consist of an icebreaker and anchor handler. Oil spill response vessels would be staged near the drillship or jackup rig. The icebreaker and anchor handler would be staged away from the drill site when not in use but would move closer to perform duties when needed.

- Drillship and support vessels would be deployed on or about July 1, traveling from Dutch Harbor, Alaska, through the Bering Sea, or from the east through the Beaufort Sea from marine bases in the Canadian Beaufort Sea (e.g. Tuktoyaktuk), arriving on location in the Chukchi Sea in early July.
- Timing of drilling operations would commence soon after arriving at the drill site in early July and typically end by early November.
- Drilling could occur on multiple drill sites with up to four wells drilled per drilling program per year.
- Marine resupply vessels would operate between the drill sites and Dutch Harbor or Wainwright. Ten resupply trips per drilling program are estimated.
- At the end of the drilling season, the drillship or jackup rig, and associated support vessels will transit south out of the Chukchi Sea.

Marine vessel traffic has been noted by residents to impact subsistence bowhead hunters as a result of whales being deflected from the area, thereby limiting potential strike opportunities for subsistence harvest. Subsistence bowhead hunters voiced concern during the scoping process for this EIS that impacts of increased vessel traffic, and regulating vessel traffic, be a part of mitigation. This is so that interference from vessel traffic does not disturb hunting activities. A North Slope resident noted that past and existing levels of barge traffic have led to disturbance:

> *I've seen barge activity that's over the past 15 years diverted bowhead whales. As a whaler, I've seen it all my life.* As commented by Thomas Napageak, Jr. at the Nuiqsut Public Scoping Meeting for this EIS, March 11, 2010.

Shipping routes through the Bering Straits and into the Beaufort and Chukchi seas are similar to the routes of migratory marine mammals. There is a remote possibility that vessel collisions that result in the death or serious injury of marine mammals could occur as a result of increased vessel traffic in the project area. At present there are relatively few known incidents of Arctic or ice-adapted marine mammal species being involved in ship strikes (Arctic Council 2009). The relatively infrequent occurrence is likely a result of low vessel traffic in high latitudes as compared to major trading routes and human population centers in lower latitudes (Arctic Council 2009). However, an increase in the number of ships transiting the Bering Straits (considered a bottleneck for Arctic shipping routes) could be expected to increase the likelihood of ship strikes.

4.5.3.6.2 Conclusion

Under Alternative 2 there would be an increase in the levels of air traffic in the regional air transportation system. However, the increase in the levels of air traffic to regional transportation would be of low intensity, and the duration would be temporary (length of survey or exploratory drilling activities each year). The impacts would be local in extent and affect resources that are considered common in context. As a result, the impact of increased aircraft traffic by implementing Alternative 2 would be considered negligible.

Only one on-ice seismic survey would be permitted in the Beaufort Sea under this alternative. While surface travel via snowmachine is a method of transportation during the winter months, it is unlikely that there would be a direct impact to surface transportation routes between coastal communities as the on-ice survey would occur in a very local area. Impacts to surface transportation via ice roads would be characterized as a low intensity, limited in spatial extent, temporary effect on a resource that is common in context. Increased vehicle traffic on local roadways would also be characterized as temporary, and affecting a resource that is common in context. The impact is considered negligible.

The increase in vessel traffic as a result of seismic and exploratory drilling operations as a result of implementation of Alternative 2 would be a direct impact to the existing levels of vessel traffic in the Beaufort and Chukchi seas. Considering the required and additional mitigation measures, direct impacts from increased vessel traffic in these seas would be temporary and occur regionally. The intensity of increased marine vessel traffic is considered low, as it would be temporary in duration, local in extent, and common in context. Industry vessel traffic associated with Alternative 2 would occur in areas that are largely offshore, within a specific region and are considered common in context. The implementation of Alternative 2 would be unlikely to adversely affect existing nearshore transportation or displace current levels of marine transportation. Direct and indirect impacts on regional vessel transportation would be of low intensity, temporary duration, and affecting resources that are common in context. Direct impacts from the anticipated increases in vessel traffic are considered minor.

4.5.3.7 Recreation and Tourism

Recreation and tourism occur at generally low levels of use in the EIS project area and are more common onshore (hiking, river float trips) than offshore (small cruise ships, kayaking). It is important to distinguish between recreation and subsistence uses. The vast majority of fishing, hunting, and boating that occurs in the project area are *subsistence*-based, managed completely apart from *recreation*-based activities, with separate rights and privileges (see Section 4.5.3.2, Subsistence for further discussion). This section discusses only recreation-based activities, a small portion of the human uses in the area.

The direct and indirect impacts for recreation and tourism will be described by setting and activities. Activity levels for seismic exploration and exploratory drilling in the EIS project area would increase; however, recreation in the area is generally low and is not expected to be considerably impacted.

The level of impacts on recreation and tourism will be based on levels of intensity, duration, geographic extent, and context, as shown in Table 4.5-31.

Table 4.5-31 Impact Levels for Effects on Recreation and Tourism

Impact Component	Effects Summary		
Magnitude or Intensity	**Low**: Changes in recreation setting or activities may not be measurable or noticeable	**Medium**: Noticeable changes in recreation setting or activities	**High**: Acute or obvious changes in recreation setting or activities
Duration	**Temporary**: Changes in recreation setting or activities last less than one year	**Long-term**: Changes in recreation setting or activities extend up to several years	**Permanent**: Changes in recreation setting or activities persist after actions that caused the impacts cease
Geographic Extent	**Local**: Affects recreation setting or activities only locally	**Regional**: Affects recreation setting or activities on a regional scale	**State-wide**: Affects recreation setting or activities beyond a regional scale
Context	**Common**: Affects usual or ordinary recreation opportunities and constraints	**Important**: Affects recreation opportunities and constraints within the locality or region protected by legislation	**Unique**: Affects unique recreation opportunities and constraints

4.5.3.7.1 Direct and Indirect Effects

Setting

The setting for recreation and tourism could potentially be impacted by Alternative 2. The primary direct impact would be on the recreation setting and the visitor experience of that setting. If a visitor was expecting a fairly isolated and undeveloped recreation setting, the presence of industrial vessels or drilling rigs could alter the experience of the setting or the sense of place (Williams & Stewart 1998), as expectations of the setting would not be met. The expectation for an isolated and undeveloped setting could be held by people traversing the project area in personal pleasure boats or yachts. Visual impacts are discussed in further detail in Section 4.4.3.8.

Implementation of Alternative 2 could have a potential indirect impact on the recreation setting including impacts on existence and bequest values (Schuster et al. 2005). Existence value refers to the knowledge that a particular resource exists and an emotional attachment to the resource is held, even if the place is never visited in person (Cordell et al. 2003, Rolston 1985) and bequest value refers to a desire to bequeath a natural resource to future generations (Cordell et al. 2003, Rolston 1985). A person who does not physically recreate in the EIS project area could hold existence or bequest values related to the Arctic Ocean environment. An increase in oil and gas exploration in the area would alter the recreation setting from a primitive or undeveloped setting to a developed setting with industrial activity. The experience of the recreation setting would also likely be altered, including the experience of recreationists that hold existence and bequest values related to the Arctic Ocean environment.

Activities

Under Alternative 2 little direct or indirect impact is expected on recreation activities. Offshore wildlife viewing may be impacted by an increase in survey vessels or drilling rigs if wildlife avoids these vessels or industrial sites. Nearshore activities are generally engaged in by residents of local communities, and levels of activity are low; little impact is expected on levels or types of recreation use. Recreation activities could also be displaced; recreationists may avoid seismic survey and exploratory drilling programs, choosing instead to recreate someplace else to avoid project activities.

Under Alternative 2, one on-ice seismic survey per year is expected in the Beaufort Sea; recreation use is more probable in the vicinity of the existing leases in the Beaufort Sea. Recreation uses would not likely occur near the lease sales in the Chukchi Sea, as they are much farther offshore. The on ice survey would not likely impact recreation activities in the project area as it would not occur during the visitor season.

4.5.3.7.2 Conclusion

Based on the criteria given in Section 4.1.3, the intensity of direct and indirect effects on recreation and tourism are expected to be low; the alternative would not noticeably alter recreation in the EIS project area. Direct impacts to the recreation setting would be temporary as they would last only for the duration of the survey season or exploratory drilling program. Indirect impacts to existence and bequest values would be temporary; the survey activity or exploratory drilling would affect the setting for the length of the seismic or drilling program. The direct impacts to visitor setting would be local, and limited to the area where the project activity is taking place. Indirect impacts to existence and bequest values would be considered state-wide (and potentially nationally or internationally) based on the criteria because recreationists beyond the EIS project area could hold existence and bequest values for the area. Recreation opportunities are not scarce in the project area and are not protected by legislation. Therefore recreation and tourism would be considered common in context.

The direct impacts would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 2 on recreation and tourism would be minor.

4.5.3.8 Visual Resources

This section discusses potential impacts on visual resources that could result from implementing Alternative 2 of the proposed project.

The level of impacts on visual resources will be based on levels of intensity, duration, geographic extent, and context, as shown in Table 4.5-32.

Table 4.5-32 Impact Levels for Effects on Visual Resources

Impact Component	Effects Summary		
Magnitude or Intensity	**High**: Acute or obvious disturbance in visual resources	**Medium**: Noticeable disturbances in visual resources	**Low**: Disturbances in visual resources may not be measurable or noticeable
Duration	**Permanent**: Disturbances in visual resources persist after actions that caused the impacts cease	**Long-term**: Disturbances in visual resources extend up to several years	**Temporary**: Disturbances in visual resources last less than one year
Geographic Extent	**State-wide**: Affects visual resources beyond a regional scale	**Regional**: Affects visual resources on a regional scale	**Local**: Affects cultural visual only locally
Context	**Unique**: Affects unique visual resources or resources protected by legislation	**Important**: Affects visual resources within the locality or region or resources protected by legislation	**Common**: Affects usual or ordinary visual resources; not protected by legislation

4.5.3.8.1 Impact Assessment Methodology

The analysis area for visual resources includes onshore and offshore areas. Onshore areas include Alaska Native communities located along the shoreline between Kotzebue, on the western side of the Arctic Coastal Plain (ACP), across the northern edge of the ACP to the U.S.-Canadian border. This portion of the analysis area was established to assess views of the EIS project area from these locations. Offshore areas include the Beaufort Sea, located north of the ACP, between Point Borrow and the U.S.-Canadian border, and the Chukchi Sea, located between Point Borrow and Kotzebue. Both the Beaufort and the Chukchi seas are located in the Arctic Ocean. The geographic extent of the offshore portion of the analysis area was defined by the EIS project area.

Indicators used to measure potential impacts to visual resources that may result from the proposed project included:

- Impacts to visual resources, measured by the estimated level of visual contrast created by the project; and
- Expected temporary change in the distribution of scenic resources, as measured by temporary change in scenic quality class.

Additional qualitative indicators included the expected level of change to the existing landscape aesthetic, such as movement, activity (measured in terms of change in vehicular traffic and amount of people), noise, or naturalness.

Methods for determining the anticipated level of contrast were developed based on the BLM's Contrast Rating procedure (BLM 1986). This method assumes that the extent to which the project results in adverse effects to visual resources is a function of the visual contrast between the project and the existing landscape character. Impact determinations are typically based on the level of contrast identified using visual simulations and <u>are not</u> a measure of the overall attractiveness of the project. Because no visual simulations were prepared for the proposed project, the level of contrast has been estimated based on analysis factors, including: distance from the project; predominant angle of observation; dominant use (i.e. recreation, subsistence, industry); and duration of typical views.

At each Scenic Quality Rating Unit (SQRU), existing landforms, vegetation, and structures were evaluated using the basic components of form, line, color, and texture. The levels of contrast are defined as follows:

- *None*: The element contrast is not visible or perceived.
- *Weak*: The element contrast can be seen but does not attract attention.
- *Moderate*: The element contrast begins to attract attention and begins to dominate the characteristic landscape.
- *Strong*: The element contrast demands attention, will not be overlooked, and is dominant in the landscape.

Temporary change in Scenic Quality Class was measured by estimating the Scenic Quality Score for each action alternative and comparing that value to the baseline Scenic Quality Score established in Section 3.3.9 (Table 3.3-46).

An overall impact determination was made based on the anticipated contrast, change in Scenic Quality Rating, the duration and geographic extent of affected views, and context of the proposed action.

Effect determinations were based on the parameters listed below:

NO EFFECT would occur if the facilities would be isolated, not noticed in the view, most often seen from background distance zones, temporary, or where no visually sensitive resources would be affected.

Effect would be considered **MINOR** where project components would result in weak contrast against the existing landscape; where deviations in the landscape character are not expected to result in a reduction of Scenic Quality Class; where project design is consistent with existing planning goals, temporary, and/or where sensitive viewers located in the background (5 to 15 miles) distance zone would be affected.

Effect would be considered **MODERATE** where project components would result in moderate contrast against the existing landscape; where deviations in the landscape character are expected to result in a reduction of Scenic Quality Class; where project design is not consistent with existing planning goals, temporary or long-term, and where sensitive viewers located in the foreground/middle ground distance zones (5 to 8 km [3 to 5 mi]) would be affected.

Effect would be considered **MAJOR** where project components would result in strong contrast against the existing landscape; where deviations in the landscape character are expected to result in a reduction of Scenic Quality Class; where project design is not consistent with existing planning goals, long-term, and where sensitive viewers located in the immediate foreground (<5 km [3 mi]) and foreground/middle ground distance zones (5 to 8 km [3 to 5 mi]) would be affected.

The following assumptions were used when analyzing effects of the project on visual resources:

All the potential operations-related impacts to visual resources that were examined as part of each Action Alternative analysis are considered short term and will not extend beyond the life of the EIS (5 years).

- The assessment of short-term construction-related impacts was limited to actions associated with exploratory drilling. Because open water / on-ice seismic surveys and hazard surveys do not require construction of facilities (i.e. artificial islands, jackup rigs), short-term construction-related impacts do not pertain to these actions and are not considered in this analysis.
- The assessment of short-term impacts that may result from decommissioning of the proposed project was limited to structures associated with exploratory drilling. Because open water / on-ice seismic surveys and hazard surveys are not reliant on any facility or related infrastructure (i.e. artificial islands, jackup rigs), it is assumed that potential impacts related to decommissioning of the project do not pertain to these actions and are not considered in this analysis.
- For the purposes of this analysis and for comparison of alternatives, indirect effects are not considered in this analysis. It is assumed that all vessels and project-related infrastructure (i.e. drill sites) would be removed at the end of the permit cycle.
- It is assumed that existing roads would be used to transport material used to construct ice-islands if obtained from on-land quarries. It is further assumed that no new quarries would be constructed to support this action.
- Because changes to landform, vegetation, water, color, adjacent scenery, and scarcity are not expected to be altered as a result of any action alternative, the discussion of potential changes to the ranking of scenic quality for key factors used to determine Scenic Quality Class is limited to "Cultural Modification."
- The effect determination was based on the highest impact identified across all portions of the analysis area.

4.5.3.8.2 Direct and Indirect Effects

Alternative 2 would include vessel-based surveys implemented in the Beaufort and Chukchi seas, and a single exploratory drilling program in both the Beaufort and Chukchi seas. Project-related actions would primarily be seen from population centers located east of Barrow, extending to the Canadian border (including the ANWR). Due to the distances offshore, views of the proposed project in the Chukchi Sea would be restricted to those of industrial workers or commercial marine traffic occurring in offshore locations in the Chukchi Sea and would not be detected by any sensitive viewer groups located in on-land or near-shore locations (see Section 3.3.9.7 for a description of viewer groups). The degree of project-related visual contrast and subsequent degree of cultural modification will depend on site-specific factors, including: viewer distance; viewer's angle of observation; duration of their view; and atmospheric conditions. It is assumed for the purposes of this analysis that the landscape/seascape type is describe as a large-scale panoramic. Viewer sensitivity to the potential impacts to views will depend on existing land use and perceived cultural value. Landscape analysis factors for each of the viewshed areas are summarized in Table 4.5-33.

Table 4.5-33 Description of Analysis Factors by Scenic Quality Rating Unit

	Scenic Quality Rating Unit			
	West Beaufort Sea	**East Beaufort Sea**	**North Chukchi Sea**	**South Chukchi Sea**
Distance from Project	Up to approximately 50 miles	Up to approximately 50 miles	>50 miles	>50 miles
Predominant Angle of Observation	Variable within a 180º arc	Variable within a 180º arc	Variable within a 180º arc	Variable within a 180º arc
Dominant Land Use	On land and near shore Industrial	Near shore Industrial; On-land ANWR	Predominantly Undeveloped, but including the NPRA[1] on shore	Predominantly Undeveloped
Duration of View	Prolonged, but short-term	Prolonged, but short-term	Prolonged, but short-term	Prolonged, but short-term

Notes:

1) NPRA = National Petroleum Reserve Alaska

Because predominant viewer distance of sensitive viewers in the North and South Chukchi SQRUs is greater than 80 km (50 mi), it is assumed that the project would not be detected when viewed from this vantage point. Viewers situated in onland and nearshore areas of these SQRUs (i.e. Cape Krusenstern National Monument, or the Alaska Native communities of Wainwright, Point Lay, Point Hope, Kivalina, or Kotzebue) may experience views of survey vessels and/or support vessels transiting to/from the proposed EIS project area via the Bering Straits or within the Chukchi Sea for resupply trips. Operations-related vessel traffic occurring in the Chukchi Sea is expected to be seen only by industrial workers stationed offshore. In both cases, viewing of transiting and operations-related vessels would be temporary and localized and therefore is not considered further in this analysis.

The operation of survey and support vessels would not entail construction or decommissioning phases, as vessels are deployed for surveys and CSEM and would not return to the surveyed area once work is completed. Operations-related vessel traffic would be transient, restricted to short time periods, and occur in localized areas. For these reasons, the operation of survey and support vessels is expected to result in an overall weak visual contrast where actions occur at close proximity (within Foreground-Middleground [FM] zone) to on-land and near-shore locations state waters of the Beaufort Sea. Visual contrast is expected to attenuate beyond 8 km (5 mi) due to the scale of the vessels relative to the landscape and the transient nature of the proposed action.

The exploratory drilling program included in this alternative would include construction, operation, and decommissioning phases. Construction-related impacts to visual resources and scenic quality would vary based on the type of infrastructure used to support the well. For example, drillships and jack-up rigs can be erected on site with no sea bottom preparation; however structures such as artificial islands or caisson-retained islands would require dredging and transport to the drill site to establish the foundation for the drilling unit. Exploratory drilling in federal waters of the Beaufort and Chukchi seas would be implemented using a drillship, CDS, or a jackup rig, and consequently no construction-related impacts to visual resources are expected.

Construction-related impacts may occur as part of exploratory drilling programs situated in state waters (located within 5 km [3 mi]) of the Beaufort Sea. It is assumed that an artificial island would be used to support exploratory drilling and that this facility would be constructed between Harrison Bay and Bullen Point. This geographic area includes the Alaska Native community of Nuiqsut and the industrial centers of Deadhorse and Prudhoe Bay. Construction-related actions would result in a temporary increase in marine barge, vehicle, and potentially air traffic around localized drill site(s). Such actions would contribute color, angular lines, and movement to the landscape; however, because oil and gas activity is underway in this area, change in visual resources and scenic quality as a result of construction of drill site(s) is not expected to create visual contrast or attract attention of the casual observer. It is assumed that actions associated with decommissioning of the ice island would be similar to those incurred during construction.

During the operational phase, the moderate to strong visual contrast may result from operation of drill sites, particularly where situated within five miles of viewers. Each drill site would require up to eleven support vessels, resulting in a noticeable increase in industrial marine traffic from this distance. The greatest contrast is expected to occur during summer daylight conditions, or during winter months when periods of low-light may result in a bold silhouette of the facility due to back-lighting. During periods of darkness, facility lighting could be detected up to and beyond the background distance zone (24 km [15 mi]). Like vessel traffic, visual contrast of drilling facilities (i.e. ice islands) and lighting would be maximized where viewed from proximate locations and would attenuate with distance from the viewer. Project-related actions in the nearshore Beaufort Sea would be viewed by both highly sensitive viewers from the Alaska Native community of Nuiqsut and viewers located in the industrial centers of Deadhorse and Prudhoe Bay characterized as having low visual sensitivity.

Project-related actions are not expected to change the Scenic Quality Class of any SQRU analyzed. Project actions and effects to visual resources expected to result from implementation of Alternative 2 are summarized in Table 4.5-34, below. An explanation of factors used to determine scenic quality scores is provided in Section 3.3.9.9.

Table 4.5-34 Potential Temporary Changes to Scenic Quality Rating under Alternative 2

	Key Factor	Scenic Quality Rating (Summer/Winter)			
		East Beaufort Sea Unit	West Beaufort Sea Unit	North Chukchi Sea Unit	South Chukchi Sea Unit
Existing Conditions	Cultural Modification	0/0	-4/-3	0/0	0/0
	Total Score	24/15	20/12	25/16	25/16
	Scenic Quality Class[1]	A/B	A/B	A/B	A/B
Alternative 2	Cultural Modification	-2/-2	-4/-3	0/0	0/0
	Total Score	22/13	20/12	25/16	25/16
	Scenic Quality Class[1]	A/B	A/B	A/B	A/B

Notes:

1) Class A = Score of 19+
2) Class B = Score of 12-18
3) Class C = Score of 11 or less

4.5.3.8.3 Conclusion

In conclusion, implementation of Alternative 2 is expected to result in *short-term moderate effects* to scenic quality and visual resources. Potential impacts could be of low to medium intensity depending on specific location of drill sites. The geographic extent of potential impacts would be localized; however they would occur in an important ecosystem.

4.5.3.9 Environmental Justice

The coastal communities of Kaktovik, Nuiqsut, Barrow, Wainwright, Point Lay, Point Hope, Kivalina, and Kotzebue are predominantly Alaska Native communities. Nome also has a substantial Alaska Native population. In the analysis of environmental effects (including human health, economic and social effects), there is the requirement under Executive Order 12898 to identify and address "disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." Therefore, the purpose of this section is to analyze potential impacts to these communities and their sociocultural systems resulting from the implementation of the alternatives.

Scoping comments (Appendix C) regarding environmental justice included:

- Ensure the requirements of Executive Order 12898 (Federal Actions to Address Environmental Justice in Minority and Low-Income Populations) are being met;
- Evaluation of any disproportionate impacts placed upon the Iñupiat people should take into account the unique interests of local Iñupiat communities; and
- Particular attention must be given to consideration of the dependence of local communities on local and regional subsistence resources, access to those resources, and perception of the quality of those resources.

The discharges associated with Alternative 2 that could impact human health and subsistence resources are detailed in Chapter 2. These may include wastes from exploration drilling, deck drainage, platform discharges, air emissions, human discharges from vessels, and/or non-permitted releases and minor oil spills. Displacement of subsistence resources or disruption of subsistence activities associated with noise and vessel traffic are described in Chapter 2, Marine Mammals Section 4.5.2.4 and Subsistence 4.5.3.2.

4.5.3.9.1 Direct and Indirect Effects

Impacts to Subsistence Foods and Human Health

As described in the Subsistence Section 4.5.3.2, the activity levels associated with Alternative 2 are expected to have a negligible to minor impact to the numbers of marine mammals harvested for subsistence use in the EIS project area. As described in the Public Health Section 4.5.3.3, increased contamination levels in subsistence food sources are likely to be negligible. Alternative 2 may have an indirect effect of adding to the perception that subsistence foods are contaminated and alter confidence in their consumption.

4.5.3.9.2 Conclusion

Activities related to implementation of Alternative 2 would have a low intensity impact on subsistence resources and human health, a temporary duration, and a regional extent. Subsistence foods and human health are unique resources, and they are protected under the MMPA and EO 12898. Thus, Alternative 2 is expected to have a minor impact to subsistence resources. Alternative 2 with Standard Mitigation Measures would also create some local employment and economic support activities, and would reduce adverse effects. There would be minor disproportionate adverse and beneficial impacts to Alaska Native communities under Alternative 2.

4.5.3.10 Standard Mitigation Measures for the Social Environment

Standard and Additional Mitigation Measures are outlined in Sections 2.4.10 and 2.4.11, respectively, and described in detail in Appendix A. Requirements for implementation depend on type, time, and location of activities and co-occurrence of multiple activities. A combination of these measures could be required for any one ITA. While the ultimate goal of the mitigation measures is to reduce adverse impacts to marine mammals and subsistence hunts of marine mammals, some of the mitigation measures have the potential to impact resources within the social environment. For example, the requirement to hire PSOs and establish Com Centers will create jobs on the North Slope. Sections 4.5.2.4.15 and 4.5.2.4.16 provide discussion and analysis of the standard and additional mitigation measures aimed at reducing impacts to marine mammals, and Sections 4.5.3.2.3 and 4.5.3.2.5 provide discussion and analysis of the standard and additional mitigation measures aimed at reducing impacts to subsistence hunts. Those analyses include a discussion of potential economic impacts as well, and those discussions are not repeated here.

4.6 Direct and Indirect Effects for Alternative 3 – Authorization for Level 2 Exploration Activity

4.6.1 Physical Environment

4.6.1.1 Physical Oceanography

4.6.1.1.1 Direct and Indirect Effects

Water Depth and General Circulation

Under Alternative 3, changes in water depth resulting from exploratory drilling programs would be the same in nature as those described for Alternative 2. Alternative 3 would allow additional drilling programs in the EIS project area, and as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact would effectively be doubled. Relative to Alternative 2, water depth would be affected over a larger area. The effects of Alternative 3 on water depth would be low-intensity, permanent, and would affect a common resource. Changes in water depth from discharged material would have only minor effects on the physical resource character of the proposed action area. Although common resources would be affected across increased spatial scales relative to Alternative 2, the overall effects of Alternative 3 on water depth would be minor.

Currents, Upwellings, and Eddies

Seismic surveys, site clearance and shallow hazards surveys, and on-ice seismic surveys would have only negligible effects on currents, upwellings, and eddies within the EIS project area under Alternative 3. Construction of artificial islands, which could occur in nearshore state waters of the Beaufort Sea at a rate of two islands per year under Alternative 3, would result in medium-intensity, permanent/temporary (permanent if gravel, temporary if ice), localized effects on nearshore currents in the waters adjacent to the artificial islands. Over the life of this EIS, those effects would be minor and would occur only if artificial islands are constructed to support exploratory drilling activities. Exploratory drilling activities in the Chukchi Sea are anticipated to occur from temporary structures, as opposed to artificial islands that could be built in the Beaufort Sea. Therefore, exploratory drilling activities in the Chukchi Sea would have only negligible effects on currents, upwellings, and eddies within the proposed action area.

Tides and Water Levels

The activities described under Alternative 3 would not affect tides or water levels within the EIS project area.

Stream and River Discharge

The activities described under Alternative 3 would not affect stream and river discharge within the EIS project area. Exploratory drilling in state waters on grounded ice could occur from manmade reinforced ice “islands” but would have negligible effects on stream and river discharge within the EIS project area.

Sea Ice

Under Alternative 3, impacts to sea ice resulting from the proposed activities would be the same in nature as those described for Alternative 2. Alternative 3 would allow additional drilling programs and additional artificial islands in the proposed action area, and, as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact would effectively be doubled. Relative to Alternative 2, sea ice would be affected over a larger area due to more extensive icebreaking activity and thermal inputs associated with exploratory drilling activities.

Although Alternative 3 would allow additional seismic surveys in both the Beaufort and Chukchi seas relative to Alternative 2, each action alternative would authorize only one survey per year in each of the seas to involve icebreaking activity. Likewise, only one on-ice seismic survey per year would be authorized under each of the action alternatives. Therefore, the level of activity contemplated for these specific types of exploration activities under Alternative 3 is the same as what is contemplated under Alternative 2.

The effects of these activities on sea ice would be medium intensity, local, temporary, and would affect a resource that is common in the EIS project area. The presence of sea ice in lease and non-lease areas targeted for open water seismic exploration and exploratory drilling could result in changes to the schedule, location, and duration of exploratory activities. The presence of ice also represents a potential hazard to vessels and exploratory drilling platforms. Industry operators in offshore areas have developed procedures for managing sea ice, including changes to schedule, vessels dedicated to ice management, and procedures for taking drill platforms off location until potential hazards subside.

Within ice and on ice exploration activities could experience similar and additional hazards from sea ice, including the potential for ice override events. In-ice exploration activities would use ice breakers and other vessels for the purpose of ice management and/or ice breaking, and protocols would be established for response to potential ice hazards. Drilling on grounded ice from artificial ice islands would not be subject to potential hazards from moving ices, but could experience potential effects from storm surge and ice override events. Within the Beaufort Sea, where drilling on constructed artificial ice islands could occur in state waters, much of the area is protected from ice override by barrier islands. Individual drilling operations would need to assess the potential for ice related hazards and develop appropriate design and operation protocols.

Although common resources would be affected across increased spatial and temporal scales relative to Alternative 2, the overall effects of Alternative 3 on sea ice would be minor.

4.6.1.1.2 Conclusion

The overall effects of the proposed actions on physical ocean resources would be of medium intensity (due to the increase in impacts to sea ice), temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. The overall effects of the proposed activity described in Alternative 3 on physical ocean resources in the proposed action area would be minor.

4.6.1.2 Climate

Under this alternative, emissions would be higher when compared to Alternative 2 because the alternative proposes additional surveys and exploration plans described as Level 2 Exploration Activity on the Arctic OCS. In the U.S. Chukchi Sea OCS Planning Area, two additional seismic surveys are planned along with two additional site clearance surveys, and an additional EP is included. In the U.S. Beaufort Sea OCS Planning Area, two additional seismic surveys are considered along with two additional site clearance surveys, and an additional EP. The majority of additional emissions are from the additional EP proposed for Level 2 Exploration Activity.

Refer to Section 3.1.4.4 (*Climate Change in the Arctic*) for a thorough discussion of climate systems and the effects of GHG emissions.

4.6.1.2.1 Direct and Indirect Effects

Direct Effects

Direct effects under this alternative are the same as those described under Alternative 2.

Indirect Effects

Indirect Effects under this alternative are the same as those described under Alternative 2.

Regulatory Reporting and Permitting

Regulatory reporting and permitting under this alternative would be the same as those described under Alternative 2.

CO_2e Emissions Inventory

The specific description and number of each of these programs and activities proposed for the Arctic OCS, on an annual basis, were summarized earlier in Table 2.4 (*Activity Definitions*), and Section 2.4.5 (*Alternative 2 – Authorization for Level 1 Exploration Activity*). The estimated potential annual emissions of CO_2e for each type of activity and program proposed under this alternative are provided in Table 4.6-1. The data in this table assumes no controls to reduce emissions.

Effects of this Alternative on Climate Change

Reporting emissions of CO_2e under this alternative would be the same as described under Alternative 2.

Effects of Climate Change on Resources under this Alternative

Effects of climate change on resources under this alternative would be the same as described under Alternative 2.

Table 4.6-1. Estimated CO_2e Emissions by Activity and Program Type for the Arctic OCS

Activity/Program Types	**U.S. Chukchi Sea OCS Annual CO_2e Emissions** (metric tons per year)
2D/3D Seismic Survey (including one survey using an ice breaker vessel)	72,048
Site Clearance and High Resolution Shallow Hazards Survey Program	12,392
Exploration Plan	186,013
Total	**270,454**
Activity/Program Types	**U.S. Beaufort Sea OCS Annual CO_2e Emissions** (metric tons per year)
2D/3D Seismic Survey (including one survey using an ice breaker vessel)	85,692
Site Clearance and High Resolution Shallow Hazards Survey Program	12,392
On-Ice Seismic Survey	25
Exploration Plan	186,013

Total	284,123

Sources: EPA. October 1996. Compilation of Air Pollutant Emission Factors (AP-42) 5th ed., Volume I, Chapter 3, Table 3.3-1 and Table 3.4-1.
EPA. July 2010. Median Life, Annual Activity and Load Factor Values for Nonroad Engine Emissions Modeling (EPa-420-R-10-016, NR-005d).

EPA. 2012. EPA and NHTSA Set Standards to Reduce GHG and Improve Fuel Economy for Model Years 2017-2025 Cars and Light Trucks. Table 1. http://www.epa.gov/oms/climate/documents/420f12051.pdf

4.6.1.2.2 Conclusion

Direct and indirect impacts associated with climate are associated mainly with potential emissions of CO_2e that could, decades from now, contribute to changes in the environmental conditions already occurring in the Arctic and throughout the world. As such, the impacts to climate change cannot be measured on a project-level basis and instead are global in scope. However, total emissions of CO_2e emissions should be disclosed in the NEPA review.

4.6.1.3 Air Quality

Under this alternative, emissions would be higher when compared to Alternative 2 because the alternative proposes additional surveys and exploration plans described as Level 2 Exploration Activity on the Arctic OCS. In the U.S. Chukchi Sea OCS Planning Area, two additional seismic surveys are planned along with two additional site clearance surveys, and an additional EP is included. In the U.S. Beaufort Sea OCS Planning Area, two additional seismic surveys are considered along with two additional site clearance surveys, and an additional EP. The majority of additional emissions are from the additional EP proposed for Level 2 Exploration Activity.

4.6.1.3.1 Direct and Indirect Effects

Direct and indirect effects under this alternative would be from the same sources of emissions as described under Alternative 2 in Section 4.5.1.3.

Exploration Plan Emission Inventory

The emission rates likely to reflect Level 2 Exploration Activity in each sea are presented in Table 4.6-2 **Estimated Annual Emission Inventory of an Exploration Plan**. The inventory assumes no application of BACT or the use of ultra-low-sulfur diesel (ULSD) fuel. The emission inventory presented in Table 4.6-3 assumes the same method of calculation and EP operational characteristics as described for Alternative 2.

Survey Emission Inventory

The emission rates likely to reflect the increased level of seismic and other surveys under this alternative as compared to Alternative 2 are presented in **Table 4.6-3** and **Table 4.6-4**.

The survey inventories assume no application of BACT or the use of ultra-low-sulfur diesel (ULSD) fuel. The emission inventory presented in Table 4.6-4 assumes the same method of calculation and survey vessel operational characteristics as described for Alternative 2.

Table 4.6-2. Estimated Annual Emission Inventory of Level 2 Exploratory drilling for each Sea

Pollutant Sources	Two (2) Exploratory Drilling Programs Annual Emissions (tons per year)

4.6.1.3.2 Air Quality Impact Analysis

The air quality impact analysis would be conducted as described under Alternative 2.

4.6.1.3.3 Level of Effect

The annual rate of air emissions and onshore pollutant concentrations are the two basic measurements for assessing a proposal's level of effect on air quality. The emission inventory provided in this section discloses the rate of emissions likely to reflect a proposal under this alternative (Alternative 3), expressed in short tpy. When necessary, an emission inventory is translated into pollutant concentrations expressed in micrograms per cubic meter ($\mu g/m^3$), a value that can be measured against the NAAQS allowing the level of effect to be categorized relative to the conditions summarized under Alternative 2 in Table 4.5-7 *Impact Levels for Effects on Air Quality*. Further information regarding level of effect under this alternative would be the same as discussed under Alternative 2.

4.6.1.3.4 Conclusion

Emissions from exploratory drilling activities proposed under this alternative would be higher than emissions estimated for Alternative 2. Without emission reduction controls on the drillship engines, there is a greater potential for one or more of the EPA SILs to be exceeded onshore. The Level 2 Exploration Activity would almost certainly require additional modeling to demonstrate the effect of pollutant concentrations on the nearest onshore area. A moderate level of effect on air quality is expected, which may be mitigated by emission control strategies to result in a minor level of effect. Cumulatively, the total estimated emissions for each Arctic OCS planning area, when considering all plans and activities described under this alternative, are summarized in Table 4.6-5.

Control of oil and gas emission sources on the OCS, and levels of effect, are considered on a project-by-project basis, as each individual operator would have the responsibility to engage any engine emission controls required by BOEM AOCSR. Emission reduction strategies have the potential to reduce at least some emissions of all pollutant types, including CO_2e. Therefore, the data provided in Table 4.6-5 would represent a worst-case scenario for each Arctic OCS planning area.

Table 4.6-5. Estimated Annual Emission Inventory for Arctic OCS – Level 2 Activity

Plan/Activity	U.S. Chukchi Sea OCS Annual Emissions (tons per year)					
	PM	NO_X	SO_2	CO	VOC	CO_2e*

4.6.1.4 Acoustics

Under Alternative 3, the number of seismic survey programs envisioned is increased from Alternative 2 by two exploration surveys and two site clearance or high resolution shallow hazards surveys in each of the Chukchi Sea and Beaufort Sea (Tables 4.2-1 and 4.2-2), using the same types of noise-generating sources. This represents an increase in seismic survey activities of approximately 65 percent in the Chukchi Sea and 50 percent in the Beaufort Sea. The amount of drilling activity has also doubled in each sea between Alternatives 2 and 3. A detailed discussion of the acoustic properties of the noise sources is given in Section 4.5.1.4; that discussion is relevant also to Alternative 3 operations.

4.6.1.4.1 Direct and Indirect Effects

Estimates of Total Surface Areas of Ensonification at Threshold Levels

Table 4.6-6 contains estimates of surface areas ensonified above given threshold levels under Alternative 3. For the purpose of computing these notional areas, the seismic survey activities listed in Table 4.2-2 for Activity Level 2 are distributed among the three environments considered in this EIS. The five exploration surveys and five site clearance or high resolution shallow hazard surveys in the Chukchi Sea are all assumed to be in the mid-depth shelf region; the six exploration surveys and five site clearance or high resolution shallow hazard surveys in the Beaufort Sea are divided between the mid-depth shelf and the shallow-depth coastal regions in the proportions of 4:2 and 3:2 respectively (giving greater representation to the shelf region makes the estimates more precautionary). The source array sizes in the three zones reflect the prevailing configurations for seismic surveys conducted in each region. The percentages are based on nominal surface areas of 263,500 km^2 for the Chukchi portion of the EIS project area and 255,350 km^2 for the Beaufort portion. The surface areas presented in Table 4.6-6 indicate the total area of each sea that would be ensonified if the maximum number of surveys allowed under this alternative were to be performed concurrently. Of note, the total surface areas do not subtract out either overlap with other isopleths of concurrent source operation, or land area where activities are closer to shore, for that reason, the area ensonified over 120 dB is likely a significant overestimate (see figures 4.3-1 through 4.5-3 illustrating conceptual examples to get a sense of this).

Table 4.6-6 Total Surface Areas Ensonified Above Sound Level Thresholds Under Alternative 3, From Averages Listed in Table 4.5-12.

		Total Surface Areas (km^2) to sound level (90% rms SPL (dB re 1 µPa rms))			
		190	**180**	**160**	**120**
Chukchi Sea Shelf 40 to 52 m depth					
	5x ~3200 in^3	4.41	48.7	1,798	141,764
	5x 40 in^3	0.03	0.29	25.3	10,619
	2x drill/support *			1044	1,044
	% Chukchi	**0.00%**	**0.02%**	**1.09%**	**58%**

*drill/support indicates area within 13-km radius around drill rig, notionally encompassing support

vessels. Indicated area is within 120-dB radius, included in 160-dB column for assessment.

4.6.1.4.2 Conclusion

The intensity rating of this alternative is high, as additional exploration activities will introduce sources with source sound levels that exceed 200 dB re 1 µPa. Because the exploration activities could continue for several years, the duration is considered as long term. The spatial extent of these activities is regional, since the distribution of exploration activities over the project areas will lead to 39 percent of the EIS area being exposed to sound levels in excess of 120 dB re 1 µPa . Therefore, the overall impact rating for direct and indirect effects to the acoustic environment would be moderate.

4.6.1.5 Water Quality

Impacts to water quality from Alternative 3 are expected to be very similar to those described above for Alternative 2. The only difference between the two alternatives is the level of activity. Any differences in impacts between the two alternatives are noted below.

4.6.1.5.1 Direct and Indirect Effects

Temperature and Salinity

Seismic Surveys

Similar to the impacts under Alternative 2, seismic surveys under Alternative 3 would not expected to have any measureable impact on temperature or salinity in the EIS project area.

Site Clearance and Shallow Hazards Surveys

Similar to the impacts under Alternative 2, site clearance and shallow hazards surveys under Alternative 3 would not be expected to have any measureable impact on temperature or salinity in the EIS project area.

On-ice Seismic Surveys

Similar to the impacts under Alternative 2, on-ice seismic surveys under Alternative 3 would not be expected to have any measureable impact on temperature or salinity in the EIS project area.

Exploratory Drilling Programs

Under Alternative 3, changes in water quality related to temperature and salinity resulting from exploratory drilling programs would be the same in nature as those described for Alternative 2. Alternative 3 would allow additional drilling programs in the EIS project area, and as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact may effectively be doubled. Relative to Alternative 2, salinity and temperature may be affected over a larger area. However, the effects of Alternative 3 on water quality resulting from changes in temperature and salinity would be low intensity, temporary, and local. Although common resources may be affected across increased spatial scales relative to Alternative 2, the overall effects of Alternative 3 on water quality related to temperature and salinity resulting from exploratory drilling programs would be minor.

Turbidity and Total Suspended Solids

Seismic Surveys

Effects on water quality resulting from increases in turbidity and total suspended solids from seismic surveys under Alternative 3, if any, would be low-intensity, temporary, local, and would affect a common resource. The nature of those effects would be similar to those described under Alternative 2.

Site Clearance and Shallow Hazards Surveys

Effects on water quality resulting from potential increases in turbidity and total suspended solids from site clearance and shallow hazard surveys under Alternative 3, if any, would be low-intensity, temporary, local, and would affect a common resource. The nature of those effects would be similar to those described under Alternative 2.

On-ice Seismic Surveys

On-ice seismic surveys would not affect turbidity or concentrations of suspended solids in the proposed action area. As they occur on the ice and not in the open-water environment, no contact is made with the seafloor during these types of surveys.

Exploratory Drilling Programs

Effects on water quality resulting from increases in turbidity and total suspended solids from exploratory drilling programs are described in detail under Alternative 2. Alternative 3 would allow additional drilling programs in the EIS project area, and, as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact may be effectively doubled. Relative to Alternative 2, turbidity and concentrations of suspended solids may be affected over a larger area. However, the effects of Alternative 3 on water quality resulting from changes in turbidity and concentrations of suspended solids would be low intensity, temporary, and local. Although common resources would be affected across increased spatial and temporal scales relative to Alternative 2, the overall effects of Alternative 3 on water quality related to turbidity and concentrations of suspended solids resulting from exploratory drilling programs are expected to be minor.

Metals

Seismic Surveys

Similar to the impacts under Alternative 2, seismic surveys are not expected to have any measureable impact on dissolved metal concentrations in the EIS project area.

Site Clearance and Shallow Hazards Surveys

Similar to the impacts under Alternative 2, site clearance and shallow hazards surveys are not expected to affect dissolved metal concentrations in the proposed action area.

On-ice Seismic Surveys

Similar to the impacts under Alternative 2, on-ice seismic surveys would not affect dissolved metal concentrations in the EIS project area.

Exploratory Drilling Programs

Direct and indirect effects on water quality resulting from increases in concentrations of metals from exploratory drilling programs are described in detail under Alternative 2. Alternative 3 would allow additional drilling programs in the EIS project area, and, as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact may effectively be doubled. Relative to Alternative 2, metal concentrations may be affected over a larger area. However, the effects of Alternative 3 on water quality resulting from changes in metal concentrations would be low intensity, temporary, and local. Although common resources would be affected across increased spatial and temporal scales relative to Alternative 2, the overall effects of Alternative 3 on water quality related to metal concentrations resulting from exploratory drilling programs would be minor.

Hydrocarbons and Organic Contaminants

Seismic Surveys

Similar to the impacts under Alternative 2, while the level of activity would double, seismic surveys are expected to have negligible impacts on concentrations of hydrocarbons and organic contaminants in the waters of the EIS project area.

Site Clearance and Shallow Hazards Surveys

Similar to the impacts under Alternative 2, while the level of activity would double, site clearance and shallow hazards surveys are expected to have negligible impacts on concentrations of hydrocarbons and organic contaminants in the waters of the EIS project area.

On-ice Seismic Surveys

Similar to the impacts under Alternative 2, on-ice seismic surveys are expected to have minor impacts on concentrations of hydrocarbons and organic contaminants in the waters of the EIS project area under Alternative 3. Alternative 3 contemplates the same level of on-ice seismic activity as Alternative 2; therefore, the level of impacts is anticipated to be the same. Contaminants from fluids entrained in the ice roads would be discharged every spring during breakup. Any entrained hydrocarbons and other organic contaminants from vehicle exhaust, oil, grease, and other vehicle-related fluids not recovered would pass into the Beaufort and/or Chukchi Sea system at each breakup as a result of on-ice seismic surveys. The effects of these discharges on water quality would be temporary and local in nature, and overall impacts to water quality from on-ice seismic surveys under Alternative 3 are expected to be minor.

Exploratory Drilling Programs

Direct and indirect effects on water quality resulting from increases in concentrations of hydrocarbons and other organic contaminants from exploratory drilling programs are described in detail under Alternative 2. Relative to Alternative 2, Alternative 3 would allow additional drilling programs in the EIS project area, and, as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact may effectively be doubled. Relative to Alternative 2, concentrations of hydrocarbons and other organic contaminants would be affected over a larger area. Impacts to water quality resulting from hydrocarbons and other organic contaminants would be temporary and would dissipate soon after the discharge is stopped. Such impacts would be local in nature due to rapid dilution of discharged compounds into the ocean. It seems probable that inputs of hydrocarbons and other organic contaminants from exploratory drilling programs under Alternative 3 would have minor to moderate effects on water quality outside of the discharge plume area. However, due to lack of applicable water quality criteria for some organic compounds in drilling fluids (EPA 2006b), it is problematic to determine whether or not inputs of hydrocarbons and other organic compounds from the proposed activity would exceed water quality regulatory limits.

Although unlikely, it is plausible that accidental or emergency events may occur within the proposed action area. Due to the rarity of such unforeseen events, and the potential magnitude and extent of their impacts relative to the effects of normal operation and maintenance activities, such accidental or emergency events are not addressed in this section and are covered in Section 4.10 of this EIS. Standard mitigation measures requiring operators to have plans in place to minimize the likelihood of a spill would reduce the potential for adverse impacts to water quality.

4.6.1.5.2 Conclusion

After mitigation, the effects of the proposed actions on water quality are expected to be low-intensity, temporary, local, and would affect a common resource. The overall effects of the proposed activity described in Alternative 3 on water quality in the EIS project area are expected to be negligible.

4.6.1.6 Environmental Contaminants and Ecosystem Functions

4.6.1.6.1 Direct and Indirect Effects

Contaminants of Concern

Contaminants of concern introduced to the EIS project area as a result of the activities proposed in Alternative 3 would be the same as those described for Alternative 2. Because Alternative 3 would authorize a greater level of activity relative to Alternative 2, the amounts of contaminants introduced to the EIS project area would potentially be greater under Alternative 3.

Proposed mitigation measures intended to reduce/ lessen non-acoustic impacts on marine mammals have the potential to reduce adverse impacts resulting from contaminants of concern.

Exposure of Habitat and Biological Resources

Pathways for exposure of habitat and biological resources to contaminants of concern as a result of the activities proposed in Alternative 3 would be the same as those described for Alternative 2.

Effects on Ecosystem Functions

In response to comments and suggestions received as part of the scoping process for this EIS, effects of (contaminants of concern from) the proposed activities on ecosystem functions are assessed in the following section. Effects of the activities proposed under Alternative 3 on the four categories of ecosystem functions (defined in Section 4.4.1.6) are assessed below.

Regulation Functions

The nature of the effects of the activities proposed under Alternative 3 on regulation functions would be the same as described under Alternative 2. The effects of greatest concern would be associated with exploratory drilling programs. Alternative 3 would authorize up to two exploratory drilling programs per year in the Beaufort Sea and up to two exploratory drilling programs per year in the Chukchi Sea, whereas Alternative 2 would authorize only one exploratory drilling program per year in each sea. Thus, the magnitude of the effects on regulation functions would be greater under Alternative 3 compared to Alternative 2. The magnitude and extent of effects of Alternative 3 on regulation functions would depend upon interrelationships between impacts to biological and physical resources, which are addressed in other sections of this EIS.

Habitat Functions

The nature of the effects of the activities proposed under Alternative 3 on habitat functions would be the same as described under Alternative 2. Effects of Alternative 3 on habitat functions would include impacts to refugium functions and nursery functions (provision of suitable reproduction habitat) associated with benthic habitats resulting from discharges from exploratory drilling. Overall effects to benthic habitat functions would be temporary, local, and low-intensity. Effects would also occur to functions associated with pelagic and epontic habitats. Functions associated with terrestrial habitats would be affected to a lesser degree. Overall, effects of Alternative 3 on habitat functions would be medium-intensity, temporary, and local. The functions affected could be common, important, or unique depending on the spatial location of the impact.

Proposed mitigation measures intended to reduce/ lessen non-acoustic impacts on marine mammals have the potential to reduce adverse impacts to habitat functions.

Production Functions

The nature of the effects of the activities proposed under Alternative 3 on production functions would be the same as described under Alternative 2. Impacts to production functions related to provision of raw materials and food (i.e. subsistence) could be affected by the activities proposed under Alternative 3. These impacts are described in the subsistence section of this EIS. In addition to introducing contaminants to secondary and tertiary consumers via trophic transfer processes, contaminants of concern could interrupt trophic transfer processes resulting in shorter food chains (less complex food webs), and reduced throughput of energy and nutrients at higher trophic levels. Oil and gas are ecosystem goods, and the flows of energy that they represent are ecosystem services. These ecosystem goods and services could potentially be derived from historical production functions in the EIS project area under Alternative 3.

Information Functions

Information functions contribute to the maintenance of human health by providing opportunities for spiritual enrichment, cognitive development, recreation, and aesthetic experience (DeGroot et al. 2002). The effects of Alternative 3 on information functions in the EIS project area would depend upon interrelationships between impacts to cultural resources, social resources and aesthetic resources, which are addressed in other sections of this EIS.

4.6.1.6.2 Conclusion

Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 3 would be medium-intensity, temporary, localized, and would affect common resources. The functional properties of ecosystems described in this section, such as nutrient cycling and habitat functions, are more robust (i.e. resistant to stressors) than are species composition and other structural properties. Because Alternative 3 would authorize a greater level of activity than Alternative 2 there is potential for increased volume of contaminants introduced to the project area. However, the overall effects of Alternative 3 on ecosystem functions would be considered minor.

4.6.1.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the physical environment are discussed under Alternative 2 (Section 4.5.1.7).

4.6.2 Biological Environment

4.6.2.1 Lower Trophic Levels

4.6.2.1.1 Direct and Indirect Effects

The direct and indirect impacts discussed in Section 4.5.3.7 for Alternative 2 are also applicable for this alternative. The increased levels of activity associated with Alternative 3 would not generate different types of impacts to lower trophic levels. The conclusions for Alternative 2 are applicable to Alternative 3; therefore, the overall impact to lower trophic levels would be moderate.

4.6.2.1.2 Conclusion

Given the implementation of the standard mitigation measures considered in this EIS, the direct and indirect effects on lower trophic levels associated with Alternative 3 would likely be low in intensity, temporary to long-term in duration, of local extent and could affect common resources; resulting in a summary impact level of negligible. The only exception to these levels of impacts would be the introduction of an invasive species due to increased vessel traffic, which could be of medium intensity, long-term or permanent duration, of regional geographic extent, and affect common or important resources, which could cause a summary impact of moderate.

4.6.2.2 Fish and Essential Fish Habitat

4.6.2.2.1 Direct and Indirect Effects

Under Alternative 3, the types of oil and gas exploration activities undertaken in the EIS project area would be the same as those in Alternative 2, but the level of activity would be higher. An increase from Level 1 to Level 2 would result in an overall increase in activity of approximately 40 percent, distributed unevenly among the different activities. It would double some activity levels while leaving others unchanged. There would be no increase in icebreaking or on-ice seismic surveys, an increase of 50 percent in seismic surveys and site clearance and high resolution shallow hazard surveys, and a doubling of exploratory drilling programs. This uneven nature of the increase would also apply to the impacts on different fish resource groups.

The types and mechanisms of effects would remain the same in Alternative 3 as in Alternative 2. For a complete discussion of the types and mechanisms of effects on fish resources, please see Section 4.5.2.2, Fish and Essential Fish Habitat.

Marine Fish

The direct and indirect effects on marine fish resulting from Alternative 3 would be very similar to those described under Alternative 2. Due to the uneven nature of the increases in activity levels by activity type, the increase in impacts to different fish assemblages would vary. The cryopelagic assemblage would have essentially no additional impacts, as the level for activities likely to affect that group (icebreaking and on-ice seismic surveys) would not change from Alternative 2. Demersal assemblages, on the other hand, would feel the additional effects from the increase in seismic survey levels and exploratory drilling, both in terms of habitat loss and the effects from noise. Pelagic assemblages would be impacted by the increase in surveys but less so by the increased drilling programs. However, in spite of the potential for different resource groups to experience uneven increases in level of effect, the overall impact would remain the same given the limited area affected compared to the distribution of fish populations. The impacts to marine fish would be considered minor.

For a complete discussion of the effects on Marine Fish, please see Section 4.5.2.2.

Migratory Fish

The direct and indirect effects on migratory fish resulting from Alternative 3 would be very similar to those described under Alternative 2. Because anadromous fish are more likely to be impacted by the activity types than amphidromous fish, as discussed under Alternative 2, they are likely to experience a disproportionate increase in adverse impacts when the two groups are compared. However, as described in Alternative 2, those anadromous species known to inhabit the area where project activities would occur are not very abundant, and they are unlikely to be impacted. Therefore, the overall impact to the resource group would remain the same. The impacts to migratory fish would be considered negligible.

For a complete discussion of the effects on Migratory Fish, please see Section 4.5.2.2.

Essential Fish Habitat

The direct and indirect effects on essential fish habitat resulting from Alternative 3 would be very similar to those described under Alternative 2, with an increase in effects due to the increase in oil and gas exploration activities. In particular, the increase in exploratory drilling programs would result in increased habitat loss and alteration, potentially to EFH for saffron cod and salmon. Since there would be no increase in icebreaking activities, EFH for Arctic cod would be impacted the least. The opportunity for habitat loss or alteration resulting from Alternative 3 is very small and only incrementally larger than for Alternative 2. Most impacts would be of such low intensity and of such small geographic extent that the effects would be considered minor.

For a complete discussion of the effects on Essential Fish Habitat, please see Section 4.5.2.2.

4.6.2.2.2 Conclusion

The overall impact of Alternative 3 on Fish Resources and EFH is minor. Despite a substantial increase in level of activity over Alternative 2, there would be no corresponding increase in the overall impact level. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 3, there would be no measurable effect on the resource.

4.6.2.3 Marine and Coastal Birds

4.6.2.3.1 Direct and Indirect Effects

Alternative 3 includes all of the same type of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on marine and coastal birds under Alternative 3 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.3. The difference between alternatives concerning marine and coastal birds is a matter of degree. Alternative 3 includes a larger number of some authorized exploration activities than Alternative 2. These activities take place in the same areas and timeframes and also involve the same standard mitigation measures. This EIS includes a number of standard and additional mitigation measures as part of each alternative that are intended to reduce adverse effects on marine mammals but may also reduce adverse effects on birds. In addition to the mitigation measures imposed by NMFS, the USFWS requires certain mitigation measures specific to ESA-listed species under its jurisdiction, including spectacled and Steller's eiders (USFWS 2009c). Section 4.5.2.3 summarizes the mitigation measures typically required by the USFWS and other agencies for oil and gas exploration activities in the Beaufort and Chukchi seas to minimize impacts on birds and these measures are incorporated into the analysis of potential effects under Alternative 3.

The direct and indirect effects of oil and gas exploration activities on marine and coastal birds would be very similar under Alternative 3 as those described under Alternative 2. Marine birds would be subject to increased disturbance from vessels and seismic sources due to the increase in seismic surveys that could be authorized under Alternative 3 in both Arctic seas. However, disturbance effects would be temporary even if they occurred over a wider area and birds could fly or swim away from acute disturbance.

With more exploration activities authorized under Alternative 3, the potential for adjacent activities to magnify effects on birds could be increased. However, the requirement to maintain a minimum distance of 24 km (15 mi) between two seismic surveys conducted concurrently would effectively limit the intensity of seismic survey effects on birds no matter where the activities take place during the open water season. The Ledyard Bay closure period would be the same under Alternative 3 as under Alternative 2 so this area would be unaffected by increases in exploration elsewhere.

The risk of birds colliding with vessels would increase incrementally. A full complement of vessels for a full season as considered under this alternative may result in a greater number of strikes than occurred during the 2012 drilling season. Based on the existing preliminary bird strike reports from 2012, four simultaneous future drilling operations could result in as many as 356 bird strikes per open-water season—this could include an estimated 197 passerines, 45 shearwaters/storm petrels/auklets, 17 shorebirds, and 96 seaducks. Of the seaducks, 47 could be king eiders, 32 could be long-tailed ducks, and 16 could be common eiders. This potential mortality for each species is small by comparison with the post-breeding population; thus, no species would experience a population-level effect. However, small flocks of eiders can strike a vessel, suggesting that the authorized incidental take of listed eiders could be exceeded in one strike event.

4.6.2.3.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to marine and coastal birds are discussed under Alternative 2 (Section 4.5.2.3). These include aircraft flight paths and altitude restrictions to reduce the chance of disturbing marine and coastal birds, and development of an oil response plan and procedures for exploratory drilling to minimize the risk of spills occurring and to expedite clean-up responses.

4.6.2.3.3 Conclusion

Most marine and coastal birds are legally protected under the Migratory Bird Treaty Act and several are protected under the ESA. Birds fulfill important ecological roles in the Arctic and many are important subsistence resources. Depending on the species, they are considered to be important or unique resources in a NEPA perspective. The effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. The overall effects of oil and gas exploration activities authorized under Alternative 3 on marine and coastal birds would therefore be considered negligible to minor according to the impact criteria in Table 4.2-1.

4.6.2.3.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to marine and coastal birds are discussed under Alternative 2 (Section 4.5.2.3).

4.6.2.3.5 Additional Mitigation Measures Conclusion

Most of the additional mitigation measures considered in this EIS would not appreciably reduce potentially adverse effects on birds except for Additional C3 and C4. These two measures would reduce the risk of contamination from discharges and drilling muds, although the reduction in adverse effects relative to the standard mitigation measures would be limited to small numbers of birds and small areas of benthic habitat. Given the implementation of standard and additional mitigation measures considered by NMFS in this EIS, and assuming no large oil spill occurred during exploration activities, the effects on birds would likely be low in intensity, temporary to long-term in duration, of local extent, and would affect important or unique resources. The effects of Alternative 3 with additional mitigation measures would therefore be considered negligible to minor for birds.

4.6.2.4 Marine Mammals

4.6.2.4.1 Bowhead Whales

4.6.2.4.1.1 Direct and Indirect Effects

The types of oil and gas exploration activities undertaken in the EIS project area under Alternative 3 would be the same as those discussed under Alternative 2, with an increased level of activity for all but icebreaking or on-ice seismic (vibroseis) surveys (Table 4.2-2). The types and mechanisms of direct and indirect effects on bowhead whales would, therefore, be the same under Alternative 3 as discussed for Alternative 2 in Section 4.5.2.4.9. The difference between alternatives is a matter of degree. An increase from Level 1 to Level 2 would result in an overall increase in activity of approximately 40 percent, distributed unevenly among the different activities. It would double some activity levels while leaving others unchanged. There would be no increase in icebreaking or on-ice seismic surveys, an increase of 50 percent in seismic surveys and site clearance and shallow water hazard surveys, and a doubling of exploratory drilling programs. These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures under both alternatives.

Behavioral Disturbance

Each of the exploration activities that would be authorized under Alternative 3 includes several mechanisms for potential disturbance to bowhead whales. Most result from noise generated by oil and gas exploration equipment and associated vessels and aircraft. The mechanisms for disturbance and the suite of potential reactions by bowheads to disturbance under Alternative 3 are as described in detail for Alternative 2 in Section 4.5.2.4.9.

There could be a significant increase in the amount of open-water activities under Alternative 3 compared to Alternative 2. Exploration activity and associated effects may increase in time and space under Alternative 3, but the resulting direct and indirect effects on bowhead whales would be similar in nature to those described under Alternative 2. Potential effects of in-ice seismic surveys with icebreaker support and on-ice vibroseis surveys would be identical to Alternative 2, since activity level would remain the same under Alternative 3.

Disturbance effects of seismic activity on bowhead whales under Alternative 3 would be of medium to high intensity. Some whales may be displaced but would not leave the EIS project area entirely. The duration is expected to be interim. Long term effects are unknown. The extent of the impact would depend on the number of seismic activities and associated support vessels in an area. Individual sound source vessels may produce localized impacts, especially if one considers potential harassment of some percentage of bowhead whales exposed to sound levels below 120 dB, as discussed in Section 4.2.6. Historical take estimates from seismic studies do not suggest that these surveys alone would warrant a "high" intensity rating, however, our draft revisions of the acoustic criteria suggest that takes resulting from these surveys might be somewhat more extensive than previously calculated. Multiple seismic activities in one area or in several areas across the migratory corridor could lead to more widespread, regional impact. Bowhead whales are considered a unique resource, due to their endangered species status.

Anticipated impacts of an additional OBC survey in the Beaufort Sea, in terms of magnitude (medium), duration (interim), extent (local), and context (unique), may be similar to those described for one OBC survey under Alternative 2. Since disturbance effects may extend 20 to 30 km (12 to 19 mi) from the sound source, the zone of impact could be expected to expand spatially in the presence of multiple OBC surveys. This could result in the geographic extent of impact broadening from localized to regional.

Direct and indirect effects of site clearance and high resolution shallow hazards surveys under Alternative 3 would be similar to those described for Alternative 2. Magnitude of effects would be medium, and duration would be temporary or interim. Given the increase in the number of surveys in each sea under this alternative, the extent could increase from local, as it was under Alternative 2, to more regional, depending on the spatial and temporal distribution of activities.

For bowhead whales, historical take estimates suggest that exploratory drilling results in more take of bowhead whales than other categories of activities (Tables 4.2-5 and 4.2-6 in Section 4.2.6). Alternative 3 doubles the level of potential drilling, which results in a substantial increase in intensity. Anticipated impacts of two exploratory drilling programs under Alternative 3 would be similar to that for Alternative 2 in terms of magnitude (medium), duration (interim), extent (local), and context (unique) but will ultimately contribute to an increase in intensity when the combined effects of all activities are considered. The extent of impact resulting from the addition of a second drilling program in each sea would depend on the spatial and temporal distribution of the activities within the open water season. Extent could potentially increase from local to regional.

Disturbance effects resulting from vessel and aircraft activity under Alternative 3 would be similar to Alternative 2. Disturbance effects of vessel and aircraft activity would likely be of medium intensity, and the duration of disturbance is expected to be interim (long term effects are unknown). The extent of impact would depend on the number of support vessels in an area. Impacts are expected to be localized for individual activities; multiple activities in one area or in several areas across the migratory corridor could result in a broader, regional impact.

Please refer to Section 4.5.2.4.9 for a complete discussion of the disturbance effects, by activity type, on bowhead whales.

Hearing Impairment, Injury, and Mortality

The primary mechanisms of potential injury or mortality due to oil and gas exploration activities are permanent hearing loss or damage (auditory injury) and collisions with vessels. These are discussed in detail in Section 4.5.2.4.9. As noted under Alternative 2, it is not currently possible to assess whether or not auditory impairment (TTS or PTS) is occurring in bowhead whales. The potential effects of ship strikes under Alternative 3 are similar to that discussed under Alternative 2. The intensity of impact could be considered medium, given past low-level occurrence and potential increased occurrence with additional vessel traffic associated with oil and gas exploration activities. The impact would be temporary, although the results (injury or mortality) would be permanent for the impacted whale. The extent of impact would be local, given the relative infrequency of occurrence and the non-random distribution of both bowhead whales and exploration activity in the EIS project area.

Please refer to Section 4.5.2.4.9 for a complete discussion of potential injury or mortality effects on bowhead whales. Although it seems difficult to rule out the potential for TTS or PTS completely, the majority of the standard mitigation measures are geared towards minimizing the likelihood of injury, and are expected to be relatively successful.

Habitat Alterations

The potential effects on bowhead whale habitat in the EIS project area under Alternative 3 would likely be similar to those summarized under Alternative 2, with the exception of acoustic habitat. Additional exploratory drilling could, however, increase the number of localized sites experiencing possible habitat effects of drilling activities.

As noted in Section 4.6.1.4, with the addition of more 2D/3D surveys and exploratory drilling, the area ensonified above the levels that bowheads are expected to respond behaviorally, but also above the levels at which masking might be expected to potentially occur for some types of signals, increases significantly. When the larger 120-dB zones around all of the potential sound sources are considered (not suggesting that all individuals exposed to this would be taken, but suggesting that they would all have to deal with a sound that is audible and potentially in the range where it would mask another important sound (including inter-species communication), the area of effect is quite large and, depending on the location of the individual activities, could (for months) span a large portion of the north-south extent of the area through which migrating bowheads, with their calves, must traverse.

Please refer to Section 4.5.2.4.9 for a complete discussion of the potential effects on bowhead whale habitat.

4.6.2.4.1.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.6.2.4.1.3 Conclusion

For Alternative 3, when all of the potential categories of activities combined are considered, and the maximum level of each is considered, the increase in potential impacts on bowheads, through a combination of behavioral harassment and loss of acoustic habitat, is potentially substantial (intensity going from medium to high). If the example take estimates from Tables 1 and 2 in Section 4.2.6 are used, the difference in maximum activity levels results in almost a two-fold increase in takes. Bowhead whales are listed as endangered, and the Beaufort and Chukchi seas are important areas for them, through which the entire population migrates with calves, occasionally stopping to feed, which places them in the context of being a unique resource. The intensity and duration of the various effects and activities considered are mostly high and interim. Potential long-term effects from repeated disturbance are, however, unknown. Although the various individual activities may affect bowhead whales on a local level, the area and extent over which the combined effects occur would likely increase with multiple activities occurring simultaneously or consecutively throughout much of the summer-fall range of this population. Considering these factors, along with potential reduced adverse impacts through the imposition of required standard mitigation measures, the overall impact of Alternative 3 on bowhead whales would be considered moderate.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	Low	
		Medium	
		High	Take of bowheads exceeds 30% of population
	Duration	Temporary	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	Local	
		Regional	Impacts should be considered regional, especially when consider area ensonified over 120 dB (>10% EIS area)
		State-wide	
	Context	Common	
		Important	
		Unique	ESA-listed species, impacts across migratory corridor through which mother/calve pairs traverse, potential disruption of feeding

Type of effect	Impact Component	Effects Summary	
Injury and mortality	Magnitude or Intensity	**Low**	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	**Temporary**	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term

4.6.2.4.1.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.16).

4.6.2.4.1.5 Additional Mitigation Measures Conclusion

Conclusions regarding the potential for these additional measures to reduce adverse impacts of oil and gas activities on bowhead whales allowed under Alternative 3 are the same as under Alternative 2. Refer to Section 4.5.2.4.16 for details.

4.6.2.4.2 Beluga Whales

4.6.2.4.2.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 3 on beluga whales. Alternative 3 includes the same types of exploration activities as in Alternative 2, so the discussion of potential direct and indirect effects on beluga whales under Alternative 3 is the same as those discussed in Section 4.5.2.4.10. The exploration activities discussed in Alternatives 2 and 3 take place in the same geographic areas and timeframes and also consider the same standard and additional mitigation measures. The difference between the alternatives is simply a matter of degree; Alternative 3 includes a larger number of authorized exploration activities than Alternative 2.

The following discussion will focus on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.10.

Behavioral Disturbance

The same number of 2D (icebreaker) and vibroseis surveys would be authorized under Alternative 3 as for Alternative 2. The level of disturbance from these types of surveys would therefore be the same for Alternative 3 as is discussed for Alternative 2, which was considered to have temporary and low magnitude effects on beluga whales.

There would be a substantial increase in the amount of open-water activities under Alternative 3 compared to Alternative 2 (meaning especially 2D/3D seismic surveys and drilling operations with their associated support vessels). These activities could affect beluga whales over a large area, and the disturbance effects would be interim in duration and medium in magnitude, characterized by avoidance of vessels. The addition of one or more seismic surveys to either the Beaufort or Chukchi seas would increase the likelihood that two or more different surveys could be operating in the same general area at the same time and the effect of the disturbances could be synergistic – with the net impact being greater than the sum of the individual impacts, or, it could be that an animal exposed to one source in a given time would not be further impacted by the vicinity of another.

Based on the historical take estimates used for beluga whales, in-ice seismic surveys are responsible for the vast majority of behavioral disturbance of beluga whales (see Tables 4.2-5 through 4.2-7 in Section 4.2.6). Since the number of in-ice seismic surveys (1 each in Beaufort and Chukchi) did not increase above Alternative 2, if one considers the combined impacts of all activity types, the overall increase in anticipated behavioral takes was only about 15%.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, the primary mechanism of potential injury or mortality to beluga whales due to oil and gas exploration activities are permanent hearing loss or damage (auditory injury) and collisions with vessels. The duration of an impact from an auditory impairment would be temporary for TTS, but permanent if PTS were to occur. The extent of such impacts would be local and the context unique, since beluga whales are an integral part of the Iñupiat subsistence lifestyle. It is not known whether there have been any ship strikes involving beluga whales and exploration vessels in the Arctic, but the intensity of the impact should be considered medium due to the belugas cultural significance. The impact would be temporary, although the results (injury or mortality) would be permanent for the impacted whale.

Habitat Loss/Alteration

Potential impacts on beluga whale habitat in the EIS project area under Alternative 3 would likely be similar to those described under Alternative 2, with the exception of acoustic habitat. As noted in the Section 4.6.1.4 with the addition of more 2D/3D surveys and exploratory drilling, the area ensonified above the levels that bowheads are expected to respond behaviorally has, increased significantly. Additionally, although the lower frequencies of these sources are not in the area of highest sensitivity for belugas or at frequencies likely to mask interspecies communication, these sounds, which are covering large areas for months, are audible and potentially in frequency ranges that could mask other important sounds.

4.6.2.4.2.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.6.2.4.2.3 Conclusion

The overall impact to beluga whales is likely to be moderate. Beluga whales in the Arctic are not listed under the ESA, but there are a couple of areas in the action area that are of specific importance to this population for feeding (Barrow Canyon and Beaufort Sea Shelf Break). The intensity and duration of the various effects and activities considered are mostly medium and interim, respectively. However, potential long-term effects from repeated disturbance are unknown. Although, individually, the various activities may elicit local effects on beluga whales, the area of extent over which effects occur will likely increase with multiple activities occurring simultaneously or consecutively throughout much of the spring-fall range of this population and would be considered regional.

For Alternative 3, when all of the potential categories of activities combined are considered, and the maximum level of each is considered, the increase in potential impacts on belugas, through a combination of behavioral harassment and loss of acoustic habitat, is potentially moderate. If the example take estimates from Tables 1, 2, and 2a in Section 4.2.6 are used, the difference in maximum activity levels results in about a 15% increase in takes. Beluga whales are not ESA listed in the EIS project area, and, although, there is not enough information to indicate a trend, Chukchi data suggest that that population is not decreasing (Allen and Angliss 2011). The intensity and duration of the various effects and activities considered are mostly medium and interim.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	**Magnitude or Intensity**	**Low**	
		Medium	Behavioral harassment occurring, but likely < 30% of population disturbed
		High	
	Duration	**Temporary**	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	**Local**	
		Regional	Combined activities considered regional
		State-wide	
	Context	**Common**	
		Important	Non-ESA listed, population status not well known, but thought not to be declining in Chukchi, important feeding and calving areas
		Unique	
Injury and mortality	**Magnitude or Intensity**	**Low**	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	**Temporary**	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	**Local**	Since unlikely, any few impacts would be considered local

4.6.2.4.2.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.16).

4.6.2.4.3 Other Cetaceans

Under Alternative 3, the types of oil and gas exploration activities undertaken in the EIS project area would be the same as those in Alternative 2, but the level of activity would be considerably higher.

The types and mechanisms of effects would remain the same in Alternative 3 as in Alternative 2. The activities involved with Level 2 exploration activity take place in the same areas and timeframes and also consider the same standard and additional mitigation measures as Level 1 activity presented in Alternative 2. Therefore, the difference between the two alternatives is a matter of scale, with an increased activity level leading to a corresponding, incremental increase in effects. For a complete discussion of the types and mechanisms of effects on other cetaceans, please see Section 4.5.2.4.11.

4.6.2.4.3.1 Direct and Indirect Effects

Behavioral Disturbance

Under Alternative 3, disturbance effects of oil and gas exploration activity on other cetaceans would be of low (for those species that were not encountered or exposed) to medium intensity, based on determinations for Alternative 2. The substantial increase in level of activity over Alternative 2 would likely result in a notable increase in impact level. Some cetaceans may be displaced a short distance, but they would not be anticipated to leave the EIS project area entirely. The duration is expected to be interim. Long term effects are unknown. The extent of the impacts would depend on the number of seismic activities and associated support vessels in an area. Individual sound source vessels may produce localized impacts. Multiple activities in one area or in several areas across migratory corridors could lead to more widespread, regional impacts.

Based on the historical take estimates used for these other cetacean species, if one considers the combined impacts of all activity types at max levels, the overall increase in anticipated behavioral takes between Alternative 2 and 3 ranges from 75-100% (see Tables 4.2-5 through 4.2-7 in Section 4.2.6). However, since these species are rare or have low densities in these areas, the numbers are still relatively low.

Please refer to Section 4.5.2.4.11 for a complete discussion of disturbance effects on Other Cetaceans.

Hearing Impairment, Injury, and Mortality

The primary mechanisms of potential injury or mortality due to oil and gas exploration activities are permanent hearing loss or damage (auditory injury) and collisions with vessels. These are discussed in detail in Section 4.5.2.4.11. As noted under Alternative 2, it is not currently possible to assess whether or not auditory impairment (TTS or PTS) is occurring in other cetaceans. The potential effects of ship strikes under Alternative 3 are similar to that discussed under Alternative 2. The intensity of impact could be considered medium, given past low-level occurrence and potential increased occurrence with additional vessel traffic associated with oil and gas exploration activities. The impact would be temporary, although the results (injury or mortality) would be permanent for the impacted whale. The extent of impact will be local, given the relative infrequency of occurrence and the non-random distribution of other cetacean species and exploration activity in the EIS project area.

Please refer to Section 4.5.2.4.11 for a complete discussion of potential injury or mortality effects on Other Cetaceans.

Habitat Alterations

The potential effects on cetacean habitat in the EIS project area under Alternative 3 would likely be similar to that described under Alternative 2, with the exception of acoustic habitat. As noted in Section 4.6.1.4, with the addition of more 2D/3D surveys and exploratory drilling, the area ensonified above the levels that other cetaceans (and especially mysticetes) are expected to respond behaviorally, but also above the levels at which masking might be expected to potentially occur for some types of signals and species (especially mysticetes), increases significantly. When the larger 120-dB zones around all of the potential sound sources are considered (not suggesting that all individuals exposed to this would be taken, but suggesting that they would all have to deal with a sound that is audible and potentially in the range where it would mask another important sound (including inter-species communication), the area of effect is quite large. However, this area is not densely populated by these other species, and represents the edge of several of their ranges, so the impacts are not expected to be great.

Please refer to Section 4.5.2.4.11 for a complete discussion of the potential effects on Other Cetacean habitat.

4.6.2.4.3.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.15).

4.6.2.4.3.3 Conclusion

Evaluated collectively, the overall impact of Alternative 3 on Other Cetaceans is minor to moderate. Despite a substantial increase in level of activity over Alternative 2, resulting in a notbable increase in potential behavioral and acoustic habitat impacts, the overall anticipated impacts are still relatively low because of the compairtively low density of these species in this area and their large ranges. For Alternative 3, impacts on the resource would be low to medium in intensity, of temporary to interim duration, and of local to regional extent. Long term impacts are unknown, but anticipated to be minor.

4.6.2.4.3.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.16).

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	**Low**	Possible that some other species may not come into contact with activities or be impacted
		Medium	If behavioral harassment occurs, would be < 30% of population disturbed

4.6.2.4.4 Ice Seals

4.6.2.4.4.1 Direct and Indirect Effects

Alternative 3 includes all of the same type of exploration activities as in Alternative 2, so the discussion of potential direct and indirect effects on ice seals under Alternative 3 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.12. The difference between alternatives concerning ice seals is a matter of degree. Alternative 3 includes a larger number of some authorized exploration activities than Alternative 2 (Table 4.2-2). These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures.

The following discussion will focus on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.12.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 3 include several mechanisms for potential disturbance to ice seals in the water and on the ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment. The two types of surveys which take place on or in sea ice, the preferred habitat of ice seals and where they are most likely to be concentrated, are the in-ice 2D surveys with icebreakers and the on-ice vibroseis surveys. For both of these types of surveys, the same number of surveys would be authorized under Alternative 3 as for Alternative 2. The level of disturbance from these types of surveys would therefore be the same for Alternative 3 as is discussed for Alternative 2, which was considered to have temporary and low magnitude effects on ice seals.

There would be a moderate increase in the amount of open-water activities under Alternative 3 compared to Alternative 2. These activities could affect ice seals over a large area, especially for the 2D/3D seismic streamer surveys, but the disturbance effects would be of interim duration and of medium intensity, characterized by avoidance of vessels but with mild or unnoticeable behavioral reactions of ice seals.

Alternative 3 could authorize up to two exploratory drilling programs in both Arctic seas. The level of disturbance to seals is likely more intense in terms of the physical presence of the ships than any types of exploratory surveys, but the geographic area involved is much smaller. The noise generated from drilling is produced on an almost continual basis, making it essentially a chronic sound source in one location and seals could become habituated to it. Given the mild reaction of seals to marine vessels and the close distances to which they often approach vessels, it is unlikely that having two drilling programs operating in the same general area at the same time will result in any additive disturbance effects on particular seals, although more seals could be affected than would occur with only one drilling program. Any disturbance and displacement of seals would cover a very small area and be considered short-term.

Based on the historical take estimates used for ice seals (see Tables 4.2-5 through 4.2-7 in Section 4.2.6), in-ice seismic surveys are responsible for the vast majority of behavioral disturbance of ringed seals, with open water 2D/3D seismic surveys contributing to the majority of the behavioral disturbance takes for other species. Although no additional in-ice surveys were added in this alternative, the number of open water surveys did increase, and total take numbers between Alternative 2 and 3 increased from anywhere from 20 to 80%. For bearded, spotted, and ribbon seals, the total takes represent a relatively small portion of the population; however, for ringed seals magnitude is medium.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, there is very little risk of any ice seals being injured as a result of high noise levels or ship strikes because they can easily detect and avoid vessels as they approach in the water or on/through the ice. There is a lack of data on the physiological thresholds for acoustic injury in ice seals but that information could only be obtained through captive studies involving potential injury to the animals and, given the behavioral avoidance of wild animals to loud seismic sources, this lack of data is not crucial for this analysis.

There is the potential for seals to be exposed to small accidental spills of oils, lubricants, and other compounds used by vessels, vehicles, and equipment during exploration activities. Spills in the offshore or onshore environments could occur during normal operations (e.g. transfer of fuel, handling of lubricants and liquid products, and general maintenance of equipment). Exposure of seals to oil products could lead to irritation of eyes, mouth, lungs, and anal and urogenital surfaces (St. Aubin 1990). Ice seals are commonly observed near exploratory activities during the open-water season and could be exposed to spills in the water or on ice. A small phocid such as a 50 kg ringed or harbor seal would have to ingest several hundred milliliters of crude oil to be at risk. It is “unrealistic to assume that pinnipeds would consume such large volumes of oil during the course of normal feeding" (St. Aubin 1988, 1990). Likewise grooming would not present much of a risk for ingesting oil because it is a relatively uncommon activity among pinnipeds (McLaren 1988, 1990). McLaren (1990) concluded pinnipeds, with the exception of benthic feeders and species that prey upon birds or other seals, are unlikely to consume significant quantities of hydrocarbons since their prey species are unlikely to accumulate residues. Smith and Geraci (1975) concluded that ringed seals in their study had a very low likelihood of ingesting large amounts of oil accidentally or through oiled food items. Geraci and Smith (1976a) found that up to 75 ml of ingested crude oil is not irreversibly harmful to seals, finding only transient liver enzyme release and negligible liver damage. Geraci and Smith (1977) noted "Reports which suggest that oil might affect seals by acute intoxication through ingestion should be viewed cautiously. Our experience has shown that immersed seals ingest very small quantities. Seals are not known to be carrion feeders, and any oil which they might consume from live prey would be negligible". If a small spill did occur, cleanup efforts would begin immediately and those activities would likely include the presence of PSOs to monitor for ice seals and other marine mammals and deter them from entering the spill area if possible. Alternative 3 could authorize a greater level of exploration activity than Alternative 2 and the resulting risk of small accidental spills occurring would be proportionally greater. However, given the mitigation measures in place to prevent and clean up spills, the risk of ice seals being exposed to small spills during exploration activities authorized under Alternative 3 is considered to be minor. The potential effects of a very large oil spill caused by a well blowout are much more serious and are discussed in Sections 4.10.6.11 and 4.10.7.11. Please refer to Section 4.5.2.4.12 for a complete discussion of potential injury or mortality effects on pinnipeds.

Habitat Alterations

The two types of activities that involve potential changes to ice habitat, icebreaking and vibroseis, would be at the same level as discussed under Alternative 2, and they were considered to have temporary effects that are similar in scope as those occurring due to natural forces in the dynamic sea ice environment. The increase from one exploratory drilling program in each Arctic sea under Alternative 2 to two drilling programs in each sea under Alternative 3 would increase the amount of intentional and unintentional discharges of drilling muds and other wastes. There is a lack of information about how any of these discharges could interact directly with ice seals or be carried through the environment to affect the food supply of ice seals (primarily fish and crustaceans). Given this lack of ecological information on the effects of these discharges on ice seal habitat, it is not possible to say whether two drilling programs constitute a substantially larger risk to habitat quality for ice seals than one drilling program. Unfortunately, the types of ecological monitoring studies required to address these issues are very difficult to conduct in the Arctic and even more difficult to interpret given the vast number of complicating factors. With the addition of more 2D/3D surveys and exploratory drilling, the area ensonified above the levels that ice seals are expected to be behaviorally disturbed, as well as the areas ensonified to to levels that might be expected to mask sounds that are important to ice seals, has increased (see Section 4.6.1.4).

4.6.2.4.4.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to pinnipeds are discussed under Alternative 2 (Section 4.5.2.4.15).

4.6.2.4.4.3 Conclusion

The four species of ice seals would likely not be affected to the same extent by exploration activities in the Beaufort and Chukchi seas based on their respective abundance and distribution. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past exploration activities and their reactions have been recorded by PSOs on board source vessels and monitoring vessels. These data indicate that seals do tend to avoid on-coming vessels and active seismic arrays but their behavioral responses are often neutral rather than swimming away and they do not appear to react strongly even as ships pass fairly close with active arrays. They also primarily appear to react to icebreaking or on-ice surveys by keeping their distance or moving away at some point to an alternate breathing hole or haulout. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and would therefore be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are legally protected (ringed and bearded seals are also listed as threatened under the ESA), and are therefore considered to be important resources. Given the standard and additional mitigation measures considered in this EIS, the effects of exploration activities that could be authorized under Alternative 3 on ice seals would likely be medium to high in magnitude (the latter for ringed seals), distributed over a local to regional geographic area, and interim in duration. The effects of Alternative 3 would therefore be considered minor to moderate (the latter for ringed seals) for ice seal species according to the criteria established in Section 4.1.3.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	**Magnitude or Intensity**	**Low**	
		Medium	Behavioral harassment occurring, but likely < 30% of population disturbed for all species but ringed seals
		High	When maximum activities considered, more than 30% ringed seals may be taken
	Duration	**Temporary**	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	**Local**	Effects of activities considered local
		Regional	Max levels potentially regional
		State-wide	
	Context	**Common**	
		Important	ESA-listed species, but impacts not occurring in areas specifically important for feeding/pupping, etc.
		Unique	
Injury and mortality	**Magnitude or Intensity**	**Low**	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	**Temporary**	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	**Local**	Since unlikely, any few impacts would be considered local
		Regional	
		State-wide	
	Context	**Common**	
		Important	ESA listed species, no reliable data available to assess population trends
		Unique	
Habitat alterations	**Magnitude or Intensity**	**Low**	
		Medium	Combination of potential habitat impacts are medium
		High	
	Duration	**Temporary**	
		Interim	Although other alterations shorter, acoustic habitat is altered for duration of activities
		Long-term	
	Geographic Extent	**Local**	Lower to mid-level of ativities considered local
		Regional	Max levels potentially regional
		State-wide	
	Context	**Common**	
		Important	ESA listed species, population status unknown, no reliable data on trends
		Unique	

4.6.2.4.4.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to pinnipeds are discussed under Alternative 2 (Section 4.5.2.4.16).

4.6.2.4.5 Walrus

4.6.2.4.5.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 3 on Pacific walrus. This species is dependent on pack ice and coastal shores for haul outs. Alternative 3 includes all of the same types of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on Pacific walrus under Alternative 3 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.13. The difference between alternatives concerning Pacific walrus is a matter of degree. Alternative 3 includes a larger number of some authorized exploration activities than Alternative 2. These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures. Walrus are distributed widely across the Chukchi Sea but are uncommon in the deeper offshore waters of the Beaufort Sea. Therefore activities that occur in the Beaufort Sea are not anticipated to impact Pacific walrus. The following discussion focuses on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.13.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 3 include several mechanisms for potential disturbance to walrus in the water and on the ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment. The one type of survey that takes place on or in sea ice (the preferred habitat for walrus and where they are most likely to be concentrated) is the in-ice 2D survey with icebreakers. On-ice vibroseis surveys would only occur in the Beaufort Sea at times when walrus would not be present. Only one such in-ice survey could be authorized for each Arctic sea under any of the action alternatives. The level of disturbance from these types of surveys would therefore be the same for Alternative 3 as is discussed for Alternative 2, which was considered to have temporary and low magnitude effects on walrus.

There would be a moderate increase in the amount of open-water activities under Alternative 3 compared to Alternative 2. These activities could affect walrus over a large area, especially for the 2D/3D seismic streamer surveys, but the disturbance effects would be temporary and low in magnitude, characterized by avoidance of vessels but with mild or unnoticeable behavioral reactions of walrus. Under standard operating procedures, seismic surveys would need to be separated by at least 24 km (15 mi). At this distance, concurrent and adjacent surveys are unlikely to disturb the same walrus at the same time, although some animals could be exposed to more than one survey vessel over time as it travels through an area. The addition of one or more seismic surveys to either the Beaufort or Chukchi seas would increase the likelihood that two or more different surveys could be operating in the same general area at the same time but the minimum distance requirement would still apply and therefore effectively minimize the concern for increased disturbance to any one group of walrus.

Alternative 3 could authorize up to two exploratory drilling programs in each sea. The level of disturbance to walrus is likely more intense from the multiple support ships associated with a drilling rig than any types of exploratory surveys, but the geographic area involved is much smaller. The noise generated from drilling is produced on an almost continual basis, making it essentially a chronic sound source in one location and walrus could become habituated to it. Given the mild reaction of walrus to marine vessels it is unlikely that having two drilling programs operating in the same general area at the same time will result in any additive disturbance effects on particular walrus, although more walrus could be temporarily affected than would occur with only one drilling program. Any disturbance and displacement of walrus would cover a very small area and be considered of interim duration.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, there is very little risk of any walrus being injured or killed as a result of high noise levels or ship strikes because they can easily detect and avoid vessels as they approach in the water or on/through the ice. It is also very unlikely that any walrus would be exposed to very loud sounds from seismic operations to the point where they might be injured.

There is a potentially dangerous situation with walrus on land-based haulouts primarily on the Chukchi coast from Point Lay to Barrow. Disturbance by low-flying aircraft or nearby vessels could cause stampedes and crushing deaths. USFWS LOA mitigation measures for exploration aircraft and vessels are intended to monitor and avoid such haulouts to avoid causing such deadly disturbance.

As discussed in Section 4.5.2.4.13 exposure to small accidental spills of oils, lubricants, and other compounds used by vessels, vehicles, and equipment during exploration activities could have substantial health effects on walrus and could spread among animals in a close herd. Alternative 3 could authorize a greater level of exploration activity than Alternative 2 and the resulting risk of small accidental spills occurring would be proportionally greater. However, given the mitigation measures in place to prevent and clean up spills and the occurrence of walrus primarily on or near the pack ice rather than swimming in open water where most exploration activities take place, the risk of walrus being exposed to small spills during exploration activities is considered to be minor. The potential effects of a very large oil spill are much more serious and are discussed in Sections 4.10.6.11 and 4.10.7.11.

Please refer to Section 4.5.2.4.13 for a complete discussion of potential injury or mortality effects on walrus.

Habitat Alterations

Benthic prey of walrus may experience disturbance/mortality from bottom-contact equipment used in exploration activities such as ocean bottom cable surveys in the Beaufort Sea, vessel anchors, and exploratory drilling. All of these activities could displace benthic mollusks and crustaceans temporarily and may cause small amounts of mortality. Alternative 3 could authorize higher levels of exploration activities that involve benthic disturbance than Alternative 2. However, given the very small areas of benthic surface that could be impacted by all of these activities and the wide distribution of prey fields for walrus, these activities would be unlikely to affect the availability of prey to walrus.

Icebreaking ships intentionally disrupt pack ice in order to conduct seismic surveys or to help manage ice floes around exploratory drilling equipment. The amount of icebreaking activity and potential impacts to under Alternative 3 would be similar to Alternative 2.

Alternative 3 could authorize a greater level of exploration activity than Alternative 2, including double the amount of exploratory drilling, and the resulting risk of small accidental spills and discharges occurring would be proportionally greater. The potential effects on the quality of walrus habitat would depend primarily on the amount of sub-surface benthic habitat disturbed during drilling operations and the richness of the invertebrate fauna at that location. Please refer to Section 4.5.2.4.13 for further discussion of potential effects on walrus habitat.

4.6.2.4.5.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.15).

4.6.2.4.5.3 Conclusion

Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. This data indicates that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest of sounds generated by the ships. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of mortality from stampedes.

Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for purposes of this analysis. Given the level and type of exploration activities that would be authorized under Alternative 3, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on walrus would likely be medium in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 3 would therefore be considered minor for Pacific walrus according to the criteria established in Section 4.1.3.

4.6.2.4.5.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.16).

4.6.2.4.6 Polar Bears

4.6.2.4.6.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 3 on polar bears. This species is dependent on pack ice for much of their denning habitat and for hunting seals. Alternative 3 includes all of the same type of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on polar bears under Alternative 3 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.14. The difference between alternatives concerning polar bears is a matter of degree. Alternative 3 includes a larger number of some authorized exploration activities than Alternative 2. These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures as Alternative 2. The following discussion focuses on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.14.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 3 include several mechanisms for potential disturbance to polar bears along leads in the ice and in broken ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment including the potential for direct bear-human encounters. The two types of surveys which take place on or in sea ice, the hunting and denning habitats for polar bears, are the in-ice 2D surveys with icebreakers and the on-ice vibroseis surveys. For both of these types of surveys, the same number of surveys would be authorized under Alternative 3 as for Alternative 2. The level of disturbance from these types of surveys would therefore be the same for Alternative 3 as is discussed for Alternative 2, which was considered to have temporary and low magnitude effects on polar bears.

There would be a moderate increase in the amount of open-water activities under Alternative 3 compared to Alternative 2. These activities could affect polar bears over a larger area, especially for the 2D/3D seismic airgun arrays; however, few polar bears are encountered in open water, so the disturbance effects would be temporary and low in magnitude, characterized by neutral or ambiguous behavioral reactions of polar bears. Some polar bears could be exposed to more than one survey vessel over time as it travels through an area, but most encounters with exploration vessels typically occur while polar bears are on ice or land. The addition of one or more seismic surveys to either the Beaufort or Chukchi seas would increase the likelihood that two or more different surveys could be operating in the same general area at the same time but the minimum distance requirement (24 km [15 mi]) would still apply and therefore effectively minimize the concern for increased disturbance to any polar bear.

Alternative 3 could authorize up to two exploratory drilling programs in each sea. The level of disturbance to polar bears is likely more intense from the multiple support ships associated with a drilling rig than any types of exploratory surveys, but the geographic area involved is much smaller. The noise generated from drilling is produced on an almost continual basis, making it essentially a chronic sound source in one location and polar bears could become habituated to it. Given the mild reaction of polar bears to marine vessels it is unlikely that having two drilling programs operating in the same general area at the same time will result in any additive disturbance effects on particular bears, although more bears could be temporarily affected than would occur with only one drilling program. Any disturbance and displacement of polar bears would cover a very small area and be considered short-term.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, there is very little risk of any polar bears being injured or killed as a result of noise levels or ship strikes used in oil and gas exploration activities because of the infrequency of polar bears being observed in the open-water areas where most exploration is conducted, and their ability to detect and avoid vessels as they approach in the water or on/through the ice. It is also very unlikely that any polar bears would be exposed to very loud sounds from seismic operations to the point where they might be injured. Exposure to accidental spills of fuel, oils, and other compounds from exploration vessels and equipment could kill a polar bear (USFWS 2008b), but given the small volume of typical spills and clean-up requirements that would include MMOs to deter polar bears if necessary, the risk of polar bears being exposed to oil spills is considered negligible. Polar bears are curious, so there is always the potential for bear-human interactions during oil and gas exploration in the Arctic, even if the activities are temporary, but continuation of diligent polar bear monitoring and safety management will decrease the risk of injury or death for humans and bears. The potential effects of a very large oil spill caused by a well blowout are much more serious and are discussed in Sections 4.10.6.11 and 4.10.7.11.

Habitat Alterations

The two types of activities that involve potential changes to polar bear habitat, ice breaking and vibroseis, would be at the same level under Alternative 3 as discussed under Alternative 2. These activities would have only temporary effects on the physical characteristics of the ice and are not likely to displace polar bear prey species (ice seals) for more than a few hours. Seal distribution and abundance would continue to be determined by ice conditions and other natural factors rather than the presence of exploration activities. Polar bear habitat quality would therefore not be affected by exploration activities. The increase from one exploratory drilling program in each sea under Alternative 2 to two drilling programs in each sea under Alternative 3 would increase the amount of intentional and unintentional discharges of drilling cuttings and other wastes. The amount of increase would depend upon the depth of the wells and other factors. However, polar bears are unlikely to be affected by discharges to the seafloor.

4.6.2.4.6.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.15).

4.6.2.4.6.3 Conclusion

Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important subsistence resources and are therefore considered a unique resource. Given the mitigation measures that would be required by USFWS LOAs and NMFS as considered in this EIS, the effects of exploration activities that could be authorized under Alternative 3 on polar bears would likely be medium in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 3 would therefore be considered minor for polar bears according to the criteria established in Section 4.1.3.

4.6.2.4.6.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.16).

4.6.2.5 Terrestrial Mammals

Alternative 3 is the same as Alternative 2 except with increased levels of activity. The impacts discussed in Section 4.5.2.5 for Alternative 2 are also applicable for this alternative. The increased levels of activity would not generate different types of impacts to terrestrial mammals. The conclusions for Alternative 2 are applicable to Alternative 3. While the level of activity would increase, due to the relatively small area affected and short term, infrequent nature of crew changes, the overall impact to terrestrial mammals from aircraft activity would be minor.

4.6.2.6 Time/Area Closure Locations

The analysis of the direct and indirect effects associated with time/area closures can be found in Sections 4.6.2.4 (Marine Mammals), 4.6.2.3 (Marine and Coastal Birds) and 4.6.3.2 (Subsistence).

4.6.2.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the biological environment, other than marine mammals and marine and coastal birds, are discussed under Alternative 2 (Section 4.5.2.7).

4.6.3 Social Environment

4.6.3.1 Socioeconomics

The following discussion of direct and indirect effects of Alternative 3 evaluates effects on public revenues and expenditures, employment and personal income, demographic characteristics, and demand on social organizations and institutions associated with an increased “Level 2” of oil and gas exploration activity.

4.6.3.1.1 Direct and Indirect Effects

Public Revenue & Expenditures

Under Alternative 3 (Level 2 activity), the categories of revenue generation are the same as Alternative 2. There could be an increased level of economic activity generated in communities hosting vessel crew changes or purchasing/staging support materials, particularly if they have a tax regime to capture direct revenue (see Table 4.5-2).

Employment & Personal Income

Under Alternative 3, there would be similar types of (direct) new local hire opportunities associated with the standard mitigation measure D2 to reduce subsistence interference, and A3 and A6 to reduce marine mammal disturbance and deflection. The level of (direct) new local hire employment opportunities may increase under Level 2 activity or remain relatively the same as Level 1, if certain positions are duplicative in nature. For example, a Com Center position would be staffed continuously during the open-water season whether there are 1 or 2 exploratory drilling operations occurring in the Chukchi Sea, and PSOs may work for multiple programs, schedule permitting. The establishment of Com Centers, prescribed in standard mitigation measure D2, would not change the employment opportunities described under Alternative 2.

Table 4.6-7 demonstrates a maximum hypothetical quantity of PSOs hired under Alternative 3. It represents an increase of less than three percent of the potential work force for the region for seasonal, part-time labor.

Table 4.6-7 Maximum PSO Positions Under Alternative 3[1]

	Alternative 3 (Annual Activity Level 2)	Vessels Deployed (PSOs required)[2]	Aerial Observers	PSOs/survey	Total PSOs
Beaufort Sea	**Six 2D/3D seismic surveys**	Source (5)	4	15	90
		2 chase/monitoring and/or icebreaker (3 each)			
	Five site clearance and high resolution shallow hazards survey programs	Source (5)	4	9	45
	Two exploratory drilling program	Drilling rig (5)	4	21	42
		2 ice management (3 each)			
		3 other various (2 each)			
Chukchi Sea	**Five 2D/3D seismic**	See Beaufort examples	4	15	75
	Five site clearance and high resolution shallow hazards survey programs		4	9	45
	Two exploratory drilling		4	21	42
			TOTAL PSOs per year	**88**	**339**

Notes:

1) Assumes all positions are unique; one PSO would not be hired for multiple surveys.
2) Numbers based on (Funk 2011) and (NMFS 2009 IHA permit)

The indirect employment opportunities associated with Alternative 3 may increase marginally under Level 2 activity because shore-based support and logistical service demands would increase, including: transport of equipment; room and board of survey/seismic crews; and administration of permits to conduct the surveys. Native Corporations and private entities may capitalize on these opportunities. As described under Alternative 2, these services are seasonal and temporary in nature.

Demographic Characteristics

As described under Alternative 2, Alternative 3 would not have a direct or indirect contribution to demographics in the EIS project area communities because Level 1 and 2 activities are seasonal and short-term in nature. It is not anticipated any workers would move themselves or their families to any of the coastal communities.

Social Organizations & Institutions

The implementation of Alternative 3 would result in marginal increases in revenues to Municipal Governments associated with sales and special taxes and employment and service contracts with Regional and Village Corporations. In the communities where crew changes occur or vessels are based, there could be marginal increases in short-term, seasonal demand on institutions and social services in Barrow, Wainwright, Nome and Unalaska/Dutch Harbor.

4.6.3.1.2 Conclusion

The magnitude of the socioeconomic impact under Alternative 2 is positive and greater than a Level 1 activity. However, the magnitude of increase of total personal income and local employment rates are still not increased by more than five percent. The duration of the socioeconomic impacts is temporary because it is not year-round; however, the activity is scheduled to occur over a fixed number of years. The positive economic impacts of the activity are statewide and even national. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat communities. The summary impact level for socioeconomic resources under Alternative 3 is minor.

4.6.3.2 Subsistence

4.6.3.2.1 Direct and Indirect Effects

The potential effects to subsistence resources and harvest from disturbance of the seismic survey (both open-water and on-ice) and exploratory drilling, aircraft and vessel traffic, icebreaking and ice management, permitted discharges under Alternative 3 would be the same as those described under Alternative 2 (Section 4.5.3.2). Table 4.5-26 describes the different subsistence hunts that occur within the EIS project area by resource, where these subsistence hunts occur, the seasons of occurrence and the potential for overlapping with proposed activities of Alternatives 2 through 5. Detailed information regarding the seasonal cycles of subsistence resources and harvest patterns is described in Section 3.3.2.

Even with the increase in the number of activities/programs that could potentially occur under Alternative 3, the impacts to subsistence resources and harvest are anticipated to be similar in type, generally of similar intensity, and comparable duration, but occurring in more locations.

Assumptions regarding the level of activity used in the analysis of impacts to subsistence for Alternative 3 are described in Table 4.5-26. Under Alternative 3, only these activities would be permitted. In the Beaufort and Chukchi seas, it is assumed that the activity/programs described in Table 2.4 would involve the sound sources and sound levels associated with individual sources, the same types of source and support vessels, and the same types of icebreakers for ice management and/or icebreaking. However, there would be more vessels conducting the activities in more sites with more support vessels and more aircraft traffic from the addition of more programs being potentially permitted. The number of days the activities could occur in a season would be the same as those as Alternative 2.

Under Alternative 3, the activity area(s) and or number of wells to be drilled could be increased with up to two exploratory drilling programs potentially permitted in both the Beaufort and Chukchi seas.

4.6.3.2.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to subsistence resources are discussed under Alternative 2 (Section 4.5.3.2).

4.6.3.2.3 Conclusion

Impacts of Seismic, High Resolution Shallow Hazard Surveys and Exploratory Drilling Noise Disturbance to Subsistence Resources

Bowhead Whales

Section 4.5.2.4.9 and Section 4.2.4.6.1 (Bowhead Whales) describe the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect bowhead whales. Any impacts of seismic and high resolution shallow hazard surveys and exploratory drilling noise that affect bowhead whales are expected to result in some temporary deviation in migratory path in the vicinity of the disturbance. However when the standard and additional mitigation measures contemplated in this EIS are applied, the impact of disturbance to subsistence resources and hunters could be of low intensity and temporary duration (i.e. for the duration of the activities). The geographic extent could be local to regional, affecting a resource of unique context, due to listing under the ESA. Impacts would not be expected at the population level, reducing long term opportunities to subsistence harvest bowhead whales. The summary impact to subsistence harvest from disturbance of bowhead whales could be considered moderate based upon the fact that the resource is considered unique in context.

Beluga Whales

Sections 4.5.2.4.10 and 4.2.4.6.2 (Beluga Whales) describe the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect beluga whales. In the Chukchi Sea, beluga whales could be displaced, i.e. would avoid areas in the vicinity of seismic survey and exploratory drilling operations in July through October during their spring and fall migrations. This would have the potential to impact and disrupt some communal beluga subsistence hunts (particularly Point Lay which heavily depends on this resource) by disturbing and altering the course of these migrating whales. In turn this could make belugas more difficult to herd into the lagoons and harvest (as in the case of Point Lay).

However, the impacts would be minimized or avoided by the required mitigation measures of this EIS. As mitigated, the effects of disturbance would be considered to be of low intensity and temporary duration, occurring for the duration of the activities offshore. These impacts are considered regional in geographic extent and affecting a resource that is unique in context. There would not be expected impacts on a population level that would result in long term impacts reducing the subsistence harvest. The summary impact to subsistence harvest from disturbance of beluga whales could be moderate based upon the fact that the resource is considered locally important in context.

Seals

Sections 4.5.2.4.12 and 4.6.2.4.4 (Ice Seals) describe the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect these seals. Subsistence hunts of seals occur either in nearshore coastal areas or onshore in the spring and winter seasons when seismic and high resolution shallow hazards surveys and exploratory drilling operations would not be present. Most ringed and bearded seals are harvested in the winter or in the spring before these assumed activities would occur. While spotted seals are harvested during the summer, the activities of seismic survey and exploration drilling activities would be expected to occur offshore from subsistence use areas. Activities within the lease areas offshore that that are likely to be explored during the open water season would have no impact on subsistence hunting for seals. One on-ice seismic survey could have the potential to disturb or displace seals in their lairs but would be mitigated to lessen the impact to seals. Any impacts to seal subsistence harvests from the on-ice seismic survey would be characterized as a low intensity, limited to a local area, temporary in duration, and important in context. Therefore the summary impact to subsistence seal harvests is negligible.

Walrus, Polar Bears, Subsistence Fishing, Bird Harvest and Egg Gathering and Harvest of Caribou

Impact to these subsistence resources and their harvests are expected to be the same as described under Alternative 2.

The potential impact of the noise produced by the proposed seismic and high resolution shallow hazards surveys and exploratory drilling on subsistence resources and harvest activities under Alternative 3 could be major in the absence of mitigation measures. However mitigation measures would be required to be implemented to minimize or completely avoid adverse effects on all marine mammals and other subsistence resources and to ensure no unmitigable adverse impact on the availability of marine mammals for subsistence uses. In consideration of the standard and additional mitigation measures, these activities are not expected to disturb or disrupt subsistence activities at a level that would make resources unavailable for harvest or significantly alter the existing levels of harvests. The summary impact of Alternative 3 is considered moderate to subsistence harvests of bowhead and beluga whales. Summary impacts to seals, walrus, polar bears, subsistence fishing, bird harvest and egg gathering, and harvest of caribou are the same as those described in Alternative 2.

Impacts of Disturbance from Aircraft Overflights to Subsistence Resources

Bowhead Whales

Information on the impacts of aircraft sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.9 and 4.6.2.4.1 (Bowhead Whales) of this EIS. The sound emitted by aircraft overflights potentially could cause some disruption to bowhead whale harvest, but aircraft overflights as mitigated are not expected to make bowhead whales unavailable to subsistence hunters. Whales could be expected to temporarily deflect from overflights, but mitigation measures analyzed in and contemplated by this EIS would limit the probability of this impact occurring. It is expected that helicopters servicing offshore seismic and high resolution shallow hazard surveys and exploratory drilling operations could traverse areas utilized by subsistence whalers during fall whaling in the Beaufort Sea and limited areas of the Chukchi Sea. Mitigation measures prescribing flight path and altitude restrictions are expected to reduce any such potential impacts to a low level.

If bowhead whales were affected by aircraft overflights, it is unlikely that large numbers or a large area used by active whaling crews would be affected, so the intensity of the impact would be considered low, and the duration would be temporary. Effects of increased levels of activity permitted under Alternative 3 are low in intensity, temporary in duration, local to regional in extent, and affecting a resource that is unique in context, due to listing under the ESA. The summary impact is considered moderate based upon the fact that the resource is considered unique in context.

Beluga Whales

Information on the impacts of aircraft sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.10 and 4.6.2.4.4 (Beluga Whales) of this EIS. Summer beluga hunting could be impacted by increased numbers of trips/aircraft overflights given the levels of activity associated with Alternative 3. Mitigation measures applied to this impact would lessen the disturbance to a point that it would be considered low in intensity, temporary in duration, local or regional in extent, and affecting a resource that is important in context.

The required mitigation measures are expected to minimize and/or avoid impacts to beluga whales and their subsistence harvest as the mitigation measures for flight path and altitude restrictions are expected to reduce impacts to the point that the summary rating is considered moderate based upon the fact that the resource is considered locally important in context.

Caribou Hunting

The higher levels of activity permitted under Alternative 3 would result in increased helicopter traffic between the expected support shorebases (Barrow, Deadhorse and potentially Wainwright) and the offshore drilling locations. It is likely that there would be a disturbance to caribou subsistence hunting from the helicopter traffic that may disturb caribou on the coast. Helicopters would be traversing routes offshore from the shorebases and small proportions of available subsistence hunting areas would be affected at altitudes of less than 305 m (1,000 ft) – most likely during takeoff and landings.

Aircraft overflights are unlikely to have an adverse effect on caribou availability for subsistence harvest. Impacts that did occur would be considered low in intensity and temporary in duration. The impact would be local to regional in extent and affecting a resource that is common to important in context. The summary impact is considered moderate.

Seals, Walrus, Polar Bears, Subsistence Fishing, Bird Hunting and Egg Gathering

Impact to these subsistence resources and their harvests are expected to be same as under Alternative 2.

The higher levels of activity permitted under Alternative 3 would increase aircraft traffic associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities, which could cause some temporary behavioral disturbance and possibly deflection away from the sound source by terrestrial or marine mammals. The level of the disturbance would depend on the size of the aircraft and repeated exposure or displacement occurring to the resources, as well as whether or not the overflights overlap in time and space with subsistence hunting grounds.

Aircraft overflights are unlikely to have an adverse effect on subsistence harvest as mitigated. Impacts that did occur would be considered of low intensity but temporary in duration. The impact would be local to regional in extent, affecting resources that range from common to unique in context. The impacts are considered moderate for bowhead whales, beluga whales, and caribou. Impacts to seals, walrus, polar bears, subsistence fishing, bird harvest and egg gathering are the same as those described in Alternative 2.

Impact of Vessel Traffic to Subsistence Resources

Bowhead Whales

Information on the impacts of vessel sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.9 and 4.6.2.4.1 (Bowhead Whales) of this EIS. The higher levels of activity permitted under Alternative 3 would increase vessel traffic and vessels present in the area associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities, which could cause bowhead whales to alter their behavior during migration and avoid the area(s) within a few kilometers of vessel activities. However the required mitigation measures would limit impacts to late migrating bowhead whales and subsistence hunting from vessel traffic. The levels of activity permitted under Alternative 3 increase the potential for disturbance on a more regional level. Impacts to bowhead whale subsistence hunting are likely to be of low intensity, temporary duration, though could be local to regional extent, and affecting a resource that is unique terms of the context, due to the listing under the ESA. The summary impact could be considered moderate in terms of the levels of subsistence hunting and sharing of the resource that would be affected.

Beluga Whales

Information on the impacts of vessel sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.10 and 4.6.2.4.4 (Beluga Whales) of this EIS. A limited number of late migrating spring beluga whales could encounter increased numbers of vessels and higher levels of activity permitted under Alternative 3 for seismic and high resolution shallow hazard surveys and exploratory drilling activities and operations. The impact of disruption to beluga whales from vessel traffic could result in temporary deflection of beluga whales from subsistence harvest areas and reduced success of these hunts. However, if additional mitigation measure D1 is applied there can be no transit of exploration vessels into the Chukchi Sea prior to July 15 or until the beluga hunt is completed at Point Lay. However the increased levels of activity permitted under Alternative 3 include the potential for disturbance on a regional level (impacts extending throughout the EIS project area) as defined in Section 4.1.3. The impact to beluga whales that do encounter vessels would be of low intensity, temporary duration, local to regional extent, and affect a resource that is important in terms of the context. The summary impact could be considered moderate in terms of the levels of subsistence hunting and sharing of the resource that would be affected.

Seals

Sections 4.5.2.4.12 and 4.6.2.4.4 (Ice Seals) describe the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect seals. Seals could be displaced or avoid areas where vessels are transiting as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities. However, under the required mitigation measures for vessels transiting into the Beaufort and Chukchi seas for these activities, impacts to seals would not be such as to adversely impact subsistence hunting activities. Subsistence seal hunts would occur in nearshore coastal areas away from areas likely to be transited by vessels. The majority of seal subsistence hunting occurs in the spring and winter seasons when vessels associated with seismic survey and exploratory drilling would not be expected to be present in subsistence harvest areas. However with the increased levels of activity permitted under Alternative 3 there would greater potential for disturbance on a regional level (impacts extending throughout the EIS project area as defined in Section 4.1.3). With spatial and seasonal separations, the impact to subsistence seal harvest would be of low intensity, temporary duration, local to regional extent, and affecting resources that are important in terms of the context. The summary impact could be considered minor in terms of the levels of subsistence hunting and sharing of the resource that would be affected.

Walrus, Polar Bears, Subsistence Fishing, Bird Harvest and Egg Gathering and Harvest of Caribou

Impact to these subsistence resources and their harvests are expected to be the same as under Alternative 2.

Under the increased level of activity with Alternative 3, the summary impacts of vessel traffic on subsistence harvest of bowhead whales, and beluga whales are expected to be moderate. The summary impact from vessel traffic to subsistence harvest of seals, walrus and polar bear is considered minor. Negligible summary impacts to subsistence harvest of fish, bird hunting and egg gathering, and caribou are expected as a result of vessel traffic and the same as Alternative 2.

Impacts of Icebreaking and Ice Management on Subsistence Resources

Bowhead Whales

Information on the impacts of icebreaking and ice management associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.9 and 4.6.2.4.1 (Bowhead Whales) of this EIS. Seismic and high resolution shallow hazard surveys and exploratory drilling activities would be expected to occur during the open water season when seismic and high resolution shallow hazard surveys and exploratory drilling vessels would not encounter large amounts of sea ice. However icebreaking and ice management may be necessary during late fall or early winter when industry is still engaged in seismic and high resolution shallow hazard surveys and exploratory drilling activities in order to protect equipment, vessels, and infrastructure. Additionally, some operators have recently proposed to conduct seismic surveys during the in-ice or shoulder season (i.e. October through December). These surveys would require the use of an icebreaker to go ahead of the seismic survey vessel. The required mitigation measures limit the time frame in which these activities occur in, and, as a result, the likelihood of impacts to subsistence harvest as a result of ice management activities is reduced and unlikely to adversely affect subsistence harvest of bowhead whales. The majority of these types of in-ice surveys would occur after the completion of fall bowhead harvests in the Beaufort and Chukchi seas. With the increased levels of activity permitted under Alternative 3 the potential for disturbance on a more regional level becomes greater (impacts extending throughout the EIS project area as defined in Section 4.1.3). In the event that icebreaking does cause bowhead whales to avoid an area the impact to subsistence resources is expected to be low in intensity, short term in duration, local to regional in extent, and affecting a resource that is unique in context. This would be considered a moderate impact to subsistence harvest of bowhead whales based upon the fact that the resource is considered unique in context.

Beluga Whales

Information on the impacts of icebreaking and ice management associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.10 and 4.6.2.4.4 (Beluga Whales) of this EIS. Icebreaking activities could increase under Alternative 3 with the greater level of permitted activity allowed for seismic survey and exploratory drilling activities. Ice management activities could be necessary as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities when ice is encountered in the late fall through early winter months of exploration activities. Icebreaking and ice management would be limited to areas where industry is actively exploring or drilling. These activities would occur in the offshore waters and would not be expected to affect beluga whale subsistence hunting. Icebreaking and ice management activities would be conducted far removed from areas typically hunted in the Chukchi Sea. No impacts are anticipated for beluga subsistence hunts in the Beaufort Sea, as beluga hunting is conducted opportunistically during the bowhead hunt, and the required mitigation measures of this project would prohibit seismic survey and exploratory drilling activities (and associated ice management) from occurring during this time.

The required mitigation measures are expected to minimize and potentially avoid impacts on beluga whales so that no adverse impacts occur to subsistence harvest. There is a low probability that impacts could occur to subsistence users in the Chukchi Sea. With the increased levels of activity permitted under Alternative 3 there is greater potential for disturbance on a regional level (i.e. across the EIS project area). In the event that icebreaking or ice management does cause beluga whales to avoid an area the impact to subsistence resources is expected to be low in intensity, short term in duration, local to regional in extent, and affecting a resource that is important in context. This would be considered a moderate summary impact to the subsistence harvest of beluga whales based upon the fact that the resource is considered locally important in context.

Seals

Sections 4.5.2.4.12 and 4.6.2.4.4 (Ice Seals) describe the mechanisms by which icebreaking and ice management activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect seals. Icebreaking could be associated with seismic survey plans that extend into the late open water season late fall to early winter (October to December) when daylight is very limited to absent and visibility is reduced making seals more difficult to spot although. At this time of year sealing efforts for subsistence are not concentrated or intense. Ice management activities could be necessary as part of seismic and high resolution shallow hazard surveys and exploratory drilling and would occur in the offshore waters during the open water season after sea ice has retreated and melted. Although a greater level of activity would occur under Alternative 3, these proposed activities would occur after the end of pupping and molting seasons for all ice seals. There would be few seals expected in the area of where the proposed activities would take place. Subsistence harvest of seals would not be expected to occur in areas of active ice management offshore. The required mitigation measures are expected to avoid and minimize impacts on seals and in turn on subsistence harvests so that no adverse impacts occur. There is a low probability that impacts would occur to subsistence users. In the event that icebreaking does cause seals to avoid an area, the impact is expected to be low in intensity, short term in duration, local to regional in extent, and affecting resources that are common to important in context. This would be considered a minor summary impact to subsistence harvest of seals.

Walrus, Polar Bears, Subsistence Fishing, Bird Harvest and Egg Gathering and Harvest of Caribou

Impact to these subsistence resources and their harvests are expected to be same as under Alternative 2.

Summary impacts to subsistence harvest of bowhead whales and beluga whales due to icebreaking and ice-management activities are expected to be moderate. Summary impacts to subsistence harvest of seals and polar bears are considered to be minor. Summary Impacts to walrus, fish, and bird hunting and egg gathering from icebreaking are expected to be negligible and the same as under Alternative 2. No impacts to caribou are expected.

Impacts of noise and vehicle movement from on-ice seismic surveys

No impacts are anticipated subsistence harvests of bowhead whales, beluga whales, Pacific walrus, and fishing as a result of the on ice seismic survey. Summary impacts to seals, marine and coastal birds and caribou are expected to be the same as under Alternative 2 and are considered negligible. The summary impacts to polar bears could be minor.

Indirect Impact to Subsistence Resources from Permitted Discharges

Permitted discharges would be conducted under the conditions and limitations of the required NPDES General Permits. Permitted discharge would be mitigated by additional mitigation measures C3 and C4, which would place requirements and limitations on the levels of discharge and discharge streams that could affect marine mammal habitat and eventually the diets of subsistence users. Under Alternative 3, there could be a higher level of activity, which would increase the levels of permitted discharges.

Mitigation measures may not alleviate the perception that a small oil spill or regulated wastewater discharge might contaminate subsistence resources. There is a perception the foods could become contaminated by discharges and/or small fuels spills could result in impacts to human health from consumption of the resources. The likelihood is low that subsistence resources or harvest would occur in the vicinity of the assumed areas where drilling and/or any associated discharge or spill might occur. In addition fuel transfers are not expected during transit between the Beaufort and Chukchi seas. The indirect impact of drill cuttings and mud discharges may displace marine mammals and fish a short distance from each drilling location. The impacts to subsistence users would be of low intensity, short term in duration, local in extent, and affecting resources that are common to unique in context. Therefore the summary impacts to subsistence resources, activities, and subsistence users would be minor, though the perception of the impact could be moderate.

Summary

Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources resulting from implementation of Alternative 3 would be of low intensity, temporary in duration, local to regional in extent, and the context would be common to unique. Protected resources (bowhead whales and polar bears are considered unique in context as these resources are protected by legislation (e.g. MMPA, ESA) or are considered an important subsistence resource (beluga whales). Therefore the summary impact level of Alternative 3 on subsistence resources and harvests would be considered to range from negligible to moderate depending upon the specific subsistence resource affected and source of disturbance.

<u>4.6.3.2.4 Additional Mitigation Measures</u>

Additional mitigation measures identified that could reduce adverse impacts to subsistence resources are discussed under Alternative 2 (Section 4.5.3.2).

4.6.3.3 Public Health

4.6.3.3.1 Direct and Indirect Effects

Anticipated effects to public health as a result of Alternative 3 are expected to be similar to those expected under Alternative 2, as discussed in Section 4.5.3.3.

4.6.3.3.2 Conclusion

Both potential beneficial and adverse impacts are anticipated as a result of Alternative 3. Possible changes could occur to health outcomes such as chronic disease and trauma and many of the pathways relate to traditional practices and subsistence activities. However, there is a very low likelihood of these health outcomes arising, and effects are unlikely to be large enough cause a measurable change in health outcomes. The magnitude or intensity of effects is estimated to be low: above background conditions, but small and within both the natural variation and adaptive ability of the local population. If health changes do occur, the duration of changes may be permanent, and multiple communities could be affected.

4.6.3.4 Cultural Resources

4.6.3.4.1 Direct and Indirect Effects

Alternative 3 is the same as Alternative 2 except with increased levels of activity. These mitigation measures do not affect cultural resources in the EIS project area, so the impacts discussed in Section 4.5.3.4 for Alternative 2 are the same for Alternative 3. The overall impact to cultural resources would be minor.

4.6.3.4.2 Conclusion

Direct and indirect impacts to cultural resources resulting from the implementation of Alternative 2 would be the same in Alternative 3. For a complete discussion of direct and indirect impacts on cultural resources, please see Section 4.5.3.2.

4.6.3.5 Land and Water Ownership, Use, and Management

4.6.3.5.1 Direct and Indirect Effects

Land and Water Ownership

The direct and indirect impacts to land and water ownership caused by Alternative 3 are similar to those caused by Alternative 2. Refer to Section 4.5.3.5 for a discussion on these topics. This includes federal, state, private, borough, and municipal owned lands and waters.

Land and Water Use

The actions in Alternative 3 are the same as for Alternative 2. However the activity levels are increased; numbers of allowed seismic surveys, shallow hazards survey programs, and exploratory programs are increased in the Beaufort and Chukchi seas. However, the amount of on-ice seismic surveys and icebreaking remained the same. Taking into consideration these increases, direct and indirect effects to the recreation, residential, mining, and protected land uses are similar to Alternative 2. Refer to Section 4.5.3.5 for a discussion on these topics.

With an increase in activity levels, the possibility for conflict increases between subsistence use and surveys. Section 4.6.3.2 discusses the direct and indirect impacts of Alternative 3 in detail.

The direct and indirect impacts caused by Alternative 3 for industrial, transportation, and commercial land uses are similar to those discussed under Alternative 2 in Section 4.5.3.5 but use would increase incrementally as survey activity levels go up. Beyond what is discussed in Section 4.5.3.5, there is a slightly higher possibility of new facilities and infrastructure, higher levels of air and vessel traffic, and commercial activity associated with survey support. No new roads or railroad lines are expected to be built under this alternative; therefore no changes are expected in land use to accommodate expanded land transportation systems. See Section 4.6.3.1 Socioeconomics for further discussion on economic opportunities under this alternative

Land and Water Management

BOEM has awarded leases in the Beaufort and Chukchi seas for the purpose of exploring for and developing petroleum resources in the federal OCS. The level of exploration activity in federal water under Alternative 3 is consistent with management of those waters. Similarly, the state applies Best Interest Findings before allowing seismic exploration activities and each must demonstrate individual consistency with state management policies before permits are issued on state lands or waters. Therefore, no inconsistencies or changes in federal or state land or water management are anticipated as a result of this alternative. The effects are similar to those discussed under Alternative 2, Section 4.5.3.5.

While no change in underlying land or water management is anticipated as a result of this project, compliance with NSB and NAB comprehensive plans and Land Management Regulations coastal management policies is undertaken on a voluntary basis for activities in state and federal waters; permit applicants for offshore exploration activities in state waters may attempt to be consistent with Borough Land Management Regulations. As activities increase under Alternative 3, the possibility for conflicts with borough offshore development and coastal management zoning policies goes up as well. As indicated in Section 3.3.6 Coastal Management, the Alaska Coastal Management Program was not reauthorized by the State legislature and is no longer in effect.

4.6.3.5.2 Conclusion

Based on Table 4.4-2, and the analyses provided in Section 4.5.3.5, the impacts on land and water ownership under Alternative 3 are described as follows. The magnitude of ownership impacts would be low because no changes in land or water ownership will result from this action. The duration of impact would be temporary because no ownership changes will occur. The extent of impacts would be local, occurring only in the activity area and involving no ownership change. The context of impact would be common because the federal waters affected have no special, rare, or unique ownership characteristics. In total, the direct and indirect impacts on land ownership/development rights are considered to be negligible; they would be low intensity, temporary, localized, and do not result in changes of ownership.

Based on Table 4.4-2 and the analyses provided above and in Section 4.5.3.5, the impacts of land and water use caused by Alternative 3 are described as follows. The magnitude of impact would be high where activity occurs where there is previously little to no activity (such as Wainwright), and the magnitude of impact would be low where activity occurs where previous activity is common (Prudhoe Bay, Barrow, Nome, Dutch Harbor). The duration of impact would be temporary because an increase in aircraft and shipping traffic would last only for that survey season, although the impact could be permanent if construction of a new facility or infrastructure to accommodate shipping traffic were built in Wainwright. The extent of impacts would be local because any changes in land use as a result of this alternative would be limited geographically to the communities that would support the survey vessels. The context of impact would be common because the areas of land and water use affected are extensively available and have no special, rare, or unique characteristics identified. In summary, the direct and indirect effects of Alternative 3 would be moderate because of the possibility for high intensity impact and long term structures in smaller communities

Based on Table 4.4-2 and the analyses provided above and in Section 4.5.3.5, the impacts on land and water management caused by Alternative 3 are described as follows. The magnitude of impact would be low because, while the level of activity would increase, they are consistent with existing management plans, subject to conditions of approval. The duration of impact would be temporary because project activities are short term in duration and would not result in long-term conflicts with management plans.

The extent of impacts would be local because proposed activities would not involve management plans beyond the localized areas of exploration and support activities. The context of impact would be common because the areas of land and water affected are extensively available and have no special, rare or unique characteristics identified in an adopted management plan. In total, the direct and indirect impacts of Alternative 3 on land and water management would be minor because they would be low intensity, would be temporary in nature, local, and common.

4.6.3.6 Transportation

4.6.3.6.1 Direct and Indirect Effects

The effects to transportation in Alternative 3 would be similar to those described under Alternative 2 (Section 4.5.3.6), though of an elevated intensity. The direct effect to transportation would be an increase in levels of air traffic and vessels present in these areas associated with the seismic survey and exploratory drilling activities in comparison to levels projected under Alternative 2. The intensity of the impact would be considered low and short term in duration (length of survey or exploratory drilling activities each year). The extent of increased aircraft presence may be on a local and regional scale given the increased number of seismic survey and exploratory drilling programs that could occur under Alternative 3. Impacts from the increased levels of air traffic would be low in intensity, temporary in duration, and local in extent and affect a common resource. The impact level could be considered minor to moderate.

4.6.3.6.2 Conclusion

Increased levels of marine vessel traffic in Alternative 3 associated with the seismic survey and exploratory drilling programs would be expected to occur in offshore areas where local marine transportation does not occur. Industry vessels would likely encounter local marine traffic when littering to designated nearshore marine facilities (which are limited). The impact of increased vessel presence and the potential for vessel strikes to marine mammals would be low in intensity, temporary in duration, limited in geographic extent to a local area, and common to potentially unique context (in respect to protected marine mammal resources). The summary impact from increases in vessel traffic would be considered minor.

4.6.3.7 Recreation and Tourism

4.6.3.7.1 Direct and Indirect Effects

Alternative 3 is the same as Alternative 2 except with increased levels of activity. The impacts discussed in Section 4.5.3.7 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to recreation and tourism. The conclusions for Alternative 2 are applicable to Alternative 3; the overall impact to recreation and tourism would be minor.

4.6.3.7.2 Conclusion

The direct impacts to recreation and tourism would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 3 on recreation and tourism would be minor.

4.6.3.8 Visual Resources

This section discusses potential impacts on visual resources that could result from implementing Alternative 3 of the proposed project.

4.6.3.8.1 Direct and Indirect Effects

Implementation of Alternative 3 would be similar to that describe in Section 4.10.4.19, however there would be an increase in the level of permitted activity and a consequent potential increase in impacts to visual resources. The proposed action is expected to result in short-term moderate effects to scenic quality and visual resources similar to that described in Alternative 2. Because of the greater number of support vessels used in the two exploratory drilling programs proposed under Alternative 3, this action could be high intensity if both programs are implemented in close proximity to each other. Potential impacts could be of low to medium intensity depending if programs are geographically separated. In either case, actions would be temporary, localized and occur in an important context.

4.6.3.8.2 Conclusion

Implementation of Alternative 3 is expected to result in *short-term moderate effects* to scenic quality and visual resources. Potential impacts could be of low to medium intensity depending on specific location of drill sites. The geographic extent of potential impacts would be localized; however they would occur in an important ecosystem.

4.6.3.9 Environmental Justice

4.6.3.9.1 Direct and Indirect Effects

Impacts to Subsistence Foods and Human Health

The activity levels associated with Alternative 3 are expected to result in similar levels of disruption of subsistence hunts by disturbing and altering the course of marine mammals harvested in the EIS project area (described in Subsistence Section 4.5.3.2 for Alternative 2). Alternative 3 activity levels are expected to cause a negligible increase in contamination levels of subsistence food sources (described in the Public Health Section 4.5.3.3), which could have the indirect effect of adding a similar perception as Alternative 2 that subsistence foods are contaminated and alter confidence in their consumption.

4.6.3.9.2 Conclusion

Activities related to implementation of Alternative 3 would have a low intensity impact on subsistence resources and human health, a temporary duration, and a regional extent. Subsistence foods and human health are unique resources and they are protected under the MMPA and EO 12898. Thus, Alternative 3 is expected to have a minor impact to subsistence resources and human health. There would also be minor disproportionate impacts to Alaska Native communities under Alternative 3.

4.6.3.10 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the social environment, other than subsistence, are discussed under Alternative 2 (Section 4.5.3.10).

4.7 Direct and Indirect Effects for Alternative 4 – Authorization for Level 3 Exploration Activity

4.7.1 Physical Environment

4.7.1.1 Physical Oceanography

4.7.1.1.1 Direct and Indirect Effects

Water Depth and General Circulation

Under Alternative 4, changes in water depth resulting from exploratory drilling programs would be the same in nature as those described for Alternative 3. Alternative 4 would allow two additional drilling programs in each OCS Planning Area, and, as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact would effectively be doubled, relative to Alternative 3. The effects of Alternative 4 on water depth would be low-intensity, long term, and would affect a common resource. Changes in water depth from discharged material would have only minor effects on the physical resource character of the proposed action area. Although common resources would be affected across increased spatial scales relative to Alternative 2, the overall effects of Alternative 4 on water depth would be minor.

Currents, Upwellings, and Eddies

Seismic surveys, site clearance and shallow hazards surveys, and on-ice seismic surveys would have only negligible effects on currents, upwellings, and eddies within the EIS project area under Alternative 4. Construction of artificial islands, which could occur in nearshore state waters of the Beaufort Sea at a rate of two islands per year under Alternative 4, would result in medium-intensity, temporary (ice), localized effects on nearshore currents in the waters adjacent to the artificial islands. Over the life of this EIS, those effects would be minor and would occur only if artificial ice islands are constructed to support exploratory drilling activities. Exploratory drilling activities in the Chukchi Sea are anticipated to occur from temporary structures, as opposed to artificial ice islands that could be built in the nearshore Beaufort Sea. Therefore, exploratory drilling activities in the Chukchi Sea would have only negligible effects on currents, upwellings, and eddies within the proposed action area.

Tides and Water Levels

The activities described under Alternative 4 would not affect tides or water levels within the EIS project area.

Stream and River Discharge

The activities described under Alternative 4 would not affect stream and river discharge within the EIS project area. Exploratory drilling in state waters on grounded ice could occur from manmade reinforced ice "islands" but would have negligible effects on stream and river discharge within the EIS project area.

Sea Ice

Under Alternative 4, impacts to sea ice resulting from the proposed activities would be the same in nature as those described for Alternative 2. Alternative 4 would allow additional drilling programs and additional artificial ice islands in the proposed action area, and, as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact would effectively be doubled. Relative to Alternative 2, sea ice would be affected over a larger area due to more potential ice management activity and localized thermal inputs associated with exploratory drilling activities.

Although Alternative 4 would allow additional seismic surveys in both the Beaufort and Chukchi seas relative to Alternative 2, each action alternative would authorize only one survey per year in each of the seas to involve icebreaking activity. Likewise, only one on-ice seismic survey per year would be authorized under each of the action alternatives and only in the Beaufort Sea. Therefore, the level of activity contemplated for these specific types of exploration activities under Alternative 4 is the same as what is contemplated under Alternative 2.

The effects of these activities on sea ice would be medium intensity, local, temporary, and would affect a resource that is common in the EIS project area. The presence of sea ice in lease and non-lease areas targeted for open water seismic exploration and exploratory drilling could result in changes to the schedule, location, and duration of exploratory activities. The presence of sea ice also represents a potential hazard to vessels and exploratory drilling platforms. Industry operators in offshore areas have developed critical operation and curtailment procedures for managing sea ice, including changes to schedule, vessels dedicated to ice management, and procedures for taking drill platforms off location until potential hazards subside.

Within ice and on ice exploration activities could experience similar and additional hazards from sea ice, including the potential for ice override events. In-ice exploration activities would use icebreakers and other vessels for the purpose of ice management and/or ic breaking, and protocols would be established for response to potential ice hazards. Drilling on grounded ice from artificial ice islands would not be subject to potential hazards from moving ice but could experience potential effects from storm surge and ice override events. Within the Beaufort Sea, where drilling on constructed artificial ice islands could occur in state waters, much of the area is protected from ice override by barrier islands. Individual drilling operations would need to assess the potential for ice related hazards and develop appropriate design and operation protocols.

Although common resources would be affected across increased spatial and temporal scales relative to Alternative 2, the overall effects of Alternative 4 on sea ice would be minor.

4.7.1.1.2 Conclusion

The overall effects of the proposed actions on to physical oceanography attributes would be of medium intensity (due to the increase in impacts to sea ice), temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. The overall effects of the proposed activity described in Alternative 4 on physical ocean resources in the proposed action area would be minor.

4.7.1.2 Climate

Under this alternative, emissions would be higher when compared to either Alternative 2 or Alternative 3 because the alternative proposes additional exploration plans described as Level 3 Exploration Activity on the Arctic OCS. The number of annual EPs proposed for each Arctic OCS planning area would increase to four. The number of proposed seismic and other surveys would remain the same as described in Alternative 3. The majority of additional emissions are from the additional EPs proposed for Level 3 Exploration Activity.

Refer to Section 3.1.4.4 (*Climate Change in the Arctic*) for a thorough discussion of climate systems and the effects of GHG emissions.

4.7.1.2.1 Direct and Indirect Effects

Direct Effects

Direct effects under this alternative are the same as those described under Alternative 2.

Indirect Effects

Indirect Effects under this alternative are the same as those described under Alternative 2.

Regulatory Reporting and Permitting

Regulatory reporting and permitting under this alternative would be the same as those described under Alternative 2.

CO_2e Emissions Inventory

Under this alternative, emissions would be higher when compared to either Alternative 2 or Alternative 3 because the alternative proposes additional exploration plans described as Level 3 Exploration Activity on the Arctic OCS. The number of annual EPs proposed for each Arctic OCS planning area would increase to four. The number of proposed seismic and other surveys would remain the same as described in Alternative 3. The majority of additional emissions are from the additional EPs proposed for Level 3 Exploration Activity. The specific description and number of each of these programs and activities proposed for the Arctic OCS, on an annual basis, were summarized earlier in Table 2.4 (*Activity Definitions*) and Section 2.4.5 (*Alternative 2 – Authorization for Level 1 Exploration Activity*). The estimated potential annual emissions of CO_2e for each type of activity and program proposed under this alternative are provided in Table 4.7-1. The data in this table assume no controls to reduce emissions.

Effects of this Alternative on Climate Change

Reporting emissions of CO2e under this alternative would be the same as described under Alternative 2.

Table 4.7-1. Estimated CO_2e Emissions by Activity and Program Type for the Arctic OCS

Activity/Program Types	U.S. Chukchi Sea OCS Annual CO_2e Emissions (metric tons per year)
2D/3D Seismic Survey (including one survey using an ice breaker vessel)	72,048
Site Clearance and High Resolution Shallow Hazards Survey Program	12,392
Exploration Plan	372,026
Total	**456,467**
Activity/Program Types	**U.S. Beaufort Sea OCS Annual CO_2e Emissions** (metric tons per year)
2D/3D Seismic Survey (including one survey using an ice breaker vessel)	85,692
Site Clearance and High Resolution Shallow Hazards Survey Program	12,392
On-Ice Seismic Survey	25
Exploration Plan	372,026
Total	**470,136**

Effects of Climate Change on Resources under this Alternative

Effects of climate change on resources under this alternative would be the same as described under Alternative 2.

4.7.1.2.2 Conclusion

Direct and indirect impacts associated with climate are associated mainly with potential emissions of CO_2e that could, decades from now, contribute to changes in the environmental conditions already occurring in the Arctic and throughout the world. As such, the impacts to climate change cannot be measured on a project-level basis and instead are global in scope. However, total emissions of CO_2e emissions should be disclosed in the NEPA review.

4.7.1.3 Air Quality

Under this alternative, emissions would be higher when compared to either Alternative 2 or Alternative 3 because the alternative proposes additional EPs described as Level 3 Exploration Activity on the Arctic OCS. The number of annual EPs proposed for each Arctic OCS planning area would increase to four. The number of proposed seismic and other surveys would remain the same as described in Alternative 3. The majority of additional emissions are from the additional EPs proposed for Level 3 Exploration Activity.

4.7.1.3.1 Direct and Indirect Effects

Direct and indirect effects under this alternative would be from the same sources of emissions as described under Alternative 2 in Section 4.5.1.3.

Exploration Plan Emission Inventory

The emission rates likely to reflect Level 3 Exploration Activity in each sea are presented in Table 4.7-2.

Table 4.7-2. Estimated Annual Emission Inventory of Four Exploration Plans for Each Sea

Pollutant Sources	Four (4) Exploratory Drilling Programs Annual Emissions (tons per year)					
	PM	NO_X	SO_2	CO	VOC	CO_2e*
Drill Rig	250.92	8,624.80	4.32	1,881.60	258.76	72,737
Ice Breakers (2 vessels each EP)	192.80	6,637.60	3.36	1,448.00	199.12	145,475
Anchor Handler	44.80	624.40	0.24	135.20	50.00	1,818
Oil Spill response Barge	96.40	3,318.80	1.68	724.00	99.56	72,737
Oil spill Response Tug	44.80	624.40	0.24	135.20	50.00	1,818
Tank Vessel for Spill Storage	96.40	3,318.80	1.68	724.00	99.56	72,737
Support Vessels (3 vessels each EP)	134.40	1,873.20	0.72	405.60	150.00	4,703
Aircraft	0.004	0.20	0.84	32.24	13.12	
Total	**860.52**	**25,022.20**	**13.08**	**5,485.84**	**920.12**	**372,026**

Notes: SO_x (sulfur oxides) includes emissions of sulfur dioxide (SO_2).
NO_x (nitrogen oxides) includes emissions of nitrogen dioxide (NO_2).
PM (particulate matter) includes emissions of coarse and fine particulate matter (PM_{10} and $PM_{2.5}$).
VOC is volatile organic compounds.
CO is carbon monoxide.
CO_2e (carbon dioxide equivalent) is a combination of emissions of the six most common greenhouse gases expressed as a rate in relation to the global warming potential of CO_2.
*CO_2e is expressed in metric tons; all other data are given in units of short tons.
** No information on CO_2e emissions is available from EPA for aircraft.
Sources: BOEM, Alaska OCS Region. 2012.

The inventory assumes no application of BACT or the use of ULSD fuel. The emission inventory presented in Table 4.7-2 assumes the same method of calculation and EP operational characteristics as described for Alternative 2.

Survey Emission Inventory

The number and type of seismic and other surveys would be the same as described for Alternative 3. The emission rates likely to reflect the increased level of seismic and other surveys under this alternative (Alternative 4) are presented in Table 4.7-3 and Table 4.7-4.

Table 4.7-3. Estimated Annual Emission Inventory of Multiple Surveys on the Chukchi Sea OCS

Vessels	**U.S. Chukchi Sea OCS Five (5) - 2D/3D Seismic Surveys Annual Emissions** (tons per year)					
	PM	**NO_X**	**SO_2**	**CO**	**VOC**	**CO_2e***
Seismic Vessel	28.60	795.10	117.55	177.95	30.15	33,448
Receiver Vessel	14.05	481.40	81.10	110.35	14.35	21,110
Monitoring Vessel	9.09	311.54	52.50	71.39	9.28	13,660
Ice Breaker Vessel (for 1 of 5 Surveys)	2.81	96.28	16.22	22.07	2.87	3,830
Total	**54.55**	**1,684.32**	**267.37**	**381.76**	**56.65**	**72,048**
Vessels	**U.S. Chukchi Sea OCS Five (5) - Site Clearance and High Resolution Shallow Hazards Surveys Annual Emissions** (tons per year)					
	PM	**NO_X**	**SO_2**	**CO**	**VOC**	**CO_2e***
Monitoring Vessel	9.09	311.54	52.50	71.39	9.28	12,392

Notes: SO_x (sulfur oxides) includes emissions of sulfur dioxide (SO_2).
NO_x (nitrogen oxides) includes emissions of nitrogen dioxide (NO_2).
PM (particulate matter) includes emissions of coarse and fine particulate matter (PM_{10} and $PM_{2.5}$).
VOC is volatile organic compounds.
CO is carbon monoxide.
CO_2e (carbon dioxide equivalent) is a combination of emissions of the six most common greenhouse gases expressed as a rate in relation to the global warming potential of CO_2.
*CO_2e is expressed in metric tons; all other data are given in units of short tons.
Sources: BOEM, Alaska OCS Region. 2012.
BOEM. 2012. ION Seismic Survey.

The survey inventories assume no application of BACT or the use of ULSD fuel. The emission inventory presented in Table 4.7-3 assumes the same method of calculation and survey vessel operational characteristics as described for Alternative 2.

Table 4.7-4. Estimated Annual Emission Inventory of Multiple Surveys on the Beaufort Sea OCS

Vessels	U.S. Beaufort Sea OCS Six (6) - 2D/3D Seismic Surveys Annual Emissions (tons per year)					
	PM	**NO_X**	**SO_2**	**CO**	**VOC**	**CO_2e***

Monitoring Vessel	9.09	311.54	52.50	71.39	9.28	12,392
Equipment	**U.S. Beaufort Sea OCS One (1) – On-Ice Seismic Survey Annual Emissions** (tons per year)					
	PM	**NO_X**	**SO_2**	**CO**	**VOC**	**CO_2e***
Trucks (2 vehicles)	0.001	0.04	0.0002	0.24	0.02	2
Bulldozer	0.26	6.05	1.76	4.59	2.59	23
Total	**0.27**	**6.09**	**1.76**	**4.83**	**2.62**	**25**

Notes: SO_x (sulfur oxides) includes emissions of sulfur dioxide (SO_2).
NO_x (nitrogen oxides) includes emissions of nitrogen dioxide (NO_2).
PM (particulate matter) includes emissions of coarse and fine particulate matter (PM_{10} and $PM_{2.5}$).
VOC is volatile organic compounds.
CO is carbon monoxide.
CO_2e (carbon dioxide equivalent) is a combination of emissions of the six most common greenhouse gases expressed as a rate in relation to the global warming potential of CO_2.
*CO_2e is expressed in metric tons; all other data are given in units of short tons.

4.7.1.3.2 Air Quality Impact Analysis

The air quality impact analysis would be conducted as described under Alternative 2.

4.7.1.3.3 Level of Effect

The annual rate of air emissions and onshore pollutant concentrations are the two basic measurements for assessing a proposal's level of effect on air quality. The emission inventory provided in this section discloses the rate of emissions likely to reflect a proposal under this alternative, expressed in short tpy. When necessary, an emission inventory is translated into pollutant concentrations expressed in μg/m^3, a value that can be measured against the NAAQS allowing the level of effect to be categorized relative to the conditions summarized under Alternative 2 in Table 4.5-7. Further information regarding level of effect under this alternative would be the same as discussed under Alternative 2.

4.7.1.3.4 Conclusion

Emissions from exploratory drilling activities proposed under this alternative would be higher than emissions estimated for Alternative 2. Without emission reduction controls on the drillship engines, there is a greater potential for one or more of the EPA SILs to be exceeded onshore. The Level 3 Exploration Activity would almost certainly require additional modeling to demonstrate the effect of pollutant concentrations on the nearest onshore area. A moderate level of effect on air quality is expected, which may be mitigated by emission control strategies to result in a minor level of effect. Cumulatively, the total estimated emissions for each Arctic OCS planning area, when considering all plans and activities described under this alternative, are summarized in Table 4.7-5.

Control of oil and gas emission sources on the OCS, and levels of effect, are considered on a project-by-project basis, as each individual operator would have the responsibility to engage any engine emission controls required by BOEM AOCSR. Emission reduction strategies have the potential to reduce at least some emissions of all pollutant types, including CO_2e. Therefore, the data provided in Table 4.7-5 would represent a worst-case scenario for each Arctic OCS planning area.

Table 4.7-5. Estimated Annual Emission Inventory for Arctic OCS – Level 3 Exploration Activity

4.7.1.4 Acoustics

Under Alternative 4, the number and types of seismic surveys and site clearance and high resolution shallow hazards survey programs is identical to Alternative 3. This alternative differs from Alternative 3 in that it adds two additional EPs to each Arctic OCS Planning Area per year for a total of four in each Planning Area. Because the acoustic output from drillships and drill rigs is typically below 180-185 dB re 1 μPa (rms), the addition of these activities will not increase sound levels above these thresholds. As noted in Table 4.5-13, the 120 dB re 1 μPa (rms) from a drillship is estimated at 2 km (1.2 mi) from the source and at 210 m (689 ft) for a jack-up rig from the source. For the sake of a more comprehensive assessment, the table below (and those in the Acoustic section descriptions in previous alternatives) delineates a circle around a drilling rig with a 13-km radius that is meant to encompass the 120-dB ensonification created by both the rig and the support vessels associated with it (which are all producing noise and generaly creating an area that would suggest animals are exposed to disturbance from multiple stimuli). However, the addition of two EPs per season in each sea would only increase the total percentage of total area ensonified per season by about one percent versus Alternative 3. Refer to Section 4.6.1.4.1 for additional information on the direct and indirect effects of this resource.

Table 4.7-6 Total Surface Area Ensonified Above Sound Level Thresholds Under Alternative 4, From Averages Listed in Table 4.5-12.

		Total Surface Areas (km²) to sound level (90% rms SPL (dB re 1 μPa rms))			
		190	**180**	**160**	**120**
Chukchi Sea Shelf 40 to 52 m depth					
	5x ~3200 in³	4.41	48.7	1,798	141,764
	5x 40 in³	0.03	0.29	25.3	10,619
	4x drill/support*			2088	2,088
	% Chukchi	**0.00%**	**0.02%**	**1.48%**	**59%**
Beaufort Sea Shelf, 15 to 40 m depth					
	4x ~3200 in³	9.96	82.9	1,633	45,238
	3x 20 in³	0.003	0.03	5.59	2,535
	4x drill/support*			2088	2,088
Beaufort Coastal, inside and outside barrier islands to 10 m depth					
	2x 880 in³	0.46	2.02	46.9	2,206
	2x 20 in³	0.02	0.12	4.35	268
	% Beaufort	**0.00%**	**0.03%**	**1.48%**	**20%**
Entire Region					
		15	**134**	**7,689**	**206,806**
	% EIS area	**0.00%**	**0.03%**	**1.48%**	**40%**

*drill/support indicates area within 13-km radius around drill rig, notionally encompassing support

vessels. Indicated area is within 120-dB radius, included in 160-dB column for assessment.

4.7.1.4.2 Conclusion

The intensity rating of this alternative is high, as additional exploration activities will introduce sources with source sound levels that exceed 200 dB re 1 μPa. Because the exploration activities could continue for several years, the duration is considered as long term. The spatial extent of these activities is regional, since the distribution of exploration activities over the project areas will lead to approximately 40 percent of the EIS area being exposed to sound levels in excess of 120 dB re 1 μPa. Therefore, the overall impact rating for direct and indirect effects to the acoustic environment would be moderate.

4.7.1.5 Water Quality

Impacts to water quality from Alternative 4 are expected to be similar to those described for Alternative 2. The difference between the two alternatives is the level of activity. Differences in impacts between the two alternatives are noted below. The same level of seismic surveys and site clearance and high resolution shallow hazards survey programs contemplated under Alternative 3 are contemplated in this alternative.

4.7.1.5.1 Direct and Indirect Effects

Temperature and Salinity

Seismic Surveys

Similar to the impacts under Alternative 2, seismic surveys under Alternative 4 would not be expected to have any measureable impact on temperature or salinity in the EIS project area.

Site Clearance and Shallow Hazards Surveys

Similar to the impacts under Alternative 2, site clearance and shallow hazards surveys under Alternative 4 would not be expected to have any measureable impact on temperature or salinity in the EIS project area.

On-ice Seismic Surveys

Similar to the impacts under Alternative 2, on-ice seismic surveys under Alternative 4 would not be expected to have any measureable impact on temperature or salinity in the EIS project area.

Exploratory Drilling Programs

Under Alternative 4, changes in water quality related to temperature and salinity resulting from exploratory drilling programs would be the same in nature as those described for Alternative 2. Alternative 4 would allow additional drilling programs in the EIS project area, and as a result of those programs the intensity as well as the spatial extent of the impact may effectively be quadrupled. Relative to Alternative 2, salinity and temperature may be affected over a larger area. However, the effects of Alternative 4 on water quality resulting from changes in temperature and salinity would be low intensity, temporary, and local. Although common resources may be affected across increased spatial scales relative to Alternative 2, the overall effects of Alternative 4 on water quality related to temperature and salinity resulting from exploratory drilling programs would be minor.

Turbidity and Total Suspended Solids

Seismic Surveys

Effects on water quality resulting from increases in turbidity and total suspended solids from seismic surveys under Alternative 4, if any, would be low-intensity, temporary, local, and would affect a common resource. The nature of those effects would be similar to those described under Alternative 2.

Site Clearance and Shallow Hazards Surveys

Effects on water quality resulting from potential increases in turbidity and total suspended solids from site clearance and shallow hazard surveys under Alternative 4, if any, would be low-intensity, temporary, local, and would affect a common resource. The nature of those effects would be similar to those described under Alternative 2.

On-ice Seismic Surveys

On-ice seismic surveys would not affect turbidity or concentrations of suspended solids in the proposed action area. As they occur on the ice and not in the open-water environment, no contact is made with the seafloor during these types of surveys.

Exploratory Drilling Programs

Effects on water quality resulting from increases in turbidity and total suspended solids from exploratory drilling programs are described in detail under Alternative 2. Alternative 4 would allow additional drilling programs in the EIS project area. As a result of the additional drilling programs the intensity as well as the spatial extent of the impact may be effectively quadrupled. Relative to Alternative 2, turbidity and concentrations of suspended solids may be affected over a larger area. However, the effects of Alternative 4 on water quality resulting from changes in turbidity and concentrations of suspended solids would be low intensity, temporary, and local. Although common resources would be affected across increased spatial and temporal scales relative to Alternative 2, the overall effects of Alternative 4 on water quality related to turbidity and concentrations of suspended solids resulting from exploratory drilling programs are expected to be minor.

Metals

Seismic Surveys

Similar to the impacts under Alternative 2, seismic surveys are not expected to have any measureable impact on dissolved metal concentrations in the EIS project area.

Site Clearance and Shallow Hazards Surveys

Similar to the impacts under Alternative 2, site clearance and shallow hazards surveys are not expected to affect dissolved metal concentrations in the proposed action area.

On-ice Seismic Surveys

Similar to the impacts under Alternative 2, on-ice seismic surveys would not affect dissolved metal concentrations in the EIS project area.

Exploratory Drilling Programs

Direct and indirect effects on water quality resulting from increases in concentrations of metals from exploratory drilling programs are described in detail under Alternative 2. Alternative 4 would allow additional drilling programs in the EIS project area. As a result of the additional drilling programs, the intensity as well as the spatial extent of the impact may effectively be quadrupled. Relative to Alternative 2, metal concentrations may be affected over a larger area. However, the effects of Alternative 4 on water quality resulting from changes in metal concentrations would be low intensity, temporary, and local. Although common resources would be affected across increased spatial and temporal scales relative to Alternative 2, the overall effects of Alternative 4 on water quality related to metal concentrations resulting from exploratory drilling programs would be minor.

Hydrocarbons and Organic Contaminants

Seismic Surveys

Impacts under this alternative would be similar to the impacts under Alternative 2. While the level of activity would approximately double, seismic surveys are expected to have negligible impacts on concentrations of hydrocarbons and organic contaminants in the waters of the EIS project area.

Site Clearance and Shallow Hazards Surveys

Impacts under this alternative would be similar to the impacts under Alternative 2. While the level of activity would approximately double, site clearance and shallow hazards surveys are expected to have negligible impacts on concentrations of hydrocarbons and organic contaminants in the waters of the EIS project area.

On-ice Seismic Surveys

Similar to the impacts under Alternative 2, on-ice seismic surveys are expected to have minor impacts on concentrations of hydrocarbons and organic contaminants in the waters of the EIS project area under Alternative 4. Alternative 4 contemplates the same level of on-ice seismic activity as Alternative 2; therefore, the level of impacts is anticipated to be the same. Contaminants from fluids entrained in the ice roads would be discharged every spring during breakup. Any entrained hydrocarbons and other organic contaminants from vehicle exhaust, oil, grease, and other vehicle-related fluids not recovered would pass into the Beaufort and/or Chukchi Sea system at each breakup as a result of on-ice seismic surveys. The effects of these discharges on water quality would be temporary and local in nature, and overall impacts to water quality from on-ice seismic surveys under Alternative 4 are expected to be minor.

Exploratory Drilling Programs

Direct and indirect effects on water quality resulting from increases in concentrations of hydrocarbons and other organic contaminants from exploratory drilling programs are described in detail under Alternative 2. Relative to Alternative 2, Alternative 4 would allow additional drilling programs in the EIS project area, and, as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact may effectively be quadrupled. Relative to Alternative 2, concentrations of hydrocarbons and other organic contaminants would be affected over a larger area. Impacts to water quality resulting from hydrocarbons and other organic contaminants would be temporary and would dissipate soon after the discharge is stopped. Such impacts would be local in nature due to rapid dilution of discharged compounds into the ocean. It is probable that inputs of hydrocarbons and other organic contaminants from exploratory drilling programs under Alternative 4 would have minor to moderate effects on water quality outside of the discharge plume area. However, due to lack of applicable water quality criteria for some organic compounds in drilling fluids (EPA 2006b), it is problematic to determine whether or not inputs of hydrocarbons and other organic compounds from the proposed activity would exceed water quality regulatory limits.

Although unlikely, it is plausible that accidental or emergency events may occur within the proposed action area. Due to the rarity of such unforeseen events, and the potential magnitude and extent of their impacts relative to the effects of normal operation and maintenance activities, such accidental or emergency events are not addressed in this section and are covered in Section 4.10 of this EIS. Regulations requiring operators to have plans in place to minimize the likelihood of a spill would reduce the potential for adverse impacts to water quality.

4.7.1.5.2 Conclusion

After mitigation, the effects of the proposed actions on water quality are expected to be low-intensity, temporary, local, and would affect a common resource. The overall effects of the proposed activity described in Alternative 4 on water quality in the EIS project area are expected to be negligible.

4.7.1.6 Environmental Contaminants and Ecosystem Functions

4.7.1.6.1 Direct and Indirect Effects

Contaminants of Concern

Contaminants of concern introduced to the EIS project area as a result of the activities proposed in Alternative 4 would be the same as those described for Alternative 2. Because Alternative 4 would authorize a greater level of activity relative to Alternative 2, the amounts of contaminants introduced to the EIS project area would potentially be greater under Alternative 4.

Proposed mitigation measures intended to reduce/ lessen non-acoustic impacts on marine mammals have the potential to reduce adverse impacts resulting from contaminants of concern.

Exposure of Habitat and Biological Resources

Pathways for exposure of habitat and biological resources to contaminants of concern as a result of the activities proposed in Alternative 4 would be the same as those described for Alternative 2.

Effects on Ecosystem Functions

In response to comments and suggestions received as part of the scoping process for this EIS, effects of (contaminants of concern from) the proposed activities on ecosystem functions are assessed in the following section. Effects of the activities proposed under Alternative 4 on the four categories of ecosystem functions (defined in Section 4.4.1.6) are assessed below.

Regulation Functions

The nature of the effects of the activities proposed under Alternative 4 on regulation functions would be the same as described under Alternative 2. The effects of greatest concern would be associated with exploratory drilling programs. Alternative 4 would authorize up to four exploratory drilling programs per year in the Beaufort Sea and up to four exploratory drilling programs per year in the Chukchi Sea, whereas Alternative 2 would authorize only one exploratory drilling program per year in each sea. Thus, the magnitude of the effects on regulation functions would be greater under Alternative 4 compared to Alternative 2. The magnitude and extent of effects of Alternative 4 on regulation functions would depend upon interrelationships between impacts to biological and physical resources, which are addressed in other sections of this EIS.

Habitat Functions

The nature of the effects of the activities proposed under Alternative 4 on habitat functions would be the same as described under Alternative 2. Effects of Alternative 4 on habitat functions would include impacts to refugium functions and nursery functions (provision of suitable reproduction habitat) associated with benthic habitats resulting from discharges from exploratory drilling. Overall effects to benthic habitat functions would be temporary, local, and low-intensity. Effects would also occur to functions associated with pelagic and epontic habitats. Functions associated with terrestrial habitats would be affected to a lesser degree. Overall, effects of Alternative 4 on habitat functions would be medium-intensity, temporary, and local. The functions affected could be common, important, or unique depending on the spatial location of the impact.

Proposed mitigation measures intended to reduce/ lessen non-acoustic impacts on marine mammals have the potential to reduce adverse impacts to habitat functions.

Production Functions

The nature of the effects of the activities proposed under Alternative 4 on production functions would be the same as described under Alternative 2. Impacts to production functions related to provision of raw materials and food (i.e. subsistence) could be affected by the activities proposed under Alternative 4.

These impacts are described in the subsistence section of this EIS. In addition to introducing contaminants to secondary and tertiary consumers via trophic transfer processes, contaminants of concern could interrupt trophic transfer processes resulting in shorter food chains (less complex food webs), and reduced throughput of energy and nutrients at higher trophic levels. Oil and gas are ecosystem goods, and the flows of energy that they represent are ecosystem services. These ecosystem goods and services could potentially be derived from historical production functions in the EIS project area under Alternative 4.

Information Functions

Information functions contribute to the maintenance of human health by providing opportunities for spiritual enrichment, cognitive development, recreation, and aesthetic experience (DeGroot et al. 2002). The effects of Alternative 4 on information functions in the EIS project area would depend upon interrelationships between impacts to cultural resources, social resources and aesthetic resources, which are addressed in other sections of this EIS.

4.7.1.6.2 Conclusion

Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 4 would be medium-intensity, temporary, localized, and would affect common resources. The functional properties of ecosystems described in this section, such as nutrient cycling and habitat functions, are more robust (i.e. resistant to stressors) than are species composition and other structural properties. Because Alternative 4 would authorize a greater level of activity than Alternative 2 there is potential for increased volume of contaminants introduced to the project area. However, the overall effects of Alternative 4 on ecosystem functions would be considered minor.

4.7.2.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the physical environment are discussed under Alternative 2 (Section 4.5.1.7).

4.7.2 Biological Environment

4.7.2.1 Lower Trophic Levels

4.7.2.1.1 Direct and Indirect Effects

The direct and indirect impacts discussed in Section 4.5.2.1 for Alternative 2 are also applicable for this alternative. The increased levels of activity associated with Alternative 4 would not generate different types of impacts to lower trophic levels. The conclusions for Alternative 2 are applicable to Alternative 4; therefore, the overall impact to lower trophic levels would be moderate.

4.7.2.1.2 Conclusion

Given the implementation of the standard mitigation measures considered in this EIS, the direct and indirect effects on lower trophic levels associated with Alternative 4 would likely be low in intensity, temporary to long-term in duration, of local extent and could affect common resources. The resulting summary impact level would be negligible. The only exception to these levels of impacts would be the introduction of an invasive species due to increased vessel traffic, which could be of medium intensity, long-term or permanent duration, of regional geographic extent, and affect common or important resources, which could cause a summary impact of moderate.

4.7.2.2 Fish and Essential Fish Habitat

4.7.2.2.1 Direct and Indirect Effects

An increase in activity level from Level 2 to Level 3 would not change the effects on fish and EFH. The types and mechanisms of effects would remain the same in Alternative 4 as in Alternative 2. For a complete discussion of the types and mechanisms of effects on fish resources, please see Section 4.5.2.2, *Fish and Essential Fish Habitat*.

Marine Fish

The direct and indirect effects on marine fish resulting from Alternative 4 would be similar to those described under Alternative 2. Due to the uneven nature of the increases in activity levels by activity type, the increase in impacts to different fish assemblages would vary. The cryopelagic assemblage would have essentially no additional impacts, as the level for activities most likely to affect that group (icebreaking and on-ice seismic surveys) would not change from Alternative 3. Demersal assemblages would also have no increase in effects from seismic survey levels, but effects from the doubling of the numbers of exploratory drilling operations would create habitat loss and effects from noise. Effects to pelagic assemblages would be identical in terms of icebreaking and on-ice surveys but result in an increase in effects from doubling the number of drilling programs. These effects would be an increase in effluents and resultant effects on water quality, although likely to be short term and local. However, in spite of the potential for different resource groups to experience uneven increases in level of effect, the overall impact would remain the same given the limited area affected compared to the distribution of fish populations. The impacts to marine fish would remain at minor.

For a complete discussion of the effects on Marine Fish, please see Section 4.5.2.2.

Migratory Fish

The direct and indirect effects on migratory fish resulting from Alternative 4 would be similar to those described under Alternative 2. Because anadromous fish are more likely to be impacted by the activity types than amphidromous fish, as discussed under Alternative 2, they are likely to experience a disproportionate increase in adverse impacts when the two groups are compared. However, as described in Alternative 2, those anadromous species known to inhabit the area where project activities would occur are not abundant, and they are unlikely to be impacted. Therefore, the overall impact to the resource group would remain the same. The impacts to migratory fish would be considered negligible.

For a complete discussion of the effects on Migratory Fish, please see Section 4.5.2.2.

Essential Fish Habitat

The direct and indirect effects on essential fish habitat resulting from Alternative 4 would be similar to those described under Alternative 3, with an increase in effects due to the doubling of oil and gas exploration activities. In particular, the increase in exploratory drilling programs would result in increased habitat loss and alteration to EFH for saffron cod and salmon. Since there would be no increase in icebreaking activities, EFH for Arctic cod would be impacted the least. The opportunity for habitat loss or alteration resulting from Alternative 4 would be double than that for Alternative 3. However, most impacts would be of relatively low intensity for the environments of the species of concern and of such small geographic extent that their effects would be considered minor.

For a complete discussion of the effects on Essential Fish Habitat, please see Section 4.5.2.2.

4.7.2.2.2 Conclusion

The overall impact of Alternative 4 on Fish Resources and EFH is minor. Despite a substantial increase in level of activity over Alternative 2, there would be little corresponding increase in the overall impact level. Due to the small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 4, there would be no measurable effect on the resource.

4.7.2.3 Marine and Coastal Birds

4.7.2.3.1 Direct and Indirect Effects

Alternative 4 includes all of the same types of exploration activities as Alternatives 2 and 3, so the discussion of potential direct and indirect effects on marine and coastal birds under Alternative 4 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.3. The difference between alternatives concerning potential effects on marine and coastal birds is a matter of degree. Alternative 4 includes a larger number of some authorized exploration activities than do Alternatives 2 and 3. These activities take place in the same areas and timeframes and also involve the same standard mitigation measures. This EIS includes a number of standard mitigation measures as part of each alternative that are intended to reduce adverse effects on marine mammals but may also reduce adverse effects on birds. In addition to the mitigation measures imposed by NMFS and BOEM, ESA section 7 consultations with USFWS require certain mitigation measures specific to ESA-listed species under USFWS jurisdiction, including spectacled and Steller's eiders (USFWS 2012 [May 8 2012 Biological Opinion]). Section 4.5.2.3 summarizes the mitigation measures typically required for oil and gas exploration activities in the Beaufort and Chukchi seas to minimize impacts on birds, and these measures are incorporated into the analysis of potential effects under Alternative 4. A discussion of additional mitigation measures is also included.

The direct and indirect effects of oil and gas exploration activities on marine and coastal birds from seismic surveys under Alternative 4 would be similar to those described under Alternatives 2 and 3. Marine birds could be subject to increased disturbance from vessels and seismic sources due to the increase in seismic surveys that could be authorized under Alternative 4 in both Arctic seas. However, disturbance effects would be temporary even if they occurred over a wider area—birds could fly or swim away from acute disturbance.

Marine and coastal birds could experience some disruption of prey resources if multiple seismic operations operate in the same general area for an extended period of time. Seismic operations are required, however, to operate at specific distances from each other, which disperses effects across a wider area. Seismic operators also leave an area once the information has been collected, so it is unlikely that multiple operators would operate in the same area for an extended period of time. Also, seabirds are constantly seeking out new prey concentrations; therefore, if seismic operations were to displace a prey patch, this is equally likely to facilitate the seabirds' search for prey as it is to hinder it. Furthermore, such effects are temporary in space and time and do not persist from one season to another.

The risk of birds colliding with vessels associated with exploratory drilling operations under Alternative 4 is likely to increase as a consequence of the greater level of support vessel traffic. As an example, Shell had many vessels in the Bering, Chukchi, and Beaufort seas during the 2012 open water season but not the full complement—approximately eight larger vessels were in operation during the truncated open-water work season in 2012. Preliminary analysis of bird strike data from the 2012 season suggests that bird mortality from striking vessels may be greater than originally considered.

The bird strikes reported generally fall into four broad categories: tubenoses/alcids (shearwaters, storm petrels, and auklets), ducks (long-tailed ducks and eiders), shorebirds (phalaropes), and passerines (i.e., wagtails, pipits, arctic warbler, Northern wheatear, American tree sparrow, and dark-eyed junco). Reports of several ducks and storm petrels striking vessels at one time confirmed that strikes can be episodic. On August 30, 2012, the drillship *Kulluk* crew reported 12 strikes from a position 43.5 km (27 mi) offshore of the Chukchi Sea coastline. The *Kulluk* crew also reported eight strikes on September 2, 2012, when 96.6

km (60 mi) offshore. The icebreaker *Fennica* crew reported nine king eiders striking their vessel on October 22, 2012, when located 37 km (23 mi) offshore in the Beaufort Sea.

A full complement of vessels for a full season as considered under this alternative may result in a greater number of strikes than occurred during the 2012 drilling season. Based on the existing preliminary bird strike reports from 2012, eight simultaneous future drilling operations could result in as many as 713 bird strikes per open-water season—this could include an estimated 395 passerines, 90 shearwaters/storm petrels/auklets, 35 shorebirds, and 192 seaducks. Of the seaducks, 95 could be king eiders, 64 could be long-tailed ducks, and 33 could be common eiders. This potential mortality for each species is small by comparison with the post-breeding population; thus, no species would experience a population-level effect. However, small flocks of eiders can strike a vessel, suggesting that the authorized incidental take of listed eiders could be exceeded in one strike event.

4.7.2.3.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to marine and coastal birds are discussed under Alternative 2 (Section 4.5.2.3). These measures include aircraft flight paths and altitude restrictions to reduce the chance of disturbing marine and coastal birds, and development of an oil response plan and procedures for exploratory drilling to minimize the risk of spills occurring and to expedite clean-up responses. There is currently no way to evaluate the effectiveness of flight altitude restrictions.

Spatial/Temporal Considerations

With more exploratory drilling activities authorized under Alternative 4, the potential for adjacent activities to magnify effects on birds could be increased. The Ledyard Bay closure period would be the same under Alternative 4 as under Alternative 2, so this area would likely be unaffected by increases in support activities for increased exploratory drilling elsewhere.

4.7.2.3.3 Conclusion

Most marine and coastal birds are legally protected under the Migratory Bird Treaty Act and several are protected under the ESA. Birds fulfill important ecological roles in the Arctic and are therefore considered to be important or unique resources. The effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary, localized, and not likely to have population-level effects for any species. The overall effects of oil and gas exploration activities authorized under Alternative 4 on marine and coastal birds would therefore be considered moderate according to the impact criteria in Table 4.5-17.

4.7.2.3.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to marine and coastal birds are discussed under Alternative 2 (Section 4.5.2.3).

4.7.2.3.5 Additional Mitigation Measures Conclusion

Most of the additional mitigation measures considered in this EIS would not appreciably reduce potentially adverse effects on birds except for Additional Mitigation Measures C3 and C4. These two measures would reduce the risk of contamination from discharges and drilling muds, although the reduction in adverse effects relative to the standard mitigation measures would be limited to small numbers of birds and small areas of benthic habitat. Given the implementation of standard and additional mitigation measures considered by NMFS in this EIS, and assuming no large oil spill occurred during exploration activities, the effects on birds would likely be low in intensity, temporary to long-term in duration, of local extent, and would affect important or unique resources. The effects of Alternative 4 with additional mitigation measures would therefore remain moderate for birds.

4.7.2.4 Marine Mammals

4.7.2.4.1 Bowhead Whales

4.7.2.4.1.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 4 on bowhead whales. Alternative 4 includes all of the same types of exploration activities as in Alternatives 2 and 3, so the discussion of potential direct and indirect effects on bowhead whales under Atlernative 4 involves all of the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.9. The only difference between alternatives 3 and 4 is the addition of drilling programs, levels of all other activity types stay the same. Specifically, Alternative 3 assumes a maximum of two exploration drilling programs active in each sea at any given time while Alternative 4 assumes a maximum of four exploration drilling programs active in each sea at any given time. These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures. The following discussion focuses on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.9.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 4 includes several mechanisms for potential disturbance to bowhead whales. Most result from noise generated by oil and gas exploration equipment and associated vessels and aircraft. The mechanisms for disturbance and the suite of potential reactions by bowheads to disturbance under Alternative 4 are as described in detail for Alternative 2 in Section 4.5.2.4.9.

There would be a moderate increase in the amount of open-water activities under Alternative 4 compared to Alternatives 2 and 3 as a result of the added drilling programs. Anticipated impacts from all types of activities, except drilling, would remain the same as in Alternative 3.

Alternative 4 could authorize up to four exploratory drilling programs in each sea, which would double the amount of exploratory drilling programs contemplated under Alternative 3. For bowhead whales, historical take estimates suggest that exploratory drilling results in more take of bowhead whales than other categories of activities (Tables 4.2-5 through 4.2-7). Alternative 4 doubles the level of potential drilling beyond alternative 3, which results in a significant increase in intensity. Anticipated impacts of four exploratory drilling programs in each sea under Alternative 4 would be similar to that for Alternative 3 in terms of magnitude (medium), duration (interim), extent (local to regional), and context (unique). The extent of impact resulting from the addition of one or two drilling programs in each sea would depend on the spatial and temporal distribution of the activities within the open water season.

Disturbance effects resulting from vessel and aircraft activity under Alternative 4 would be similar to Alternative 3. However, with the increase in the number of explatory drilling programs, this could require additional vessels and aircraft overflights for resupply and crew change, as well as for marine mammal monitoring. Disturbance effects of vessel and aircraft activity would likely be of medium intensity, and the duration of disturbance is expected to be temporary (long term effects are unknown). The extent of impact would depend on the number of support vessels in an area. Please refer to Section 4.5.2.4.9 for a complete discussion of the disturbance effects, by activity type, on bowhead whales.

Hearing Impairment, Injury, and Mortality

The primary mechanisms of potential injury or mortality due to oil and gas exploration activities are permanent hearing loss or damage (auditory injury) and collisions with vessels. These are discussed in detail in Section 4.5.2.4.9. As noted under Alternative 2, it is not currently possible to assess whether or not auditory impairment (TTS or PTS) is occurring in bowhead whales. The potential effects of ship strikes under Alternative 4 are similar to that discussed under Alternatives 2 and 3. The intensity of impact could be considered medium, given past low-level occurrence and potential increased occurrence with additional vessel traffic associated with oil and gas exploration activities. The impact would be temporary, although the results (injury or mortality) would be permanent for the impacted whale. The extent of impact would be local to regional, given the relative infrequency of occurrence and the non-random distribution of both bowhead whales and exploration activity in the EIS project area.

Please refer to Section 4.5.2.4.9 for a complete discussion of potential injury or mortality effects on bowhead whales.

Habitat Alterations

Doubling the number of potential drilling programs could increase the number of localized sites experiencing possible habitat effects of drilling activities. However, this addition only makes a relatively small change in the impacted acoustic habitat (an increase of 1% of EIS area ensonified) (see Table 4.7-7 in Section 4.7.1.4).

Please refer to Section 4.5.2.4.9 for a complete discussion of the potential effects on bowhead whale habitat.

4.7.2.4.1.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.7.2.4.1.3 Conclusion

Impacts of individual activities associated with oil and gas exploration in the EIS project area under Alternative 4 are similar to Alternative 3, with the exception of the added drilling programs, which increase the impacts to acoustic habitat slightly beyond those anticipated in Alternative 3 and increase the anticipated behavioral disturbance by over 40%. Bowhead whales are listed as endangered, and the Arctic slope is an important area for them, through which the entire population migrates with calves, occasionally stopping to feed, which places them in the context of being a unique resource. The intensity and duration of the various effects and activities considered are high and interim, respectively. Potential long-term effects from repeated disturbance are, however, unknown. Although the various individual activities may affect bowhead whales on a local to regional level, the area and extent over which the combined effects occur, would likely increase with multiple activities occurring simultaneously or consecutively throughout much of the summer-fall range of this population and at that point would be considered regional. Considering these factors, along with potential reduced adverse impacts through the imposition of required standard mitigation measures, the overall impact of Alternative 4 on bowhead whales would be considered moderate to major.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	Low	
		Medium	
		High	Take of bowheads exceeds 30% of population
	Duration	Temporary	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	Local	
		Regional	Impacts considered regional
		State-wide	
	Context	Common	
		Important	
		Unique	ESA-listed species, impacts across migratory corridor through which mother/calve pairs traverse, potential disruption of feeding
Injury and mortality	Magnitude or Intensity	Low	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	Temporary	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	Local	Since unlikely, any few impacts would be considered local
		Regional	
		State-wide	
	Context	Common	
		Important	ESA listed species, but population is increasing
		Unique	
Habitat alterations	Magnitude or Intensity	Low	
		Medium	Combination of potential habitat impacts, including acoustic habitat, are medium
		High	
	Duration	Temporary	
		Interim	Although other alterations shorter, acoustic habitat is altered for duration of activities
		Long-term	
	Geographic Extent	Local	
		Regional	Impacts considered regional, especially when consider area over which sound exceeds 120 dB, and the communication distances of baleen whales.
		State-wide	
	Context	Common	
		Important	ESA listed species, but population is increasing
		Unique	

4.7.2.4.1.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.16).

4.7.2.4.1.5 Additional Mitigation Measures Conclusion

Conclusions regarding the potential for these additional measures to reduce adverse impacts of oil and gas activities on bowhead whales allowed under Alternative 4 are the same as under Alternative 2. Refer to Section 4.5.2.4.9 for details.

4.7.2.4.2 Beluga

4.7.2.4.2.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 4 on beluga whales. Alternative 4 includes the same types of exploration activities as in Alternatives 2 and 3, so the discussion of potential direct and indirect effects on beluga whales under Alternative 4 is the same as those discussed in Section 4.5.2.4.10. The exploration activities discussed in Alternatives 2 and 3 take place in the same geographic areas and timeframes and also consider the same standard and additional mitigation measures. The difference between the alternatives is simply a matter of degree; Alternative 4 includes a larger number of authorized exploratory drilling activities than Alternative 3, but all other activity types remain at the same levels as Alternative 3.

The following discussion will focus on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.10.

Behavioral Disturbance

There would be a moderate increase in the amount of open-water activities under Alternative 4 compared to Alternative 3 but only in the addition of exploratory drilling programs, which are expected to result in comparatively minor increases in impacts to belugas. Potential effects of seismic surveys and site clearance and high resolution shallow hazards survey programs would be identical to Alternative 3, since activity level would remain the same for these types of activities under Alternative 4.

Based on the historical take estimates used for beluga whales, in-ice seismic surveys are responsible for the vast majority of behavioral disturbance of beluga whales (Tables 4.2-5 through 4.2-7). Since neither the number of in-ice seismic surveys (1 each in Beaufort and Chukchi), nor the larger 2D/3D seismic surveys increased above Alternative 3, if one considers the combined impacts of all activity types, the overall increase in anticipated behavioral takes above Altenrative 3 was only about 2%.

These activities could affect beluga whales over a large area, especially with regard to the 2D/3D seismic streamer surveys, and the disturbance effects would be interim in duration and medium in magnitude, characterized by avoidance of vessels but with mild or unnoticeable behavioral reactions of beluga whales.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, the primary mechanism of potential injury or mortality to beluga whales due to oil and gas exploration activities are permanent hearing loss or damage (auditory injury) and collisions with vessels. The duration of an impact from an auditory impairment would be temporary for TTS, but permanent if PTS were to occur. The extent of such impacts would be local and the context unique, since beluga whales are an integral part of the Iñupiat subsistence lifestyle. It is not known whether there have been any ship strikes involving beluga whales and exploration vessels in the Arctic, but the intensity of the impact should be considered medium due to the belugas cultural significance. The impact would be temporary, although the results (injury or mortality) would be permanent for the impacted whale.

Habitat Loss/Alteration

Potential impacts on beluga whale habitat in the EIS project area under Alternative 4 would likely be slightly greater than those in Alternative 3. Additional exploratory drilling could increase the number of localized sites experiencing possible habitat effects of drilling activities and also increase the area of acoustic habitat impacts by about 1% within the EIS area (see Section 4.7.1.4). Please refer to Section 4.5.2.4.10 for a complete discussion of the potential effects on beluga whale habitat.

4.7.2.4.2.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.7.2.4.2.3 Conclusion

The overall impact to beluga whales from Alternative 4 is likely to be moderate. Beluga whales in the Arctic are not listed under the ESA, but there are a couple of important feeding areas in the Arcitc that are important for this population. The intensity and duration of the various effects and activities considered are mostly medium and interim. However, potential long-term effects from repeated disturbance are unknown. Although, individually, the various activities may elicit local effects on beluga whales, the area and extent over which the combined effects occur will likely increase with multiple activities occurring simultaneously or consecutively throughout much of the spring-fall range of this population and are considered regional.

4.7.2.4.2.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.16).

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	Low	
		Medium	Behavioral harassment occurring, but likely < 30% of population disturbed
		High	
	Duration	Temporary	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	Local	
		Regional	Combined activities considered regional
		State-wide	
	Context	Common	
		Important	Non-ESA listed, population status not well known, but thought not to be declining in Chukchi, important feeding and calving areas
		Unique	
Injury and mortality	Magnitude or Intensity	Low	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	Temporary	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	Local	Since unlikely, any few impacts would be considered local

4.7.2.4.3 Other Cetaceans

4.7.2.4.3.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 4 on cetaceans in the EIS project area other than bowhead and beluga whales. Alternative 4 includes all of the same types of exploration activities as in Alternatives 2 and 3, so the discussion of potential direct and indirect effects on bowhead whales under Atlernative 4 involves all of the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.11. The difference is that Alternative 4 includes a larger number of exploratory drilling operations than Alternative 3. Specifically, Alternative 3 assumes a maximum of two exploration drilling programs active in each sea at any given time while Alternative 4 assumes a maximum of four exploration drilling programs active in each sea at any given time. These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures. The following discussion focuses on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.11.

Behavioral Disturbance

Under Alternative 4, disturbance effects of oil and gas exploration activity on other cetaceans would be of low intensity (for those species that were not encountered or exposed) or medium, based on determinations for Alternative 2. Despite an increase in the level of exploratory drilling activity by a factor of two over Alternative 3, there would be little increase in the overall impact level for the species that occur in low densities (see Tables 4.2-5 through 4.2-7). Some whales may be displaced a short distance, but they would not be anticipated to leave the EIS project area entirely. The duration is expected to be interim. Long term effects are unknown. The extent of the impacts would depend on the number of seismic and exploratory drilling activities and associated support vessels in an area. Individual sound sources may produce localized impacts. Multiple activities in one area or in several areas across migratory corridors would be expected to lead to more widespread, regional impacts.

Please refer to Section 4.5.2.4.11 for a complete discussion of disturbance effects on Other Cetaceans.

Hearing Impairment, Injury, and Mortality

The primary mechanisms of potential injury or mortality due to oil and gas exploration activities are permanent hearing loss or damage (auditory injury) and collisions with vessels. These are discussed in detail in Section 4.5.2.4.11. As noted under Alternative 2, it is not currently possible to assess whether or not auditory impairment (TTS or PTS) is occurring in other cetaceans. The potential effects of ship strikes under Alternative 4 are similar to that discussed under Alternative 2. The intensity of impact could be considered medium, given past low-level occurrence and potential increased occurrence with additional vessel traffic associated with oil and gas exploration activities. The impact would be temporary, although the results (injury or mortality) would be permanent for the impacted whale. The extent of impact will be local, given the relative infrequency of occurrence and the non-random distribution of other cetacean species and exploration activity in the EIS project area.

Please refer to Section 4.5.2.4.11 for a complete discussion of potential injury or mortality effects on Other Cetaceans.

Habitat Alterations

The potential effects on cetacean habitat in the EIS project area under Alternative 4 would likely be similar to those under Alternative 3. Additional exploratory drilling could increase the number of localized sites experiencing possible habitat effects of drilling activities and increase the area over which temporary impacts to acoustic habitat could occur by about 1% (see Section 4.7.1.4).

Please refer to Section 4.5.2.4.11 for a complete discussion of the potential effects on Other Cetacean habitat.

4.7.2.4.3.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.15).

4.7.2.4.3.3 Conclusion

Evaluated collectively, the overall impact of Alternative 4 on Other Cetaceans is minor to moderate. Despite an increase in the level of exploratory drilling activity over Alternative 3, there would be little increase in the impact level. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the interim nature of the majority of the activities associated with Alternative 4, impacts on the resource would be low to medium in intensity, of interim duration, and regional extent. Long term impacts are unknown, but anticipated to be minor.

4.7.2.4.3.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.16).

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	**Low**	Possible that some other species may not come into contact with activities or be impacted
		Medium	If behavioral harassment occurs, would be < 30% of population disturbed
		High	
	Duration	**Temporary**	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	**Local**	Effects primarily considered local
		Regional	Impacts from max levels of activity might be considered regional for gray whales when consider area ensonified over 120 dB (>10% EIS area) and fact that gray whales are more likely to be encountered than other species.
		State-wide	
	Context	**Common**	
		Important	Although not ESA listed, important areas exist for gray whales.
		Unique	

Type of effect	Impact Component	Effects Summary	
Injury and mortality	Magnitude or Intensity	**Low**	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	**Temporary**	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	**Local**	Since unlikely, any few impacts would be considered local

4.7.2.4.4 Ice Seals

4.7.2.4.4.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 4 on ice seals. Alternative 4 includes all of the same type of exploration activities as in Alternatives 2 and 3, so the discussion of potential direct and indirect effects on ice seals under Alternative 4 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.12. The difference between alternatives concerning ice seals is a matter of degree. Alternative 4 includes a larger number of drilling activities, specifically, four programs in both the Chukchi and Beaufort seas instead of two programs in each sea (Table 4.2-2). These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures.

The following discussion will focus on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.12.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 4 include several mechanisms for potential disturbance to ice seals in the water and on the ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment. The two types of surveys which take place on or in sea ice, the preferred habitat of ice seals and where they are most likely to be concentrated, are the in-ice 2D surveys with icebreakers and the on-ice vibroseis surveys. For both of these types of surveys, the same number of surveys would be authorized under Alternative 4 as for Alternatives 2 and 3. The level of disturbance from these types of surveys would therefore be the same for Alternative 4 as is discussed for Alternative 3, which was considered to have temporary and low magnitude effects on ice seals.

There would be a moderate increase in the amount of open-water activities under Alternative 4 compared to Alternative 3. These activities could affect ice seals over a large area, but the disturbance effects would be of interim duration and medium in magnitude, characterized by avoidance of vessels but with mild or unnoticeable behavioral reactions of ice seals.

Alternative 4 could authorize up to four exploratory drilling programs in both Arctic seas. The level of disturbance to seals is likely more intense in terms of the physical presence of the ships than any types of exploratory surveys, but the geographic area involved is much smaller. The noise generated from drilling is produced on an almost continual basis, making it essentially a chronic sound source in one location, and seals could become habituated to it. Given the mild reaction of seals to marine vessels and the close distances to which they often approach vessels, it is unlikely that having up to four drilling programs operating in the same general area at the same time will result in any additive disturbance effects on particular seals, although more seals could be affected than would occur with only one or two drilling programs operating at any one time. Any disturbance and displacement of seals would cover a very small area and be considered short-term.

Based on the historical take estimates used for ice seals (Tables 4.2-5 through 4.2-7), in-ice seismic surveys are responsible for the vast majority of behavioral disturbance of ringed seals, with open water 2D/3D seismic surveys contributing to the majority of the behavioral disturbance takes for other species. Because the level of activity for these survey types did not increase in Alternative 4, total behavioral take numbers between Alternatives 3 and 4 only increased by a small amount.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, there is very little risk of any ice seals being injured as a result of high noise levels or ship strikes because they can easily detect and avoid vessels as they approach in the water or on/through the ice. There is a lack of data on the physiological thresholds for acoustic injury in ice seals, but that information could only be obtained through captive studies involving potential injury to the animals, and, given the behavioral avoidance of wild animals to loud seismic sources, this lack of data is not crucial for this analysis.

As discussed in Section 4.5.2.4.12, there is the potential for seals to be exposed to small accidental spills of oils, lubricants, and other compounds used by vessels, vehicles, and equipment during exploration activities. Spills in the offshore or onshore environments could occur during normal operations (e.g. transfer of fuel, handling of lubricants and liquid products, and general maintenance of equipment). Exposure of seals to oil products could lead to irritation of eyes, mouth, lungs, and anal and urogenital surfaces (St. Aubin 1990). Ice seals are commonly observed near exploratory activities during the open-water season and could be exposed to spills in the water or on ice. If a small spill did occur, cleanup efforts would begin immediately, and those activities would likely include the presence of PSOs to monitor for ice seals and other marine mammals and deter them from entering the spill area if possible. Alternative 4 could authorize a greater level of exploratory drilling activity than Alternative 3, and the resulting risk of small accidental spills occurring would be proportionally greater. However, given the mitigation measures in place to prevent and clean up spills, the risk of ice seals being exposed to small spills during exploration activities authorized under Alternative 4 is considered to be minor. The potential effects of a very large oil spill caused by a well blowout are much more serious and are discussed in Sections 4.10.6.11 and 4.10.7.11. Please refer to Section 4.5.2.4.12 for a complete discussion of potential injury or mortality effects on pinnipeds.

Habitat Alterations

The two types of activities that involve potential changes to ice habitat, icebreaking and on-ice vibroseis, would be at the same level as discussed under Alternative 2, and they were considered to have temporary effects that are similar in scope as those occurring due to natural forces in the dynamic sea ice environment. The increase from two exploratory drilling programs in each Arctic sea under Alternative 3 to four drilling programs in each sea under Alternative 4 would increase the amount of intentional and unintentional discharges of drilling muds and other wastes. There is a lack of information about how any of these discharges could interact directly with ice seals or be carried through the environment to affect the food supply of ice seals (primarily fish and crustaceans). Given this lack of ecological information on the effects of these discharges on ice seal habitat, it is not possible to say whether four drilling programs constitute a substantially larger risk to habitat quality for ice seals than one or two drilling programs. Unfortunately, the types of ecological monitoring studies required to address these issues are very difficult to conduct in the Arctic and even more difficult to interpret given the vast number of complicating factors. The addition of the drilling programs would also add to a slight increase in acoustic habitat impacts.

4.7.2.4.4.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to pinnipeds are discussed under Alternative 2 (Section 4.5.2.4.15).

4.7.2.4.4.3 Conclusion

The four species of ice seals would likely not be affected to the same extent by exploration activities in the Beaufort and Chukchi seas based on their respective abundance and distribution. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past exploration activities, and their reactions have been recorded by PSOs onboard source vessels and monitoring vessels. These data indicate that seals tend to avoid on-coming vessels and active seismic arrays but their behavioral responses are often neutral rather than swimming away, and they do not appear to react strongly even as ships pass fairly close with active arrays. They also appear to primarily react to icebreaking or on-ice surveys by keeping their distance or moving away at some point to an alternate breathing hole or haulout. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and would therefore be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are legally protected (two of which are also protected under the ESA) and are therefore considered to be important resources. Given the standard and additional mitigation measures considered in this EIS, the effects of exploration activities that could be authorized under Alternative 4 on ice seals would likely be medium to high (the latter for ringed seals) in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 4 would therefore be considered minor to moderate (the latter for ringed seals) for ice seal species according to the criteria established in Section 4.1.3.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	Low	
		Medium	Behavioral harassment occurring, but likely < 30% of population disturbed for all species but ringed seals
		High	When maximum activities considered, more than 30% ringed seals may be taken
	Duration	Temporary	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	Local	Effects of activities considered local
		Regional	Max levels potentially regional
		State-wide	
	Context	Common	
		Important	ESA-listed species, but impacts not occurring in areas specifically important for feeding/pupping, etc.
		Unique	
Injury and	Magnitude	Low	Injury or death unlikely

Type of effect	Impact Component	Effects Summary	
mortality	or Intensity	Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	Temporary	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	Local	Since unlikely, any few impacts would be considered local
		Regional	
		State-wide	
	Context	Common	
		Important	ESA listed species,no reliable data available to assess population trends
		Unique	
Habitat alterations	Magnitude or Intensity	Low	
		Medium	Combination of potential habitat impacts are medium
		High	
	Duration	Temporary	
		Interim	Although other alterations shorter, acoustic habitat is altered for duration of activities
		Long-term	
	Geographic Extent	Local	Lower to mid-level of ativities considered local
		Regional	Max levels potentially regional
		State-wide	
	Context	Common	
		Important	ESA listed species, population status unknown, no reliable data on trends
		Unique	

4.7.2.4.4.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to pinnipeds are discussed under Alternative 2 (Section 4.5.2.4.16).

4.7.2.4.5 Walrus

4.7.2.4.5.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 4 on Pacific walrus. This species is dependent on pack ice, barrier islands, and coastal shorelines for haul outs. Alternative 4 includes all of the same types of exploration activities as in Alternatives 2 and 3, so the discussion of potential direct and indirect effects on Pacific walrus under Alternative 4 involves all the same mechanisms and types of effects as discussed for Alternatives 2 and 3 in Section 4.5.2.4.13. The difference between alternatives concerning Pacific walrus is a matter of degree. Alternative 4 includes a larger number of some authorized exploration activities than Alternative 3. Specifically, Alternative 3 assumes a maximum of two exploration drilling programs active in each sea at any given time while Alternative 4 assumes a maximum of four exploration drilling programs active in each sea at any given time. These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures. Walrus are distributed widely across the Chukchi Sea but are uncommon in the deeper offshore waters of the Beaufort Sea. Therefore activities that occur in the Beaufort Sea are not anticipated to impact Pacific walrus. The following discussion focuses on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.13.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 4 include several mechanisms for potential disturbance to walrus in the water and on the ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment. The one type of survey that takes place on or in sea ice (the preferred habitat for walrus and where they are most likely to be concentrated) is the in-ice 2D survey with icebreakers. Only one such in-ice survey could be authorized for each Arctic sea under any of the action alternatives. On-ice vibroseis surveys would only occur in the Beaufort Sea at times when walrus would not be present. The level of disturbance from these types of surveys would therefore be the same for Alternative 4 as is discussed for Alternative 3, which was considered to have temporary and low magnitude effects on walrus.

There would be a moderate increase in the amount of open-water activities under Alternative 4 compared to Alternative 3. The increase in exploration drilling activities could affect walrus over a larger area, but the disturbance effects would be temporary and low in magnitude, characterized by avoidance of vessels associated with drilling and of the drill sites but with mild or unnoticeable behavioral reactions of walrus. Exploration drilling activities have a foot print of a few square kilometers. Alternative 4 increases the footprint of benthic foraging habitat that would be unavailable to walrus during exploration operations. Some walrus could be exposed to or displaced from more than one exploratory drilling site over time as it travels through an area. The addition of one or two additional exploration drilling operations to the Beaufort and /or Chukchi seas would slightly decrease the benthic foraging habitat available to walrus during drilling and afterward until the sea floor is recolonized by the benthic invertebrates which are primary food sources for walrus. This decrease in available habitat would be very small when compared with the available foraging habitat within the Chukchi Sea. Past exploration drilling activities in the Chukchi Sea have not been shown to impact either individual walrus or the walrus population.

Alternative 4 could authorize up to four exploratory drilling programs in each sea. The level of disturbance to walrus is likely more intense from the multiple support ships associated with a drilling rig than any types of exploratory surveys, but the geographic area involved is much smaller. The noise generated from drilling is produced on an almost continual basis, making it essentially a chronic sound source in one location, and walrus could become habituated to it. Given the mild reaction of walrus to marine vessels, it is unlikely that having four drilling programs operating in the same general area at the same time will result in any additive disturbance effects on particular walrus, although more walrus could be temporarily affected than would occur with only two drilling programs. Any disturbance and displacement of walrus would cover a small area and be considered short-term.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, there is very little risk of any walrus being injured or killed as a result of high noise levels or ship strikes because they can easily detect and avoid vessels as they approach in the water or on/through the ice. It is also very unlikely that any walrus would be exposed to very loud sounds from seismic or exploratory drilling operations to the point where they might be injured.

There is a potentially dangerous situation with walrus on land-based haulouts, primarily on the Chukchi coast from Point Lay to Barrow. Disturbance by low-flying aircraft or nearby vessels could cause stampedes and crushing deaths. USFWS LOA mitigation measures for exploration aircraft and vessels are intended to monitor and avoid such haulouts to avoid causing such deadly disturbance.

As discussed in Section 4.5.2.4.13 exposure to small accidental spills of oils, lubricants, and other compounds used by vessels, vehicles, and equipment during exploration activities could have substantial health effects on walrus and could spread among animals in a close herd. Alternative 4 could authorize a greater level of exploration activity than Alternative 3, and the resulting risk of small accidental spills occurring would be proportionally greater. However, given the mitigation measures in place to prevent and clean up spills and the occurrence of walrus primarily on or near the pack ice rather than swimming in open water where most exploration activities take place, the risk of walrus being exposed to small spills during exploration activities is considered to be negligible. The potential effects of a very large oil spill are much more serious and are discussed in Sections 4.10.6.11 and 4.10.7.11.

Please refer to Section 4.5.2.4.13 for a complete discussion of potential injury or mortality effects on walrus.

Habitat Alterations

Benthic prey of walrus may experience disturbance/mortality from bottom-contact equipment used in exploration activities such as OBC surveys in the Chukchi Sea, vessel anchors, and exploratory drilling. All of these activities could disturb benthic mollusks and other invertebrates temporarily and may cause mortality. Alternative 4 could authorize higher levels of exploration activities that involve benthic disturbance than Alternative 3. However, given the very small areas of benthic surface that could be impacted by all of these activities and the wide distribution of prey fields for walrus, these activities would be unlikely to affect the availability of prey to walrus.

Icebreaking ships intentionally disrupt pack ice in order to conduct seismic surveys or to help manage ice floes around exploratory drilling equipment. The amount of icebreaking and ice management activity and potential impacts to walrus under Alternative 4 would increase from that discussed in Alternatives 2 and 3. These impacts would primarily be limited to displacement of walrus from preferred sea ice habitat.

Alternative 4 could authorize a greater level of exploration activity than Alternative 3, including doubling the amount of exploratory drilling, and the resulting risk of small accidental spills and discharges occurring would be proportionally greater. The potential effects on the quality of walrus habitat would also increase. Please refer to Section 4.5.2.4.13 for further discussion of potential effects on walrus habitat.

4.7.2.4.5.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.13).

4.7.2.4.5.3 Conclusion

Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs onboard seismic source vessels and monitoring vessels. These data indicate that walrus do not react strongly to vessels and active seismic arrays, and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest of sounds generated by the ships. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of calf and juvenile mortality from stampedes.

Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for purposes of this analysis. Given the level and type of exploration activities that would be authorized under Alternative 4, and considering the mitigation measures that would be required by USFWS LOAs, the effects on walrus would likely be low in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 4 would therefore be considered minor for Pacific walrus according to the criteria established in Section 4.1.3.

4.7.2.4.5.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.13).

4.7.2.4.6 Polar Bears

4.7.2.4.6.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 4 on polar bears. This species is dependent on pack ice for much of their denning habitat and for hunting seals. Alternative 4 includes all of the same type of exploration activities as in Alternatives 2 and 3, so the discussion of potential direct and indirect effects on polar bears under Alternative 4 involves all the same mechanisms and types of effects as discussed for Alternatives 2 and 3 in Section 4.5.2.4.14. The difference between alternatives concerning polar bears is a matter of degree. Alternative 4 includes a larger number of some authorized exploration activities than Alternative 3. Specifically, Alternative 3 assumes a maximum of two exploration drilling programs active in each sea at any given time while Alternative 4 assumes a maximum of four exploration drilling programs active in each sea at any given time. These activities take place in the same areas and timeframes and also consider the same standard and additional mitigation measures as Alternatives 2 and 3. The following discussion focuses on the differences between alternatives rather than repeating the same information presented in Section 4.5.2.4.14.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 4 include several mechanisms for potential disturbance to polar bears along leads in the ice and in broken ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment including the potential for direct bear-human encounters. The two types of surveys which take place on or in sea ice, the hunting and denning habitats for polar bears, are the in-ice 2D surveys with icebreakers and the on-ice vibroseis surveys. For both of these types of surveys, the same number of surveys would be authorized under Alternative 4 as for Alternatives 2 and 3. The level of disturbance from these types of surveys would therefore be the same for Alternative 4 as is discussed for Alternatives 2 and 3, which were considered to have temporary and low magnitude effects on polar bears.

There would be a moderate increase in the amount of open-water activities under Alternative 4 compared to Alternative 3. These activities could affect polar bears over a larger area, but the disturbance effects would be temporary and low in magnitude, characterized by neutral or ambiguous behavioral reactions of polar bears. Some polar bears could be exposed to more than one exploration drilling operation over time as they travel through an area, but most encounters with exploration drilling operations and vessels typically occur while polar bears are on ice or land. The addition of one or more exploration drilling projects to either the Beaufort or Chukchi seas would increase the likelihood that two or more different projects could be in the same general area at the same time. Few polar bears are likely to be moving through offshore drilling areas during the open water season. Polar bears routinely move through the Prudhoe Bay oil field areas and do not appear to be excluded from available habitat by drilling operations taking place nearby.

Alternative 4 could authorize up to four exploratory drilling programs in both Arctic seas. The level of disturbance to polar bears is likely more intense from the multiple support ships associated with a drilling rig than any types of exploratory surveys, but the geographic area involved is much smaller. The noise generated from drilling is produced on an almost continual basis, making it essentially a chronic sound source in one location, and polar bears could become habituated to it. Given the mild reaction of polar bears to marine vessels or drilling rigs it is unlikely that having four drilling programs operating in the same general area at the same time will result in any additive disturbance effects on particular bears, although more bears could be temporarily affected than would occur with only one or two drilling programs. Any disturbance and displacement of polar bears would cover a very small area and be considered short-term.

Hearing Impairment, Injury, and Mortality

As discussed under Alternative 2, there is very little risk of any polar bears being injured or killed as a result of noise levels or ship strikes from oil and gas exploration activities because of the infrequency of polar bears being observed in the open-water areas where most exploration is conducted and their ability to detect and avoid vessels as they approach in the water or on/through the ice. It is also very unlikely that any polar bears would be exposed to very loud sounds from seismic operations to the point where they might be injured. Exposure to accidental spills of fuel, oils, and other compounds from exploration vessels and equipment could kill a polar bear (USFWS 2008b), but given the small volume of typical spills and clean-up requirements that would include PSOs to deter polar bears if necessary, the risk of polar bears being exposed to oil spills is considered minor. Polar bears are curious, so there is always the potential for bear-human interactions during oil and gas exploration in the Arctic, even if the activities are temporary, but continuation of diligent polar bear monitoring and safety management will decrease the risk of injury or death for humans and bears. The potential effects of a very large oil spill are much more serious and are discussed in Sections 4.10.6.11 and 4.10.7.11.

Habitat Alteration

One of the two types of activities that involve potential changes to polar bear habitat, icebreaking and ice management, could increase under Alternative 4 as compared to Alternatives 2 and 3. Ice management activities are sometimes necessary to move ice floes away from drilling rigs in offshore waters. These activities would have only temporary effects on the physical characteristics of the ice and are not likely to displace polar bear prey species (ice seals) for more than a few hours. Seal distribution and abundance would continue to be determined by ice conditions and other natural factors rather than the presence of exploration activities. Polar bear habitat quality would therefore not be affected by exploration activities. The increase from two exploratory drilling programs in each sea under Alternative 3 to four drilling programs in each sea under Alternative 4 would increase the footprint of the drilling operations and associated fleets of vessels and could increase the amount of ice management necessary. The effects of ice management would be short term and isolated to a small footprint and are not anticipated to impact the availability of sea ice for polar bears as habitat.

4.7.2.4.6.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.14).

4.7.2.4.6.3 Conclusion

Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays or to exploration drilling operations, and their behavioral responses are often neutral rather than running or swimming away. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point, but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important subsistence resources and are therefore considered a unique resource. Given the mitigation measures that would be required by USFWS LOAs, the effects of exploration activities that could be authorized under Alternative 4 on polar bears would likely be low in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 4 would therefore be considered minor for polar bears according to the criteria established in Section 4.1.3.

4.7.2.4.6.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.14).

4.7.2.5 Terrestrial Mammals

Activity levels in Alternative 4 are the same as in Alternative 3, except for the allowance of four exploratory drilling operations in the Beaufort and Chukchi seas in each season. By doubling the number of potential drilling operations, support activity such as air travel could be expected to increase. However, the effects of the additional drilling and corresponding support activities proposed under Alternative 4 would add very little to the direct and indirect effects of Alternative 4 on terrestrial mammals and their habitat in the EIS project area. Consequently, the impacts discussed in Section 4.5.2.5 and Section 4.6.2.5 for Alternatives 2 and 3, respectively, are slightly less than those for Alternative 4; however, overall level of effects on terrestrial mammals from the implementation of Alternative 4 would remain minor.

4.7.2.6 Time/Area Closure Locations

The analysis of the direct and indirect effects associated with time/area closures can be found in Sections 4.5.2.4 and 4.6.2.4 (Marine Mammals), 4.5.2.3 and 4.6.2.3 (Marine and Coastal Birds), and 4.5.3.2 and 4.6.3.2 (Subsistence).

4.7.2.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the biological environment, other than marine mammals and marine and coastal birds, are discussed under Alternative 2 (Section 4.5.2.7).

4.7.3 Social Environment

4.7.3.1 Socioeconomics

The following discussion of direct and indirect effects of Alternative 4 evaluates effects on employment and personal income, public revenues and expenditures, demographic characteristics, and demand on social organizations and institutions associated with an increased “Level 3” of oil and gas exploration activity.

4.7.3.1.1 Direct and Indirect Effects

Alternative 4 (Level 3 activity) would generate the same categories of activity as Alternative 3 (Section 4.6.3.1), with marginal increases in direct and indirect effects in each category. Alternative 4 would generate increases in the level of activity in communities hosting vessel crew changes and purchasing/staging of support materials and increases in direct revenues from property taxes derived from potential new onshore infrastructure.

The indirect employment opportunities associated with Alternative 4 may increase marginally under Level 3 activity because shore-based support and logistical service demands would increase, including: transport of equipment; room and board of survey/seismic crews; and administration of permits to conduct the surveys. Native Corporations and private entities may capitalize on these opportunities. As described under Alternative 2, these services are seasonal and temporary in nature.

4.7.3.1.2 Conclusion

The magnitude of the socioeconomic impact under Alternative 4 is positive and greater than a Level 2 activity. The socioeconomic impact under Alternative 4 is similar to Alternative 3, with Level 3 activities generating increased socioeconomic benefits from additional employment, income, and revenues. The increased socioeconomic benefits associated with Level 3 activity under Alternative 4 could be somewhat offset by potential time/area closures that could reduce total local employment rates and personal income, leading to a lower intensity of beneficial socioeconomic impact to communities, and a low to medium intensity economic impact to lease holders that incur costs or lose productivity. The duration of the socioeconomic impacts is temporary because it is not year-round; however, the activity is scheduled to occur over a fixed number of years. The positive economic impacts of the activity are statewide and even national. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat communities. The summary impact level for Socioeconomics under Alternative 4 is minor.

The magnitude of the socioeconomic impact under Alternative 4 is positive and greater than a Level 1 activity. However, the magnitude of increase of total personal income and local employment rates are still not increased by more than five percent. The duration of the socioeconomic impacts is temporary because it is not year-round; however, the activity is scheduled to occur over a fixed number of years.

4.7.3.2 Subsistence

4.7.3.2.1 Direct and Indirect Effects

The potential effects to subsistence resources and harvest from disturbance of the seismic survey (both open-water and on-ice) and exploratory drilling, aircraft and vessel traffic, icebreaking and ice management, and permitted discharges under Alternative 4 would be the same as those described under Alternative 2 (Section 4.5.3.2). Table 4.5-26 describes the different subsistence hunts that occur within the EIS project area by resource, where these subsistence hunts occur, the seasons of occurrence, and the potential for overlapping with proposed activities of Alternatives 2 through 6. Detailed information regarding the seasonal cycles of subsistence resources and harvest patterns is described in Section 3.3.2.

Even with the increase in the number of activities/programs that could potentially occur under Alternative 4, the impacts to subsistence resources and harvest are anticipated to be similar in type, generally of similar intensity and comparable duration, but occurring in more locations.

Assumptions regarding the level of activity used in the analysis of impacts to subsistence for Alternative 4 are described in Table 4.5-26. Under Alternative 4, only these activities would be permitted. In the Beaufort and Chukchi seas, it is assumed that the activity/programs described in Table 2.4 would involve the sound sources and sound levels associated with individual sources, the same types of source and support vessels, and the same types of icebreakers for ice management and/or icebreaking. However, there would be more vessels conducting the activities in more sites with more support vessels and more aircraft traffic from the addition of more programs being potentially permitted. The number of days the activities could occur in a season would be the same as those in Alternative 3. Under Alternative 4, the activity area(s) and or number of wells to be drilled could be increased with up to four exploratory drilling programs potentially permitted in both the Beaufort and Chukchi seas.

4.7.3.2.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to subsistence resources are discussed under Alternative 2 (Section 4.5.3.2).

4.7.3.2.3 Conclusion

Impacts of Seismic, High Resolution Shallow Hazard Surveys and Exploratory Drilling Noise Disturbance to Subsistence Resources

Bowhead Whales

Section 4.5.2.4.9 (Bowhead Whales) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect bowhead whales. Any impacts of seismic and high resolution shallow hazard surveys and exploratory drilling noise that affect bowhead whales are expected to result in some temporary deviation in migratory path in the vicinity of the disturbance. However when the standard and additional mitigation measures contemplated in this EIS are applied, the impact of disturbance to subsistence resources and hunters could be of low intensity and temporary duration (i.e. for the duration of the activities). The geographic extent could be local to regional, affecting a resource of unique context, due to listing under the ESA. Impacts would not be expected at the population level, reducing long term opportunities to subsistence harvest bowhead whales. The summary impact to subsistence harvest from disturbance of bowhead whales could be considered moderate.

Beluga Whales

Sections 4.5.2.4.10 (Beluga Whales) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect beluga whales. In the Chukchi Sea, beluga whales could be displaced, i.e. would avoid areas in the vicinity of seismic survey and exploratory drilling operations in July through October during their spring and fall migrations. While belugas are harvested during late June through mid-July at Point Lay, the activities of seismic survey and exploration drilling activities would be expected to occur offshore from subsistence use areas. As described previously, Traditional Knowledge asserts that beluga whales have a keen sense of hearing; thus, activities would have the potential to impact and disrupt some communal beluga subsistence hunts (particularly Point Lay, which heavily depends on this resource) by disturbing and altering the course of these migrating whales. In turn this could make belugas more difficult to herd into the lagoons and harvest (as in the case of Point Lay).

However, the impacts would be minimized or avoided by the required mitigation measures of this EIS. As mitigated, the effects of disturbance would be considered to be of low intensity and temporary duration, occurring for the duration of the activities offshore. These impacts are considered regional in geographic extent. There would not be expected impacts on a population level that would result in long term impacts reducing the subsistence harvest. The summary impact to subsistence harvest from disturbance of beluga whales could be moderate.

Seals

Section 4.5.2.4.12 (Ice Seals) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect these seals. Subsistence hunts of seals occur either in nearshore coastal areas or onshore in the spring and winter seasons when seismic and high resolution shallow hazards surveys and exploratory drilling operations would not be present. Most ringed seals, an ESA-threatened species, are harvested in the winter or in the spring before these assumed activities would occur. While bearded and spotted seals are harvested during the summer, the activities of seismic survey and exploration drilling activities would be expected to occur offshore from subsistence use areas. Activities within the lease areas offshore that are likely to be explored during the open water season would have no impact on subsistence hunting for seals. One on-ice seismic survey could have the potential to disturb or displace ringed seals in their lairs but would be mitigated to lessen the impact to seals. Any impacts to seal subsistence harvests from the on-ice seismic survey would be low intensity, limited to a local area, temporary in duration, and unique in context. The geographic extent could be local to regional, affecting a resource of unique context due to the threatened status under the

ESA for two of the species and their importance to subsistence communities. Therefore the summary impact to subsistence ice seal harvests is moderate.

Walrus, Polar Bears, Subsistence Fishing, Bird Harvest and Egg Gathering and Harvest of Caribou

Impact to these subsistence resources and their harvests are expected to be the same as described under Alternative 3 with the exception of polar bear.

The potential impact of the noise produced by the proposed seismic and high resolution shallow hazards surveys and exploratory drilling on subsistence resources and harvest activities under Alternative 4 could be major in the absence of mitigation measures. However mitigation measures would be required to be implemented to minimize or completely avoid adverse effects on all marine mammals and other subsistence resources and to ensure no unmitigable adverse impact on the availability of marine mammals for subsistence uses. In consideration of the standard mitigation measures, these activities are not expected to disturb or disrupt subsistence activities at a level that would make resources unavailable for harvest or significantly alter the existing levels of harvests. The summary impact of Alternative 4 is considered moderate to subsistence harvests of bowhead, ice seals, walrus, and polar bear; due to the candidate or ESA status of these species, they are in the unique context, which means that any effect would likely be a moderate effect. The summary impact to beluga whales is also assessed at the moderate level due to TK observations that they possess keen senses of hearing and are easily disturbed. Summary impacts to subsistence fishing, bird harvest and egg gathering, and harvest of caribou are the same as those described in Alternative 3.

Impacts of Disturbance from Aircraft Overflights to Subsistence Resources

Bowhead Whales

Information on the impacts of aircraft sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.9 and 4.6.2.4.1 (Bowhead Whales) of this EIS. The sound emitted by aircraft overflights potentially could cause some disruption to bowhead whale harvest, but aircraft overflights as mitigated are not expected to make bowhead whales unavailable to subsistence hunters. Whales could be expected to temporarily deflect from overflights, but mitigation measures analyzed in and contemplated by this EIS would limit the probability of this impact occurring. It is expected that helicopters servicing offshore seismic and high resolution shallow hazard surveys and exploratory drilling operations could traverse areas utilized by subsistence whalers during fall whaling in the Beaufort Sea and limited areas of the Chukchi Sea. Mitigation measures prescribing flight path and altitude restrictions are expected to reduce any such potential impacts to a low level.

If bowhead whales were affected by aircraft overflights, it is unlikely that large numbers or a large area used by active whaling crews would be affected, so the intensity of the impact would be considered low, and the duration would be temporary. Effects of increased levels of activity permitted under Alternative 4 are low in intensity, temporary in duration, local to regional in extent, and affecting a resource that is unique in context, due to listing under the ESA. The summary impact is considered moderate.

Beluga Whales

Information on the impacts of aircraft sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.10 and 4.6.2.4.4 (Beluga Whales) of this EIS. Summer beluga hunting could be impacted by increased numbers of trips/aircraft overflights given the levels of activity associated with Alternative 4. Mitigation measures applied to this impact would lessen the disturbance to a point that it would be considered low in intensity, temporary in duration, local or regional in extent, and affecting a resource that is important in context.

The required mitigation measures are expected to minimize and/or avoid impacts to beluga whales and their subsistence harvest as the mitigation measures for flight path and altitude restrictions are expected to reduce impacts to the point that the summary rating is considered moderate.

Caribou Hunting

The higher levels of activity permitted under Alternative 4 would result in increased helicopter traffic between the expected support shorebases (Barrow, Deadhorse and potentially Wainwright) and the offshore drilling locations. It is likely that there would be a disturbance to caribou subsistence hunting from the helicopter traffic that may disturb caribou on the coast. Helicopters would be traversing routes offshore from the shorebases and small proportions of available subsistence hunting areas would be affected at altitudes of less than 305 m (1,000 ft) – most likely during takeoff and landings.

Aircraft overflights are unlikely to have an adverse effect on caribou availability for subsistence harvest. Impacts that did occur would be considered low in intensity and temporary in duration. The impact would be local to regional in extent and affecting a resource that is common to important in context. The summary impact is considered moderate.

Seals, Walrus, Polar Bears, Subsistence Fishing, Bird Hunting and Egg Gathering

Impact to these subsistence resources and their harvests are expected to be the same as under Alternative 2.

The higher levels of activity permitted under Alternative 4 would increase aircraft traffic associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities, which could cause some temporary behavioral disturbance and possibly deflection away from the sound source by terrestrial or marine mammals. The level of the disturbance would depend on the size of the aircraft and repeated exposure or displacement occurring to the resources, as well as whether or not the overflights overlap in time and space with subsistence hunting grounds.

Aircraft overflights are unlikely to have an adverse effect on subsistence harvest as mitigated. Impacts that did occur would be considered of low intensity but temporary in duration. The impact would be local to regional in extent, affecting resources that range from common to unique in context. The impacts are considered moderate for bowhead whales, beluga whales, and caribou. Impacts to seals, walrus, polar bears, subsistence fishing, bird harvest and egg gathering are the same as those described in Alternative 2.

Impact of Vessel Traffic to Subsistence Resources

Bowhead Whales

Information on the impacts of vessel sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.9 and 4.6.2.4.1 (Bowhead Whales) of this EIS. The higher levels of activity permitted under Alternative 4 would increase vessel traffic and vessels present in the area associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities, which could cause bowhead whales to alter their behavior during migration and avoid the area(s) within a few kilometers of vessel activities. However the required mitigation measures would limit impacts to late migrating bowhead whales and subsistence hunting from vessel traffic. The levels of activity permitted under Alternative 4 increase the potential for disturbance on a more regional level. Impacts to bowhead whale subsistence hunting are likely to be of low intensity, temporary duration, though could be local to regional extent, and affecting a resource that is unique in terms of the context (due to the listing under the ESA). The summary impact could be considered moderate in terms of the levels of subsistence hunting and sharing of the resource that would be affected.

Beluga Whales

Information on the impacts of vessel sounds associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Sections 4.5.2.4.10 and 4.6.2.4.4 (Beluga Whales) of this EIS. A limited number of late migrating spring beluga whales could encounter increased numbers of vessels and higher levels of activity permitted under Alternative 4 for seismic and high resolution shallow hazard surveys and exploratory drilling activities and operations. The impact of disruption to beluga whales from vessel traffic could result in temporary deflection of beluga whales from subsistence harvest areas and reduced success of these hunts. However, if additional mitigation measure D1 is applied there can be no transit of exploration vessels into the Chukchi Sea prior to July 15 or until the beluga hunt is completed at Point Lay. However, the increased levels of activity permitted under Alternative 4 include the potential for disturbance on a regional level (impacts extending throughout the EIS project area) as defined in Section 4.1.3. The impact to beluga whales that do encounter vessels would be of low intensity, temporary duration, local to regional extent, and affect a resource that is important in terms of the context. The summary impact could be considered moderate in terms of the levels of subsistence hunting and sharing of the resource that would be affected.

Walrus, Polar Bears, Seals

Section 4.5.2.4.12 (Ice Seals) describes the mechanisms by which activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect seals. Seals could be displaced or avoid areas where vessels are transiting as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities. However, under the required mitigation measures for vessels transiting into the Beaufort and Chukchi seas for these activities, impacts to seals would not be such as to adversely impact subsistence hunting activities. Subsistence seal hunts would occur in nearshore coastal areas away from areas likely to be transited by vessels. The majority of seal subsistence hunting occurs in the spring and winter seasons when vessels associated with seismic survey and exploratory drilling would not be expected to be present in subsistence harvest areas. However, with the increased levels of activity permitted under Alternative 4 there would greater potential for disturbance on a regional level (impacts extending throughout the EIS project area as defined in Section 4.1.3). With spatial and seasonal separations, the impact to subsistence seal harvest would be of low intensity, temporary duration, local to regional extent, and affecting resources that are important in terms of the context. The summary impact could be considered minor in terms of the levels of subsistence hunting and sharing of the resource that would be affected.

Subsistence Fishing, Bird Harvest and Egg Gathering and Harvest of Caribou

Impact to these subsistence resources and their harvests are expected to be the same as under Alternative 2.

Under the increased level of activity with Alternative 4, the summary impacts of vessel traffic on subsistence harvest of bowhead whales and beluga whales are expected to be moderate. The summary impact from vessel traffic to subsistence harvest of seals, walrus, and polar bear is considered minor. Negligible summary impacts to subsistence harvest of fish, bird hunting and egg gathering, and caribou are expected as a result of vessel traffic and the same as Alternative 2.

Impacts of Icebreaking and Ice Management on Subsistence Resources

Bowhead Whales

Information on the impacts of icebreaking and ice management associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.9 (Bowhead Whales) of this EIS. Seismic and high resolution shallow hazard surveys and exploratory drilling activities would be expected to occur during the open water season when seismic and high resolution shallow hazard surveys and exploratory drilling vessels would not encounter large amounts of sea ice. However icebreaking and ice management may be necessary during late fall or early winter when industry is still engaged in seismic and high resolution shallow hazard surveys and exploratory drilling activities in order to protect equipment, vessels, and infrastructure. Additionally, some operators have recently proposed to conduct seismic surveys during the in-ice or shoulder season (i.e. October through December). These surveys would require the use of an icebreaker to go ahead of the seismic survey vessel. The required mitigation measures limit the time frame in which these activities occur, and, as a result, the likelihood of impacts to subsistence harvest as a result of ice management activities is reduced and unlikely to adversely affect subsistence harvest of bowhead whales. The majority of these types of in-ice surveys would occur after the completion of fall bowhead harvests in the Beaufort and Chukchi seas. With the increased levels of activity permitted under Alternative 4 the potential for disturbance on a more regional level becomes greater (impacts extending throughout the EIS project area as defined in Section 4.1.3). In the event that icebreaking does cause bowhead whales to avoid an area the impact to subsistence resources is expected to be low in intensity, short term in duration, local to regional in extent, and affecting a resource that is unique in context. This would be considered a moderate impact to subsistence harvest of bowhead whales.

Beluga Whales

Information on the impacts of icebreaking and ice management associated with seismic and high resolution shallow hazard surveys and exploratory drilling activities is included in Section 4.5.2.4.10 (Beluga Whales) of this EIS. Icebreaking activities could increase under Alternative 4 with the greater level of permitted activity allowed exploratory drilling activities. Ice management activities could be necessary as part of seismic and high resolution shallow hazard surveys and exploratory drilling activities when ice is encountered in the late fall through early winter months of exploration activities. Icebreaking and ice management would be limited to areas where industry is actively exploring or drilling. These activities would occur in the offshore waters and would not be expected to affect beluga whale subsistence hunting, particularly since, as migratory species, they are not found in these waters during the late fall and winter. Icebreaking and ice management activities would be conducted far removed from areas typically hunted in the Chukchi Sea. No impacts are anticipated for beluga subsistence hunts in the Beaufort Sea, as beluga hunting is conducted opportunistically during the fall bowhead hunt, and the required mitigation measures of this project would prohibit seismic survey and exploratory drilling activities (and associated ice management) from occurring during this time.

The required mitigation measures are expected to minimize and potentially avoid impacts on beluga whales so that no adverse impacts occur to subsistence harvest. There is a low probability that impacts could occur to subsistence users in the Chukchi Sea. With the increased levels of activity permitted under Alternative 4 there is greater potential for disturbance on a regional level (i.e. across the EIS project area). In the event that icebreaking or ice management does cause beluga whales to avoid an area the impact to subsistence resources is expected to be low in intensity, short term in duration, local to regional in extent, and affecting a resource that is important in context. This would be considered a moderate summary impact to the subsistence harvest of beluga whales.

Seals

Section 4.5.2.4.12 (Ice Seals) describes the mechanisms by which icebreaking and ice management activities associated with oil and gas exploration in the Beaufort and Chukchi seas could directly or indirectly affect seals. Icebreaking could be associated with seismic survey plans that extend into the late open water season late fall to early winter (October to December) when daylight is very limited to absent and visibility is reduced, making seals more difficult to spot. At this time of year sealing efforts for subsistence are not concentrated or intense. Ice management activities could be necessary as part of seismic and high resolution shallow hazard surveys and exploratory drilling and would occur in the offshore waters during the open water season after sea ice has retreated and melted. Although a greater level of activity would occur under Alternative 4, these proposed activities would occur after the end of pupping and molting seasons for all ice seals. There would be few seals expected in the area where the proposed activities would take place. Subsistence harvest of seals would not be expected to occur in areas of active ice management offshore. The required mitigation measures are expected to avoid and minimize impacts on seals such that no adverse impacts to subsistence harvests of seals would occur. In the event that icebreaking does cause seals to avoid an area, the impact is expected to be low in intensity, short term in duration, local to regional in extent, and affecting resources that are common to important in context. This would be considered a moderate summary impact to subsistence harvest of seals because of their unique context attributable to the threatened status for two of the species.

Walrus, Polar Bears, Subsistence Fishing, Bird Harvest and Egg Gathering and Harvest of Caribou

Impact to these polar bears and walrus is expected to be moderate based on their listing as threatened or candidate species under the ESA, thus elevating the context to unique and effects to moderate. Subsistence resources of other species and their harvests are expected to be same as under Alternative 4. Summary impacts to subsistence harvest of bowhead whales, ringed seals, and beluga whales due to icebreaking and ice-management activities are expected to be moderate. Summary impacts to subsistence harvest of walrus and polar bears are considered to be moderate. Summary impacts to other seals species, fish, and bird hunting and egg gathering from icebreaking are expected to be negligible and the same as under Alternative 3. No impacts to caribou are expected.

Impacts of noise and vehicle movement from on-ice seismic surveys

No impacts are anticipated to subsistence harvests of bowhead whales, beluga whales, Pacific walrus, and fishing as a result of the on ice seismic survey. Summary impacts to seals, marine and coastal birds, and caribou are expected to be the same as under Alternative 3 and are considered negligible. The summary impacts to polar bears could be minor.

Indirect Impact to Subsistence Resources from Permitted Discharges

Permitted discharges would be conducted under the conditions and limitations of the required NPDES General Permits. Permitted discharge would be mitigated by additional mitigation measures C3 and C4, which would place requirements and limitations on the levels of discharge and discharge streams that could affect marine mammal habitat and eventually the diets of subsistence users. Under Alternative 4, there could be a higher level of activity, which would increase the levels of permitted discharges.

Mitigation measures may not alleviate the perception that a small oil spill or regulated wastewater discharge might contaminate subsistence resources. There is a perception the foods could become contaminated by discharges and/or small fuels spills could result in impacts to human health from consumption of the resources. The likelihood is low that subsistence resources or harvest would occur in the vicinity of the assumed areas where drilling and/or any associated discharge or spill might occur. In addition fuel transfers are not expected during transit between the Beaufort and Chukchi seas. The indirect impact of drill cuttings and mud discharges may displace marine mammals and fish a short distance from each drilling location. The impacts to subsistence users would be of low intensity, short term in duration, local in extent, and affecting resources that are common to unique in context. Therefore the summary impacts to subsistence resources, activities, and subsistence users would be minor, though the perception of the impact could be moderate.

Summary

Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources resulting from implementation of Alternative 4 would be of low to medium intensity, temporary to interim in duration, local to regional in extent, and the context would be common to unique. Therefore the summary impact level of Alternative 4 on subsistence resources and harvests would be considered to range from negligible to moderate depending upon the specific subsistence resource affected and source of disturbance.

4.7.3.2.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to subsistence resources are discussed under Alternative 2 (Section 4.5.3.2).

4.7.3.3 Public Health

4.7.3.3.1 Direct and Indirect Effects

Anticipated effects to public health as a result of Alternative 4 are expected to be similar to those expected under Alternative 2, as discussed in Section 4.5.3.3.

4.7.3.3.2 Conclusion

Both potential beneficial and adverse impacts are anticipated as a result of Alternative 4. Possible changes could occur to health outcomes such as chronic disease and trauma and many of the pathways relate to traditional practices and subsistence activities. However, there is a very low likelihood of these health outcomes arising, and effects are unlikely to be large enough cause a measurable change in health outcomes. The magnitude or intensity of effects is estimated to be low: above background conditions, but small and within both the natural variation and adaptive ability of the local population. If health changes do occur, the duration of changes may be permanent, and multiple communities could be affected.

4.7.3.4 Cultural Resources

4.7.3.4.1 Direct and Indirect Effects

Alternative 4 is the same as Alternative 3 except with increased levels of exploratory drilling activity. These mitigation measures do not affect cultural resources in the EIS project area, so the impacts discussed in Section 4.5.3.4 for Alternative 2 are the same for Alternative 4. The overall impact to cultural resources is difficult to assess in an offshore context, but disturbance would be limited to setting arrays of cables on the seabed, jackup rigs positioning for drilling, drill ships anchoring preparatory to drilling, and drilling associated with exploratory and G&G coring. If any of these activities were to impact a previously unidentified cultural resource, the impacts would be adverse, and all such actions would require consultation with the Alaska State Historic Preservation Officer in compliance with 36 CFR 800.

4.7.3.4.2 Conclusion

The overall impact to cultural resources is difficult to assess in an offshore context, but disturbance would be limited to setting arrays of cables on the seabed, jackup rigs positioning for drilling, drill ships anchoring preparatory to drilling, and drilling associated with exploratory and G&G coring.

4.7.3.5 Land and Water Ownership, Use, and Management

4.7.3.5.1 Direct and Indirect Effects

Land and Water Ownership

The direct and indirect impacts to land and water ownership caused by Alternative 4 are similar to those caused by Alternative 2. Refer to Section 4.5.3.5 for a discussion on these topics. This includes federal, state, private, borough, and municipal owned lands and waters.

Land and Water Use

The actions in Alternative 4 are the same as for Alternative 2. However the activity levels are increased; numbers of allowed seismic surveys, shallow hazards survey programs, and exploratory programs are increased in the Beaufort and Chukchi seas. However, the amount of on-ice seismic surveys and icebreaking remained the same. Taking into consideration these increases, direct and indirect effects to the recreation, residential, mining, and protected land uses are similar to Alternative 2. Refer to Section 4.5.3.5 for a discussion on these topics.

With an increase in activity levels, the possibility for conflict increases between subsistence use and surveys. Section 4.7.3.2 discusses the direct and indirect impacts of Alternative 4 in detail.

The direct and indirect impacts caused by Alternative 4 for industrial, transportation, and commercial land uses are similar to those discussed under Alternative 2 in Section 4.5.3.5 but use would increase incrementally as survey activity levels go up. Beyond what is discussed in Section 4.5.3.5, there is a slightly higher possibility of new facilities and infrastructure, higher levels of air and vessel traffic, and commercial activity associated with survey support. No new roads or railroad lines are expected to be built under this alternative; therefore no changes are expected in land use to accommodate expanded land transportation systems. See Section 4.7.3.1 Socioeconomics for further discussion on economic opportunities under this alternative

Land and Water Management

BOEM has awarded leases in the Beaufort and Chukchi seas for the purpose of exploring for and developing petroleum resources in the federal OCS. The level of exploration activity in federal water under Alternative 4 is consistent with management of those waters. Similarly, the state applies Best Interest Findings before allowing seismic exploration activities and each must demonstrate individual consistency with state management policies before permits are issued on state lands or waters. Therefore, no inconsistencies or changes in federal or state land or water management are anticipated as a result of this alternative. The effects are similar to those discussed under Alternative 2, Section 4.5.3.5.

While no change in underlying land or water management is anticipated as a result of this project, compliance with NSB and NAB comprehensive plans and Land Management Regulations coastal management policies is undertaken on a voluntary basis for activities in state and federal waters; permit applicants for offshore exploration activities in state waters may attempt to be consistent with Borough Land Management Regulations. As activities increase under Alternative 3, the possibility for conflicts with borough offshore development and coastal management zoning policies goes up as well. As indicated in Section 3.3.6 Coastal Management, the Alaska Coastal Management Program was not reauthorized by the State legislature and is no longer in effect.

4.7.3.5.2 Conclusion

Based on Table 4.4-2, and the analyses provided in Section 4.5.3.5, the impacts on land and water ownership under Alternative 4 are described as follows. The magnitude of ownership impacts would be low because no changes in land or water ownership will result from this action. The duration of impact would be temporary because no ownership changes will occur. The extent of impacts would be local, occurring only in the activity area and involving no ownership change. The context of impact would be common because the federal waters affected have no special, rare, or unique ownership characteristics. In total, the direct and indirect impacts on land ownership/development rights are considered to be negligible; they would be low intensity, temporary, localized, and do not result in changes of ownership.

Based on Table 4.4-2 and the analyses provided above and in Section 4.5.3.5, the impacts of land and water use caused by Alternative 4 are described as follows. The magnitude of impact would be high where activity occurs where there is previously little to no activity (such as Wainwright), and the magnitude of impact would be low where activity occurs where previous activity is common (Prudhoe Bay, Barrow, Nome, Dutch Harbor). The duration of impact would be temporary because an increase in aircraft and shipping traffic would last only for that survey season, although the impact could be permanent if construction of a new facility or infrastructure to accommodate shipping traffic were built in Wainwright. The extent of impacts would be local because any changes in land use as a result of this alternative would be limited geographically to the communities that would support the survey vessels. The context of impact would be common because the areas of land and water use affected are extensively available and have no special, rare, or unique characteristics identified. In summary, the direct and indirect effects of Alternative 3 would be moderate because of the possibility for high intensity impact and long term structures in smaller communities

Based on Table 4.4-2 and the analyses provided above and in Section 4.5.3.5, the impacts on land and water management caused by Alternative 4 are described as follows. The magnitude of impact would be low because, while the level of activity would increase, they are consistent with existing management plans, subject to conditions of approval. The duration of impact would be temporary because project activities are short term in duration and would not result in long-term conflicts with management plans. The extent of impacts would be local because proposed activities would not involve management plans beyond the localized areas of exploration and support activities. The context of impact would be common because the areas of land and water affected are extensively available and have no special, rare or unique characteristics identified in an adopted management plan. In total, the direct and indirect impacts of Alternative 3 on land and water management would be minor because they would be low intensity, would be temporary in nature, local, and common.

4.7.3.6 Transportation

4.7.3.6.1 Direct and Indirect Effects

The effects to transportation in Alternative 4 would be similar to those described under Alternative 2 (Section 4.5.3.6), though of an elevated intensity. The direct effect to transportation would be an increase in levels of air traffic and vessels present in these areas associated with the seismic survey and exploratory drilling activities in comparison to levels projected under Alternative 2. The intensity of the impact would be considered low and short term in duration (length of survey or exploratory drilling activities each year). The extent of increased aircraft presence may be on a local and regional scale given the increased number of seismic survey and exploratory drilling programs that could occur under Alternative 4. Impacts from the increased levels of air traffic would be low in intensity, temporary in duration, and local in extent and affect a common resource. The impact level could be considered minor to moderate.

4.7.3.6.2 Conclusion

Increased levels of marine vessel traffic in Alternative 4 associated with the seismic survey and exploratory drilling programs would be expected to occur in offshore areas where local marine transportation does not occur. Industry vessels would likely encounter local marine traffic when littering to designated nearshore marine facilities (which are limited). The impact of increased vessel presence and the potential for vessel strikes to marine mammals would be low in intensity, temporary in duration, limited in geographic extent to a local area, and common to potentially unique context (in respect to protected marine mammal resources). The summary impact from increases in vessel traffic would be considered minor.

4.7.3.7 Recreation and Tourism

4.7.3.7.1 Direct and Indirect Effects

Alternative 4 is the same as Alternative 2 except with increased levels of activity. The impacts discussed in Section 4.5.3.7 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to recreation and tourism. The conclusions for Alternative 2 are applicable to Alternative 4; the overall impact to recreation and tourism would be minor.

4.7.3.7.2 Conclusion

The direct impacts to recreation and tourism would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 4 on recreation and tourism would be minor.

4.7.3.8 Visual Resources

This section discusses potential impacts on visual resources that could result from implementing Alternative 4 of the proposed project.

4.7.3.8.1 Direct and Indirect Effects

Implementation of Alternative 4 would be similar to that described in Section 4.5.3.8.1; however, there would be an increase in the level of permitted activity and a consequent potential increase in impacts to visual resources. The proposed action is expected to result in short-term moderate effects to scenic quality and visual resources similar to that described in Alternative 2. Because of the greater number of support vessels used in the two exploratory drilling programs proposed under Alternative 4, this action could be high intensity if both programs are implemented in close proximity to each other. Potential impacts could be of low to medium intensity depending if programs are geographically separated. In either case, actions would be temporary, localized and occur in an important context.

4.7.3.8.2 Conclusion

Implementation of Alternative 4 is expected to result in short-term moderate effects to scenic quality and visual resources. Potential impacts could be of low to medium intensity depending on specific location of drill sites. The geographic extent of potential impacts would be localized; however they would occur in an important ecosystem.

4.7.3.9 Environmental Justice

4.7.3.9.1 Direct and Indirect Effects

Impacts to Subsistence Foods and Human Health

The activity levels associated with Alternative 4 are expected to result in similar levels of effects to subsistence hunts by potential deflection of marine mammals harvested in the EIS project area (described in Subsistence Section 4.5.3.2 for Alternative 2). Alternative 4 activity levels are expected to cause a negligible increase in contamination levels of subsistence food sources (described in the Public Health Section 4.5.3.3), which could have the indirect effect of adding a similar perception as Alternative 2 that subsistence foods are contaminated and alter confidence in their consumption.

4.7.3.9.2 Conclusion

Activities related to implementation of Alternative 4 would have a low intensity impact on subsistence resources and human health, a temporary duration, and a regional extent. Subsistence foods and human health are unique resources and they are protected under the MMPA and EO 12898. Thus, Alternative 4 is expected to have a minor impact to subsistence resources and human health. There would also be minor disproportionate impacts to Alaska Native communities under Alternative 4.

4.7.3.10 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the social environment, other than subsistence, are discussed under Alternative 2 (Section 4.5.3.10).

4.8 Direct and Indirect Effects for Alternative 5 – Authorization for Level 3 Exploration Activity with Additional Required Time/Area Closures

4.8.1 Physical Environment

4.8.1.1 Physical Oceanography

4.8.1.1.1 Direct and Indirect Effects

Water Depth and General Circulation

The effects of Alternative 5 on water depth and general circulation would be the same as those described for Alternative 4.

Currents, Upwellings, and Eddies

The effects of Alternative 5 on currents, upwellings, and eddies would be the same as those described for Alternative 4.

Tides and Water Levels

The time/area closures described under Alternative 5 would not affect tides or water levels within the EIS project area.

Stream and River Discharge

The time/area closures described under Alternative 5 would not affect stream and river discharge within the EIS project area.

Sea Ice

The effects of Alternative 5 on sea ice would be substantially the same as those described for Alternative 4. The time area closures included as additional mitigation measures in Alternative 5 would not substantially change the effects of the alternative on sea ice resources in the proposed action area.

4.8.1.1.2 Conclusion

The effects of Alternative 5 on physical ocean resources would be medium-intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. The overall effects of the proposed activity described in Alternative 4 on physical ocean resources in the EIS project area would be minor.

4.8.1.2 Climate

Under this alternative, emissions would be the same as for Alternative 4 because the alternative proposes exploration plans described as Level 3 Exploration Activity on the Arctic OCS. The specific description and number of each of these programs and activities proposed for the Arctic OCS, on an annual basis, were summarized earlier in Table 2.4 (*Activity Definitions*) and Section 2.4.5 (*Alternative 2 – Authorization for Level 1 Exploration Activity*).

Refer to Section 3.1.4.4 (*Climate Change in the Arctic*) for a thorough discussion of climate systems and the effects of GHG emissions.

4.8.1.2.1 Direct and Indirect Effects

Direct Effects

Direct effects under this alternative are the same as those described under Alternative 2.

Indirect Effects

Indirect effects under this alternative are the same as those described under Alternative 2.

Regulatory Reporting and Permitting

Regulatory reporting and permitting under this alternative would be the same as those described under Alternative 2.

CO_2e Emissions Inventory

The CO_2e emissions inventory is the same for this alternative as given for Alternative 4.

Effects of this Alternative on Climate Change

The effects of this alternative are the same as those described for Alternative 4.

Effects of Climate Change on Resources under this Alternative

Effects of climate change on resources under this alternative would be the same as described under Alternative 2.

4.8.1.2.2 Conclusion

The conclusion of the assessment under this alternative is the same as for Alternative 4.

4.8.1.3 Air Quality

Under this alternative, emissions would be the same as described for Alternative 4 and proposes Level 3 Exploration Activity on the Arctic OCS, which is four EPs for each planning area. The majority of additional emissions are from the EPs proposed for Level 3 Exploration Activity.

4.8.1.3.1 Direct and Indirect Effects

Direct and indirect effects under this alternative would be from the same sources of emissions as described under Alternative 2 in Section 4.5.1.3.

Exploration Plan Emission Inventory

The emission rates likely to reflect Level 3 Exploration Activity in each sea are the same as those presented for Alternative 4 in Table 4.7-3.

The inventory assumes no application of BACT or the use of ULSD fuel. The emission inventory presented in Table 4.7-3 assumes the same method of calculation and EP operational characteristics as described for Alternative 2.

Survey Emission Inventory

The number and type of seismic and other surveys would be the same as described for Alternative 4. The emission rates likely to reflect the increased level of seismic and other surveys under this alternative are the same as those presented for Alternative 4 in Tables 4.7-3 and 4.7-4.The survey inventories assume no application of BACT or the use of ULSD fuel. The emission inventory presented in Table 4.7-5 assumes the same method of calculation and survey vessel operational characteristics as described for the previous alternatives.

4.8.1.3.2 Air Quality Impact Analysis

The air quality impact analysis would be conducted as described under Alternative 2.

4.8.1.3.3 Level of Effect

The annual rate of air emissions and onshore pollutant concentrations are the two basic measurements for assessing a proposal's level of effect on air quality. The emission inventory provided in this section discloses the rate of emissions likely to reflect a proposal under this alternative, expressed in short tpy. When necessary, an emission inventory is translated into pollutant concentrations expressed in micrograms per cubic meter (µg/m3), a value that can be measured against the NAAQS allowing the level of effect to be categorized relative to the conditions summarized under Alternative 2 in Table 4.5-7 *Impact Levels for Effects on Air Quality*. Further information regarding level of effect under this alternative would be the same as discussed under Alternative 4.

4.8.1.3.4 Conclusion

Emissions from exploratory drilling activities proposed under this alternative would be higher than emissions estimated for Alternative 2. Without emission reduction controls on the drillship engines, there is a greater potential for one or more of the EPA SILs to be exceeded onshore. The Level 2 Exploration Activity would almost certainly require additional modeling to demonstrate the effect of pollutant concentrations on the nearest onshore area. A moderate level of effect on air quality is expected, which may be mitigated by emission control strategies to result in a minor level of effect. Cumulatively, the total estimated emissions for each Arctic OCS planning area, when considering all plans and activities described under this alternative, are the same as those summarized for Alternative 4 in Table 4.7-5.

Control of oil and gas emission sources on the OCS, and levels of effect, are considered on a project-by-project basis, as each individual operator would have the responsibility to engage any engine emission controls required by BOEM AOCSR. Emission reduction strategies have the potential to reduce at least some emissions of all pollutant types, including CO_2e. Therefore, the data provided in Table 4.7-5 would represent a worst-case scenario for each Arctic OCS planning area.

4.8.1.4 Acoustics

Under Alternative 5, the number and types of exploration programs envisioned is identical to Alternative 4 (see Section 4.7.1.4). A detailed discussion of the acoustic properties of the noise sources is given in Section 4.5.1.4.

Alternative 5 differs from Alternative 4 only in that it implements time/area closures for avoidance of higher marine mammal densities during migration or periods of feeding or subsistence use.

4.8.1.4.1 Direct and Indirect Effects

Implementation of time closures does not reduce the spatial distribution of sound levels. The distances and areal extent to the pertinent thresholds for Alternative 5 are identical to those provided in Alternative 4 in the case of time closures. Area closures would reduce the sound levels in the closure area, but may result in higher sound levels should the activities be concentrated to an area outside of the closure.

4.8.1.4.2 Conclusion

While Alternative 5 presents the same level of activity as Alternative 4, lower levels of exploration activities may actually occur under Alternative 5 due to inclusion of periods of closure. The amount by which activity will be reduced depends on the ability of seismic operators to schedule around blackouts. One potential effect of the time/area closures associated with Alternative 5 would be that available exploration time in certain locations will be compressed. As a consequence, there could be less ability for different exploration operators to schedule activities to avoid working in close vicinity of each other. Operations in close vicinity could lead to higher exposures for marine mammals that happen to be near the activities outside of the closure periods or areas. This issue is discussed in Section 4.5.1.4.

Alternative 5 could represent a smaller increase in activity over current levels than Alternatives 2, 3, and 4. The intensity rating of this alternative is high, as the exploration activities in non-closure periods will introduce sources with source sound levels that exceed 200 dB re 1 μPa. Because the exploration activities could continue for several years, the duration is considered as long term. Under a closure the sound levels will be decreased at a regional scale, however the spatial extent for Alternative 5 is still considered to be regional, as in Alternatives 2, 3, and 4. Therefore, the overall impact rating for direct and indirect effects to the acoustic environment under Alternative 5 would be moderate.

4.8.1.5 Water Quality

Impacts to water quality from Alternative 5 are expected to be very similar to those described above for Alternative 4. The only difference between Alternative 4 and Alternative 5 is the addition of required time/area closures; the level of activity would stay the same, but may vary by area and when the activity will occur. Any differences in impacts between Alternative 4 and Alternative 5 are noted below.

4.8.1.5.1 Direct and Indirect Effects

Temperature and Salinity

Seismic Surveys

Similar to impacts for Alternatives 2, 3, and 4, seismic surveys would not be expected to have any measureable impact on temperature or salinity in the proposed action area.

Site Clearance and Shallow Hazards Surveys

Similar to impacts for Alternatives 2, 3, and 4, site clearance and shallow hazards surveys would not be expected to have any measureable impact on temperature or salinity in the proposed action area.

On-ice Seismic Surveys

Similar to impacts for Alternatives 2, 3, and 4, on-ice seismic surveys would not be expected to have any measureable impact on temperature or salinity in the proposed action area.

Exploratory Drilling Programs

Effects on water quality resulting from increases in temperature and salinity from exploratory drilling programs would be similar to those described under Alternatives 2, 3, and 4. Time/area closures established under Alternative 5 as additional mitigation measures would eliminate adverse impacts to water quality in sensitive areas during certain times. Overall, the effects of Alternative 5 on water quality resulting from changes in temperature and salinity would be low intensity, temporary, and local. The overall effects of Alternative 5 on water quality related to temperature and salinity resulting from exploratory drilling programs are expected to be minor.

Turbidity and Total Suspended Solids

Seismic Surveys

Similar to impacts for Alternatives 2, 3, and 4, effects on water quality resulting from increases in turbidity and total suspended solids from seismic surveys under Alternative 5, if any, are expected to be low-intensity, temporary, local, and would affect a common resource. The nature of those effects would be the same described under Alternative 2.

Site Clearance and Shallow Hazards Surveys

Similar to impacts for Alternatives 2, 3, and 4, effects on water quality resulting from potential increases in turbidity and total suspended solids from site clearance and shallow hazard surveys under Alternative 5, if any, are expected to be low-intensity, temporary, local, and would affect a common resource. The nature of those effects would be the same described under Alternative 2.

On-ice Seismic Surveys

On-ice seismic surveys would not affect turbidity or concentrations of suspended solids in the proposed action area.

Exploratory Drilling Programs

Effects on water quality resulting from increases in turbidity and total suspended solids from exploratory drilling programs are described in detail under Alternatives 2 and 3. Time/area closures established under Alternative 5 as additional mitigation measures would eliminate adverse impacts to water quality in sensitive areas during certain times. The effects of Alternative 5 on water quality resulting from changes in turbidity and concentrations of suspended solids are expected to be low intensity, temporary, and local. The overall effects of Alternative 5 on water quality related to turbidity and concentrations of suspended solids resulting from exploratory drilling programs are expected to be minor.

Proposed mitigation measures intended to reduce/lessen non-acoustic impacts on marine mammals have the potential to further reduce adverse impacts to water quality.

Metals

Seismic Surveys

Similar to impacts for Alternatives 2, 3, and 4, seismic surveys are not expected to have any measureable impact on dissolved metal concentrations in the proposed action area.

Site Clearance and Shallow Hazards Surveys

Similar to impacts for Alternatives 2, 3, and 4, site clearance and shallow hazards surveys would not affect dissolved metal concentrations in the proposed action area.

On-ice Seismic Surveys

Similar to impacts for Alternatives 2, 3, and 4, on-ice seismic surveys would not affect dissolved metal concentrations in the proposed action area.

Exploratory Drilling Programs

Effects on water quality resulting from increases in turbidity and total suspended solids from exploratory drilling programs are described in detail under Alternatives 2, 3, and 4. Time/area closures established under Alternative 5 as additional mitigation measures would eliminate adverse impacts to water quality in sensitive areas during certain times. The effects of Alternative 5 on water quality resulting from changes in metal concentrations are expected to be low intensity, temporary, and local. The overall effects of Alternative 5 on water quality related to metal concentrations resulting from exploratory drilling programs are expected to be minor.

Hydrocarbons and Organic Contaminants

Seismic Surveys

Similar to impacts for Alternatives 2, 3, and 4, seismic surveys are expected to have negligible impacts on concentrations of hydrocarbons and organic contaminants in the waters of the proposed action area. Despite being negligible, time/area closures established under Alternative 5 as additional mitigation measures would eliminate adverse impacts to water quality in sensitive areas during certain times.

Site Clearance and Shallow Hazards Surveys

Similar to impacts for Alternatives 2, 3, and 4, site clearance and shallow hazards surveys are expected to have negligible impacts on concentrations of hydrocarbons and organic contaminants in the waters of the proposed action area. Despite being negligible, time/area closures established under Alternative 5 as additional mitigation measures would eliminate adverse impacts to water quality in sensitive areas during certain times.

On-ice Seismic Surveys

Similar to impacts for Alternatives 2, 3, and 4, on-ice seismic surveys are expected to have minor impacts on concentrations of hydrocarbons and organic contaminants in the waters of the proposed action area under Alternative 5. The effects of these discharges on water quality would be temporary and local in nature, and overall impacts to water quality from on-ice seismic surveys under Alternative 5 are expected to be minor (i.e. effects are below regulatory thresholds for marine water quality).

Exploratory Drilling Programs

Direct and indirect effects on water quality resulting from increases in concentrations of hydrocarbons and other organic contaminants from exploratory drilling programs are described in detail under Alternatives 2, 3, and 4. Time/area closures established under Alternative 5 as mitigation measures would reduce adverse impacts to water quality in sensitive areas during certain times. The effects of Alternative 5 on water quality resulting from changes in concentrations of hydrocarbons and other organic compounds are expected to be temporary and local. It is probable that inputs of hydrocarbons and other organic contaminants from exploratory drilling programs under Alternative 5 would have minor to moderate effects on water quality outside of the discharge plume area. However, due to lack of applicable water quality criteria for some organic compounds in drilling fluids (EPA 2006b), it is problematic to determine whether or not inputs of hydrocarbons and other organic compounds from the proposed activity would exceed water quality regulatory limits.

4.8.1.5.2 Conclusion

After mitigation, the effects of the proposed actions on water quality are expected to be low-intensity, temporary, local, and would affect a common resource. The overall effects of the proposed activity described in Alternative 5 on water quality in the EIS project area are expected to be minor.

4.8.1.6 Environmental Contaminants and Ecosystem Functions

4.8.1.6.1 Direct and Indirect Effects

Contaminants of Concern

Contaminants of concern introduced to the EIS project area as a result of the activities proposed in Alternative 5 would be the same as those described for Alternative 2.

Proposed mitigation measures intended to reduce/ lessen non-acoustic impacts on marine mammals have the potential to reduce adverse impacts resulting from contaminants of concern.

Exposure of Habitat and Biological Resources

Pathways for exposure of habitat and biological resources to contaminants of concern as a result of the activities proposed in Alternative 5 would be the same as those described for Alternative 2.

Potential Effects on Ecosystem Functions

In response to comments and suggestions received as part of the scoping process for this EIS, effects of (contaminants of concern from) the proposed activities on ecosystem functions are assessed in the following section. Effects of the activities proposed under Alternative 5 on the four categories of ecosystem functions (defined in Section 4.4.1.6) are assessed below.

Regulation Functions

Additional mitigation measures related to time area closures under Alternative 5 would potentially result in decreased impacts to regulation functions relative to Alternative 4. The capacity of natural systems to maintain essential ecological processes (such as nutrient cycles) and life support systems (such as provision of clean water) is not distributed evenly over space and time (Naidoo et al. 2008). Coastal areas, as well as nutrient rich convergence zones in the open ocean, generally involve greater and more dynamic levels of chemical and biological activity relative to oligotrophic open ocean areas, and therefore generally play a greater role in the maintenance of essential ecological processes. The time area closures proposed under Alternative 5 would limit impacts to certain coastal areas and convergence zones during particular times and therefore have the potential to reduce adverse impacts to regulation functions.

Habitat Functions

Additional mitigation measures related to time area closures under Alternative 5 would potentially result in decreased impacts to habitat functions relative to Alternative 4. The capacity of natural systems to provide refuge and reproduction habitat is not distributed evenly over space and time. Coastal areas, as well as nutrient rich convergence zones in the open ocean, generally involve greater and more dynamic levels of chemical and biological activity relative to oligotrophic open ocean areas, and therefore generally play a greater role in the provision of refuge and reproduction habitats. The time area closures proposed under Alternative 5 would limit impacts to certain coastal areas and convergence zones during particular times, and therefore have the potential to reduce adverse impacts to habitat functions.

Production Functions

Additional mitigation measures related to time area closures under Alternative 5 would potentially result in decreased impacts to production functions relative to Alternative 4. The capacity of natural systems to convert energy and nutrients into biomass and support subsequent trophic transfers and biogeochemical processes is not distributed evenly over space and time (Naidoo et al. 2008). Coastal areas, as well as nutrient rich convergence zones in the open ocean, generally involve greater and more dynamic levels of chemical and biological activity relative to oligotrophic open ocean areas, and therefore generally play a greater role in energy conversion and production processes. The time area closures proposed under Alternative 5 would limit impacts to certain coastal areas and convergence zones during particular times and therefore have the potential to reduce adverse impacts to production functions.

Oil and gas are ecosystem goods, and the flows of energy that they represent are ecosystem services. These ecosystem goods and services could potentially be derived from historical production functions in the EIS project area under Alternative 5.

Information Functions

Additional mitigation measures related to time area closures under Alternative 5 would potentially result in decreased impacts to information functions relative to Alternative 4. The capacity of natural systems to contribute to the maintenance of human health by providing opportunities for spiritual enrichment, cognitive development, recreation, and aesthetic experience is not distributed evenly over space and time. Coastal areas, as well as nutrient rich convergence zones in the open ocean, generally involve greater and more dynamic levels of chemical and biological activity relative to oligotrophic open ocean areas, and therefore generally play a greater role in providing the opportunities associated with information functions. The time area closures proposed under Alternative 5 would limit impacts to certain coastal areas and convergence zones during particular times, and therefore have the potential to reduce adverse impacts to information functions.

4.8.1.6.2 Conclusions

Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 5 would be medium-intensity, temporary, and local. The functional properties of ecosystems described in this section, such as nutrient cycling and habitat functions, are more robust (i.e. resistant to stressors) than are species composition and other structural properties. Overall effects of Alternative 5 on ecosystem functions would be minor.

4.8.1.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the physical environment are discussed under Alternative 2 (Section 4.5.1.7).

4.8.2 Biological Environment

4.8.2.1 Lower Trophic Levels

4.8.2.1.1 Direct and Indirect Effects

Activity levels in Alternative 5 are the same as in Alternative 4, and there are additional mitigation measures for seasonal closures for certain areas. These mitigated closures do not affect lower trophic levels in the EIS project area, so the impacts discussed in Sections 4.5.2 and 4.6.2 for Alternatives 2 and 3 are the same for Alternative 5, making the overall impact to lower trophic levels be minor.

4.8.2.1.2 Conclusion

Given the potential for implementation of the standard mitigation measures considered in this EIS, the direct and indirect effects on lower trophic levels associated with Alternative 5 would likely be low in intensity, temporary to long-term in duration, of local extent and could affect common resources; resulting in a summary impact level of negligible. The only exception to these levels of impacts would be the introduction of an invasive species due to increased vessel traffic, which could be of medium intensity, long-term or permanent duration, of regional geographic extent, and affect common or important resources, which could cause a summary impact of moderate.

4.8.2.2 Fish and Essential Fish Habitat

4.8.2.2.1 Direct and Indirect Effects

Alternative 5 assumes the same level of oil and gas exploration activity as Alternative 4, described as Level 3. The activities are divided identically among the different activity types in both alternatives, and the number and types of surveys, exploration, and drilling are all assumed to be the same. Likewise, the Standard and Additional Mitigation Measures are also identical. The analyses for direct and indirect effects are the same for Alternative 5 as for Alternative 4.

Alternative 5 differs from Alternative 4 in the creation and application of time/area closures that would be required for all activities as opposed to being considered on a case-by-case basis under the Additional Mitigation Measures for Alternatives 2, 3, 4, and 5. Time/area closures are intended to reduce impacts to marine mammals during sensitive times and locations in their life cycle and to decrease conflict with Native Alaskan marine mammal subsistence activities. Specific locations have been identified and will be closed to oil and gas exploration activities during periods of high use by marine mammals.

It is important to note that under this alternative, there would be no reduction in the overall amount of activity occurring. The total noise emitted or habitat lost or altered would remain the same, only the times and locations of those impacts would change. However, fish are not evenly distributed across the EIS project area and instead congregate in desirable habitats. Many of the areas identified as being important to marine mammals are also likely to be important to other marine species as well. Productive marine environments are shared by many animal groups; therefore, the time/area closures will likely correspond to locations and periods important to fish species and will result in unintended beneficial impacts to fish resources. A seismic survey performed in an area of low fish density will have lower adverse impacts on fish resources than a seismic survey performed in an area of high fish density. If activities can be reduced or eliminated in areas of high fish density, the overall number of fish likely to be impacted will be smaller by reducing the total number of fish exposed to high sound levels, and the amount of altered or damaged habitat would also be reduced.

An analysis of each time/area closure area is included here, as well as the anticipated mitigating impact each closure could have on fish and fish resources. Any benefits or mitigated effects described would only occur if exploration activities in other, less productive areas replaced activities that would otherwise occur within the time/area closures. Additionally, impacts in these areas would be reduced if the exploration activity occurred at other times of year when fewer marine mammals (and possibly other marine species) were present in those locations. The temporal offset of activity within these areas is unlikely to result in any discernible reduction in overall impact levels.

For a complete discussion of the effects of direct and indirect effects on fish resources, please see Section 4.5.2.2.

4.8.2.2.2 Time/Area Closures

Barrow Canyon/Western Beaufort Sea

The northwest corner of the Beaufort Sea, near the Chukchi Sea, has been shown to be the most productive fish habitat in the region (see Section 3.2.2.1, Logerwell and Rand 2010). Although Barrow Canyon sits on the southern boundary of this highly productive area, it is still much more productive than surrounding areas of the Beaufort Sea. Fish densities are higher here and to the north than in surrounding areas. This closure area does not contain any lease areas, eliminating drilling from the list of activities potentially impacting the resources. Therefore, the main consideration to fish resources would be a reduction in sound emitted from seismic surveys, with a small amount of habitat loss or alteration potentially mitigated through the elimination of anchoring and icebreaking in the area.

Reducing oil and gas exploration activities in this area would reduce overall impacts to fish resources primarily by decreasing the overall amount of exposure to sound by fish on a population level and also providing a small decrease in habitat loss and alteration. The elimination of all exploration activities would benefit all assemblages of marine fish the most, with some anticipated benefit to migratory fish.

Shelf Break of the Beaufort Sea

The shelf break of the Beaufort Sea has been shown to be the most productive fish habitat in the region, particularly the northwest corner near the Chukchi Sea (see Section 3.2.2.1, Logerwell and Rand 2010). As such, reducing oil and gas exploration activities in this area would reduce overall impacts to fish resources by decreasing the amount of high quality habitat lost or altered and reducing the overall amount of exposure to sound by fish on a population level. The elimination of all exploration activities would benefit all assemblages of marine fish the most, with some anticipated benefit to migratory fish.

Hanna Shoal

The Hanna Shoal is known to be a highly productive and important biological area, with high concentrations of sea birds, walrus and whales (Nelson et al. 1993). Although the fish resources in the area are not well understood, studies are currently being undertaken to better catalogue and describe the importance of the area. From the number of other species known to use the area, it can be assumed that it is important fish habitat, likely showing a high density of fish resources, particularly compared to the rest of the Chukchi Sea. This closure area contains very few lease sales, with a limited number located in the far southwestern corner. Therefore, drilling would be essentially eliminated from the list of activities potentially impacting the resources. The main consideration to fish resources would be a reduction in sound emitted from seismic surveys, with a small amount of habitat loss or alteration potentially mitigated through the elimination of anchoring and icebreaking in the area.

Reducing oil and gas exploration activities in this area would reduce overall impacts to fish resources by decreasing the amount of high quality habitat lost or altered and reducing the overall amount of exposure to sound by fish on a population level. The elimination of all exploration activities would benefit all assemblages of marine fish the most, with some anticipated benefit to migratory fish.

Kasegaluk Lagoon and Ledyard Bay

The Kasegaluk Lagoon and Ledyard Bay are shallow, nearshore areas of the Chukchi Sea. These closure areas do not contain any lease areas, eliminating drilling from the list of activities potentially impacting the resources. Therefore, the main consideration to fish resources would be a reduction in sound emitted from surveys, with a small amount of habitat loss or alteration potentially mitigated through the elimination of anchoring and icebreaking in the area.

Migratory fish are likely to benefit from this closure. Juvenile salmon are known to congregate in shallow estuaries near river mouths before moving off to sea, and many amphidromous species also use brackish water for substantial portions of their lives (see Section 3.2.2.6). Therefore, increased protection of these areas would be beneficial to the migratory species that use these habitats regularly. Nearshore marine species would also benefit from this closure, due to the shallow habitat characterizing the area.

4.8.2.2.3 Conclusion

The effect of the Time/Area Closures outlined in Alternative 5 on Fish Resources and EFH would be a reduction in the overall impact. Although the overall impact is considered to be negligible based on Alternative 4 alone, any further reduction in impacts resulting from the Time/Area Closures would be beneficial. The already low impact levels would be decreased by each of the individual closures, and any combination would reduce the impacts further. Implementing all of the Time/Area Closures would substantially decrease all effects on fish resources by protecting the most important fish habitats where the highest fish densities are found. Due to the substantial decrease to the already very small scale of any potential effects relative to overall population levels and available habitat, there would be no measurable effect on the resource.

4.8.2.3 Marine and Coastal Birds

4.8.2.3.1 Direct and Indirect Effects

Alternative 5 includes all of the same type of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on birds under Alternative 5 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.3. Rather than repeating the same information presented in Section 4.5.2.3, the following discussion will focus on the differences between Alternative 2 and Alternative 5.

The difference between alternatives concerning birds is a matter of degree. Alternative 5 includes a larger number of some authorized exploration activities than Alternative 2. Alternative 5 would authorize the same number and types of exploration activities in the Arctic seas as Alternative 4, including the same suite of standard mitigation measures with the addition of mandatory time/area closures. The closure areas are the same as those discussed in Additional mitigation measure B1: Kaktovik and Cross Island, the Beaufort Sea Shelf Break, Barrow Canyon and the Western Beaufort Sea, Hanna Shoals, Kasegaluk Lagoon, and Ledyard Bay. The difference between Additional Mitigation Measure B1 and Alternative 5 is that specific time periods have been specified under Alternative 5 corresponding to periods of high biological productivity or important life functions for some species, primarily bowhead and beluga whales. However, the most important of these areas to birds, the LBCHU, would be subject to the same closure period as any of the other alternatives, after July 1, because this restriction is one of the mitigation measures imposed by the USFWS and BOEM to protect ESA-listed spectacled eiders.

The direct and indirect effects of oil and gas exploration activities on marine and coastal birds would be very similar under Alternative 5 as those described under Alternative 2. Marine birds would be subject to increased disturbance from vessels and seismic sources due to the increase in seismic surveys that could be authorized under Alternative 5 in both Arctic seas. However, disturbance effects would be temporary even if they occurred over a wider area and birds could fly or swim away from acute disturbance. With more exploration activities authorized under Alternative 5, the potential for adjacent activities to magnify effects on birds could be increased. However, the requirement to maintain a minimum distance of 24 km (15 mi) between two seismic surveys conducted concurrently would effectively limit the intensity of seismic survey effects on birds no matter where the activities take place during the open water season. The Ledyard Bay closure period would be the same under Alternative 5 as under Alternative 2 so this area would be unaffected by increases in exploration elsewhere.

The risk of birds colliding with vessels would increase incrementally but, given mitigation measures to adjust lighting strategies to reduce those effects, fatal collisions are still expected to be rare and not likely to affect the population of any species. The risk of small oil spills would also increase incrementally as the number of vessels increase but these effects are also mitigated and considered to present very small risks to birds unless the spill occurred in or persisted in a lead or polynya system. A very large oil spill due to an exploration well blowout could have much more serious effects on birds and is discussed in Section 4.10.

4.8.2.3.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to marine and coastal birds are discussed under Alternative 2 (Section 4.5.2.3).

4.8.2.3.3 Conclusion

Most marine and coastal birds are legally protected under the Migratory Bird Treaty Act and several are protected under the ESA. Birds fulfill important ecological roles in the Arctic and many are important subsistence resources. Depending on the species, they are considered to be important or unique resources from a NEPA perspective. The effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. The overall effects of oil and gas exploration activities authorized under Alternative 5 on marine and coastal birds would therefore be considered minor according to the impact criteria in Table 4.5-17.

4.8.2.3.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to marine and coastal birds are discussed under Alternative 2 (Section 4.5.2.3).

4.8.2.3.5 Additional Mitigation Measures Conclusion

Most of the additional mitigation measures considered in this EIS would not appreciably reduce potentially adverse effects on birds except for Additional C3 and C4. These two measures would reduce the risk of contamination from discharges and drilling muds, although the benefits relative to the standard mitigation measures would be limited to small numbers of birds and small areas of benthic habitat. Given the implementation of standard and additional mitigation measures considered by NMFS in this EIS, and assuming no large oil spill occurred during exploration activities, the effects on birds would likely be low in intensity, temporary to long-term in duration, of local extent, and would affect important or unique resources. The effects of Alternative 5 with additional mitigation measures would therefore be considered minor for birds.

4.8.2.4 Marine Mammals

Alternative 5 differs from Alternative 4 in the creation and application of Time/Area Closures that would be required for all oil and gas exploration activities within a particular time and location. The closure areas are the same as those discussed in Additional Mitigation Measure B1: Kaktovik, the Beaufort Sea Shelf Break, Barrow Canyon and the Western Beaufort Sea, Hanna Shoal, Kasegaluk Lagoon, and Ledyard Bay. No oil and gas industry exploration activities would be permitted to occur in the areas specified here during the listed timeframes. Under this alternative, buffer zones around these time/area closures would be included. Buffer zones would require that activities emitting pulsed sounds would need to operate far enough away from these closure areas so that sounds at 160 dB re 1 µPa rms do not propagate into the area or that activities emitting continuous sounds would need to operate far enough away from these closure areas so that sounds at 120 dB re 1 µPa rms do not propagate into the area. The purpose of Time/Area Closures is twofold: 1) to reduce adverse impacts to marine mammals (in either number or severity) in areas (and times) of known importance to marine mammals (e.g., feeding or calving areas), in which behavioral disturbance could potentially result in a reduction in the fitness of the disturbed individuals, either through energetic effects or direct interference with critical behaviors (e.g, cow/calf communication), and/or 2) to minimize conflicts with Alaska Native marine mammal subsistence hunting activities. Table 4.8-1 summarizes the resources and mitigated functions associated with each area. Analyses of the Time/Area Closure areas, along with the anticipated mitigating impact each closure could have on the indicated species, are described in the species sections below.

Of note, in this alternative, only the buffer zone noted above is considered, and only the implementation of *all* the areas is considered. However, when time/area limitations are considered as additional mitigations in the other alternatives, we may consider the implememntation of some subset of the areas or a smaller buffer, depending on the situation and practicability for the specific project in consideration.

Table 4.8-1 Proposed required Time/Area closure locations under Alternative 5. This table identifies the species and subsistence hunts that would be mitigated by requiring these closures.

	Kaktovik	**Barrow Canyon and the Western Beaufort Sea**	**Beaufort Sea Shelf Break**	**Hanna Shoal**	**Kasegaluk Lagoon and Ledyard Bay**
Proposed closure period under Alternative 5	August 25 - September 15	Mid-July - October	Mid-July - late September	September 15 - early October	Mid-June - mid-July for the Lagoon and July 1 – November 15 for the LBCHU
Bowhead Whale	Migrating and feeding: late August - October	Migrating and feeding: late August - October	Migrating: late August - October	Part of migratory corridor: September - October	Do not occur (migrate offshore)
Beluga Whale	Uncommon	Migrating and feeding: mid-July - late August	Feeding: mid-July - late September	Unknown	Feeding, molting, calving: June and July
Spotted Seal	Present	Present	Present	Present	Present; Some feeding habitat
Walrus	Not present	Not present	Not Present	Feeding: July - August	Resting habitat: Spring and early winter
Whaling Hunts	bowheads: late August - mid-September	bowheads: September - October	Uncommon	None	belugas: mid-June - mid-July in the Lagoon only
Sealing Hunts	Mostly October - June	Mostly November - January and spring	Uncommon	None	Mostly October - June

4.8.2.4.1 Bowhead Whales

4.8.2.4.1.1 Direct and Indirect Effects

Alternative 5 includes the same level of oil and gas exploration activity as Alternative 4 (Level 3 Exploration). The number and types of surveys, exploration, and drilling are all assumed to be the same. Standard and Additional Mitigation Measures for Alternative 5 are also identical to those for Alternatives 2, 3, and 4 except that the time/area closures discussed as additional measures in Alternatives 2, 3, and 4 are required in this alternative. The analyses for Direct and Indirect Effects, Standard Mitigation Measures, and Additional Mitigation Measures are the same for Alternative 5 as for Alternative 4, with the exception of the anticipated effects of restricting activities from occurring in the time/area closure areas. The time/area closures expected to affect impacts on bowhead whales (Kaktovik and Barrow Canyon and the Western Beaufort Sea) are discussed below.

Time/Area Closures Required Under Alternative 5

Kaktovik

Kaktovik is considered a time/area closure location by NMFS for analysis purposes in this EIS (Figure 3.2-25) and would be closed to all exploration activities from August 25 to September 15. Data collected during ASAMM surveys in the Beaufort Sea from 2008-2011 noted feeding groups of bowhead whales in September most of those years (Clarke et al. 2011b, c, 2012). Additionally, hunters from Kaktovik traditionally conduct hunts in the nearshore waters from the community in the fall. Hunts typically begin in late August/early September and continue until mid- to late September, depending on upon migration patterns, weather and ice conditions, etc. Closing the area to oil and gas activities during this time period would reduce adverse impacts, particularly those associated with noise disturbance (e.g. displacement and avoidance), on bowhead whales feeding, resting, or migrating through this area. Reducing impacts on concentrations of bowhead whales in an important feeding area could be energetically beneficial to the whales. Prohibiting activities in this area during the period of highest use by bowheads could result in a decreased intensity of effects during the closure period. Reduced adverse impacts on bowhead whales would, however, be limited to the closure area. Noise effects of activities occurring outside of this closure area could continue to impact bowhead whales in the vicinity that are either outside the closure zone or within the zone, but at a distance from the sound source within which behavioral reactions are still possible. However, the implementation of the buffer zones around the required closure areas would help to reduce further impacts from occurring within this important location.

The nearshore waters of Kaktovik are also used for bowhead hunting during this time period, as discussed in further detail in Section 4.8.3.2.

Barrow Canyon/Western Beaufort Sea

Barrow Canyon/Western Beaufort Sea is considered a time/area closure location by NMFS for analysis purposes in this EIS (Figure 3.2-25) and would be closed to all exploration activities from mid-July – October. Due to sub-sea topography and the ocean currents, Barrow Canyon is one of the two primary concentration areas for bowhead whales in the Beaufort Sea, particularly as a staging/feeding area during the fall migration of bowheads out of the Beaufort Sea. Physical and oceanographic features of Barrow Canyon promote a bowhead whale feeding “hotspot” here during late-summer and fall. Bowhead whales congregate in the area to exploit dense prey concentrations (Ashjian et al. 2010, Moore et al. 2010, Okkonen et al. 2011). Barrow Canyon is also an important feeding area for beluga whales (Clarke et al. 2011b, 2011c, Moore et al. 2000). Time/Area closures for this area proposed under Alternative 5 are to mitigate effects on bowhead whales (late August to early October), belugas (mid-July to late August), and the fall bowhead whale subsistence hunt out of Barrow (September 15 to close of the hunt). Closing the area to oil and gas activities during these time periods would reduce adverse impacts, particularly those associated with noise disturbance (e.g. displacement and avoidance), on bowhead whales feeding, resting, or migrating through this area, as well as for belugas. Reducing impacts on concentrations of bowhead whales in an important feeding area could be energetically beneficial to the whales. Prohibiting activities in this area during the period of highest use by bowheads could result in a decreased intensity of effects during the closure period. Reduced adverse impacts on bowhead whales would, however, be limited to the closure area. Noise effects of activities occurring outside of this closure area could continue to impact bowhead whales in the vicinity that are either outside the closure zone or within the zone, but at a distance from the sound source within which behavioral reactions are still possible. However, the implementation of the buffer zones around the required closure areas would help to reduce further impacts from occurring within these biologically important areas.

This area and time is also important for beluga feeding (Section 4.8.2.4.2), as well as the fall bowhead hunt (Section 4.8.3.2).

Behavioral Disturbance

Since the exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, the types and mechanisms for disturbance to bowhead whales would be the same. As discussed above, though, implementation of time/area closures has the potential to reduce the intensity of behavioral disturbance to bowhead whales through potential reduction in the numbers of disturbed whales (if whales were more densely congregated in these areas) or reduction in the severity by avoiding potential adverse energetic effects that might result from displacement from preferred feeding habitat. The degree of reduced impacts would depend on the level of acticvities which would otherwise have occurred in these areas, which is difficult to predict (of note, these areas do not overlap any leases), however, the same total level of activities would still be expected to occur outside of these closures (still in the bowhead migratory corridor), so the degree of reduced impacts, as compared to the whole, would be relatively minor and would not change the impact criteria conclusions, which are of high intensity, interim duration, regional extent, and unique context.

Please refer to Section 4.5.2.4.9 for a complete discussion of disturbance effects, by activity type, on bowhead whales.

Hearing Impairment, Injury, and Mortality

Since the exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, the mechanisms for injury and mortality to bowhead whales would be the same. Because the proposed time/area closures are not expected to reduce the likelihood of injury or mortality, these remain identical to those discussed for Alternative 4 in Section 4.7.2.4: medium intensity, generally interim in duration (except in instances of mortality or serious injury), regional in extent and of important context.

Please refer to Section 4.5.2.4.9 for a complete discussion of potential injury or mortality effects on bowhead whales.

Habitat Alterations

Since the exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, the mechanisms for habitat alteration would be the same. However, the implementation of these time/area closures could create some level of reduced effect on acoustic habitat in an area/time where interspecies communication and interpretation of acoustic cues may be of increased importance (i.e., for feeding), although, when compared to the overall level of effects outside these areas, the level of effects on bowhead whale habitat from Alternative 5 could be slightly less, but not significantly different than those discussed for Alternative 4 in Section 4.7.2.4.

Please refer to Section 4.5.2.4.9 for a complete discussion of the potential effects on bowhead whale habitat.

4.8.2.4.1.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.8.2.4.1.3 Conclusion

As described above, effects of disturbance on bowhead whales, as well as impacts on acoustic habitat, from open-water exploration activities would be reduced in the closure areas during time periods specified in Alternative 5 relative to how much exploration activity would have occurred there if permitted to do so. Exploration activities could, however, occur during different time periods within these areas, leading to a short-term reduction of effects. In addition, industry may relocate exploration activities to other, possibly adjacent, areas until the closure areas are available. Overall, exploration effort would not likely be reduced, but, rather, redistributed and possibly concentrated in other areas. Time/Area closures that mitigate adverse impacts on feeding bowhead whales could reduce impacts to a lower intensity. However, bowhead whale habitat use in the EIS project area is dynamic and extensive, and, when migration corridors are considered (through which mothers and calves are passing), it includes large portions of the Beaufort and Chukchi seas not included in the Time/Area closures that could coincide with oil and gas exploration activities throughout the region. Effects of concurrent closures also need to be considered. Time/area closures in the Beaufort Sea (Kaktovik, Barrow Canyon and Beaufort Sea Shelf Break) overlap in September and, for the former two, in October as well. Concurrent closures could result in excluded activities concentrating in areas not included in the closure areas, such as on the Beaufort shelf between Harrison Bay and Camden Bay, during those time periods. Although the Time/Area closures specified in Alternative 5 could mitigate adverse impacts in particular times and locations, the overall impact on bowhead whales of oil and gas exploration activities allowed under this alternative would be similar to Alternative 4 (Section 4.7.2.4) however, with a slight decrease, and would be considered moderate.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	Low	
		Medium	
		High	Take of bowheads exceeds 30% of population
	Duration	Temporary	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	Local	
		Regional	Impacts considered regional
		State-wide	
	Context	Common	
		Important	
		Unique	ESA-listed species, impacts across migratory corridor through which mother/calve pairs traverse, potential disruption of feeding
Injury and mortality	Magnitude or Intensity	Low	Injury or death unlikely
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	Temporary	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	Local	Since unlikely, any few impacts would be considered local
		Regional	
		State-wide	
	Context	Common	
		Important	ESA listed species, but population is increasing

Type of effect	Impact Component	Effects Summary	
		Unique	
Habitat alterations	**Magnitude or Intensity**	**Low**	
		Medium	Combination of potential habitat impacts, including acoustic habitat, are medium
		High	
	Duration	**Temporary**	
		Interim	Although other alterations shorter, acoustic habitat is altered for duration of activities
		Long-term	
	Geographic Extent	**Local**	
		Regional	Impacts considered regional, especially when consider area over which sound exceeds 120 dB, and the communication distances of baleen whales.
		State-wide	
	Context	**Common**	
		Important	ESA listed species, but population is increasing
		Unique	

4.8.2.4.1.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.16). All time/area closures included in Additional Mitigation Measure B1 would be required under Alternative 5.

4.8.2.4.1.5 Additional Mitigation Measures Conclusion

Conclusions regarding the potential for these additional measures to reduce adverse impacts of oil and gas activities on bowhead whales allowed under Alternative 5 are the same as under Alternative 2. Refer to Section 4.5.2.4.16 for details.

4.8.2.4.2 Beluga Whales

4.8.2.4.2.1 Direct and Indirect Effects

Alternative 5 includes the same level of oil and gas exploration activity as Alternative 4 (Level 3 Exploration). The number and types of surveys, exploration, and drilling are all assumed to be the same. Standard and Additional Mitigation Measures for Alternative 5 are also identical to those for Alternatives 2, 3, and 4 except that the time/area closures discussed as additional measures in Alternatives 2, 3, and 4 are required in this alternative. The analyses for Direct and Indirect Effects, Standard Mitigation Measures, and Additional Mitigation Measures are the same for Alternative 5 as for Alternative 4, with the exception of the anticipated effects of restricting activities from occurring in the time/area closure areas. The time/area closures expected to affect impacts on beluga whales (Barrow Canyon and the Western Beaufort Sea, the Beaufort Sea Shelf, and Kasegaluk Lagoon) are discussed below.

Time/Area Closures Required Under Alternative 5

Barrow Canyon/Western Beaufort Sea

Barrow Canyon/Western Beaufort Sea is considered a time/area closure location by NMFS for the purposes of analysis in this EIS and would be closed to all oil and gas exploration activities from mid-July – October. Barrow Canyon is an important feeding area for beluga whales, primarily during summer to early fall (Clarke et al. 2011b, 2011c, Moore et al. 2000). Closing the area to oil and gas activities during these time periods could reduce adverse impacts, particularly those associated with noise disturbance (e.g. displacement, avoidance, potential adverse energetic impacts from interrupted feeding). Reduced adverse impacts on beluga whales would likely be limited to the closure area. Implementing buffer zones around the required closure areas could, however, help to reduce impacts of noise from activities occurring in areas adjacent to the closure areas.

This area is also important for bowheads (feeding area; Section 4.8.2.4.1) and the fall bowhead whale subsistence hunt (Section 4.8.3.2).

Shelf Break of the Beaufort Sea

The shelf break of the Beaufort Sea is considered a time/area closure location by NMFS for the purposes of analysis in this EIS and would be closed to all oil and gas exploration activities from mid-July – to late September. It is an important feeding habitat for belugas whales, prompting proposed closure of the area. Active leases in the Beaufort Sea are generally on the shelf, inshore of the shelf break; drilling activities would, therefore, not be impacted through this closure. Seismic activities and associated vessel traffic would be affected, thereby reducing potential adverse impacts on beluga whales, particularly those associated with noise disturbance. The time and location of reduced adverse impacts would be limited to the area defined by the shelf break. Implementing buffer zones around the required closure areas could further reduce impacts of noise on the closure area generated by activities occurring in areas adjacent to the closure areas.

Kasegaluk Lagoon and Ledyard Bay

Kasegaluk Lagoon and Ledyard Bay are considered a biologically important area for analysis purposes in this EIS (Figure 3.2-26). Kasegaluk Lagoon provides important habitat for beluga whales and spotted seals. Belugas of the eastern Chukchi Sea stock congregate in Kasegaluk Lagoon in June and July (Frost et al.1993, Huntington et al. 1999). Omalik Lagoon, south of Kasegaluk Lagoon, is also an important gathering area for belugas in June, except in years when there is heavy ice along the shore (Huntington et al. 1999). This closure area does not contain any lease areas, so drilling activities would not be affected by the closure. Seismic surveys and associated vessel and aircraft traffic would, except in emergency situations, be required to divert around the closure area. This could decrease disturbance effects of vessel activity within these important habitats and closure areas, while shifting vessel activity further offshore.

Behavioral Disturbance

Since the exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, the types and mechanisms for disturbance to beluga whales would be the same. As discussed above, though, implementation of time/area closures has the potential to reduce the intensity of behavioral disturbance to beluga whales through potential reduction in the numbers of disturbed whales (if whales were more densely congregated in these areas) or reduction in the severity by avoiding potential adverse energetic effects that might result from displacement from preferred feeding or calving habitat. The degree of reduced impacts would depend on the level of acticvities which would otherwise have occurred in these areas, which is difficult to predict (of note, these areas do not overlap any leases), however, the same total level of activities would still be expected to occur outside of these closures, so the degree of reduced impacts, as compared to the whole, would be relatively minor and would not change the impact criteria conclusions, which are medium intensity, interim duration, regional extent, and important context.

Hearing Impairment, Injury, and Mortality

As discussed under Alternatives 2 and 3 (Sections 4.5.2.4.10 and 4.6.2.4.2), the primary mechanism of potential injury or mortality to beluga whales due to oil and gas exploration activities are permanent hearing loss or damage (auditory injury) and collisions with vessels. Since the exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, the mechanisms for injury and mortality to beluga whales would be the same. Because the proposed time/area closures are not expected to reduce the likelihood of injury or mortality, these remain identical to those discussed for

Alternative 4 in Section 4.7.2.4, medium intensity, interim in duration (except in instances of mortality or serious injury), regonal in extent and of important context.

Habitat Loss/Alteration

Since the exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, the mechanisms for habitat alteration would be the same. However, the implementation of these time/area closures could create some level of reduced effect on acoustic habitat in an area/time where interspecies communication and interpretation of acoustic cues may be of increased importance (i.e., for feeding), although, when compared to the overall level of effects outside these areas, the level effects on beluga whale habitat from Alternative 5 could be slightly less, but not significantly different than thos discussed for Alternative 4 in Section 4.7.2.4.

4.8.2.4.2.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.8.2.4.2.3 Conclusion

As described above, effects of disturbance on beluga whales, as well as impacts on acoustic habitat from open-water exploration activities would be reduced in the closure areas during time periods specified in Alternative 5 relative to how much exploration activity would have occurred there if permitted to do so. In addition, industry may relocate exploration activities to other, possibly adjacent, areas until the closure areas are available. Overall, exploration effort would not be reduced, but, rather, redistributed and possibly concentrated in other areas.

Time/Area closures that mitigate adverse impacts on concentrations of beluga whales (feeding and caluving areas) could reduce impacts to a lower intensity. However, beluga whale habitat use in the EIS project area is dynamic and extensive and, includes large portions of the Beaufort and Chukchi seas not included in the Time/Area closures that could coincide with oil and gas exploration activities throughout the region. Although the Time/Area closures specified in Alternative 5 could mitigate adverse impacts in particular times and locations, the overall impact on beluga whales of oil and gas exploration activities allowed under this alternative would be similar to Alternative 4 (Section 4.7.2.4) however, could be slightly reduced, and would be considered minor to moderate.

4.8.2.4.2.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.16).

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	Low	
		Medium	Behavioral harassment occurring, but likely < 30% of population disturbed
		High	
	Duration	Temporary	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	Local	
		Regional	Combined activities considered regional
		State-wide	
	Context	Common	
		Important	Non-ESA listed, population status not well known, but thought not to be declining in Chukchi, important feeding and calving areas
		Unique	

Type of effect	Impact Component	Effects Summary	
Injury and mortality	Magnitude or Intensity	**Low**	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	**Temporary**	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	**Local**	Since unlikely, any few impacts would be considered local
		Regional	
		State-wide	
	Context	**Common**	Not ESA listed, populations not thought to be decreasing
		Important	
		Unique	
Habitat alterations	Magnitude or Intensity	**Low**	
		Medium	Combination of potential habitat impacts, including acoustic habitat, are medium
		High	
	Duration	**Temporary**	
		Interim	Although other alterations shorter, acoustic habitat is altered for duration of activities
		Long-term	
	Geographic Extent	**Local**	
		Regional	When acoustic habitat is considered, impacts considered regional
		State-wide	
	Context	**Common**	Not ESA listed, populations not thought to be decreasing
		Important	
		Unique	

4.8.2.4.3 Other Cetaceans

Alternative 5 assumes the same level of oil and gas exploration activity as Alternative 4, described as Level 3. The activities are divided identically among the different activity types in both alternatives, and the number and types of surveys, exploration, and drilling are all assumed to be the same. Likewise, the Standard and Additional Mitigation Measures are also identical. The analyses for Direct and Indirect Effects, Standard Mitigation Measures, and Additional Mitigation Measures are the same for Alternative 5 as for Alternative 4.

Alternative 5 differs from Alternative 4 in the creation and application of Time/Area Closures. Time/Area Closures are intended to reduce impacts to certain marine mammal species during sensitive times and locations in their life cycle, and to decrease conflict with Native subsistence. The Time/Area Closures have been chosen to coincide with periods and locations important for marine mammal development and subsistence activities. Specific locations have been identified, and will be closed to oil and gas exploration activities during periods of high use. The closure areas are the same as those discussed in Additional Mitigation Measure B1: Kaktovik, the Beaufort Sea Shelf Break, Barrow Canyon and the Western Beaufort Sea, Hanna Shoal, Kasegaluk Lagoon, and Ledyard Bay. Oil and gas exploration activities also would not be allowed to occur outside of these areas within a certain distance (i.e. buffer zones).

The table below indicates the occurrence of other cetacean species in the specified Time/Area Closures. However, these areas do not coincide with areas that are of specific importance for these other cetacean species, with the exception of gray whales, which use some of the same feeding areas as bowheads (see Bowhead Barrow Canyon in Section 4.8.2.4.1), although they are not generally present during the time that the Kaktovik area is closed. Therefore, addition of these Time/Area closures in Alternative 5 is not expected to notably change the anticipated impacts to these other species, and the analysis remains identical to Alternative 4.

Table 4.8-2 Other Cetaceans Presence in Closure Areas Required Under Alternative 5

Species	Shelf Break of the Beaufort Sea	Kaktovik and Cross Island	Barrow Canyon	Hanna Shoals	Ledyard Bay
Baleen whales (mysticetes)					
Gray whale	Uncommon -- July-September	Unknown – very rare, if present	Present July-September, possibly overwintering	Present July-September	Not present
Humpback whale	Rare – August to October	Unknown – very rare, if present	Rare – August to October	Rare – August to October	Not present
Fin whale	Rare – August to October	Not present	Not present	Rare – August to October	Not present
Minke whale	Rare – August to October	Unknown – very rare, if present	Unknown – very rare, if present	Rare – August to October	Not present
Toothed whales (Odontocetes)					
Harbor porpoise	Present	Present	Present	Present	Present
Killer whale	Occasionally present during open water season	Occasionally present during open water season	Occasionally present during open water season	Occasionally present during open water season	Occasionally present during open water season
Narwhal	Very rare, likely extra-limital	Very rare, likely extra-limital	Very rare, likely extra-limital	Very rare, likely extra-limital	Very rare, likely extra-limital

4.8.2.4.3.1 Direct and Indirect Effects

As Alternative 5 has the same level of activity as Alternative 4, the Direct and Indirect Effects for the two alternatives are identical. For a complete discussion of the effects of Direct and Indirect Effects on other cetaceans, please see Section 4.5.2.4.

4.8.2.4.3.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.15). Because the activity levels in both alternatives are identical, the effects of the Standard Mitigating Measures will also be the same.

4.8.2.4.3.3 Conclusion

As noted above, these measure are not expected to change the anticipated impacts to other cetacean species, with the possible exception of a slight reduction of impacts to feeding gray whales (see section 4.8.2.4.1). Gray whales are the most common species of the baleen and toothed whales (excluding bowhead and beluga whales) within the EIS project area, and share many migratory, feeding and life history traits with bowhead whales. Although the Time/Area closures specified in Alternative 5 could potentially mitigate adverse impacts in Barrow Canyon when gray whales are feeding there or nearby, the overall impact on Other Cetaceans of oil and gas exploration activities allowed under this alternative would be similar to Alternative 4 (see Section 4.7.2.4) and would be considered minor.

4.8.2.4.3.5 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.16). Because the activity levels in both alternatives are identical, the effects of the additional mitigating measures will also be the same. For a complete discussion of the effects of additional mitigation measures on other cetaceans, please see Section 4.5.2.4.11.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	Low	Possible that some other species may not come into contact with activities or be impacted
		Medium	If behavioral harassment occurs, would be < 30% of population disturbed
		High	
	Duration	Temporary	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	Local	Effects primarily considered local
		Regional	Impacts from max levels of activity might be considered regional for gray whales when consider area ensonified over 120 dB (>10% EIS area) and fact that gray whales are more likely to be encountered than other species.
		State-wide	
	Context	Common	
		Important	Although not ESA listed, important areas exist for gray whales.
		Unique	
Injury and mortality	Magnitude or Intensity	Low	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	Temporary	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	Local	Since unlikely, any few impacts would be considered local
		Regional	
		State-wide	
	Context	Common	Not ESA listed species, but trends of some species not known
		Important	Not ESA listed species, but trends of some species not known
		Unique	
Habitat alterations	Magnitude or Intensity	Low	
		Medium	Combination of potential habitat impacts, including acoustic habitat, are medium
		High	
	Duration	Temporary	
		Interim	Although other alterations shorter, acoustic habitat is altered for duration of activities
		Long-term	
	Geographic Extent	Local	Lower to mid-level of ativities considered regional
		Regional	
		State-wide	
	Context	Common	
		Important	Not ESA listed species, but trends of some species not known
		Unique	Not ESA listed species, but trends of some species not known

4.8.2.4.4 Ice Seals

4.8.2.4.4.1 Direct and Indirect Effects

Alternative 5 assumes the same level of oil and gas exploration activity as Alternative 4, described as Level 3. The activities are divided identically among the different activity types in both alternatives, and the number and types of surveys, exploration, and drilling are all assumed to be the same. Likewise, the Standard and Additional Mitigation Measures are also identical. The analyses for Direct and Indirect

Effects, Standard Mitigation Measures, and Additional Mitigation Measures are the same for Alternative 5 as for Alternative 4.

Alternative 5 differs from Alternative 4 in the creation and application of Time/Area Closures. Time/Area Closures are intended to reduce impacts to certain marine mammal species during sensitive times and locations in their life cycle, and to decrease conflict with Native subsistence. The Time/Area Closures have been chosen to coincide with periods and locations important for marine mammal development and subsistence activities. Specific locations have been identified, and will be closed to oil and gas exploration activities during periods of high use. The closure areas are the same as those discussed in Additional Mitigation Measure B1: Kaktovik and Cross Island, the Beaufort Sea Shelf Break, Barrow Canyon and the Western Beaufort Sea, Hanna Shoals, Kasegaluk Lagoon, and Ledyard Bay. Oil and gas exploration activities also would not be allowed to occur outside of these areas within a certain distance (i.e. buffer zones).

Although the time/area closures are primarily designed to protect bowhead and beluga whales, Hanna Shoal has been noted as an important feeding habitat for bearded seals and Kasegaluk Lagoon and Ledyard Bay are noted as an important haulout/feeding area for spotted seals. The other areas also support ice seals so time/area closures would reduce potentially adverse effects on seals in those areas.

Behavioral Disturbance

The exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, so the types and mechanisms for disturbance to ice seals would be the same. The level of disturbance and potential direct and indirect effects on pinnipeds would therefore be the same for Alternative 5 as is discussed for Alternative 4 in Section 4.7.2.4.4, the components of which were considered to be of medium to high intensity, interim duration, local to regional in extent, and of important context. See Section 4.5.2.4 for a complete discussion of disturbance effects, by activity type, on ice seals.

Hearing Impairment, Injury, and Mortality

The exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, so the types and mechanisms for injury and mortality to ice seals would be the same. The level of potential direct and indirect physical effects on ice seals would therefore be the same for Alternative 5 as is discussed for Alternative 4 in Section 4.7.2.4.4. See Section 4.5.2.4.12 for a complete discussion of potential injury or mortality effects on ice seals.

Habitat Alterations

The exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, so the types and mechanisms for habitat alteration would be the same. The level of potential direct and indirect effects on pinniped habitat would therefore be the same for Alternative 5 as is discussed for Alternative 4 in Section 4.7.2.4.4. See Section 4.5.2.4.12 for a discussion of potential effects oil and gas exploration activities on ice seal habitat.

4.8.2.4.4.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to ice seals are discussed under Alternative 2 (Section 4.5.2.4.15). They would all function to the same level in regard to minimizing disturbance to ice seals as discussed under Alternative 2. The key mitigation measures in this respect concern on-ice activities.

4.8.2.4.4.4 Conclusion

The four species of ice seals would likely not be affected to the same extent by exploration activities in the Beaufort and Chukchi seas based on their respective abundance and distribution. The time/area closures would also have variable capacities to reduce effects on different species proportional to their presence and abundance in the area. Given the standard and additional mitigation measures considered in this EIS, the effects of exploration activities that could be authorized under Alternative 5 on ice seals would likely be medium to high in magnitude, interim in duration, local to regional in extent, and important in context. The effects of Alternative 5 would therefore be considered minor for all ice seal species according to the criteria established in Section 4.1.3.

Type of effect	Impact Component	Effects Summary	
Behavioral disturbance	Magnitude or Intensity	**Low**	
		Medium	Behavioral harassment occurring, but likely < 30% of population disturbed for all species but ringed seals
		High	When maximum activities considered, more than 30% ringed seals may be taken
	Duration	**Temporary**	
		Interim	All activity types last more than month, but combination < 6 months
		Long-term	
	Geographic Extent	**Local**	Effects of activities considered local
		Regional	Max levels potentially regional
		State-wide	
	Context	**Common**	
		Important	ESA-listed species, but impacts not occurring in areas specifically important for feeding/pupping, etc.
		Unique	
Injury and mortality	Magnitude or Intensity	**Low**	Injury or death unlikley
		Medium	Though unlikely, cannot rule out PTS
		High	
	Duration	**Temporary**	
		Interim	Type of potential injury (though unlikely) would likely have moderate effects
		Long-term	
	Geographic Extent	**Local**	Since unlikely, any few impacts would be considered local
		Regional	
		State-wide	
	Context	**Common**	
		Important	ESA listed species,no reliable data available to assess population trends
		Unique	
Habitat alterations	Magnitude or Intensity	**Low**	
		Medium	Combination of potential habitat impacts are medium
		High	
	Duration	**Temporary**	
		Interim	Although other alterations shorter, acoustic habitat is altered for duration of activities
		Long-term	
	Geographic Extent	**Local**	Lower to mid-level of ativities considered local
		Regional	Max levels potentially regional
		State-wide	
	Context	**Common**	
		Important	ESA listed species, population status unknown, no reliable data on trends
		Unique	

4.8.2.4.4.5 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to pinnipeds are discussed under Alternative 2 (Section 4.5.2.4.16).

4.8.2.4.5 Walrus

4.8.2.4.5.1 Direct and Indirect Effects

Alternative 5 includes the same level of oil and gas exploration activity as Alternative 4 (Level 3 Exploration). The number and types of surveys, exploration, and drilling are all assumed to be the same. Standard and Additional Mitigation Measures for Alternative 5 are also identical to those for Alternatives 2, 3, and 4 except that the time/area closures discussed as additional measures in Alternatives 2, 3, and 4 are required in this alternative. The analyses for Direct and Indirect Effects, Standard Mitigation Measures, and Additional Mitigation Measures are the same for Alternative 5 as for Alternative 4, with the exception of the anticipated effects of restricting activities from occurring in the time/area closure areas. The time/area closure expected to affect impacts on walrus (Hanna Shoal) is discussed below.

Time/Area Closures Required Under Alternative 5

Hanna Shoal

Hanna Shoal is considered as a time/area closure location for analysis purposes in this EIS (Figure 3.2-26) from September 15 to early October. It is currently an important feeding area for Pacific walrus (USGS 2011) and was historically important as a feeding area for gray whales (Moore et al. 2000, Nelson et al. 1994). Additionally, the area is used as part of the bowhead whale fall migratory corridor. Closure of Hanna Shoal proposed under Alternative 5 is primarily to mitigate potential impacts on subsistence hunters during the fall bowhead whale hunt (September 15 to close of the hunt). Barrow and Wainwright conduct fall subsistence hunts for bowhead whales in the northeast Chukchi Sea where they could be impacted by vessels transiting between the coast and Hanna Shoal. Harvested whales are generally taken well inshore of Hanna Shoal (Ashjian et al. 2010). Closure of the area to all oil and gas exploration activities during September and October could reduce adverse effects of these activities, especially those associated with noise disturbance, such as displacement, on marine mammals migrating across the area.

Behavioral Disturbance

The exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, so the types and mechanisms for disturbance to walrus would be the same. The level of disturbance and potential direct and indirect effects on walrus would therefore be the same for Alternative 5 as is discussed for Alternative 4 in Section 4.7.2.4.5. A more thorough discussion of disturbance effects, by activity type, on walrus can be found in Section 4.5.2.4.13.

Hearing Impairment, Injury, and Mortality

The exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, so the types and mechanisms for injury and mortality to walrus would be the same. The level of potential direct and indirect physical effects on walrus would therefore be the same for Alternative 5 as is discussed for Alternative 4 in Section 4.7.2.4.5. A more thorough discussion of potential injury or mortality effects on walrus can be found in Section 4.5.2.4.13.

Habitat Alterations

The exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, so the types and mechanisms for habitat alteration would be the same. The level of potential direct and indirect effects on walrus habitat would therefore be the same for Alternative 5 as is discussed for Alternative 4 in Section 4.7.2.4.5. A more thorough discussion of potential impacts on walrus habitat can be found in Section 4.5.2.4.13.

4.8.2.4.5.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.15). They would all function to the same level in regard to minimizing disturbance to walrus as discussed under Alternative 2. The key mitigation measures in this respect concern in-ice activities and the presence of PSOs.

4.8.2.4.5.3 Conclusion

Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. This data indicates that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest of sounds generated by the ships. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of calf and juvenile mortality from stampedes.

Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for NEPA purposes. Given the level and type of exploration activities that would be authorized under Alternative 4, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on walrus would likely be low in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 5 would therefore be considered minor for Pacific walrus according to the criteria established in Table 4.5-17.

4.8.2.4.5.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.16). They would all function to the same level in regard to minimizing the risk to walrus and their habitats as discussed under Alternative 2 except that Additional Mitigation Measure B1 would be further defined to include specific closure dates or time periods determined by real-time information. The key additional mitigation measures in this respect concern in-ice activity, the reduction or elimination of discharges from drilling, and the presence of PSOs.

4.8.2.4.6 Polar Bears

4.8.2.4.6.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 5 on polar bears. This species is dependent on pack ice for much of their denning habitat and for hunting seals. Alternative 5 includes all of the same type of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on polar bears under Alternative 5 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.

Alternative 5 would authorize the same number and types of exploration activities in the Arctic seas as Alternative 4, including the same suite of standard mitigation measures with the addition of mandatory time/area closures. The closure areas are the same as those discussed in Additional Mitigation Measure B1: Kaktovik and Cross Island, the Beaufort Sea Shelf Break, Barrow Canyon and the Western Beaufort Sea, Hanna Shoal, Kasegaluk Lagoon, and Ledyard Bay. Oil and gas exploration activities also would not be allowed to occur outside of these areas within a certain distance (i.e. buffer zones). Specific time periods have been specified for each closure area corresponding to periods of high biological productivity or important life functions for some species. Although the time/area closures are primarily designed to protect bowhead and beluga whales and to avoid conflicts with subsistence hunts during the open-water season, these areas may also be important for ice seals, a primary food source for polar bears. Because

Hanna Shoal is relatively shallow, sea ice often gets grounded and contributes to the consistent formation of leads and polynyas which are important habitat for migrating whales, walrus, ice seals, and hunting polar bears. Additional discussion of the time/area closures follows the summary information on direct and indirect effects and standard mitigation measures.

The exploration activities that would be authorized under Alternative 5 are identical to those under Alternative 4, so the types and mechanisms for disturbance, injury and mortality, and habitat alteration to polar bears would be the same. The level of disturbance and potential direct and indirect effects on polar bears would therefore be the same for Alternative 5 as is discussed for Alternative 4 in Section 4.7.2.4.6. A more thorough discussion of disturbance effects of oil and gas exploration activities on polar bears, and potential impacts to polar bear habitat can be found in Section 4.5.2.4.14.

4.8.2.4.6.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.15). They would all function to the same level in regard to minimizing disturbance to polar bears as discussed under Alternative 2. The key mitigation measures in this respect concern on-ice activity and the presence of PSOs to monitor for polar bears and help reduce the risk of bear-human encounters.

4.8.2.4.6.3 Conclusion

The specified time/area closures under Alternative 4 are primarily intended to reduce impacts on bowhead and beluga whales and avoid interference with subsistence hunts, not to reduce overall exploration activity. The overall effects on polar bears would therefore be similar to what would occur under Alternative 4 but it may occur in somewhat different times and places. Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important subsistence resources and are therefore considered a unique resource. Given the mitigation measures that would be required by USFWS LOAs and NMFS as considered in this EIS, the effects of exploration activities that could be authorized under Alternative 4 on polar bears would likely be low in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 5 would therefore be considered minor for polar bears according to the criteria established in Section 4.1.3.

4.8.2.4.6.5 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.16). They would all function to the same level in regard to minimizing the risk to polar bears and their habitats as discussed under Alternative 2 except that Additional B1 would be further defined under Alternative 5 to include specific closure dates or time periods determined by real-time information. The key mitigation measures in this respect concern on-ice activity and the presence of PSOs to monitor for polar bears and help reduce the risk of bear-human encounters.

4.8.2.5 Terrestrial Mammals

Activity levels in Alternative 5 are the same as in Alternative 4, with the added requirement for seasonal closures for certain areas. These required closures under Alternative 5 do not affect terrestrial mammals in the EIS project area, so the impacts discussed in Section 4.5.2.5 for Alternatives 2 and 3 are the same for Alternative 5; the overall impact to terrestrial mammals would be minor.

4.8.2.6 Time/Area Closures

The analysis of the direct and indirect effects associated with time/area closures can be found in Sections 4.8.2.4 (Marine Mammals), 4.8.2.3 (Marine and Coastal Birds) and 4.8.3.2 (Subsistence).

4.8.2.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the biological environment, other than marine mammals and marine and coastal birds, are discussed under Alternative 2 (Section 4.5.2.7).

4.8.3 Social Environment

4.8.3.1 Socioeconomics

4.8.3.1.1 Direct and Indirect Effects

Time/area closures may cause a reduction in or shift the timing of some support service activities described under Alternative 4. To the extent that time/area closures provide additional benefits to marine mammals and reduce impacts on subsistence activities, there would be some potential socioeconomic benefits. This would apply to all time/area closure areas. Time/area closures may result in productivity costs to lease holders. For example, the underutilization of equipment and the employment of “caretaker” crews to maintain idle equipment, vessels, and camps during closures.

4.8.3.1.2 Conclusion

The socioeconomic impact under Alternative 5 is similar to Alternative 4 except there could be a lower intensity beneficial impact to local communities because time/area closures could reduce total local employment rates and personal income, and a low to medium intensity economic impact to lease holders that incur costs or lose productivity. The duration of the socioeconomic impacts is temporary because it is not year-round; however, the activity is scheduled to occur over a fixed number of years. The positive economic impacts of the activity are statewide and even national. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat communities. The summary impact level for Socioeconomics under Alternative 4 is minor, not exceeding the significance threshold.

4.8.3.2 Subsistence

4.8.3.2.1 Direct and Indirect Effects

Direct and indirect effects to subsistence resources and subsistence harvest would be expected to be at reduced levels relative to those discussed under Alternative 2 (Section 4.5.3.2.). Alternative 5 differs from Alternative 4 in the creation and application of Time/Area Closures that would be required for all oil and gas exploration activities within a particular time and location. The closure areas are the same as those discussed in Additional Mitigation Measure B1: Kaktovik and Cross Island, the Beaufort Sea Shelf Break, Barrow Canyon and the Western Beaufort Sea, Hanna Shoal, Kasegaluk Lagoon and Ledyard Bay. The intent of Time/Area Closures is to reduce adverse impacts to marine mammals in areas (and times) important to biological productivity and life history functions and to minimize conflicts with Alaskan

Native marine mammal subsistence hunting activities. Section 4.8.2.4 contains a full description of the importance of these required closures to individual marine mammal species. In addition to their importance to life functions of certain marine mammal species, some of the areas are also important subsistence hunting grounds, as noted in Section 4.8.2.4. The areas of Kaktovik and Barrow Canyon and the Western Beaufort Sea are important areas for fall bowhead whaling. Hunters from Point Lay hunt beluga whales in Kasegaluk Lagoon from mid-June to mid-July. Seal hunts also occur at various times of the year near Kaktovik and in the waters of Barrow Canyon and the Western Beaufort Sea, Kasegaluk Lagoon, and Ledyard Bay. Limiting activities in these locations during times when hunts also occur will reduce impacts to subsistence resources in those areas.

4.8.3.2.2 Standard Mitigation Measures

The same Standard Mitigation Measures described for subsistence harvest and subsistence resources in Alternative 2 (Section 4.5.3.2) would be contemplated in Alternative 5. However, under Alternative 5, required time/area closures would be applied in all circumstances instead of being considered as additional mitigation measures, as is the case for Alternatives 2, 3, 4, and 6. These required closures would be considered beneficial as they would further limit potential impacts to subsistence harvests and users. The required time/area closures for Kaktovik, Barrow Canyon, the Western Beaufort Sea, and the Shelf Break in the Beaufort Sea would reduce potential impacts from disturbance on specific subsistence harvests areas utilized by the communities of Kaktovik and Barrow for marine mammal harvest of bowhead whales, seals, walrus, and polar bear.

As noted by Harry Brower of the AEWC in written comments submitted for this EIS on April 9, 2010:

> *We strongly encourage NMFS to implement protective measures for critical subsistence use areas, including: - areas used by the Village of Kaktovik in the eastern Beaufort; - areas around Cross Island used by the Village of Nuiqsut; - areas used by the Village of Barrow in the western Beaufort; and - areas used by Wainwright and Pt. Lay along the Chukchi Sea coast. NMFS should consider deferring these areas from industrial activity or implementing seasonal closure and restrictions … Because of the potential impacts to bowhead whales, we encourage NMFS to implement specific protections for areas that provide important habitat characteristics, including deferring industrial activity in these areas or implementing seasonal closures and restrictions. In particular, NMFS must provide proven protections for the following areas: - critical feeding and resting grounds near Camden Bay in the mid-Beaufort; and - critical feeding grounds in the eastern Beaufort and near Barrow Canyon in the western Beaufort. NMFS should also focus on key behavioral characteristics and vulnerable members of the population, including feeding and resting during the migration, communication, and impacts to mothers and calves.*

The time/area closures required under Alternative 5 for Kasegaluk Lagoon and Ledyard Bay in the Chukchi Sea would be reduce any potential adverse impacts from distribution of subsistence harvest and use for the communities of Wainwright, Point Lay, and Point Hope. These are areas where marine mammal hunting is concentrated and where important bird hunting and fishing occur. Kasegaluk Lagoon and Ledyard Bay are areas where Point Lay subsistence hunts occur for harvest of beluga whales, walrus, bearded, ringed and spotted seals, and polar bear, as well as birds and fish. Point Hope subsistence users would benefit from this time/area closure, as they hunt in Ledyard Bay for seals and walrus. However, the protection would be in addition to that provided by BOEM OCS Lease Stipulation 7, which requires that "except for emergencies or human/navigation safety, surface vessels associated with exploration and delineation of drilling operations will avoid travel within the LBCHU between July 1 and November 15."

4.8.3.2.3 Conclusion

Direct and indirect impacts to subsistence harvest and subsistence resources are likely to be similar or less than those of Alternative 2 as discussed in Section 4.5.3.2. The impacts of implementing Alternative 5 could be considered beneficial to subsistence harvests and users as the time and area closures would be applied in all circumstances instead of being considered as additional mitigation measures. Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources resulting from implementation of Alternative 5 would be of low intensity, temporary to interim in duration, local to regional in extent, and the context would be common to important. Therefore the summary impact level of Alternative 5 on subsistence resources and harvests would be considered to range from negligible to minor depending upon the specific subsistence resource affected and source of disturbance, as there is the potential for these time/area closures to reduce the impact levels from those for Alternative 4.

4.8.3.2.4 Additional Mitigation Measures

The same Additional Mitigation Measures described for subsistence harvest and subsistence resources in Alternative 2 (Section 4.5.3.2) would be contemplated in Alternative 5.

4.8.3.3 Public Health

4.8.3.3.1 Direct and Indirect Effects

Anticipated effects to public health as a result of Alternative 5 are expected to be similar to those expected under Alternative 2, as discussed in Section 4.5.3.3. The effect of the time/area closures on subsistence resources is described in Section 4.8.3.2, which concludes that the closures will have a beneficial effect on subsistence harvests in Kaktovik and Barrow of bowhead whales, seals, walrus, and polar bear. Section 4.8.3.2 concludes that there would be beneficial effects for the communities of Wainwright, Point Lay, and Point Hope because of the closure of Kasegaluk Lagoon and Ledyard Bay. To the extent that these time/area closures improve the likelihood of maintaining a strong subsistence harvest, there will also be resulting benefits to public health. Similarly, insofar as time and area closures minimize dispersion of marine mammals and allow hunters to complete their hunts with less travel time, the potential impact to safety should be reduced. However, these benefits do not affect the overall impact criteria rating, as the anticipated results to public health are already negligible.

4.8.3.3.2 Conclusion

Both potential beneficial and adverse impacts are anticipated as a result of Alternative 5. Possible changes could occur to health outcomes such as chronic disease and trauma and many of the pathways relate to traditional practices and subsistence activities. However, there is a very low likelihood of these health outcomes arising, and effects are unlikely to be large enough cause a measurable change in health outcomes. The magnitude or intensity of effects is estimated to be low: above background conditions, but small and within both the natural variation and adaptive ability of the local population. If health changes do occur, the duration of changes may be permanent, and multiple communities could be affected.

4.8.3.4 Cultural Resources

4.8.3.4.1 Direct and Indirect Effects

Activity levels in Alternative 5 are the same as in Alternative 4. These mitigation measures do not affect cultural resources in the EIS project area, so the impacts discussed in Section 4.5.3.4 for Alternative 2 are the same for Alternative 5. The overall impact to cultural resources would be minor.

4.8.3.4.2 Conclusion

Direct and indirect impacts to cultural resources resulting from the implementation of Alternatives 2, 3, and 4 would be the same in Alternative 5. For a complete discussion of direct and indirect impacts on cultural resources, please see Section 4.5.3.4.

4.8.3.5 Land and Water Ownership, Use, and Management

4.8.3.5.1 Direct and Indirect Effects

Land and Water Ownership

The direct and indirect impacts to land and water ownership resulting from Alternative 5 are similar to those resulting from Alternative 4. Refer to Section 4.5.3.5 for a discussion on these topics. This includes federal, state, private, borough, and municipal owned lands and waters.

Land and Water Use

As time/area closures are implemented, the likelihood of conflicts decreases because the closures would lessen the exposure of subsistence species to seismic activities and exploratory drilling at critical locations and during critical seasons of the year. See Section 4.8.3.2, Subsistence for further discussion.

The direct and indirect impacts to land and water use resulting from Alternative 5 are similar to those resulting from Alternative 4 for recreational, residential, and mining land uses. Refer to Section 4.5.3.5 for a discussion on these topics.

Alternative 5 includes the same activity level as Alternative 4 but with required time/area closures during important biological and subsistence activities. This would effectively remove these areas from uses other than subsistence activities during the closure season and temporarily increase the area of land and water devoted to ecological and subsistence purposes.

The direct and indirect impacts caused by Alternative 5 for industrial, transportation, and commercial land uses are similar to those discussed under Alternative 4 in Section 4.7.3.5, except that time/area closures would shorten the timeframe available for oil and gas exploration activities and potentially impede exploration activity. As a result, there may be a reduction in transportation and commercial uses during certain times of the year.

Land and Water Management

Constraining exploration to certain times and locations may have varied effects on state and federal management policies. On the one hand, the use of time/area closures may result in more moderate state and federal resource development goals, while on the other hand promoting management practices to protect the human, marine and coastal environments, and improve consistency with North Slope Borough and Northwest Arctic Borough comprehensive plans and Land Management Regulations. Therefore, because these techniques reflect one approach to balanced management and do not prohibit resource development, no inconsistencies or changes in federal or state land or water management are anticipated as a result of this alternative. The effects are the same as discussed under Alternative 2, Section 4.5.3.5.

The direct and indirect impacts to borough land and water management caused by Alternative 5 are similar to those caused by Alternative 4. Refer to Section 4.6.3.5 for a discussion on these topics.

4.8.3.5.2 Conclusion

Based on Table 4.4-2 and the analyses provided in Section 4.5.3.5, the impacts on land and water ownership under Alternative 5 are described as follows. The magnitude of ownership impacts would be low because no changes in land or water ownership will result from this action. The duration of impact would be temporary because no ownership changes will occur. The extent of impacts would be local, occurring only in the activity area and involving no ownership change. The context of impact would be common because the federal waters affected have no special, rare, or unique ownership characteristics. In total, the direct and indirect impacts on land ownership are considered to be negligible; they would be low intensity, temporary, localized, and do not result in changes of ownership.

Based on Table 4.4-2 and the analyses provided above and in Sections 4.5.3.5 and 4.6.3.5, the impacts of land and water use caused by Alternative 5 are described as follows. The magnitude of impact would be high when activity occurs in areas of little to no previous activity (such as Wainwright), and the magnitude of impact would be low in areas where previous activity is common (Prudhoe Bay, Barrow, Nome, Dutch Harbor). The duration of impact would be temporary because an increase in aircraft and shipping traffic would last only for that survey season, although the impact could be permanent if construction of a new facility or infrastructure to accommodate shipping traffic were built in Wainwright. The extent of impacts would be local because any changes in land use as a result of this alternative would be limited geographically to the communities that would support the survey vessels. The context of impact would be common because the areas of land and water use affected are extensively available and have no special, rare, or unique characteristics identified. In summary, the direct and indirect effects of Alternative 4 would be moderate because of the possibility for high magnitude activities and long term construction in smaller communities.

Based on Table 4.4-2 and the analyses provided above and in Sections 4.5.3.5 and 4.6.3.5, the impacts on land and water management caused by Alternative 5 are described as follows. The magnitude of impact would be low because the action is consistent with existing management plans. The duration of impact would be long term because area closures would happen annually for several years. The extent of impacts would be local because proposed activities would not involve management plans beyond the localized areas of seismic exploration and support activities. The context of impact would be common because the areas of land and water affected are extensively available and have no special, rare, or unique characteristics identified in an adopted management plan. In total, the direct and indirect impacts of Alternative 4 on land and water management would be moderate because they would be low intensity, long term in nature, local, and common.

4.8.3.6 Transportation

4.8.3.6.1 Direct and Indirect Effects

The effects to transportation in Alternative 5 would be similar to those described under Alternative 2 (Section 4.5.3.6) though of elevated intensity and over a wider range of the spatial and temporal orientations given the potential simultaneous occurrence of activities that could occur under Alternative 5 versus Alternative 2. Increased traffic outside of the time/area closures could be the result.

Under Alternative 5, the required time/area closures associated with Kaktovik and Cross Island, Barrow Canyon and the Western Beaufort Sea, the Beaufort Sea shelf break, Hanna Shoal, Kasegaluk Lagoon, and Ledyard Bay would prevent activities from occurring in these areas and would therefore limit the amount of aircraft overflights in these areas associated with seismic survey and exploratory drilling programs. Because of the additional requirements associated with Alternative 5, aircraft could be prevented from overflying and/or operating in these areas, and there would therefore be no direct or indirect impact from transportation in these areas. In the event that inclement weather necessitated emergency flights through these special use areas, the intensity of the action would be low and temporary in duration. Any direct impact would be limited in geography to a local area and common in context. The probability of occurrence would be low, and any direct impact that did occur would be considered negligible to minor.

The direct impact in an increase in the amount of oil and gas exploration activities would be an increase in levels of air traffic and vessels present in these areas associated with seismic survey and exploratory drilling activities in comparison to levels projected under Alternative 2. The intensity of the impact would be considered low and short term in duration (length of survey or exploratory drilling activities each year). The extent of increased aircraft presence may be on a local and regional scale given the increased number of seismic survey and exploratory drilling programs that could occur. Impacts from the increased levels of air traffic would be to a common to potentially unique context (in respect to protected marine mammal resources), and, as a result, the impact level could be considered minor.

4.8.3.6.2 Conclusion

It is assumed that vessel traffic associated with the seismic survey and exploratory drilling programs would be prevented from transiting or operating in these closed areas under Alternative 5. Any direct impact to regional marine transportation would be low in intensity, temporary in duration, and limited in geographic extent to a local area and common in context. The probability of occurrence would be low, and any summary impact that did occur would be considered minor.

4.8.3.7 Recreation and Tourism

4.8.3.7.1 Direct and Indirect Effects

To the extent that the required time/area closures contemplated in Alternative 5 provide benefit to marine mammals, they would be beneficial to tourism based on wildlife viewing, and similar to the benefits of other standard and additional mitigation measures. The potential impacts discussed in Sections 4.5.3.7 and 4.6.3.7 for Alternatives 2 and 3 are the same for Alternative 5; the overall impact to recreation and tourism would be minor.

4.8.3.7.2 Conclusion

The direct impacts would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 4 on recreation and tourism would be minor.

4.8.3.8 Visual Resources

This section discusses potential impacts on visual resources that could result from implementing Alternative 5 of the proposed project.

4.8.3.8.1 Direct and Indirect Effects

Implementation of Alternative 5 is expected to result in short-term moderate effects to scenic quality and visual resources identical to those described in Alternative 4. Potential impacts could be of low to medium intensity, depending on the geographic separation of programs. In either case, actions would be temporary, localized and occur in an important context.

4.8.3.8.2 Conclusion

Implementation of Alternative 5 is expected to result in *short-term moderate effects* to scenic quality and visual resources. Potential impacts could be of low to medium intensity depending on specific location of drill sites. The geographic extent of potential impacts would be localized; however they would occur in an important ecosystem.

4.8.3.9 Environmental Justice

4.8.3.9.1 Direct and Indirect Effects

With the incorporation of time/area closures, the impacts to subsistence activities could be further minimized but would remain as minor impacts to subsistence foods and human health (see Subsistence Section 4.7.3.2). Contamination of subsistence foods would be the same as discussed under Alternative 4.

4.8.3.9.2 Conclusion

Activities related to implementation of Alternative 5 would have a low intensity impact on subsistence resources and human health, a temporary duration, and a regional extent. Subsistence foods and human health are unique resources, and they are protected under the MMPA and EO 12898. Thus, Alternative 5 is expected to have a minor impact to subsistence resources and minor disproportionate impacts to Alaska Native communities.

4.8.3.10 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the social environment, other than subsistence, are discussed under Alternative 2 (Section 4.5.3.10).

4.9 Direct and Indirect Effects for Alternative 6 – Authorization for Level 3 Exploration Activity with Use of Alternative Technologies

This section analyzes how the alternative technologies described in Section 2.3.5 of this EIS could potentially reduce impacts to the physical, biological, and social environments, especially for marine mammals and subsistence uses of marine mammals. Under Alternative 6, the number of exploration programs envisioned is identical to Alternatives 4 and 5 (see Sections 4.7.1.4 and 4.8.1.4), but allows for the use of alternative technologies to replace or augment traditional airgun-based seismic exploration techniques used for some of these surveys. Alternative 6 contemplates Level 3 activities with the number of activity types to be considered for analysis purposes defined in Table 4.2-2.

The level of reduction in impacts is dependent upon how many traditional seismic surveys (i.e. use of airgun arrays) can be replaced or augmented by these alternative technologies. Because the majority of these technologies have not yet been built and/or tested, it is difficult to fully analyze the level of impacts from these devices. Therefore, additional NEPA analyses (i.e. tiering) will likely be required if applications are received requesting to use these technologies during seismic surveys. Additional detail on the implementation of this EIS is discussed in Chapter 5.

4.9.1 Physical Environment

4.9.1.1 Physical Oceanography

4.9.1.1.1 Direct and Indirect Effects

Water Depth and General Circulation

The effects of Alternative 6 on water depth and general circulation would be the same as those described for Alternative 4 and remain minor.

Currents, Upwellings, and Eddies

The effects of Alternative 6 on currents, upwellings, and eddies would be the same as those described for Alternative 4.

Tides and Water Levels

The activities described under Alternative 6 would not affect tides or water levels within the EIS project area.

Stream and River Discharge

The activities described under Alternative 6 would not affect stream and river discharge within the EIS project area.

Sea Ice

The effects of Alternative 6 on sea ice would be the same as those described for Alternative 4. The additional mitigation measures included in Alternative 6 would not substantially change the effects of the alternative on sea ice resources in the proposed action area.

4.9.1.1.2 Conclusion

The effects of the proposed actions on physical ocean resources would be medium-intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. The overall effects of the proposed activity described in Alternative 6 on physical ocean resources in the proposed action area would be minor.

4.9.1.2 Climate

Under this alternative, emissions would be the same as for Alternative 4 and Alternative 5 because the alternative proposes exploration plans described as Level 3 Exploration Activity on the Arctic OCS. The specific description and number of each of these programs and activities proposed for the Arctic OCS, on an annual basis, were summarized earlier in Table 2.4 (*Activity Definitions*) and Section 2.4.5 (*Alternative 2 – Authorization for Level 1 Exploration Activity*).

Refer to Section 3.1.4.4 Climate Change in the Arctic for a thorough discussion of climate systems and the effects of GHG emissions.

4.9.1.2.1 Direct and Indirect Effects

Direct Effects

Direct effects under this alternative are the same as those described under Alternative 2.

Indirect Effects

Indirect effects under this alternative are the same as those described under Alternative 2.

Regulatory Reporting and Permitting

Regulatory reporting and permitting under this alternative would be the same as those described under Alternative 2.

CO_2e Emissions Inventory

The CO_2e emissions inventory is the same for this alternative as given for Alternative 4.

Effects of this Alternative on Climate Change

The effects of this alternative are the same as those described for Alternative 4.

Effects of Climate Change on Resources under this Alternative

Effects of climate change on resources under this alternative would be the same as described under Alternative 2.

4.9.1.2.2 Conclusion

The conclusion of the assessment under this alternative is the same as for Alternative 4.

4.9.1.3 Air Quality

Under this alternative, emissions would be the same as described for Alternative 4 and Alternative 5 and proposes any level of EPs up to the maximum which is four EPs for each planning area. The majority of additional emissions are from the EPs proposed for Level 3 Exploration Activity.

4.9.1.3.1 Direct and Indirect Effects

Direct and indirect effects under this alternative would be from the same sources of emissions as described under Alternative 2 in Section 4.5.1.3.

Exploration Plan Emission Inventory

The emission rates likely to reflect Level 3 Exploration Activity in each planning area are the same as those presented for Alternative 4 in Table 4.7-2.

The inventory assumes no application of BACT or the use of ULSD fuel. The emission inventory assumes the same method of calculation and EP operational characteristics as described for Alternative 2.

Survey Emission Inventory

The number and type of seismic and other surveys would be the same as described for Alternative 4 and Alternative 5. The emission rates likely to reflect the increased level of seismic and other surveys under this alternative are the same as those presented for Alternative 4 in Tables 4.7-3 and 4.7-4.The survey inventories assume no application of BACT or the use of ULSD fuel. The emission inventory assumes the same method of calculation and survey vessel operational characteristics as described for the previous alternatives.

4.9.1.3.2 Air Quality Impact Analysis

The air quality impact analysis would be conducted as described under Alternative 2.

4.9.1.3.3 Level of Effect

The annual rate of air emissions and onshore pollutant concentrations are the two basic measurements for assessing a proposal's level of effect on air quality. The emission inventory provided in this section discloses the rate of emissions likely to reflect a proposal under this alternative, expressed in short tpy. When necessary, an emission inventory is translated into pollutant concentrations expressed in micrograms per cubic meter ($\mu g/m^3$), a value that can be measured against the NAAQS allowing the level of effect to be categorized relative to the conditions summarized under Alternative 2 in Table 4.5-7 *Impact Levels for Effects on Air Quality*. Further information regarding level of effect under this alternative would be the same as discussed under Alternative 4.

4.9.1.3.3 Conclusion

Emissions from exploratory drilling activities proposed under this alternative would be higher than emissions estimated for Alternative 2. Without emission reduction controls on the drillship engines, there is a greater potential for one or more of the EPA SILs to be exceeded onshore. The Level 2 Exploration Activity would almost certainly require additional modeling to demonstrate the effect of pollutant concentrations on the nearest onshore area. A moderate level of effect on air quality is expected, which may be mitigated by emission control strategies to result in a minor level of effect. Cumulatively, the total estimated emissions for each Arctic OCS planning area, when considering all plans and activities described under this alternative, are the same as those summarized for Alternative 4 in Table 4.7-5.

Control of oil and gas emission sources on the OCS, and levels of effect, are considered on a project-by-project basis, as each individual operator would have the responsibility to engage any engine emission controls required by BOEM AOCSR. Emission reduction strategies have the potential to reduce at least some emissions of all pollutant types, including CO_2e. Therefore, the data provided in Table 4.7-5 would represent a worst-case scenario for each Arctic OCS planning area.

4.9.1.4 Acoustics

Under Alternative 6, the number of exploration programs envisioned is the same as for Alternatives 4 and 5 (see Sections 4.7.1.4 and 4.8.1.4), but this alternative considers the use of alternate technologies to replace airgun array systems used in these surveys.

Section 2.3.5 provides a discussion of possible alternate technologies that are in various stages of development. The benefits of using these sources would primarily be at reducing impulsive sound levels near seismic survey sources. Some of the alternate technologies use longer-duration signals at lower amplitude. Extended duration signals may be more audible to marine mammals than short duration impulsive signals having the same amplitude. Nevertheless, the possible reduction in ensonification zone radii corresponding to reductions in source signal amplitude only is considered for this alternative.

The source pressure level reductions that will be achieved using alternate sources are presently unknown, but might expect reductions by approximately 10 to 20 dB from current airgun array source levels. For this analysis it will be assumed that source pressure level can be reduced by up to 10 dB. The received SPL at distance from the source depends on sound transmission loss between the source and receiver. Transmission loss is frequency dependent and also influenced by source depth and source directivity. If the alternate source operates at a different depth than standard airguns or has different directivity or spectral density function (sound energy at different frequencies), then received SPL will be different than that of an airgun array with the same broadband source level. A further complicating factor is that the 90% rms SPL metric used for impulsive source pressure signals is dependent on the pulse duration. Three assumptions have to be made to estimate reductions in received SPL for alternate source types: (a) the alternate source operates at the same depth as the airgun array source, (b) the alternate source has the same spectral distribution and directivity as the airgun array source and (c) the pulse duration remains the same as that of the airgun array.

Under the above assumptions, the reduction in distances to sound level thresholds can be made based on the sound level versus distance functions that have been measured for all of the seismic survey programs listed in Table 4.5-9. As an example, the function for Statoil's 2010 3-D survey near their Amundsen prospect in the Chukchi Sea is defined by L_{P90}. = 235.1 – 17.5 Log(r) – 0.00051 r, where L_{P90} is the 90% rms received SPL and r is the distance from the source in meters (O'Neill et al., 2011). Using this formula, and a 10 dB source level reduction factor, the distance reductions to several acoustic thresholds is given in Table 4.9-1.

Table 4.9-1 Acoustic threshold radii reductions from use of an alternate source operating with source level 10 dB less than a 3000 in^3 airgun array (see text).

SPL Threshold 90% rms (dB re 1 µPa)	Original radius (m)	Reduced radius (m)
190	370	100
180	1290	370
160	10000	4000
120	61000	46000

It is helpful to consider the change in ensonified area arising from assumed reductions in sound for various source intensity reductions under different acoustic propagation conditions. Table 4.9-2 shows the total ensonified surface area (as a percentage of the full EIS project area) to threshold levels of 120 and 160 dB for the case of no reduction (Alternative 3; see Table 4.6-6) and reductions of 3, 5 and 10 dB. The influence of the sound reduction on the area depends on the acoustic propagation regime; transmission loss rates (drop in dB level with distance from the source) of 25, 20 and 15 log (range) are shown in the table, encompassing conditions potentially encountered in the EIS project area. When considering the notional results shown in this table it should be noted that sound propagation at long ranges is subject to losses that may exceed the predictions of a geometric spreading law k log(r) applicable at shorter ranges. Because of this, the reduction in ensonified area size associated with a given decrease in source level may be not as pronounced as shown in the table.

Table 4.9-2 Ensonified area (as % of EIS project area) for assumed reductions in source level using alternative technologies. Estimates are shown for three propagation loss rates.

	Percent Surface Area Ensonified to 120 dB re 1 μPa (90% rms SPL)				Percent Surface Area Ensonified to 160 dB re 1 μPa (90% rms SPL)		
Reduction in source intensity	25 log R	20 log R	15 log R		25 log R	20 log R	15 log R
0 dB (none)	40%	40%	40%		0.67%	0.67%	0.67%
3 dB	22%	20%	15%		0.39%	0.34%	0.27%
5 dB	15%	12%	8%		0.27%	0.21%	0.15%
10 dB	6%	4%	2%		0.11%	0.07%	0.03%

<u>4.9.1.4.1 Direct and Indirect Effects</u>

Table 4.9-1 provides examples of sound level threshold distance reductions that would result from an alternate source type capable of lowering the source levels of a standard 3000 in^3 airgun array by 10 dB. The 190 dB re 1 µPa radius is reduced by 73 percent, while the 120 dB re 1 µPa radius is reduced by 24 percent. The reduction of surface area ensonified to 120 dB re 1 µPa assuming a 10 dB in source level varies from an 85 percent reduction assuming 25logR geometric spreading loss to a 95 percent reduction for a spreading loss of 15logR.

<u>4.9.1.4.2 Conclusion</u>

Alternative 6 proposes the same level of exploration activities as Alternative 4 but suggests the implementation of alternative technologies that reduce sound emission levels from seismic survey sources. The intensity rating of this alternative is maintained at high because it is unlikely the technologies will entirely preclude the generation of source sound levels exceeding 200 dB re 1 μPa. Likewise the duration is unchanged from the other alternatives and remains long term, as no change in activity duration is anticipated. The extent for this alternative is still considered to be regional if the alternate source has a source sound level that is lower than that for a 3,000 in^3 airgun array by less than 10dB. However, the estimates in Table 4.9-2 indicate that a 10dB reduction in source intensity would change the extent for this alternative to local since less than 10 percent of the EIS project area would be exposed to sound levels in excess of 120 dB re 1 μPa in this case. Because implementation of these technologies is not certain within the timeframe for this EIS, the overall impact rating for direct and indirect effects to the acoustic environment would be moderate.

4.9.1.5 Water Quality

Impacts to water quality resulting from the activities proposed under Alternative 6 are expected to be very similar to those described above for Alternatives 4 and 5. Alternative 6 includes mitigation measures that focus on the use of alternative technologies to replace or augment traditional airgun-based seismic exploration techniques. However, these mitigation measures are not expected to affect the level of water quality impacts. Any differences in impacts between Alternative 5 and the previous alternatives are noted below. See Chapter 2 for descriptions of the mitigation measures included under Alternative 6.

4.9.1.5.1 Direct and Indirect Effects

Temperature and Salinity

Seismic Surveys

Similar to impacts for Alternatives 2, 3, 4, and 5, seismic surveys would not be expected to have any measureable impact on temperature or salinity in the proposed action area.

Turbidity and Total Suspended Solids

Seismic Surveys

Similar to impacts for Alternatives 2, 3, 4, and 5, effects on water quality resulting from increases in turbidity and total suspended solids from seismic surveys under Alternative 6, if any, are expected to be low-intensity, temporary, local, and would affect a common resource.

Proposed mitigation measures intended to reduce/lessen non-acoustic impacts on marine mammals have the potential to further reduce adverse impacts to water quality.

Metals

Seismic Surveys

Similar to impacts for Alternatives 2, 3, 4, and 5, seismic surveys are not be expected to have any measureable impact on dissolved metal concentrations in the proposed action area.

Hydrocarbons and Organic Contaminants

Seismic Surveys

Similar to impacts for Alternatives 2, 3, 4, and 5, seismic surveys are expected to have negligible impacts on concentrations of hydrocarbons and organic contaminants in the waters of the proposed action area.

4.9.1.5.2 Conclusion

Alternative 6 could potentially require the use of alternative technologies that may replace or augment traditional airgun-based seismic exploration techniques. Such alternative technologies are not expected to affect impacts to water quality. After mitigation, the effects of the proposed actions on water quality are expected to be low-intensity, temporary, local, and would affect a common resource. The overall effect of the proposed activity described in Alternative 5 on water quality in the proposed action area would be minor.

4.9.1.6 Environmental Contaminants and Ecosystem Functions

4.9.1.6.1 Direct and Indirect Effects

Contaminants of Concern

Contaminants of concern introduced to the EIS project area as a result of the activities proposed in Alternative 6 would be the same as those described for Alternative 2.

Proposed mitigation measures intended to reduce/ lessen non-acoustic impacts on marine mammals have the potential to reduce adverse impacts resulting from contaminants of concern.

Exposure of Habitat and Biological Resources

Pathways for exposure of habitat and biological resources to contaminants of concern as a result of the activities proposed in Alternative 6 would be the same as those described for Alternative 2.

Potential Effects on Ecosystem Functions

In response to comments and suggestions received as part of the scoping process for this EIS, effects of (contaminants of concern from) the proposed activities on ecosystem functions are assessed in the following section. Effects of the activities proposed under Alternative 6 on the four categories of ecosystem functions (defined in Section 4.4.1.6) are assessed below.

Regulation Functions

The effects of the activities proposed under Alternative 6 on regulation functions would be the same as those described under Alternative 4.

Habitat Functions

Alternative technologies associated with Alternative 6 have the potential to decrease adverse impacts to habitat functions that could result from traditional airgun-based exploration techniques. The extent and nature of the reduction to adverse impacts to habitat functions are described in detail in the sections of this EIS related to acoustics and marine mammals.

Production Functions

The effects of the activities proposed under Alternative 6 on production functions would be the same as those described under Alternative 4.

Information Functions

The effects of the activities proposed under Alternative 6 on information functions would be the same as those described under Alternative 4.

4.9.1.6.2 Conclusion

Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 6 would be medium-intensity, temporary, and local. The functional properties of ecosystems described in this section, such as nutrient cycling and habitat functions, are more robust (i.e. resistant to stressors) than are species composition and other structural properties. Overall effects of Alternative 6 on ecosystem functions would be minor.

4.9.1.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the physical environment are discussed under Alternative 2 (Section 4.5.1.7).

4.9.2 Biological Environment

4.9.2.1 Lower Trophic Levels

4.9.2.1.1 Direct and Indirect Effects

Activity levels in Alternative 6 are the same as in Alternative 4, but this alternative includes the option of using alternative technologies for seismic exploration. This requirement does not affect lower trophic levels in the EIS project area, so the impacts discussed previously for Alternatives 2, 3, 4, and 5 are the same for Alternative 6; the overall impact to lower trophic levels would be minor.

4.9.2.1.2 Conclusion

The direct and indirect effects associated with Alternative 6 would likely be low in intensity, temporary to long-term in duration, of local extent and would affect common resources; resulting in a summary impact level of negligible. The only exception to these levels of impacts would be the introduction of an invasive species due to increased vessel traffic, which could be of medium intensity, long-term or permanent duration, of regional geographic extent, and affect common or important resources, which could cause a summary impact of moderate.

4.9.2.2 Fish and Essential Fish Habitat

4.9.2.2.1 Direct and Indirect Effects

Alternative 6 applies the same levels of activity as Alternative 4, described as Level 3. The activities are divided identically among the different activity categories in both alternatives, and the number and types of surveys, exploration, and drilling are all assumed to be the same. Likewise, the Standard and Additional Mitigation Measures are also identical. Alternative 6 differs from Alternative 4 in the application of alternative technologies.

Five different technologies are currently being developed, and all are at different stages in the testing process, although none of the systems with the potential to augment or replace airguns as a seismic source are currently commercially available. For the purposes of this EIS, it is assumed that they will be implemented over time as further testing and refinement makes them available for general application.

The analysis for this alternative focuses on the mitigating effects of each of the individual alternative technologies and how they would reduce impacts from the levels described in Alternative 4. Many of these technologies are in the early stages of development or have not yet been developed, and it is therefore difficult to offer a thorough analysis. Instead, general impacts based on limited information have been provided.

For a complete analysis of the effects on fish and fish resources from Alternative 2, see Section 4.5.2.2.

4.9.2.2.2 Alternative Technologies

Hydraulic Marine Vibrators

The replacement of each airgun with a hydraulic marine vibrator would likely reduce adverse impacts through the manner in which sound is emitted into the marine environment. Marine vibrators emit sounds at lower pressure levels than airguns and over a narrower range of frequencies than do airguns, thereby potentially reducing the amount of damage caused to any fish in the immediate vicinity of the source, and reducing the number of fish able to hear the sound.

Electric Marine Vibrators

The replacement of each airgun with an electric marine vibrator would likely reduce adverse impacts through the manner in which sound is emitted into the marine environment. Marine vibrators emit sounds at lower pressure levels than airguns and over a narrower range of frequencies than do airguns, thereby potentially reducing the amount of damage caused to any fish in the immediate vicinity of the source, and reducing the number of fish able to hear the sound.

Low Frequency Acoustic Source (LACS)

This technology is still in the early phases of development and therefore difficult to analyze. However, in theory, the LACS uses a sound generating method that results in lowered amounts of energy put into the water compared to a traditional airgun array. This would reduce potentially adverse impacts to fish by decreasing the number of fish exposed to high sound levels and potentially reduce the impacts from high sound levels as the maximum levels would be lower.

Deep-Towed Acoustics/Geophysics System (DTAGS)

For the purposes of analysis under this alternative, it is assumed that a DTAGS system could someday replace a single airgun array. Based on an analysis of its operations, it is possible that it could increase adverse impacts by increasing the total amount of exposure by fish resources to sound energy. By offsetting the location of the sound source from the near surface to the vicinity of the seafloor, the number of fish exposed to high sound levels would increase, provided the sound levels emitted were similar to airguns. Demersal habitats are typically more productive than pelagic ones, with higher fish densities and more feeding and spawning regions susceptible to sonic damage.

Low Frequency Passive Seismic Methods for Exploration

Low Frequency Passive Seismic Methods for Exploration are already in use but not yet proven in all environments. Of all the technologies, this one shows the most promise for mitigating adverse effects on fish, due to its passive acoustic nature. No sound would be emitted into the marine environment, resulting in the elimination of all seismic noise impacts.

4.9.2.2.3 Conclusion

The effect of the alternative technologies outlined in Alternative 6 on fish resources and EFH are difficult to determine with any certainty but are anticipated to result in a reduction in the overall impact. Although the overall impact is considered to be negligible based on Alternative 4 alone, any replacement of airgun arrays with alternative technologies would be reduce potentially adverse effects on fish. However, the limited number of airgun arrays that could be replaced by any of these technologies is fairly limited, thereby resulting in minimal reductions of overall impact levels. Therefore, there would be no measurable effect on the resource, and overall impact is considered to be negligible.

4.9.2.3 Marine and Coastal Birds

4.9.2.3.1 Direct and Indirect Effects

Alternative 6 includes all of the same type of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on marine and coastal birds under Alternative 6 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.3. This EIS includes a number of standard and additional mitigation measures as part of each alternative that are intended to reduce adverse effects on marine mammals but may also reduce adverse effects on birds. In addition to the mitigation measures imposed by NMFS, the USFWS requires certain mitigation measures specific to ESA-listed species under its jurisdiction, including spectacled and Steller’s eiders (USFWS 2009c). Section 4.5.2.3 summarizes the mitigation measures typically required by the USFWS and other agencies for oil and gas exploration activities in the Beaufort and Chukchi seas to minimize impacts on birds and these measures are incorporated into the analysis of potential effects under Alternative 6.

The number of different exploration activities authorized under Alternative 6 would be the same as under Alternatives 4 and 5. However, implementation of Alternative 6 could potentially encourage industry to gradually replace current seismic airgun technology with alternative methodologies intended to reduce the amount of loud seismic sounds introduced into the marine environment that could have adverse effects on marine mammals. Because birds are able to fly away from approaching seismic source vessels as they approach and thus effectively avoid potentially adverse effects from the seismic arrays, changes in technology to reduce seismic sound levels would not change the effects of seismic surveys on birds. The direct and indirect effects of oil and gas exploration activities on marine and coastal birds would therefore be the same under Alternative 6 as those described under Alternatives 4 and 5. Marine birds would be subject to disturbance from vessels and seismic sources but these effects would be temporary. With more exploration activities authorized under Alternative 6, the potential for adjacent activities to magnify effects on birds could be increased. However, the requirement to maintain a minimum distance of 24 km (15 mi) between two seismic surveys conducted concurrently would effectively limit the intensity of seismic survey effects on birds no matter where the activities take place during the open water season. The Ledyard Bay closure period would be the same under Alternative 6 as under Alternative 2 so this area would be unaffected by increases in exploration elsewhere.

The risk of birds colliding with vessels would be mitigated and fatal collisions are expected to be rare and not likely to affect the population of any species. The risk of small oil spills would also be mitigated and considered to present very small risks to birds unless the spill occurred in or persisted in a lead or polynya system. A very large oil spill could have much more serious effects on birds and is discussed in Section 4.10.

4.9.2.3.2 Conclusion

Most marine and coastal birds are legally protected under the Migratory Bird Treaty Act and several are protected under the ESA. Birds fulfill important ecological roles and many are important subsistence resources. Depending on the species, they are considered to be important or unique resources from a NEPA perspective. The effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. The overall effects of oil and gas exploration activities authorized under Alternative 6 on marine and coastal birds would therefore be considered negligible to minor according to the impact criteria in Table 4.5-17

4.9.2.4 Marine Mammals

4.9.2.4.1 Bowhead Whales

4.9.2.4.1.1 Direct and Indirect Effects

Alternative 6 includes the same level of oil and gas exploration activity as Alternative 4. The number and types of surveys, exploration, and drilling are all assumed to be the same. Standard and Additional Mitigation Measures for Alternative 6 are also identical to those considered for Alternative 4. The analyses for Direct and Indirect Effects, Standard Mitigation Measures, and Additional Mitigation Measures are the same for Alternative 6 as for Alternative 4. These are briefly summarized below.

Alternative 6 differs from Alternative 4 in the application of alternative technologies. Alternative 6 considers the gradual augmentation or replacement of current seismic airgun technology with alternative methodologies intended to reduce the amount of loud seismic sounds introduced into the marine environment. Five technologies are considered in this EIS (Table 2.3). All are in different stages of research or testing and development, and could be implemented over time if they become available for general application. Commercial availability at some point in the future is assumed for the purposes of this EIS. This, however, depends on research, development, and commercial implementation schedules.

The analysis for this alternative focuses on the potential mitigating effects of each of the individual alternative technologies and how they could reduce adverse impacts from levels described in Alternative 4. Many of these technologies are in the early stages of development and are difficult to assess. For example, Table 4.9-2 illustrates the estimated change in *near-field* ensonified area above different thresholds if certain incremental source level reductions are considered likely, from which we could infer some quantitative reduction of impacts. However, because of the early stages of development that many of these technologies are in, it is not always possible to know exactly what the operational trade-off of using the alternative technology might be (for example, is it 10 dB quieter, but needs to survey an area with twice the density of survey lines). Of potentially more important note, though, is the potential significant reduction in far-field effects on acoustic habitat and how that reduction could reduce chronic noise impacts to marine mammals. An analysis of each alternative technology follows the summary information on direct and indirect effects and standard mitigation measures.

Behavioral Disturbance

Since the exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4, the types and mechanisms for disturbance to bowhead whales would be the same. However, if several seismic surveys utilizing airguns are eventually able to be replaced by alternative technologies, some of which have much lower source levels than traditional airguns, behavioral disturbance to bowhead whales could also be reduced as the areas ensonified above behavioral disturbance thresholds could be reduced by anywhere from half to 50 times (i.e., only 2% the former area). Although the behavioral disturbance of marine mammals is quantitatively evaluated based on the number of animals likely to be exposed above a certain received level, which means that anticipated impacts from any given activity could majorly decrease (i.e., by an order of magnitude or more) if the technology were replaced, because of the current state of the technology , it is unlikely that enough activites would change technologies within the life of this EIS, to make a difference in our overall assessment of effects.

The level of disturbance and potential direct and indirect effects on bowhead whales would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4, the components of which were considered to be of medium intensity, interim duration, local to regional extent, and unique context.

Please refer to Section 4.5.2.4 for a complete discussion of disturbance effects, by activity type, on bowhead whales.

Hearing Impairment, Injury, and Mortality

The exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4; therefore, the mechanisms for hearing impairment, injury, and mortality to bowhead whales would be the same. Because of the low likelihood of injury from Alternative 4 activities, combined with the fact that the use of alternative technologies would only slightly lower injury risk of an acoustic nature, and would not lower the likelyhood of ship-strike or other injury, and the fact that only a small amount of alternate technology use would be anticipated pursuant to this alternative, the level of hearing impairment, injury, and mortality effects on bowhead whales would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4, the components of which were primarily considered to be of medium intensity, interim in duration (except in instances of mortality or serious injury), local in extent and of unique context.

Please refer to Section 4.5.2.4 for a complete discussion of potential injury or mortality effects on bowhead whales.

Habitat Alterations

The exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4; therefore, the mechanisms for habitat alteration would be the same. The effects of alternative technology on acoustic habitat and chronic effects on marine mammals (especially mysticetes) could be more significant than the more immediately quantifiable and near-field reduction in behavioral disturbance. High level, low frequency sounds (like those produced by airguns) contribute to growing ambient noise levels at great distances from the source (hundreds of miles). This increased noise can contribute to chronic, long-term effects on the ability of animals to effectively interact with their environment and conspecifics. Even small reductions in source levels can make big differences in the far-field reductions at lower levels and over very large areas. The level of potential direct and indirect effects on bowhead whale habitat would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.

Please refer to Section 4.5.2.4 for a complete discussion of the potential effects on bowhead whale habitat.

4.9.2.4.1.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.9.2.4.1.3 Alternative Technologies to Augment and/or Replace Traditional Airgun-Based Seismic Surveys

The intent of implementing alternative technologies is to reduce impulsive sound levels generated during seismic exploration. As discussed in Section 4.9.1.4, Acoustics, sound pressure level reductions resulting from using these proposed technologies are not currently known, although reductions of 10 to 20 dB might be expected. Alternate sound sources with source levels 10 dB lower than standard 3,000 in^3 airgun arrays, could, theoretically, substantially reduce acoustic threshold radii and areas of ensonification (Tables 4.9-1 and 4.9-2).

Hydraulic Marine Vibrators

Replacing an airgun with a hydraulic marine vibrator could reduce adverse impacts by the manner and level in which sound is emitted into the marine environment. Marine vibrators emit sounds at lower pressure levels and over a narrower range of frequencies than do airguns. The low frequency (10 to 250 Hz) produced is within the hearing range of bowhead whales (7 Hz to 22 kHz [Southall et al. 2007]), so it could therefore still be in the range of detectability by this species. Potential auditory impacts to bowhead whales, as well as behavioral disturbance and displacement due to noise exposure, may, however, be reduced through reduced noise output. Any reduction in adverse impacts would be on a limited and localized scale with the current schedule of implementation. The use of this system by industry is currently uncertain as previous use did not result in increased data quality, reduced operation costs, or penetrate as deeply as some companies require.

Electric Marine Vibrators

The replacement of each airgun with an electric marine vibrator could reduce adverse impacts by the manner in which sound is emitted into the marine environment. Marine vibrators emit sounds at lower pressure levels and over a narrower frequency range than do airguns (6 to 100 Hz). This is within the hearing range of bowhead whales (7 Hz to 22 kHz [Southall et al. 2007]), so it could therefore still be in the range of detectability by this species. Potential auditory impacts to bowhead whales, as well as behavioral disturbance and displacement due to noise exposure, may, however, be reduced. Any reduction in adverse impacts would be on a limited and localized scale with the currently uncertain schedule of implementation. In addition, industry interest in this system may be limited by its inability to penetrate as deeply as some companies require for exploration.

Low Frequency Acoustic Source (LACS)

This technology is still in the early phases of development and currently impossible to analyze and compare with airgun arrays for effectiveness and noise generation. The shallow water system has been tested a few times, with only fair data quality. The larger system that could produce frequencies low enough to penetrate to exploration depths has not yet been developed. The LACS, theoretically, uses a sound generating method that results in lowered amounts of energy put into the water compared to a traditional airgun array. This could potentially reduce adverse acoustic impacts to bowhead whales, but the level of reduced impacts and efficacy for mitigating impacts cannot presently be determined.

Deep-Towed Acoustics/Geophysics System (DTAGS)

This system was developed by the Navy and is not currently available for commercial use. It has been used extensively to map out deep-water gas hydrate systems. The DTAGS system generates very high frequencies, so it cannot be used as a source for exploration seismic data collection. It is theoretically possible to create a DTAGS system that could penetrate to exploration depths below the seafloor, but the deep-tow configuration of the source would make it logistically difficult to use with a streamer array. This would need to be adjusted for the much shallower depths of the Beaufort and Chukchi seas where it could possibly augment shallow hazards data collection. The potential acoustic impacts or possible mitigation of auditory impairment or disturbance of bowhead whales through the use of DTAGS is impossible to assess without further information regarding sound level output and transmission in the EIS project area or in a comparable environment.

Low Frequency Passive Seismic Methods for Exploration

Low frequency passive seismic methods for exploration are already in use but not yet proven in all environments, nor have they been tested in the Arctic. Since low frequency passive seismic methods do not emit sound into the marine environment, this technology could mitigate adverse effects of noise on bowhead whales in the areas in which it is employed. Passive seismic surveys cannot, however, replace active seismic acquisition, so broad scale replacement of airguns is impossible in the future.

4.9.2.4.1.4 Conclusion

Mitigating capabilities and effects of alternative technologies introduced under Alternative 6 on bowhead whales are difficult to determine but could reduce adverse impacts (both behavioral impacts and acoustic habitat impacts, as described in the sections above) associated with the use of airgun arrays (see Section 4.5.2.4 for details on effects of airgun noise on bowhead whales). Because of the current state of the technology, however, the overall reduction during the life of this EIS would likely be minimal. The gradual introduction of these alternative technologies could, ultimately, reduce the amount of seismic noise introduced into the marine environment and the impacts on marine mammals. Airgun noise would not be eliminated, however, since these alternative technologies would not completely replace the existing technology, and what may be replaced is limited. In addition, surveys conducted with alternative technologies would still use marine vessels to tow or deploy equipment which could disturb bowhead whales as described in Section 4.5.2.4. A sizable ramp-up in the development and implementation of alternative technologies could potentially reduce behavioral and acoustic habitat impacts to the degree that the rating in the impact criteria might change. However, based on our understanding of the degree to which these technologies are expected to come into use in the next five to ten years, we expect that the impact categorization would not change. Effects of existing technology on bowhead whales, as described in Alternative 4, would be mostly of high intensity, interim duration, be of regional extent, and important to unique in context. Alternative technologies could reduce the extent to localized areas on a small scale; it is not currently possible to assess potential behavioral reactions and determine if intensity level would change, as a result. Despite possible localized mitigating capabilities of using alternative technologies in lieu of limited numbers of airgun arrays, the overall impact of Alternative 6 on bowhead whales is considered to be moderate to major.

4.9.2.4.1.5 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to bowhead whales are discussed under Alternative 2 (Section 4.5.2.4.16).

4.9.2.4.2 Beluga Whales

Alternative 6 includes the same types of exploration activities described in Alternative 2, and the same number of exploration activities as Alternative 4. Alternative 6 differs, however, from Alternatives 2, 3, and 4 as it considers the gradual augmentation or replacement of current seismic airgun technology with alternative methodologies intended to reduce the amount of loud seismic sounds introduced into the marine environment. Five technologies are considered (Table 2.3). All are in different stages of research, testing and development and could be implemented over time if they become available for general application. Commercial availability at some point in the future is assumed for the purposes of this EIS.

The analysis for this alternative focuses on the potential mitigating effects of each of the individual alternative technologies and how they could reduce adverse impacts from levels described in previous alternatives. Many of these technologies are in the early stages of development and are difficult to assess. For example, Table 4.9-2 illustrates the estimated change in *near-field* ensonified area above different thresholds if certain incremental source level reductions are considered likely, from which we could infer some quantitative reduction of impacts. However, because of the early stages of development that many of these technologies are in, it is not always possible to know exactly what the operational trade-off of using the alternative technology might be (for example, is it 10 dB quieter, but needs to survey an area with twice the density of survey lines). Of potentially more important note, though, is the potential significant reduction in far-field effects on acoustic habitat and how that reduction could reduce chronic noise impacts to marine mammals. An analysis of each alternative technology follows the summary information on direct and indirect effects and standard mitigation measures.

Behavioral Disturbance

The exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4. Therefore, the types and mechanisms for disturbance to beluga whales would be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.2, as would the resulting level of disturbance and potential direct and indirect effects on beluga whales. Potential effects were considered to be of medium intensity, interim duration, regional in extent, and of important context. Refer to Sections 4.5.2.4.10 and 4.6.2.4.2 for complete discussions of disturbance effects, by activity type, on beluga whales.

Hearing Impairment, Injury, and Mortality

The level of exploration that would be authorized under Alternative 6 is identical to Alternative 4. Because of the low likelihood of injury from Alternative 4 activities, combined with the fact that the use of alternative technologies would only slightly lower injury risk of an acoustic nature, and would not lower the likelihood of ship-strike or other injury, and the fact that only a small amount of alternate technology use would be anticipated pursuant to this alternativeso the primary mechanisms of hearing impairment, injury, or mortality due to oil and gas exploration activities are anticipated to be the same. The potential direct and indirect physical effects on beluga whales would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.

Habitat Loss/Alteration

The exploration activities that would be authorized under Alternative 6 are the same as under Alternative 4. The effects of alternative technology on acoustic habitat and chronic effects on marine mammals could be more significant than the more immediately quantifiable and near-field reduction in behavioral disturbance. High level, low frequency sounds (like those produced by airguns) contribute to growing ambient noise levels at great distances from the source (hundreds of miles). This increased noise can contribute to chronic, long-term effects on the ability of animals to effectively interact with their environment and conspecifics. Even small reductions in source levels can make big differences in the far-field reductions at lower levels and over very large areas. The potential direct and indirect effects on beluga whale habitat would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.

4.9.2.4.2.1 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.15).

4.9.2.4.2.2 Alternative Technologies to Augment and/or Replace Traditional Airgun-Based Seismic Surveys

See Bowhead Whales (Section 4.9.2.4.1) above for an analysis of the efficacy and practicability of using the proposed alternative technologies to reduce effects of noise from seismic exploration on marine mammals. Only technologies for which there is information specific to beluga whales (e.g. hydraulic and electric marine vibrators) are included below. Refer to the above bowhead whales section for information on LACS, DTAGS, and Low Frequency Passive Seismic Methods for Exploration.

Hydraulic Marine Vibrators

The low frequency (10 to 250 Hz) sounds produced by hydraulic marine vibrators are at the lower end of the estimated auditory bandwidth of belugas whales (150 Hz to 160 kHz [Southall et al. 2007]), so they could still be in the range of detectability by this species. Potential auditory impacts to beluga whales, as well as behavioral disturbance and displacement due to noise exposure, could be reduced through reduced noise output. Any reduction in adverse impacts would likely be on a limited and localized scale with the current schedule of implementation. The use of this system by industry is currently uncertain as previous use did not result in increased data quality, reduced operation costs, or penetrate as deeply as some companies require.

Electric Marine Vibrators

Marine vibrators emit sounds at lower pressure levels and over a narrower frequency range than do airguns (6 to 100 Hz). This is below the estimated auditory bandwidth of belugas whales (150 Hz to 160 kHz [Southall et al. 2007]), so it might not be detectable by this species. Potential auditory impacts to beluga whales, as well as behavioral disturbance and displacement due to noise exposure, could, therefore, be reduced. Any reduction in adverse impacts would likely be on a limited and localized scale with the current schedule of implementation. In addition, industry interest in this system may be limited by its inability to penetrate as deep as some companies require for exploration.

4.9.2.4.2.3 Conclusion

The use of alternative technologies would reduce noise impacts to beluga whales (both behavioral impacts and acoustic habitat impacts, as described in the sections above) as many of them produce sound outside the frequency range audible by belugas. The gradual introduction of these alternative technologies could eventually reduce the amount of seismic noise introduced into the marine environment and impacts to marine mammals. Airgun noise would not be completely eliminated, however, since these alternative technologies would not completely replace the existing technology, and what may be replaced is limited. In addition, surveys conducted with alternative technologies would still use marine vessels to tow or deploy equipment which could disturb beluga whales as described in Section 4.5.2.4.10. A sizable ramp-up in the development and implementation of alternative technologies could potentially reduce behavioral and acoustic habitat impacts to the degree that the rating in the impact criteria might change. However, based on our understanding of the degree to which these technologies are expected to come into use in the next five to ten years, we expect that the impact categorization would not change

The overall impact to beluga whales is likely to be moderate. Beluga whales in the Arctic are not listed under the ESA, but are found feeding in certain essential areas, which places them in the context of being an importantresource. The intensity and duration of the various effects and activities considered are mostly medium and interim. However, potential long-term effects from repeated disturbance are unknown. Although, individually, the various activities may elicit local effects on beluga whales, the area and extent of the population over which effects occur will likely increase with multiple activities occurring simultaneously or consecutively throughout much of the spring-fall range of this population.

4.9.2.4.2.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to beluga whales are discussed under Alternative 2 (Section 4.5.2.4.16).

4.9.2.4.3 Other Cetaceans

Alternative 6 applies the same levels of activity as Alternative 4, described as Level 3. The activities are divided identically among the different activity categories in both alternatives, and the number and types of surveys, exploration, and drilling are all assumed to be the same. Likewise, the Standard and

Additional Mitigation Measures are also identical. Alternative 6 differs from Alternative 4 in the application of Alternative Technologies.

Alternative 6 considers the gradual augmentation or replacement of current seismic airgun technology with alternative methodologies intended to reduce the amount of loud seismic sounds introduced into the marine environment. Five technologies are considered (Table 2.3). All are in different stages of research, testing and development and could be implemented over time if they become available for general application. Commercial availability at some point in the future is assumed for the purposes of this EIS.

The analysis for this alternative focuses on the potential mitigating effects of each of the individual alternative technologies and how they could reduce adverse impacts from levels described in Alternative 4. Many of these technologies are in the early stages of development and are difficult to assess. For example, Table 4.9-2 illustrates the estimated change in *near-field* ensonified area above different thresholds if certain incremental source level reductions are considered likely, from which we could infer some quantitative reduction of impacts. However, because of the early stages of development that many of these technologies are in it is not always possible to know exactly what the operational trade-off of using the alternative technology might be (for example, is it 10 dB quieter, but needs to survey an area with twice the density of survey lines). Of potentially more important note, though, is the potential significant reduction in far-field effects on acoustic habitat and how that reduction could reduce chronic noise impacts to marine mammals.

An analysis of each alternative technology follows the summary information on direct and indirect effects and standard mitigation measures.

4.9.2.4.3.1 Direct and Indirect Effects

As Alternative 6 has the same level of activity as Alternative 4, the direct and indirect effects for the two alternatives are identical. For a complete discussion of the effects of direct and indirect effects on other cetaceans, please see Section 4.5.2.4.3.

4.9.2.4.3.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.15).

4.9.2.4.3.3 Alternative Technologies to Augment and/or Replace Traditional Airgun-Based Seismic Surveys

See Bowhead Whales (Section 4.9.2.4.1) above for an analysis of the efficacy and practicability of using the proposed alternative technologies to reduce effects of noise from seismic exploration on marine mammals. Only technologies for which there is information specific to beluga whales (e.g., hydraulic and electric marine vibrators) are included below. Refer to the above bowhead whales section for information on DTAGS and Low Frequency Passive Seismic Methods for Exploration.

Hydraulic Marine Vibrators

The low frequency (10 to 250 Hz) sound produced by hydraulic marine vibrators is within the hearing range of baleen whales (7 Hz to 22 kHz) and at the lower edge of most toothed whales (150 Hz to 160 kHz or 200 Hz to 180 kHz for mid- and high- frequency functional hearing groups, respectively) [Southall et al. 2007]), so could still be in the range of detectability. Potential auditory impacts to cetaceans, as well as behavioral disturbance and displacement due to noise exposure, may, however, be reduced through reduced noise output. Any reduction in adverse impacts would be on a limited and localized scale with the current schedule of implementation. The use of this system by industry is currently uncertain as previous use did not result in increased data quality, reduced operation costs, or penetrate as deeply as some companies require.

Electric Marine Vibrators

Electric marine vibrators emit sounds at lower pressure levels and over a narrower frequency range than do airguns. The low frequency (6 to 100 Hz) produced is within the hearing range of baleen whales (7 Hz to 22 kHz) but outside the range of most toothed whales (150 Hz to 160 kHz or 200 Hz to 180 kHz for mid- and high- frequency functional hearing groups, respectively) [Southall et al. 2007]). Therefore, baleen whales would be able to detect the sound, but toothed whales would likely not. Potential auditory impacts to baleen whales, as well as behavioral disturbance and displacement due to noise exposure, may, however, be reduced due to the lower frequency. Any reduction in adverse impacts would be on a limited and localized scale with the current schedule of implementation. In addition, industry interest in this system may be limited by its inability to penetrate as deep as some companies require for exploration.

Low Frequency Acoustic Source (LACS)

This could potentially reduce adverse acoustic impacts to cetaceans, but the level of reduced impacts and efficacy for mitigating impacts cannot presently be determined. See Section 4.9.2.4.1 for further details. Depending on the exact frequencies used, it is possible that baleen and toothed whales would have divergent benefits due to their different auditory ranges, similar to the implementation of marine vibrators.

4.9.2.4.3.4 Conclusion

Mitigating capabilities and effects of alternative technologies introduced under Alternative 6 on Other Cetaceans are difficult to determine, but could reduce adverse impacts (both behavioral impacts and acoustic habitat impacts, as described in the sections above) associated with the use of airgun arrays (see Section 4.5.2.4 for details on effects of airgun noise on marine mammals and other cetaceans). Because of the current state of the technology, however, the overall reduction during the life of this EIS would likely be minimal. The gradual introduction of these alternative technologies might reduce the frequency, although not the duration, of seismic noise introduced into the marine environment and the impacts to marine mammals. Airgun noise would not be eliminated, however, since these alternative technologies would not completely replace the existing technology and what may be replaced is limited. In addition, surveys conducted with alternative technologies would still use marine vessels to tow or deploy equipment which could disturb bowhead whales as described in Section 4.5.2.4. A sizable ramp-up in the development and implementation of alternative technologies could potentially reduce behavioral and acoustic habitat impacts to the degree that the rating in the impact criteria might change. However, based on our understanding of the degree to which these technologies are expected to come into use in the next five to ten years, we expect that the impact categorization would not change. Effects of existing technology on cetaceans, as described in Alternative 4, would be mostly of low to medium intensity and interim duration and be of regional extent. Alternative technologies could reduce the extent to localized areas on a small scale; it is not currently possible to assess potential behavioral reactions and determine if intensity level would change, as a result. Species within the Other Cetacean group are considered common to unique, but many are very rarely encountered due to infrequent use of the habitat. Despite possible localized mitigating capabilities of using alternative technologies in lieu of limited numbers of airgun arrays, the overall impact of Alternative 6 on Other Cetaceans is considered to be minor to moderate.

4.9.2.4.3.5 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to other cetaceans are discussed under Alternative 2 (Section 4.5.2.4.16).

4.9.2.4.4 Ice Seals

4.9.2.4.4.1 Direct and Indirect Effects

Alternative 6 includes the same type of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on ice seals under Alternative 6 involves the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.

The number of the different exploration activities authorized under Alternative 6 would be the same as under Alternatives 4 and 5. However, under Alternative 6, NMFS could potentially require the industry to (or the industry could voluntarily) gradually replace current seismic airgun technology with alternative methodologies intended to reduce the amount of loud seismic sounds introduced into the marine environment that could have adverse effects on marine mammals. Cetaceans are the primary focus for consideration of these alternative technologies because they are the most susceptible of marine mammals to underwater noise disturbance. These technologies and their potentials for reducing impacts to cetaceans are described in sections 4.9.2.4.1 and 4.9.2.4.3 above. Analysis of the potential for these technologies to reduce impacts on ice seals is incorporated into the following subsections.

Behavioral Disturbance

Each of the different types of exploration activities that would be authorized under Alternative 6 include several mechanisms for potential disturbance to ice seals in the water and on the ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment. The two types of surveys which take place on or in sea ice, the preferred habitat of ice seals and where they are most likely to be concentrated, are the in-ice 2D surveys with icebreakers and the on-ice vibroseis surveys. For both of these types of surveys, the same number of surveys would be authorized under Alternative 6 as for Alternative 2. The physical presence of the icebreakers and vibroseis tracked vehicles likely have as much or more to do with the disturbance of ice seals during these surveys as does the introduced seismic sounds. Alternative seismic technologies for in-ice surveys would likely still require the use of ice breakers and would therefore have similar disturbance effects on ice seals as those technologies currently in use. Additional development and testing would be needed prior to use of any of the alternative technologies under consideration in sea ice. The level of disturbance from these types of in-ice/on-ice surveys would therefore be similar for Alternative 6 as is discussed for Alternative 2, which was considered to have temporary and low magnitude effects on ice seals.

The level of open-water activities under Alternative 6 would be the same as for Alternative 4. These activities could affect ice seals over a large area, especially for the 2D/3D seismic streamer surveys. The gradual introduction of various alternative technologies could reduce the amount of seismic noise introduced into the marine environment but would not eliminate it because these alternate technologies could not completely replace the existing technology and most of the alternative technologies still emit sound into the ocean. As described for Alternative 2 in Section 4.5.2.4, disturbance effects using the existing technology would be temporary and low in magnitude, characterized by avoidance of vessels but with mild or unnoticeable behavioral reactions of ice seals. Any surveys conducted with alternative technologies would presumably reduce the amount of noise introduced but would still use marine vessels which could disturb seals in the water. The effects on ice seals would still be considered temporary and low in magnitude with the same types of mild behavioral reactions.

Hearing Impairment, Injury, and Mortality

The exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4, so the types and mechanisms for injury and mortality to pinnipeds would be the same. The level of potential direct and indirect physical effects on pinnipeds would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.4. Refer to Section 4.5.2.4.12 for a discussion of potential injury or mortality effects of oil and gas exploration activities on pinnipeds.

Habitat Alterations

The exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4, so the types and mechanisms for habitat alteration would be the same. The level of potential direct and indirect effects on pinnipeds habitat would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.4. Refer to Section 4.5.2.4.12 for a discussion of potential effects oil and gas exploration activities on pinniped habitat.

4.9.2.4.4.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to pinnipeds are discussed under Alternative 2 (Section 4.5.2.4.15).

4.9.2.4.4.3 Alternative Technologies to Augment and/or Replace Traditional Airgun-Based Seismic Surveys

See Bowhead Whales (Section 4.9.2.4.1) above for an analysis of the efficacy and practicability of using the proposed alternative technologies to reduce effects of noise from seismic exploration on marine mammals. There is no specific information regarding how these technologies may reduce impacts to ice seals at this time. However, because of the different hearing frequencies of ice seals from mysticetes, impacts would likely be slightly different.

4.9.2.4.4.4 Conclusion

The four species of ice seals would likely not be affected to the same extent by exploration activities in the Beaufort and Chukchi seas based on their respective abundance and distribution. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past exploration activities and their reactions have been recorded by PSOs on board source vessels and monitoring vessels. These data indicate that seals do tend to avoid on-coming vessels and active seismic arrays but their behavioral responses are often neutral rather than swimming away and they do not appear to react strongly even as ships pass fairly close with active arrays. The gradual introduction of various alternative technologies could reduce the amount of seismic noise introduced into the marine environment but would not eliminate it because these alternate technologies could not completely replace the existing technology and most of the alternative technologies still emit sound into the ocean. Any surveys conducted with alternative technologies would presumably reduce the amount of noise introduced but would still use marine vessels which are at least as important for disturbance to seals in the water. Seals do not appear to react strongly to icebreaking or on-ice surveys, keeping their distance or moving away at some point to an alternate breathing hole or haulout, but the scope of these behavioral responses appears to be within their natural abilities and responses to their naturally dynamic environment. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and would therefore be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are legally protected (all under the MMPA and two under the ESA as well). Given the standard and additional mitigation measures considered in this EIS, the effects of exploration activities that could be authorized under Alternative 6 on ice seals would likely be medium to high in magnitude (the latter for ringed seals), distributed over a wide geographic area, and interim in duration. The effects of Alternative 6 would therefore be considered minor to moderate (the latter for ringed seals) for ice seal species according to the criteria established in Section 4.1.3.

4.9.2.4.4.5 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to pinnipeds are discussed under Alternative 2 (Section 4.5.2.4.16).

4.9.2.4.5 Pacific Walrus

4.9.2.4.5.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 6 on Pacific walrus. This species is dependent on pack ice and coastal shores for haul outs. Alternative 6 includes all of the same types of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on Pacific walrus under Alternative 6 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.

The number of different exploration activities authorized under Alternative 6 would be the same as under Alternatives 4 and 5. However, under Alternative 6, NMFS could potentially require the industry to (or the industry could voluntarily) gradually replace current seismic airgun technology with alternative methodologies intended to reduce the amount of loud seismic sounds introduced into the marine environment that could have adverse effects on marine mammals. Cetaceans are the primary focus for consideration of these alternative technologies because they are the most susceptible of marine mammals to underwater noise disturbance. These technologies and their potentials for reducing impacts to cetaceans are described in sections 4.9.2.4.1 and 4.9.2.4.3 above. Analysis of the potential for these technologies to reduce impacts on walrus is incorporated into the following subsections.

Behavioral Disturbance

The exploration activities that would be authorized under Alternative 6 include several mechanisms for potential disturbance to walrus in the water and on the ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment. The one type of survey that takes place on or in sea ice (the preferred habitat for walrus and where they are most likely to be concentrated) is the in-ice 2D survey with icebreakers. On-ice vibroseis surveys would only occur in the Beaufort Sea at times when walrus would not be present. Only one such in-ice survey could be authorized for each Arctic sea under any of the action alternatives. The physical presence of the icebreakers likely has as much or more to do with the disturbance of walrus during these surveys as does the introduced seismic sounds. Alternative seismic technologies for in-ice surveys would likely still require the use of ice breakers and would therefore have similar disturbance effects on walrus as do technologies currently in use. Additional development and testing would be needed prior to use of any of the alternative technologies under consideration in sea ice. The level of disturbance from these types of in-ice surveys would therefore be similar for Alternative 6 as is discussed for Alternative 2, which was considered to have temporary and low magnitude effects on walrus.

The number of open water activities authorized under Alternative 6 would be the same as under Alternative 4 and likely to elicit similar disturbance effects. These activities could affect walrus over a large area, especially for the 2D/3D seismic streamer surveys. The gradual introduction of various alternative technologies could reduce the amount of seismic noise introduced into the marine environment but would not eliminate it because these alternate technologies could not completely replace the existing technology. As described for Alternative 2 in Section 4.5.2.4, disturbance effects using the existing technology would be temporary and low in magnitude, characterized by avoidance of vessels but with mild or unnoticeable behavioral reactions of walrus. Any surveys conducted with alternative technologies would presumably reduce the amount of noise introduced but would still use marine vessels which could disturb walrus in the water. The effects on walrus would still be considered temporary and low in magnitude with the same types of mild behavioral reactions.

Hearing Impairment, Injury, and Mortality

Since the exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4, the types and mechanisms for injury and mortality to walrus would be the same. The level of potential direct and indirect physical effects on walrus would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.5. A more thorough discussion of potential injury or mortality effects on walrus can be found in Section 4.5.2.4.13.

Habitat Alterations

Since the exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4, the types and mechanisms for habitat alteration would be the same. The level of potential direct and indirect effects on walrus habitat would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.5. A more thorough discussion of potential impacts on walrus habitat can be found in Section 4.5.2.4.13.

4.9.2.4.5.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.15). All mitigation measures required under the USFWS LOA will be applicable here.

4.9.2.4.5.3 Conclusion

Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. This data indicates that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest of sounds generated by the ships. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of calf and juvenile mortality from stampedes.

Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for analysis purposes in this EIS. Given the level and type of exploration activities that would be authorized under Alternative 6, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on walrus would likely be low in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 6 would therefore be considered minor for Pacific walrus according to the criteria established in Table 4.5-17.

4.9.2.4.5.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to Pacific walrus are discussed under Alternative 2 (Section 4.5.2.4.16).

4.9.2.4.6 Polar Bears

4.9.2.4.6.1 Direct and Indirect Effects

This section discusses the potential direct and indirect effects of Alternative 6 on polar bears. This species is dependent on pack ice for much of their denning habitat and for hunting seals. Alternative 6 includes all of the same type of exploration activities as in Alternative 2 so the discussion of potential direct and indirect effects on polar bears under Alternative 5 involves all the same mechanisms and types of effects as discussed for Alternative 2 in Section 4.5.2.4.

The number of different exploration activities authorized under Alternative 5 would be the same as under Alternatives 4 and 5. However, under Alternative 6, NMFS could potentially require the industry to (or the industry could voluntarily) gradually replace current seismic airgun technology with alternative methodologies intended to reduce the amount of loud seismic sounds introduced into the marine environment that could have adverse effects on marine mammals. Cetaceans are the primary focus for consideration of these alternative technologies because they are the most susceptible of marine mammals to underwater noise disturbance. These technologies and their potentials for reducing impacts to cetaceans are described in sections 4.9.2.4.1 and 4.9.2.4.3 above. Analysis of the potential for these technologies to reduce impacts on polar bears is incorporated into the following subsections, where relevant.

Behavioral Disturbance

The exploration activities that would be authorized under Alternative 6 include several mechanisms for potential disturbance to polar bears along leads in the ice and in broken ice, primarily involving the noise generated by and the physical presence of vessels and associated exploration equipment including the potential for direct bear-human encounters. The two types of surveys which take place on or in sea ice, the hunting and denning habitats for polar bears, are the in-ice 2D surveys with icebreakers and the on-ice vibroseis surveys. For both of these types of surveys, the same number of surveys would be authorized under Alternative 6 as for Alternative 2. The physical presence of the icebreakers and vibroseis, tracked vehicles likely have as much or more to do with the disturbance of polar bears during these surveys as does the introduced seismic sounds. Alternative seismic technologies for in-ice surveys would likely still require the use of ice breakers and would therefore have similar disturbance effects on polar bears as those technologies currently in use. The level of disturbance from these types of in-ice/on-ice surveys would therefore be similar for Alternative 6 as is discussed for Alternative 2, which was considered to have temporary and low magnitude effects on polar bears.

The number of exploration activities that would be authorized under Alternative 6 is identical to those under Alternative 4, so the types and mechanisms for disturbance to polar bears would be the same. Introduction of alternative technologies would likely have little impact on polar bears, so the overall level of disturbance and potential direct and indirect effects on polar bears would be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.6. A more thorough discussion of disturbance effects of oil and gas exploration activities on polar bears can be found in Section 4.5.2.4.14.

Hearing Impairment, Injury, and Mortality

The exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4, so the types and mechanisms for injury and mortality to polar bears would be the same. The level of potential direct and indirect physical effects on polar bears would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.5. A more thorough discussion of potential injury or mortality effects of oil and gas exploration activities on polar bears can be found in Section 4.5.2.4.14.

Habitat Alterations

Since the exploration activities that would be authorized under Alternative 6 are identical to those under Alternative 4, the types and mechanisms for habitat alteration would be the same. The level of potential direct and indirect effects on polar bear habitat would therefore be the same for Alternative 6 as is discussed for Alternative 4 in Section 4.7.2.4.6. A more thorough discussion of potential impacts on polar bear habitat can be found in Section 4.5.2.4.14.

4.9.2.4.6.2 Standard Mitigation Measures

Standard mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.15).

4.9.2.4.6.3 Conclusion

Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. However, in 2012, Shell recorded a total of 49 sightings of 61 polar bears in the Chukchi Sea and a total of 29 sightings of 104 indvidual s in the Beaufort Sea during monitoring efforts in conjunction with exploratory drilling activities (Bisson et al. 2013). During the activities associated with the exploratory drilling programs, Bisson et al. (2013) noted the most common reactions to the presence of both moving and stationary vessels as looking at the vessel or no observable reaction. The gradual introduction of various alternative technologies could reduce the amount of seismic noise introduced into the marine environment but would not eliminate it because these alternate technologies could not completely replace the existing technology. Any surveys conducted with alternative technologies would presumably reduce the amount of noise introduced, but would still use marine vessels which are at least as important for disturbance to polar bears in the water. Polar bears do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important subsistence resources and are therefore considered unique resources. Given the mitigation measures that would be required by USFWS LOAs and NMFS as considered in this EIS, the effects of exploration activities that could be authorized under Alternative 6 on polar bears would likely be low in magnitude, distributed over a wide geographic area, and interim in duration. The effects of Alternative 6 would therefore be considered minor for polar bears according to the criteria established in Section 4.1.3.

4.9.2.4.6.4 Additional Mitigation Measures

Additional mitigation measures identified that could reduce adverse impacts to polar bears are discussed under Alternative 2 (Section 4.5.2.4.16).

4.9.2.5 Terrestrial Mammals

Activity levels in Alternative 6 are the same as in Alternative 4, and this alternative includes mitigation measures that focus on alternative technologies for seismic exploration. These mitigation measures do not affect terrestrial mammals in the EIS project area, so the impacts discussed in Section 4.5.2.5 are the same for Alternative 6; the overall impact to terrestrial mammals would be minor.

4.9.2.6 Time/Area Closures

The analysis of the direct and indirect effects associated with time/area closures can be found in Sections 4.8.2.4 (Marine Mammals), 4.8.2.3 (Marine and Coastal Birds) and 4.8.3.2 (Subsistence).

4.9.2.7 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the biological environment, other than marine mammals and marine and coastal birds, are discussed under Alternative 2 (Section 4.5.2.7).

4.9.3 Social Environment

4.9.3.1 Socioeconomics

4.9.3.1.1 Direct and Indirect Effects

Impacts to the socioeconomic categories of public revenue and expenditures, employment and personal income, demographic characteristics, and social organizations and institutions would be the same as those discussed under Alternative 4 (Level 3 activity). With the incorporation of alternative technologies, there would be negligible impact to the monetized economy. It is feasible that the effectiveness and practicability of alternative technologies may result in longer surveys to get equivalent data, and as such result in additional costs to lease holders. The description of alternative technologies for hydrocarbon exploration (Section 2.3.5) discusses how alternative acoustic source technologies generally put the same level of useable energy into the water as airguns, but over a longer period of time with a resulting reduced acoustic footprint. Therefore, the lease holders could be surveying for a longer period of time which would cause greater associated cost. For a discussion of reduced impacts to the non-monetized economy, see the Subsistence Section 4.9.3.2.

4.9.3.1.2 Conclusion

The socioeconomic impacts under Alternative 6 are similar to Alternative 4 except there could be additional costs incurred by lease holders associated with lost productivity. The duration of the socioeconomic impacts is temporary because it is not year-round; however, the activity is scheduled to occur over a fixed number of years. The positive economic impacts of the activity are statewide and even national. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat communities. The summary impact level for Socioeconomics under Alternative 6 is minor.

4.9.3.2 Subsistence

4.9.3.2.1 Direct and Indirect Effects

Direct and indirect effects to subsistence resources and subsistence harvest would be expected to be the same as those discussed under Alternative 2 (Section 4.5.3.2). The number and types of surveys, exploration, and drilling are all assumed to be the same. Standard and additional mitigation measures for Alternative 6 are also identical to those for Alternative 4. Alternative 6 differs from Alternative 4 in the application of alternative technologies. The implementation of alternative technologies depends on research and development schedules, and usage during the timeframe of this EIS is unknown.

The use of alternative technology to either replace or traditional seismic surveys or augment the use of airguns in traditional seismic surveys would be introduced slowly if available during the timeframe of this EIS. At present, none of these alternative technologies are fully tested or developed. The number of airgun surveys these technologies could potentially replace or augment cannot be estimated until the technology is beyond the testing phase.

Hydraulic marine vibrators could be used as technologies that replace airguns or augment traditional seismic surveys for certain prospects in limited environments. This system is the only one that has been offered commercially. However, it is currently not considered successful because there was no increase in data quality or reduction in operations cost. The system does not have the low frequencies to penetrate as deep as some companies require for exploration. Low frequency passive seismic methods (not yet proven in all environments) may be used to enhance recovery through better resolutions than magnetic or gravimetric methods but would not replace airgun surveys. However, there is no evidence that this is a reliable new alternative technology reliable and therefore it is not likely to be used.

Electric marine vibrators would not be available to replace existing technologies. There has been no industry interest in supporting the development of this system. The system does not have the low frequencies to penetrate as deep as some companies require for exploration and electric marine vibrators would be available for use in only limited environments.

Low-frequency acoustic source (LACS) would not be available to replace or augment existing technologies. There has been no industry interest in supporting the development of this system. The system does not have the low frequencies to penetrate as deep as some companies require for exploration. The LACS 8A system has not yet been built and/or tested; therefore its availability to be used as an alternative technology to airguns and considered in this EIS is difficult.

The deep-towed acoustics/geophysics system (DTAGS) is not designed for conducting deep penetration for oil and gas explorations. Only one DTAGS currently exists. There is no projection of a timeframe in which a low-frequency DTAGS would be fully developed or available. However, it is impossible to compare this system to currently used airgun arrays, and the effectiveness of this alternative technology is unknown.

The effectiveness of these alternative technologies to be used to further reduce adverse impacts to subsistence uses is at present unknown. These alternative technologies are only expected to be employed in certain environments, and some are not yet proven in all environments.

Alternative 6 proposes the same level of exploration activities as Alternative 4 but suggests the implementation of alternative technologies that reduce sound emission levels from seismic survey sources. The gradual introduction of these alternative technologies could, ultimately, reduce the amount of seismic noise introduced into the marine environment. The intention is that the use of these alternative technologies would reduce the likelihood of disturbance to marine mammals (Section 4.9.1.4 and Section 4.9.2.4), which in turn could be beneficial in reducing any subsequent impacts to subsistence users.

Airgun noise would not be eliminated, however, since these alternative technologies would not completely replace the existing technology, and what may be replaced is limited. In addition, surveys conducted with alternative technologies would still use marine vessels to tow or deploy equipment which could disturb marine mammals (Section 4.5.2) and in turn affect subsistence resources. Effects of existing technology on subsistence would be of low intensity and temporary duration and range from localized to regional in extent. The context would range from common to unique. Bowhead whales, beluga whales and polar bears would be considered unique in context. Despite possible localized mitigating capabilities of using alternative technologies in lieu of limited numbers of airgun arrays, the impact of Alternative 5 on subsistence resources would be considered to be negligible to moderate.

4.9.3.2.2 Conclusion

The summary impacts to subsistence harvest and subsistence resources from alternative technologies under Alternative 6 are likely to be similar to Alternative 2 as discussed in Section 4.5.3.2.

4.9.3.3 Public Health

4.9.3.3.1 Direct and Indirect Effects

Anticipated effects to public health as a result of Alternative 6 are expected to be similar to those expected under Alternative 2, as discussed in Section 4.5.3.3.

In addition, there could potentially be requirements for the use of alternative technologies under Alternative 5. The intention is that the use of these alternative technologies will reduce the likelihood of disturbance to marine mammals, which in turn could be beneficial in reducing detrimental impacts to subsistence users. However, as discussed in Section 4.9.3.2, the effectiveness of these alternative technologies in reducing adverse impacts to subsistence uses is at present unknown, and thus the benefits of the use of these technologies are theoretical.

Therefore, these additional mitigations do not affect the overall impact criteria rating for public health for Alternative 6. If, however, the alternative technologies are demonstrated to be effective and feasible to implement, there is the possibility that additional benefit to public health may accrue.

4.9.3.3.2 Conclusion

Both potential beneficial and adverse impacts are anticipated as a result of Alternative 6. Possible changes could occur to health outcomes such as chronic disease and trauma and many of the pathways relate to traditional practices and subsistence activities. However, there is a very low likelihood of these health outcomes arising, and effects are unlikely to be large enough cause a measurable change in health outcomes. The magnitude or intensity of effects is estimated to be low: above background conditions, but small and within both the natural variation and adaptive ability of the local population. If health changes do occur, the duration of changes may be permanent, and multiple communities could be affected.

4.9.3.4 Cultural Resources

4.9.3.4.1 Direct and Indirect Effects

Activity levels in Alternative 6 are the same as in Alternative 4, and this alternative includes mitigation measures for that focus on alternative technologies for seismic exploration. These mitigation measures do not affect cultural resources in the EIS project area, so the impacts discussed in Section 4.5.3.4 for Alternative 2 are the same for Alternative 6. The overall impact to cultural resources would be minor.

4.9.3.4.2 Conclusion

Direct and indirect impacts to cultural resources resulting from the implementation of Alternatives 2, 3, and 4 would be the same in Alternative 6. For a complete discussion of direct and indirect impacts on cultural resources, please see Section 4.5.3.2.

4.9.3.5 Land and Water Ownership, Use, and Management

4.9.3.5.1 Direct and Indirect Effects

Land and Water Ownership

The direct and indirect impacts to land and water ownership caused by Alternative 6 are similar to those caused by Alternative 4. Refer to Section 4.5.3.5 for a discussion on these topics. This includes federal, state, private owned, borough, and municipal lands and waters.

Alternative 6 also includes mitigation measures that focus on the use of alternative technologies that have the potential to augment or replace traditional airgun-based seismic exploration activities. Some of this technology may be impracticable or not yet available, which could violate lease compliance terms for the timing of exploration.

Land and Water Use

The direct and indirect impacts to land and water use resulting from Alternative 6 are similar to those resulting from Alternative 4 for recreational, residential, and mining land uses. Refer to Section 4.5.3.5 for a discussion on these topics.

The direct and indirect impacts to land and water use resulting from Alternative 6 are similar those resulting from Alternative 4 for protected lands, subsistence, industrial, transportation, and commercial land uses. Refer to Section 4.6.3.5 for a discussion on these topics

Land and Water Management

The direct and indirect impacts to land and water management resulting from Alternative 6 are similar to those resulting from Alternative 4 for federal, state and borough and lands and waters. Refer to Section 4.6.3.5 for a discussion on these topics.

4.9.3.5.2 Conclusion

Based on Table 4.4-2, and the analyses provided above and in Section 4.5.3.5, the impacts on land and water ownership under Alternative 6 are described as follows. The magnitude of ownership impacts would be low because no changes in land or water ownership will result from this action. The duration of impact would be temporary because no ownership changes will occur. The extent of impacts would be local, occurring only in the activity area and involving no ownership change. The context of impact would be common because the federal waters affected have no special, rare, or unique ownership characteristics. In total, the direct and indirect impacts on land ownership are considered to be negligible; they would be low intensity, temporary, localized, and do not result in changes of ownership.

Based on Table 4.4-2 and the analyses provided above and in Sections 4.5.3.5 and 4.6.3.5, the impacts of land and water use caused by Alternative 6 are described as follows. The magnitude of impact would be high where activity occurs in areas of little to no activity (such as Wainwright), and the magnitude of impact would be low in areas where previous activity is common (Prudhoe Bay, Barrow, Nome, Dutch Harbor). The duration of impact would be temporary because an increase in aircraft and shipping traffic would last only for that survey season, although the impact could be permanent if construction of a new facility or infrastructure to accommodate increased shipping traffic were built in Wainwright. The extent of impacts would be local because any changes in land use as a result of this alternative would be limited geographically to the communities that would support the survey vessels. The context of impact would be common because the areas of land and water use affected are extensively available and have no special, rare, or unique characteristics identified. In summary, the direct and indirect effects of Alternative 6 would be moderate because of the possibility for high intensity impact and long term structures in smaller communities.

Based on Table 4.4-2 and the analyses provided above and in Sections 4.5.3.5 and 4.6.3.5, the impacts on land and water management caused by Alternative 6 are described as follows. The magnitude of impact would be low because the action is consistent with existing management plans. The duration of impact would be temporary because project activities are short term in duration and would not result in long-term conflicts with management plans. The extent of impacts would be local because proposed activities would not involve management plans beyond the localized areas of seismic exploration and support activities. The context of impact would be common because the areas of land and water affected are extensively available and have no special, rare or unique characteristics identified in an adopted management plan. In total, the direct and indirect impacts of Alternative 6 on land and water management would be minor because they would be low intensity, would be short term in nature, local, and common.

4.9.3.6 Transportation

4.9.3.6.1 Direct and Indirect Effects

Direct and indirect regional transportation systems and existing infrastructure would be expected to be the same as those discussed under Alternative 2 as discussed in Section 4.5.3.2. Alternative technologies are likely to use the same types of transportation equipment and infrastructure at the same levels as that currently used for seismic surveys, on-ice surveys and exploratory drilling as Alternatives 2, 3, 4, and 5.

4.9.3.6.2 Conclusion

The impacts of using alternative technologies would occur slowly. It is assumed that these new alternative technologies would require the same levels of aircraft and surface and vessel support as under Alternative 4, and, therefore, the impacts would be expected to be similar.

4.9.3.7 Recreation and Tourism

4.9.3.7.1 Direct and Indirect Effects

Activity levels in Alternative 6 are the same as in Alternative 4, and this alternative includes mitigation measures for that focus on alternative technologies for seismic exploration. These mitigation measures do not affect recreation or tourism in the EIS project area, so the impacts discussed in Section 4.5.3.7 for Alternative 2 are the same for Alternative 6; the overall impact to recreation and tourism would be minor.

4.9.3.7.2 Conclusion

The direct impacts would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 6 on recreation and tourism would be minor.

4.9.3.8 Visual Resources

This section discusses potential impacts on visual resources that could result from implementing Alternative 6 of the proposed project.

4.9.3.8.1 Direct and Indirect Effects

Implementation of Alternative 6 is expected to result in short-term moderate effects to scenic quality and visual resources identical to those described in Alternative 4. Potential impacts could be of low to medium intensity, depending on the geographic separation of programs. In either case, actions would be temporary, localized and occur in an important context.

4.9.3.8.3 Conclusion

Implementation of Alternative 6 is expected to result in *short-term moderate effects* to scenic quality and visual resources. Potential impacts could be of low to medium intensity depending on specific location of drill sites. The geographic extent of potential impacts would be localized; however they would occur in an important ecosystem.

4.9.3.9 Environmental Justice

4.9.3.9.1 Direct and Indirect Effects

With the incorporation of alternative technologies, the impacts to subsistence foods and human health could be further minimized (see Subsistence Section 4.9.3.2). Contamination of subsistence foods would be the same as discussed under Alternative 4.

4.9.3.9.2 Conclusion

Activities related to implementation of Alternative 6 would have a lower intensity impact on subsistence resources and human health due to the incorporation of alternative technologies than Alternatives 4 and 5, but not eliminate all impacts. Level 3 activities are of a temporary duration and a regional extent. Subsistence foods and human health are unique resources, and they are protected under the MMPA and EO 12898. Thus, Alternative 6 is expected to have a minor impact to subsistence resources and minor disproportionate impacts to Alaska Native communities.

4.9.3.10 Standard and Additional Mitigation Measures

Standard and additional mitigation measures that could reduce impacts to the social environment, other than subsistence, are discussed under Alternative 2 (Section 4.5.3.10).

4.10 Very Large Oil Spill Scenario

This section contains a discussion of the potential environmental effects of a low-probability, high impact event, a hypothetical very large oil spill (VLOS) in the Chukchi Sea and also one in the Beaufort Sea. The analysis of a VLOS also allows NMFS and BOEM to understand possible effects of spills of smaller sizes as well. New rules and rulemaking procedures, as described below, have been instituted to help reduce even further the probability of a VLOS from occurring. Additionally, conditions at potential drill sites in the Beaufort and Chukchi seas are quite different from those at the site of the Deepwater Horizon oil spill event in the Gulf of Mexico (i.e., shallower water depths and lower formation pressures in the Beaufort and Chukchi seas), thereby reducing the likelihood of loss of well control in the EIS project area. Lastly, as described in Section 2.3.3 of this EIS, oil and gas operators are required to complete plans that reduce the likelihood of an oil spill from occurring.

The discussion of oil spill scenarios relies heavily on the recent BOEM Lease Sale 193 Final Supplemental EIS (BOEMRE 2011b) and the Outer Continental Shelf Oil and Gas Leasing Program: 2012-2017 Final Programmatic EIS (BOEM 2012). Much (although not all) of the information summarized in Sections 4.10.1 through 4.10.5 has been taken verbatim from these two documents.

4.10.1 Background and Rationale

The discussion provided in Section 4.10.1 is taken from the BOEM (2011b) Lease Sale 193 analysis and discussion. Summaries of this information are provided in the resource discussions below. As allowed by CEQ regulations in 40 C.F.R. 1502.21, NMFS has incorporated the information presented in the BOEM FSEIS into this EIS by reference.

On March 18, 2011, the U.S. Coast Guard (USCG) issued a final action memorandum that identified 4.9 million barrels (MMbbls) (and an unknown quantity of natural gas) as the total estimated amount spilled by the Deepwater Horizon (DWH) in 2010. Of that, most (74%) was recovered, burned, skimmed, chemically or naturally dispersed, or evaporated/dissolved. About 1.3 of the 4.9 MMbbls (26%) was categorized as residual oil (USCG 2011: Appendix V).

<u>**Government Reports and Recommendations**</u>

Since the DWH event, several entities within or commissioned by the Federal government have offered formal recommendations regarding review and regulation of OCS oil and gas activities.

Council on Environmental Quality (CEQ). As a direct result of the DWH event, the CEQ reviewed the MMS NEPA policies, practices and procedures relating to OCS oil and gas exploration and development and issued a report on August 16, 2010 (CEQ 2010b). This report recommended that MMS, since renamed BOEM, "ensure that NEPA documents provide decision makers with a robust analysis of reasonably foreseeable impacts, including an analysis of reasonably foreseeable impacts associated with low probability catastrophic spills for oil and gas activities on the Outer Continental Shelf." This report also asked BOEM to "Consider supplementing existing NEPA practices, procedures, and analyses to reflect changed assumptions and environmental conditions, due to circumstances surrounding the [Macondo] Oil Spill.

National Commission on the BP Deepwater Horizon Oil Spill and Offshore Drilling. On January 11, 2011, the National Commission on the BP Deepwater Horizon Oil Spill and Offshore Drilling (Commission) issued its final report. This report described the causes of the DWH event and recommended reforms intended to make offshore energy production safer. The Commission also reviewed and made recommendations concerning oil spill prevention and response.

U.S. Coast Guard. BOEM and the USCG are conducting a joint investigation to identify the causes of the DWH event and any procedural or policy changes that could prevent such tragedies in the future. On April 22, 2011, the Deepwater Horizon Joint Investigation Team released a preliminary report covering issues under Coast Guard jurisdiction. The investigation continues into the Deepwater Horizon's blowout preventer issue and other issues under the jurisdiction of BOEM. BOEMRE and the USCG conducted a joint investigation of areas under the jurisdiction of the Coast Guard and BOEMRE to investigate the causes of the Deepwater Horizon explosion, loss of life, and resulting oil spill, and to make recommendations for safe operations of future oil and gas activities on the U.S. Outer Continental Shelf (OCS). The JIT held seven sessions of public hearings, received testimony from more than 80 witnesses and experts, and reviewed a large number of documents and exhibits pertaining to all aspects of the investigation.

Volume I, released April 22, 2011, includes findings on five aspects of the disaster under Coast Guard jurisdiction – including the explosions on the Mobile Offshore Drilling Unit (MODU) Deepwater Horizon; the resulting fire; evacuations; the flooding and sinking of the Deepwater Horizon; and the safety systems of the MODU and its owner, Transocean.

Volume II, released September 14, 2011, includes findings on the causes, both direct and contributing, of the Macondo blowout and the resulting explosion and fire aboard the Deepwater Horizon.

Rule Changes Following the *Deepwater Horizon* Event

The aftermath of the DWH event provided new information about drilling on the OCS; in particular, it provided new information about (1) systemic safety issues, (2) deficiencies of blowout containment technologies and strategies, and (3) shortcomings in oil spill response strategies and resources relative to spills in deepwater. BOEM has addressed these issues by strengthening its regulations of OCS activities. Notable initiatives are discussed below. For additional discussion on advancements in safety and their meaning for OCS activities going forward, the reader is referred to an October 1, 2010 memorandum from the Director of BOEM to the Secretary, which supported lifting the suspension of certain offshore permitting and drilling activities on portions of the OCS (available at http://www.doi.gov/news/pressreleases/loader.cfm?csModule=security/getfile&PageID=64703).

New rules and rulemaking procedures, along with new and revised Notices to Lessees, are listed below. Further discussion of more notable developments is then provided.

- The Drilling Safety Rule, Oil and Gas and Sulphur Operations on the Outer Continental Shelf—Increased Safety Measures for Energy Development on the Outer Continental Shelf (Drilling Safety Rule). This rule strengthens requirements for safety equipment, well control systems, and blowout prevention practices in offshore oil and gas regulations.
- The Workplace Safety Rule on Safety and Environmental Management Systems (SEMS Rule). This rule requires operators to develop and implement a comprehensive SEMS for identifying, addressing, and managing operational safety hazards and impacts; for promoting both human safety and environmental protection; and for improving workplace safety by reducing risk of human error.
- NTL 2010-N06, "Information Requirements for Exploration Plans, Development and Production Plans, and Development Operations Coordination Documents on the OCS," effective June 18, 2010 (Plans NTL).
- NTL-2010-N10, "Statement of Compliance with Applicable Regulations and Evaluation of Information Demonstrating Adequate Spill Response and Well Containment Resources," effective November 9, 2010 (Certification NTL).

The Drilling Safety Rule. On August 22, 2012, BSEE issued a final rule entitled "Oil and Gas and Sulphur Operations on the Outer Continental Shelf— Increased Safety Measures for Energy Development on the Outer Continental Shelf" (77 FR 163). The final rulemaking revised selected sections of 30 CFR 250 Subparts D, E, F, O, and Q. The Drilling Safety Rule includes new standards and requirements related to the design of wells and testing of the integrity of wellbores, the use of drilling fluids, and the functionality and testing of well control equipment including blowout preventers. To these ends, the rule promulgated OCS-wide provisions that amended its drilling regulations related to subsea and surface blowout preventers, well casing and cementing, secondary intervention, unplanned disconnects, recordkeeping, well completion, and well plugging.

Safety and Environmental Management Systems Rule. A new subpart to 30 CFR Part 250: Subpart S – Safety and Environmental Management Systems (SEMS) is designed to reduce the hazards associated with drilling operations and further reduce the likelihood of a blowout scenario such as described for this VLOS analysis. The SEMS Rule requires all OCS operators to develop and implement a comprehensive management program for identifying, addressing, and managing operational safety hazards and impacts, with the goal of promoting both human safety and environmental protection. The interim final rule was published in the *Federal Register* on October 14, 2010 (75 FR 63345), requiring full implementation of a SEMS program by November 15, 2011. The 13 elements of the industry standard (American Petroleum Institute, Recommended Practice 75) that 30 CFR 250 Subpart S now makes mandatory are as follows:

- defining the general provisions for implementation, planning and management review, and approval of the SEMS program;
- identifying safety and environmental information needed for any facility such as design data, facility process such as flow diagrams, and mechanical components such as piping and instrument diagrams;
- requiring a facility-level risk assessment;
- addressing any facility or operational changes including management changes, shift changes;
- contractor changes;
- evaluating operations and written procedures;
- specifying safe work practices, manuals, standards, and rules of conduct;
- training, safe work practices, and technical training, including contractors;
- defining preventative maintenance programs and quality control requirements;
- requiring a pre-startup review of all systems;
- responding to and controlling emergencies, evacuation planning, and oil-spill contingency plans in place and validated by drills;
- investigating incidents, procedures, corrective action, and follow-up;
- requiring audits every 4 years, to an initial 2-year reevaluation and then subsequent 3-year;
- audit intervals; and
- specifying records and documentation that describe all elements of the SEMS program.

NTL (Notice to Lessees) 2010-N06. Though not a rulemaking, a recent NTL issued by BOEM warrants discussion here. Effective November 8, 2010, NTL No. 2010-NO6 requires that blowout intervention information be submitted with future Exploration or Development and Production Plans. The blowout scenarios required by 30 CFR 250.213(g) and 250.243(h) provide a potential blowout of the proposed well expected to have the highest volume of hydrocarbons, and must include supporting information for any assertion that well bridging will constrain or terminate the flow or that surface intervention will stop the blowout. The availability of a rig to drill a relief well and rig package constraints must also be addressed. These scenarios must also specify as accurately as possible the time it would take to contract for a rig, move it on site, and drill a relief well, including the possibility of drilling a relief well from a neighboring platform or an onshore location.

NTL (Notice to Lessees) 2010-N10. Also released on November 8, 2010 was NTL 2010-N10. This NTL explains that applications for well permits must include a statement that all authorized activities will be conducted in compliance with all applicable regulations, to include the new measures discussed above. For operations using subsea BOPs or surface BOPs on floating facilities, BOEM will evaluate whether each operator has submitted adequate information demonstrating that it has access to and can deploy subsea containment resources that can adequately and promptly respond to a blowout or other loss of well control. BOEM will also evaluate whether each operator has adequately described the types and quantities of surface and subsea containment equipment that the operator can access in the event of a spill or threat of a spill.

The operating regulations for BOEM and BSEE are at: http://www.gpo.gov/fdsys/pkg/FR-2011-10-18/pdf/2011-22675.pdf

Joint Industry Task Forces. In response to the DWH event, several entities within the oil and gas industry cooperatively formed Joint Industry Task Forces. The stated purpose of each Task Force is "to review and evaluate current capacities, and to develop and implement a strategy to address future needs and requirements in equipment, practices or industry standards" applicable to the studied activity. Where possible, information developed by these Tasks Forces will be augmented with input from regulatory agencies, oil spill response and well control specialists, investigation panels, and other public sector and non-governmental organizations. To date, Task Forces on "Oil Spill Preparedness and Response" and "Subsea Well Control and Containment" have submitted draft recommendations. Joint Industry Task Force recommendations will not have the force of regulation, but may provide the basis for enhanced industry standards or future rulemaking processes."

4.10.2 Very Large Oil Spill (VLOS) Scenario

Determining the appropriate volume to analyze for a VLOS can be difficult. In the BOEM Lease Sale 193 FSEIS document (2011), BOEM provided the rationale for using a spill volume of 2.2 MMbbls for the assessment of the potential environmental effects of a VLOS in the Chukchi Sea over a period of 74 days. In the 2012-2017 OCS Oil and Gas Leasing Program Draft Programmatic EIS (BOEM 2011d), BOEM provided the rationale for using a spill volume of 1.4 to 2.2 MMbbls over a period of 40 to 75 days for the Chukchi Sea and 1.7 to 3.9 Mbbl over a period of 60 to 300 days for the Beaufort Sea as the basis for considering impacts from a Catastrophic Discharge Event. These analyses from BOEM are incorporated into Sections 4.10.3 and 4.10.4 below.

Implicit in these analyses is the view that different hypothetical spill sizes are not expected to affect a particular individual of a species differently. The basic mechanisms by which individuals of the various Arctic species are affected by spilled oil are known to some extent and are not dependent on spill size. That is to say that if a bird were oiled from a crude oil spill, the effect on the particular bird would likely be essentially the same regardless of the size of the spill. A key difference that spill size makes is how many individuals of a species would have potential contact with a spill, be expected to die or be adversely affected, the extent of effects on their habitat, and whether those impacts would be significant under NEPA. Further investigation on fate and effects of dispersed crude oil on Arctic species is ongoing through a Joint Industry Program (Word et al. 2008).

4.10.3 General Assumptions

The discussion provided in Section 4.10.3 is taken from the BOEMRE FSEIS for the Chukchi Sea Oil and Gas Lease Sale 193 (BOEMRE 2011), which is substantially similar to the discussion presented in the 2012-2017 OCS Oil and Gas Leasing Program Draft Programmatic EIS (BOEM 2011d). Summaries of this information are provided in the resource discussions below. As allowed for by CEQ regulations in §1502.21, NMFS has incorporated the information presented in the BOEMRE FSEIS into this EIS by reference.

Very Large Spill Scenario vs. Worst Case Discharge

To facilitate analysis of the potential environmental impacts of a VLOS in the Chukchi and Beaufort seas, it is first necessary to develop VLOS scenarios. Scenarios are conceptual views of the future and represent possible sets of activities. They serve as planning tools that make possible an objective and organized analysis of hypothetical events. These VLOS scenarios are not to be confused with what would be expected to occur as a result of any of the action alternatives.

The VLOS scenario is sometimes confused with worst-case discharge (WCD) analyses which are used to evaluate an Exploration Plan (EP) or Development and Production Plan (DPP). Both calculations are alike to the extent that they are performed by BOEM using similar assumptions and identical analytical methods and software. However, these calculations differ in several important ways:

> ***Very Large Oil Spill:*** Rather than analyzing a specific drilling proposal, the VLOS model selected a prospect within an area that potentially maximizes the variables driving high flow rates. Therefore, the VLOS scenario in the Chukchi Sea represents an extreme case in flow rate and discharge period that, in turn, represents the largest discharge estimated from any site in the [EIS project area].
>
> ***Worst-Case Discharge:*** Site-specific WCDs at locations identified in a submitted plan in the [EIS project area] would typically result in much lower initial rates and aggregate discharges if discharge periods are held equal [i.e. regardless of the location of an exploration project in the Chukchi Sea, BOEM assumes that the discharge period would be the same]. The calculations also differ in their purpose. Whereas the VLOS scenario is a planning tool for NEPA environmental impacts analysis, a WCD is the calculation required by 30 CFR Part 250 to accompany an EP or DPP and provide a basis for an Oil Spill Response Plan.

The VLOS scenario is predicated on an unlikely event—a loss of well control during exploration drilling that leads to a long duration blowout and a resulting VLOS.

It is recognized that the frequency for a VLOS on the OCS from a well control incident is very low. From 1971-2010 there has been one very large oil spill during exploratory and development/production operations on 41,781 wells, or 2.39×10^{-5} per well.

The low ‘geological’ chance that the exploration well will successfully locate a large oil accumulation, coupled with the observed low incidence rates for accidental discharges in the course of actual drilling operations, predicts a very small, but not impossibly small, chance for the occurrence of a VLOS event. But this consideration of probability is not, nor should it be, integrated into the VLOS model. The VLOS discharge quantity is ‘conditioned’ upon the assumption that all of the necessary chain of events required to create the VLOS actually occur (successful geology, operational failures, escaping confinement measures, reaching the marine environment, etc.). The VLOS discharge quantity is, therefore, not “risked” or reduced by the very low frequency for the occurrence of the event.

Rate, Time and Composition of Hypothetical Spill

The [Chukchi Sea] VLOS scenario assumes a blowout leading to a very large oil spill. In developing this scenario, BOEM first generated a hypothetical oil discharge model that estimates the highest possible uncontrolled flow rate that could occur from any known prospect in the Lease Sale 193 area, given real world constraints. The discharge model was constructed using a geologic model for a specific prospect in conjunction with a commercially-available computer program (AVALON/MERLIN) that forecasts the flow of fluids from the reservoir into the well, models the dynamics of multiphase (primarily oil and gas) flow up the wellbore, and assesses constraints on flow rate imposed by the open wellbore and shallower well casing. This model utilized information and selected variables that, individually and collectively, provided a maximized rate of flow. The most important variables for the discharge model included thickness, permeability, oil viscosity, gas content of oil, and reservoir pressure. Many other variables of lesser importance were also required.

The oil discharge climbs rapidly to over 61,000 bbls/day during Day 1. After peaking in Day 1, (BOEMRE 2011: Figure 4) the oil discharge declines rapidly through the first 40 days of flow as the reservoir is depressurized by approximately 1,400 pounds per square inch (psi) (BOEMRE 2011: Table 2). The decline in the flow rate flattens somewhat after Day 40, falling to 20,479 bbls/day (33 percent of the Day 1 peak rate) by Day 74 when the near-wellbore reservoir pressure has fallen to [2,567 psi which is] 58 percent of the initial reservoir pressure (4,392 psi). The total oil discharge by the end of the flow period on Day 74 is 2,160,200 bbls.

Additional Parameters

The following discussion describes additional parameters of the Chukchi Sea VLOS scenario. These parameters are based on reasonably foreseeable factors related to oil spills based on past VLOS events (i.e. the Exxon Valdez Oil Spill (EVOS), DWH event, and the Ixtoc oil spill), published scientific reports, consideration of Arctic-specific conditions, and application of best professional judgment. The result is a framework for identifying the most likely and most significant impacts of the hypothetical VLOS event. Key aspects of the scenario are listed below:

- A loss of well control during exploration drilling leads to a blowout and an ongoing, high volume release of crude oil and gas that continues for up to 39-74 days;
- Oil remains on the surface of the water for up to a few weeks after flow has stopped or after meltout from sea ice during the Arctic spring;
- The total volume of the oil is nearly 2.2 MMbbls and the volume of the gas is [51 million cubic meters or] 1.8 billion cubic feet (Bcf)—within 74 days;
- Roughly 30 percent of the VLOS evaporates. A small portion of the spill remains in the water column as small droplets. The remaining oil could be physically or chemically dispersed, sedimented, beached, weathered into tar balls, or biodegraded; and
- Information about where a very large spill could go and how long it takes to contact resources is estimated by an oil spill trajectory model.
- For the Beaufort Sea, summer is defined as July 1-September 30 and winter October 1-June 30. For the Chukchi Sea, summer is defined as June 1-October 31 and winter November 1-May 31.

4.10.4 VLOS Scenario for the Chukchi Sea

The discussion provided in Section 4.10.4 is taken from the BOEM FSEIS for the Chukchi Sea Oil and Gas Lease Sale 193 (BOEM 2011b), which is substantially similar to the discussion presented in the 2012-2017 OCS Oil and Gas Leasing Program Draft Programmatic EIS (BOEM 2011d). Summaries of this information are provided in the resource discussions below. As allowed for by CEQ regulations in §1502.21, NMFS has incorporated the information presented in the BOEM documents (2011, 2011e) into this EIS by reference.

4.10.4.1 Cause of Spill

This scenario begins with an unlikely event – a loss of well control during exploration drilling that leads to a long duration blowout and a VLOS in the Chukchi Sea.

For the purpose of analysis in this EIS, an explosion and subsequent fire are assumed to occur. A blowout associated with the drilling of a single exploratory well could result in a fire that would burn for one or two days. The exploration drilling rig or platform may sink. If the blowout occurs in shallow water, the sinking rig or platform may land in the immediate vicinity; if the blowout occurs in deeper water, the rig or platform could land a great distance away. For example, the DWH drilling rig sank, landing [457 m or] 1,500 feet from the subsea wellhead. Water depths in the majority of the Lease Sale 193 area range from about [29 m or] 95 feet to approximately [80 m or] 262 feet; this range is considered shallow water. A small portion of the northeast corner of the Lease Sale 193 area deepens to approximately [2,987 m or] 9,800 feet.

For the purpose of modeling flow rates, the location of the blowout and leak was specified as occurring near the mudline (at the top of the BOP [blowout preventer]). For the purpose of environmental effects analysis, it is acknowledged that a blowout could occur in other locations, such as at the sea surface, along the riser anywhere from the seafloor to the sea surface, or below the seafloor (outside the wellbore). The forthcoming environmental effects analysis encompasses all these possibilities. As different blowout and leak locations may have bearing on spill response and intervention options, additional discussion of these issues is provided [below in] Opportunities for Intervention and Response.

DOI determines the risk of such an event occurring on a per EP basis; therefore, increasing the number of EPs increases the potential amount of risk. The amount of risk of such an event occurring can also increase when an operator needs to disconnect in the middle of operations.

4.10.4.2 Timing of the Initial Event

For purposes of analysis, the hypothetical VLOS in the Chukchi Sea is estimated to commence between July 15 and October 31. These dates coincide with the open water drilling season.

4.10.4.3 Volume of Spill

Well blowouts generally involve two types of hydrocarbons, namely crude oil (or condensate) and natural gas. The volume ratio of these two fluids is a function of the characteristics of the fluids and the producing reservoir.

Table 3 in BOEMRE (2011) summarizes the results of the discharge model for the hypothetical VLOS. The oil discharge climbs rapidly to over 61,000 bbls/day during day one. After peaking in Day 1, Figure 15 shows that the oil discharge declines rapidly through the first 40 days of flow as the reservoir is depressurized by approximately 1,400 psi (BOEMRE 2011: Table 3). The decline in the flow rate flattens somewhat after Day 40. As shown in BOEMRE (2011) Table 3, the cumulative oil discharge over a 74-day spill is 2,160,200 bbls.

To simplify the analysis, it is estimated 2.2 MMbbls of oil are spilled in the VLOS scenario.

4.10.4.4 Duration of Spill

The duration of the offshore spill from a blowout depends on the time required for successful intervention. Intervention may take a variety of forms. . . . [T]here exists a variety of methods by which an operator or responder can stop the flow of oil. The availability of some of these techniques could vary under individual drilling plans. [A]ll exploration plans must specify as accurately as possible the time it would take to contract for a rig, move it on site, and drill a relief well. For purposes of analysis within this VLOS scenario, it is estimated the discharge would be stopped within 74 days of the initial event.

This duration reflects the longest of three estimated time periods for completing a relief well as described in Table 4 in BOEMRE (2011).

4.10.4.5 Area of Spill

When oil reaches the sea surface, it spreads. The speed and extent of spreading depends on the type of oil and volume that is spilled. A spill of the size analyzed here would likely spread hundreds of square miles. Also, the oil slick may break into several smaller slicks, depending on local wind patterns that drive the surface currents in the spill area. Estimates of where the oil spill would go were taken from the OSRA [Oil Spill Risk Analysis] trajectory analysis [see Appendix B of BOEM (2011)].

4.10.4.6 Oil in the Environment: Properties and Persistence

The fate of oil in the environment depends on many factors, such as the source and composition of the oil, as well as its persistence (National Research Council 2003c). Persistence can be defined and measured in different ways (Davis et al. 2004), but the National Research Council (NRC) generally defines persistence as how long oil remains in the environment (National Research Council 2003c). Once oil enters the environment, it begins to change through physical, chemical, and biological weathering processes (National Research Council 2003c). These processes may interact and affect the properties and persistence of the oil through:

- evaporation (volatilization);
- emulsification (the formation of a mousse);
- dissolution;
- oxidation; and
- transport processes (National Research Council 2003c, Scholz et al., 1999).

Horizontal transport takes place via spreading, advection, dispersion, and entrainment, while vertical transport takes place via dispersion, entrainment, Langmuir circulation, sinking, overwashing, partitioning, and sedimentation (Sale 193 FEIS, Appendix A.1, Figure A.1 and A.2). The persistence of an oil slick is influenced by the effectiveness of oil-spill response efforts and affects the resources needed for oil recovery (Davis et al. 2004). The persistence of an oil slick may also affect the severity of environmental impacts as a result of the spilled oil.

Crude oils are not a single chemical but instead are complex mixtures with varied compositions. Thus, the behavior of the oil and the risk the oil poses to natural resources depends on the composition of the specific oil encountered (Michel 1992). Generally, oils can be divided into three groups of compounds: (1) light-weight, (2) medium-weight, and (3) heavy-weight components.

The oil discharged from the hypothetical Chukchi Sea VLOS well is 35° API [American Petroleum Institute] crude oil. This oil would be considered light-weight as shown in Table 5 in BOEMRE (2011). On average, light-weight crude oils are characterized as outlined in Table 5 in BOEMRE (2011).

Previous studies (Boehm and Fiest 1982) supported the estimate that most released oil in shallow waters similar to the Chukchi Sea would reach the surface of the water column. A small portion (one to three percent) of the Ixtoc oil remained in the water column (dispersants were used), although limited scientific investigation occurred and analytical chemical methods 30 years ago may not have been as sensitive as today (Boehm and Fiest 1982, Reible 2010). [BOEM (2011) does not indicate how long the oil would remain in the water column. The purpose of dispersants is to put the oil in suspension in the water column where it stays until diluted to the point of not being measurable and/or is ingested by bacteria.]

4.10.4.7 Release of Natural Gas

The quality and quantity of components in natural gas vary widely by the field, reservoir, or location from which the natural gas is produced. The oil in the VLOS reservoir is assumed to be initially saturated (with gas) at a gas-oil ratio of [26 cubic meters or] 930 cubic feet/barrel (cf/bbl) (quantities at standard conditions of 60°F and 1.0 atm.) and this is reflected by the fact that the initial (Day 0.1) produced gas-oil ratio in the model (BOEMRE 2011: Table 2) is also 930 cf/bbl. As shown in Table 2 in BOEMRE (2011), the produced gas-oil ratio falls to a minimum of 757 cf/bbl between Day 15 and Day 27—while early oil and gas production rates fall rapidly with de-pressurization of the reservoir near the wellbore—but then rises to 1,202 cf/bbl by Day 74 of the discharge.

Gas discharge reaches a peak of 50,677 Mcf/d [1 Mcf/d equals 1000 cf per day] in Day 1 of the flow, falls to a minimum rate of 19,513 Mcf/d by Day 45, then rises to 24,608 Mcf/d by Day 74. The pattern of gas flow reflects the process of gas break-out in the reservoir that progressively converts the initial oil reservoir into a gas reservoir. The cumulative gas discharge over the 74-day period (use of new platform and drilling equipment) estimated for completion of a relief well (very large discharge case) is 1,808 MMcf [1MMcf equals 1,000,000 cf]. For purposes of analysis, it is estimated 1.8 Bcf. Natural gas is primarily made up of methane (CH_4) and ethane (C_2H_6) which make up 85-90 percent of the volume of the mixture.

4.10.4.8 Duration of Subsea and Shoreline Oiling

The duration of the shoreline oiling is measured from initial shoreline contact until the well is capped or killed and the remaining surface oil dissipates offshore. Depending on the spill's location in relation to winds, ice, and currents and the well's distance to shore, oil could reach the coast within 10 days to 360 days based on BOEM oil spill trajectory analysis (MMS 2007, BOEMRE 2011). While it is estimated that the majority of spilled surface oil would evaporate and naturally disperse offshore within 30 days of stopping the flow or after meltout in the Arctic spring, some oil may remain in coastal areas until cleaned, as seen following the EVOS and DWH event (The State of Louisiana 2010a-d). The generation of oil suspended particulate material or subsurface plumes from the well head would stop when the well was capped or killed. Subsurface plumes would dissipate over time due to mixing and advection (Boehm and Fiest 1982).

4.10.4.9 Volume of Oil Reaching Shore

In the event of a VLOS, not all of the oil spilled would contact shore. The volume of oil recovered and chemically or naturally dispersed would vary. For example, the following are recovery and cleanup rates from previous high-volume, extended spills (Wolfe et al. 1994, Gundlach and Boehm 1981, Gundlach et al. 1983, Lubchenco et al. 2010):

- 10-40 percent of oil recovered or reduced (including burned, chemically dispersed, and skimmed);
- 25-40 percent of oil naturally dispersed, evaporated, or dissolved; and
- 20-65 percent of the oil remains offshore until biodegraded or until reaching shore.

[In the case of the DWH event] it is estimated that burning, skimming and direct recovery from the wellhead removed one quarter (25 percent) of the oil released from the wellhead. One quarter (25 percent) of the total oil naturally evaporated or dissolved, and just less than one quarter (24 percent) was dispersed (either naturally or as a result of operations) as microscopic droplets into Gulf waters. The residual amount— just over one quarter (26 percent)—is either on or just below the surface as light sheen and weathered tar balls, has washed ashore or been collected from the shore, or is buried in sand and sediments (Inter- agency 2010a). For planning purposes, USCG estimates that 5-30 percent of oil will reach shore in the event of an offshore spill (33 CFR Part 154, Appendix C, Table 2).

4.10.4.10 Length of Shoreline Contacted

While larger spill volumes increase the chance of oil reaching the shoreline, other factors that influence the length and location of shoreline contacted include the duration of the spill and the well's location in relation to winds, ice, currents, and the shoreline. As estimated from the OSRA model . . . the length of oiled shoreline increases over time as the spill continues (BOEMRE 2011: Table 6). Dependent upon winds and currents throughout the VLOS event, already impacted areas could have oil refloated and oil other areas increasing the estimates above.

A VLOS from a nearshore site would allow less time for oil to be weathered, dispersed, and/or recovered before reaching shore. This could result in a more concentrated and toxic oiling of the shoreline. A release site farther from shore could allow more time for oil to be weathered, dispersed, and recovered. This could result in a broader, patchier oiling of the shoreline.

4.10.4.11 Severe and Extreme Weather

Wind and wave action can drive oil floating on the surface into the water column, and oil stranded on shorelines can be moved into nearshore waters and sediment during storms. Episodes of severe and extreme weather over the Arctic could affect the behavior of sea-surface oil, accelerate biodegradation of the oil, impact shoreline conditions, and put marine vessels at risk. For instance, recovery of sea-surface oil could be impeded by the formation of sea ice during severe cold outbreaks that occur typically over the Arctic winter. In addition, episodes of severe storms characterized by strong winds (25 to 30 miles per hour) and precipitation can dictate the movement of sea-surface oil drift and also direct oil toward the coastline following a VLOS occurring during summer or winter. The severe storms, referred to as mesoscale cyclones (MCs), form when a cold air mass over land (or an ice sheet) moves over warmer open water (Nihoul and Kostianoy 2009). These storms are usually small-scale and short-lived; and the lower the atmospheric pressure in the storm center, the stronger the storm. More intense versions of MCs occur mainly during the Arctic winter when the lowest pressure polar mesoscale cyclones (PMCs) are associated with the semi-permanent Aleutian low. These storms can cause extreme weather conditions in areas near ice/ocean or land/ocean boundaries (Jackson and Apel 2004). While less common, these storms cover a larger area and can cause surface winds at or near gale force, up to 45 miles per hour, with waves [4.6 to 6 meters or] 15 to 20 feet. As such, a PMC is sometimes characterized as an arctic hurricane. Wind and wave action caused by these extreme storms can pose a risk to marine vessels, drive sea-surface oil into the water column, enhance weathering of the oil, or cause oil stranded on the coastline to move into nearshore waters and sediment. Any of these conditions could temporarily delay or stop the response and recovery effort.

4.10.4.12 Recovery and Cleanup

The hypothetical VLOS scenario outlined thus far for the Chukchi Sea would trigger an extensive spill recovery and cleanup effort. It is anticipated that efforts to respond to a VLOS in the Chukchi Sea would include the recovery and cleanup techniques and estimated levels of activities described below. A more detailed description of the available methods to respond to an oil spill is provided in the Arctic Multi-Sale Draft EIS, in Section 4.3.3.5.5 (USDOI, MMS, 2008a). It is noted that severe weather and/or the presence of ice could interfere with or temporarily preclude each of these methods. For a comprehensive summary report of the 31 Arctic oil spill response research projects that BOEM has funded, the reader is referred to a report called *Arctic Oil Spill Response Research and Development Program: A Decade of Achievement* which can be accessed at: http://www.bsee.gov/Research-and-Training/Technology-Assessment-and-Research/tarprojectcategories/MMSArcticResearch-pdf.aspx

In the event of a VLOS, two governmental organizations would assume prominent roles in coordinating response efforts: the Federal On-Scene Coordinator (FOSC) and the Alaska Regional Response Team (ARRT). The ARRT is an advisory board to the FOSC that provides federal, state, and local governmental agencies with means to participate in response to pollution incidents. During a response, the FOSC would consult with the ARRT on a routine basis for input regarding response operations and priorities. In addition to their advisory role during a response event, the ARRT is responsible for developing the Alaska Federal/State Preparedness Plan for Response to Oil and Hazardous Substance Discharges/Releases (Unified Plan) which details governmental incident response planning and responsibilities for the State of Alaska and 10 Subarea Contingency Plans that provide region-specific response planning information for establishing operations in the event of a major response effort to an oil spill or hazardous material release. The Subarea Contingency Plans identify notification requirements, emergency response command structures, response procedures, community profiles, in-region response assets, logistics guidance, spill scenarios that could be encountered in the region and sensitive areas identification along with geographic response strategies which provide suggested response actions to protect the resources at risk from a release of oil. For exploration activities in the Chukchi Sea, the North Slope Subarea Contingency Plan and the Northwest Arctic Subarea Contingency Plan are the applicable documents for addressing oil spill response in the region.

Mechanical Recovery. Both mechanical and non-mechanical methods of oil spill response can be utilized in the Chukchi Sea to mitigate the impacts of an oil spill on the environment. The preferred means of spill response is mechanical recovery of the oil, which physically removes oil from the ocean. Mechanical recovery is accomplished through the use of devices such as containment booms and skimmers. A containment boom is deployed in the water and positioned within an oil slick to contain and concentrate oil into a pool thick enough to permit collection by a skimmer. The skimmer collects the oil and transfers it to a storage vessel (storage barges or oil tankers) where it will eventually be transferred to shore for appropriate recycling or disposal.

Dispersants. Use of chemical dispersants is a response option for the Chukchi Sea. Research has shown that dispersants can be effective in cold and ice infested waters when employed in a timely manner (S.L. Ross Environmental Research Ltd., 2002, 2003, 2006, 2007; Belore 2003). Recently completed field scale tests conducted by Sintef (Sintef 2010) as part of the Oil in Ice Joint Industry Project (JIP) in the Barents Sea has demonstrated that results from lab scale and large wave tank tests hold true in actual ocean conditions. Oil released into the ocean during broken ice conditions was readily dispersed, and the dispersion was enhanced with the addition of vessel propeller wash for more energy in these conditions. It was also demonstrated that in these cold conditions, weathering of the oil was significantly slowed, providing a greater window of opportunity in which to successfully apply dispersants. Dispersant application can be accomplished by means of injection at the source or through aerial or vessel based application. There are dispersant stockpiles located in Prudhoe Bay, Anchorage, and the Lower 48 states [dispersants can be flown to Alaska from the Lower 48 if stockpiles are inadequate]. Dispersant use is limited to ocean application in waters generally deeper than 10 meters; this depth restriction is used to avoid or reduce potential toxicity concerns to nearshore organisms.

The State of Alaska does not have preapproved dispersant application zones for the Chukchi Sea, so each request for dispersant application would be evaluated and approved or disapproved on a case-by-case basis by the FOSC with the concurrence of the EPA representative to the RRT and, as appropriate, the concurrence of the RRT representative from the State of Alaska and COC and DOI natural resource trustees. The decision regarding how and when dispersants would be applied would also reside with the FOSC and the above listed agency representatives. Procedures governing the application of dispersants are provided in "The Alaska Federal and State Preparedness Plan for Response to Oil and Hazardous Substance Discharges and Releases" (Unified Plan) (ARRT 2010). However, the FOSC is not limited to this procedure and may utilize other sources of information in determining what the most appropriate dispersant method would be given a specific situation.

In-situ Burning. In-situ burning is also a viable response method for the Chukchi Sea and could be approved by the FOSC in consultation with the Unified Command and the above listed agency representatives. Any in-situ burning would be conducted in accordance with the Alaska Unified Plan In-situ Burn Guidelines (ARRT 2010). In-situ burning is a method that can be used in open ocean, broken ice, near shore, and shoreline cleanup operations. In broken ice conditions, the ice serves to act as a natural containment boom, limiting the spread of oil and concentrating it into thicker slicks, which aid in starting and maintaining combustion. In-situ burning has the potential to remove in excess of 90 percent of the volume of oil involved in the burn. In-situ burning experiments of oil in ice conducted as part of the Sintef JIP (Sintef 2010) has likewise demonstrated that cold temperatures serve to slow weathering of the oil, in turn expanding the window of opportunity for in-situ burning application over that experienced in more temperate regions.

Effect of Ice on Response Actions. For all response options, the presence of ice can both aid and hinder oil spill response activities. Ice acts as a natural containment device, preventing the rapid spread of oil across the ocean surface. It also serves to concentrate and thicken the oil, allowing for more efficient skimming, dispersant application, and in-situ burning operations. Once shore fast ice is formed, it serves as a protective barrier, limiting or preventing oil from contacting shorelines. Cold temperatures and ice will slow the weathering process by reducing volatilization of lighter volatile compounds of the oil, reducing impact of wind and waves, and extending the window of opportunity in which responders may utilize their response tools.

Conversely ice can limit a responder's ability to detect and locate the oil, access the oil by vessel, prevent the flow of oil to skimmers, require thicker pools to permit in-situ burning, and eventually encapsulate the oil within a growing ice sheet making access difficult or impossible. Once incorporated into the ice sheet, further recovery operations would have to cease until the ice sheet becomes stable and safe enough to support equipment and personnel to excavate and/or trench through the ice to access the oil. The other response option is embedding tracking devices in the ice and monitoring its location until the ice sheet begins to melt and the oil surfaces through brine channels at which time it could be collected or burned.

Levels of Recovery and Cleanup Activities. The levels of activities required to apply the techniques described above are dependent on the specific timing and location of a spill. As weather, ice, and logistical considerations allow, the number of vessels and responders would increase exponentially as a spill continues. The levels of activities described below are reasonable estimates provided as a basis for analysis. These estimates are based on Subarea Contingency Plans for the North Slope and Northwest Arctic subareas, past spill response and cleanup efforts, including the EVOS and DWH events, and the best professional judgment of BOEM spill response experts:

- Between five and 10 staging areas would be established;
- About 15 to 20 large skimming vessels (such as the Nanuq, Endeavor Barge, Tor Viking, other barges from Prudhoe Bay, USCG skimming vessels, vessels from Cook Inlet and Prince William Sound) could be used in offshore areas. The majority of open ocean vessels would be positioned relatively close to the source of the oil spill to capture oil in the thickest slicks, thus enabling the greatest rate of recovery;
- Thousands of responders (from industry, the federal government, private entities) could assist spill response and cleanup efforts as the spill progresses. Weather permitting, roughly 300-400 skimming, booming, and lightering vessels could be used in areas closer to shore. Based on the trajectory of the slick, shallow water vessels would be deployed to areas identified as priority protection sites;
- Booming would occur, dependent upon the location of the potentially impacted shoreline, environmental considerations, and agreed upon protection strategies involving the local potentially impacted communities. About 100 booming teams could monitor and operate in multiple areas;
- Use of dispersants and/or in-situ burning could occur if authorized by the FOSC. Use of dispersants would likely concentrate on the source of the flow or be conducted so as to protect

sensitive resources. In-situ burning operations would likewise be conducted in the area of thickest concentration to ensure the highest efficiency for the effort. In-situ burning may also be utilized in nearshore and shoreline response where approved by FOSC;

- Dozens of planes and helicopters would fly over the spill area, including impacted coastal areas. Existing airport facilities along the Arctic coast (including airports at Kotzebue, Point Hope, Point Lay, Wainwright, Barrow, and any other suitable airstrips) would be used to support these aircraft. If aircraft are to apply dispersants, they could do so from altitudes of [15 to 30.5 m or] 50 to 100 ft; and
- Workers could be housed offshore on vessels or in temporary camps at the staging areas.

Depending on the timing and location of the spill, the above efforts could be affected by seasonal considerations. In the event that response efforts continue into the winter season, small vessel traffic would come to a halt once the forming ice begins to cover the ocean surface. Larger skimming vessels could continue until conditions prevent oil from flowing into the skimmers. At this point, operations could shift to in-situ burning if sufficient thicknesses are encountered. The lack of daylight during winter months would increase the difficulties of response.

As ice formation progresses, the focus of the response would shift to placing tracking devices in the forming ice sheet to follow the oil as it is encapsulated into the ice sheet. Once the ice sheet becomes solid and stable enough, recovery operations could resume by trenching through the ice to recover the oil using heavy equipment. This would most likely occur in areas closer to shore because the ice will be more stable. In late spring and early summer, as the ice sheet rots, larger ice-class vessels could move into the area and begin recovery or in-situ burning operations as the oil is released from the ice sheet. The ice would work as a natural containment boom keeping the oil from spreading rapidly. As the ice sheet decays, oil encapsulated in the ice would begin surfacing in melt pools at which time responders will have additional opportunities to conduct in-situ burn operations. Smaller vessels could eventually re-commence skimming operations in open leads and among ice flows, most likely in a free skimming mode (without boom) along the ice edge.

While it is estimated that the majority of spilled oil on the water's surface would be dissipated within a few weeks of stopping the flow (Inter-agency 2010a) during open water or after meltout in the Arctic spring, oil has the potential to persist in the environment long after a spill event and has been detected in sediment 30 years after a spill (Etkin, McCay, and Michel 2007). On coarse sand and gravel beaches, oil can sink deep into the sediments. In tidal flats and salt marshes, oil may seep into the muddy bottoms (USFWS 2010g).

Effectiveness of intervention, response, and cleanup efforts depend on the spatial location of the blowout, leak path of the oil, and amount of ice in the area. For the purpose of analysis, effectiveness of response techniques is not factored into the spill volume posited by this scenario and considered during OSRA modeling.

4.10.4.13 Scenario Phases and Impact-Producing Factors

The events comprising the VLOS scenario are first categorized into five distinct phases. These phases, which range from the initial blowout event to long-term recovery, are presented chronologically. Within each phase are one or more components that may cause adverse impacts to the environment. These components are termed "Impact Producing Factors," or IPFs, and will be used later to guide the environmental impacts analysis. The specific IPFs listed here are intended to inform, rather than limit, the discussion of potential impacts.

4.10.4.13.1 Well Control Incident (Phase 1)

Phase 1 of the hypothetical VLOS scenario is comprised of the catastrophic blowout and its immediate consequences. Potential IPFs associated with Phase 1 include the following:

- **Explosion**. Natural gas released during a blowout could ignite, causing an explosion.
- **Fire**. A blowout could result in a fire that could burn for one to two days.
- **Re-distribution of Sediments**. A blowout could re-distribute sediment along the seafloor.
- **Sinking of Rig.** The drill rig could sink to the sea floor.
- **Psychological/Social Distress**. News and images of a traumatic event could cause various forms of distress.

4.10.4.13.2 Offshore Spill (Phase 2)

Phase 2 of the scenario encompasses the continuing release of an oil spill in federal and state offshore waters. Potential IPFs associated with Phase 2 include the following:

- **Contact with Oil**. Offshore resources (including resources at surface, water column, and sea floor) could be contacted with spilled oil.
- **Contamination**. Pollution stemming from an oil spill may contaminate environmental resources, habitat, subsistence resources, and/or food sources.
- **Loss of Access**. The presence of oil could prevent or disrupt access to and use of affected areas.

4.10.4.13.3 Onshore Contact (Phase 3)

Phase 3 of the scenario focuses on the continuing release of an oil spill and contact to coastline and state nearshore waters. Potential IPFs associated with Phase 3 include the following:

- **Contact with Oil**. Onshore resources could come into direct contact with spilled oil.
- **Contamination**. Pollution stemming from an oil spill may contaminant environmental resources, habitat, and/or food sources.
- **Loss of Access**. The presence of oil could prevent or disrupt access to and use of affected areas.

4.10.4.13.4 Spill Response and Cleanup (Phase 4)

Phase 4 of the scenario encompasses spill response and cleanup efforts in offshore Federal and State waters as well as onshore Federal, State and private lands along the coastline. Potential IPFs associated with Phase 4 include the following:

- **Vessels**. Vessels could be used in support of spill response and cleanup activities.
- **Aircraft**. Aircraft could be used in support of spill response and cleanup efforts.
- **In-situ burning**. Remedial efforts may include burning of spilled oil.
- **Animal Rescue**. Animals may be hazed or captured and sent to rehabilitation centers.
- **Dispersants**. Dispersants could be introduced into the environment.
- **Skimmers**. Boats equipped to skim oil from the surface.
- **Booming**. Responders could deploy booms—long rolls of oil absorbent materials that float on the surface and corral oil.

- **Beach cleaning**. Cleanup efforts including hot water washing, hand cleaning using oil absorbent materials, and placement and recovery of absorbent pads, could be used on beaches and other coastal areas contacted by an oil spill.
- **Drilling of Relief Well**. A relief well could be drilled by the original drilling vessel or by a second vessel with additional support.
- **Co-opting of resources**. Funds, manpower, equipment, and other resources required for spill response and cleanup would be unavailable for other purposes.
- **Bioremediation**. Contaminated material could be removed or treated by adding fertilizers or microorganisms that "eat" oil.

4.10.4.13.5 Post-Spill, Long-Term Recovery (Phase 5)

Phase 5 of the scenario focuses on the long-term. The exact length of time considered during this phase will vary by resource. Potential IPFs associated with Phase 5 include the following:

- **Unavailability of environmental resources**. Environmental resources and food sources may become unavailable or more difficult to access or use.
- **Contamination**. Pollution stemming from an oil spill may contaminate environmental resources, habitat, and/or food sources.
- **Perception of contamination**. The perception that resources are contaminated may alter human use and subsistence patterns.
- **Co-opting of human resources**. Funds, manpower, equipment, and other resources required to study long-term impacts and facilitate recovery would curtail availability for other purposes.
- **Psychological/Social Distress**. Distress stemming from a VLOS could continue into the long-term.

4.10.4.14 Opportunities for Intervention and Response

In providing a duration for the hypothetical oil spill described above, it is stated for the purposes of analysis that the discharge would cease within 74 days of the initial event. The use of 74 days corresponds to the longest of three time periods estimated for a second drilling vessel to arrive on scene from the far east and complete a relief well (see BOEMRE 2011: Table 3). This is a reasonable but conservative estimate because it does not take into consideration the variety of other methods that would likely be employed to halt the spill within this period. Moreover, specific exploration plans may include intervention and response methods that could control or contain the flow of oil sooner than 74 days. This point is illustrated by recent exploration plans submitted for the Alaska OCS, such as the Shell Gulf of Mexico, Inc. 2012 Revised Exploration Plan (EP) for leases in the Chukchi Sea (Shell 2011b). Between the Chukchi Sea Regional Exploration Oil Discharge Prevention and Contingency Plan (C-Plan) submitted with the EP application and this proposal contained measures including:

- Shell would use state-of-the-art automatic kick-detection equipment, including pit-volume totalizers, a flow detector, and various gas detectors placed about the rig, to provide early warning of a potential well-control event.
- The blowout preventer Shell would install on the high-pressure wellhead housing on the 20-in conductor casing on each exploration well includes redundant mechanical barriers to provide multiple means of closing in the well to prevent oil flow to the surface.
- Shell would install multiple barriers, including manual and automated valves, on the drilling rig to prevent flows from coming up the drill string.

- Shell has developed and would implement a Well Control Contingency Plan (WCCP) in the extremely unlikely event of a well-control event to minimize the risk of oil coming in contact with the water. As part of the WCCP, Shell would prepare a Relief Well Drilling Plan for each location in advance of spudding the well to ensure that a relief well can be started quickly to kill the well.
- Shell would station and maintain its OSRVs in the immediate vicinity of its drilling operations to ensure timely response to any spill event.
- In addition to the OSR fleet, capping stack equipment will be available for use in the unlikely event of a blowout. The capping stack system will be carried as equipment on an ice management vessel and the containment barge will be located in the Beaufort Sea where it can respond as required.
- Capping Stack equipment will be stored aboard one of the ice management vessels and will be available for immediate deployment in the unlikely event of a blowout. Capping Stack equipment consist of subsea devices assembled to provide direct surface intervention capability with the following priorities:
    - Attaching a device or series of devices to the well to affect a seal capable of withstanding the maximum anticipated wellhead pressure (MAWP) and closing the assembly to completely seal the well against further flows (commonly called “capping and killing”)
    - Attaching a device or series of devices to the well and diverting flow to surface vessel(s) equipped for separation and disposal of hydrocarbons (commonly called “capping and diverting”)

Potential intervention and response methods are qualitatively discussed below because their inclusion in individual exploration plans could serve to substantially decrease the duration, volume, and environmental effects of a VLOS. These methods are not mutually exclusive; several techniques may be employed if necessary. It may also be possible to pursue multiple techniques contemporaneously. Again, these opportunities for intervention and response could be employed prior to drilling a relief well and are not factored into the estimated spill duration as described in the VLOS scenario above. The availability and effectiveness of these techniques may vary depending on the nature of the blowout, as well as seasonal considerations, including the seasonal presence of sea ice.

Well Intervention. If a blowout occurred, the original drilling vessel would initiate well control procedures. The procedures would vary given the specific blowout situation, but could include:

- Activating blowout preventer equipment;
- Pumping kill weight fluids into the well to control pressures;
- Replacing any failed equipment to remedy mechanical failures that may have contributed to the loss of well control; and/or
- Activating manual and automated valves to prevent flows from coming up the drill string.
- These techniques cure loss-of-well-control events the vast majority of the time without any oil being spilled.

Natural bridging or plugging could also occur. These terms refer to circumstances where a dramatic loss of pressure within the well bore (as could occur in the event of a blowout) causes the surrounding formation to cave in, thereby bridging over or plugging the well. While natural bridging or plugging could render certain forms of operator-initiated well control infeasible, it could also impede or block the release of hydrocarbons from the reservoir from reaching the surface.

Containment Domes. In the event that well intervention is unsuccessful and the flow of oil continues, a marine well containment system (MWCS) could be deployed with associated support vessels. The design for a MWCS specific to Arctic operations is currently in progress and will be required to receive BOEM review under future permitting activities. The MWCS is anticipated to provide containment domes, well intervention connections, remotely operated vehicle capabilities, barge with heavy lift operations, separation equipment, and oil and gas flaring capabilities.

Relief Wells. If the above techniques are unavailable or unsuccessful, a relief well could be drilled. The relief well is a second well, directionally drilled, that intersects the original well at, near, or below the source of the blowout. Once the relief well is established, the operator pumps kill weight fluids into the blowout well to stop the flow and kill the well. Both wells are then permanently plugged and abandoned.

Some exploratory drilling vessels are capable of drilling their own relief well. Mobile Offshore Drilling Units, or MODUs, can disconnect from the original well, move upwind and up current from the blowout location, and commence the drilling of a relief well. Bottom-founded vessels are by definition not capable of maneuvering in this manner.

Second Vessel. Should the original drilling vessel sustain damage or prove otherwise incapable of stopping the blowout, a second vessel could be brought in to terminate or otherwise contain the blowout. A second vessel, with support from additional vessels as needed, could employ similar techniques to those described above. The time required by a second vessel to successfully stop the flow of oil must factor in the time needed for travel to the site of the blowout. The location of a second vessel is thus critical when considering a scenario in which same vessel intervention or response is unavailable. The estimate used in the VLOS scenario described above conservatively allots 30 days for transporting a second vessel across the Pacific Ocean. The availability of a second vessel in-theater (within the Chukchi Sea or possibly the Beaufort Sea) or on site would substantially reduce transport time and, therefore, the time needed for successful intervention. This could equate to shorter spill duration and smaller overall spill volume.

As previously mentioned, the availability and/or effectiveness of certain response and intervention techniques can depend on the type and exact location of the blowout. Five major distinctions with respect to the specific location of a blowout are important to consider. A blowout and leak could occur: (1) at the sea surface (but the rig is not destroyed or sunk on location), (2) along the riser anywhere from the seafloor to the sea surface, (3) at the seafloor through leak paths on the BOP/wellhead, (4) below the seafloor, outside the wellbore, or (5) at the sea surface (but the rig is destroyed and sinks at the location). Opportunities for operational intervention and response vary in each of these circumstances (BOEMRE 2011: Table 6).

4.10.5 VLOS Scenario for the Beaufort Sea

The 2012-2017 OCS Oil and Gas Leasing Program Final Programmatic EIS (BOEM 2012) contains the first post-DWH event scenario for the Beaufort Sea. Summaries of this information are provided in the resource discussions below. As allowed for by CEQ regulations in §1502.21, NMFS has incorporated the information presented in the BOEM Final Programmatic EIS (2012) into this EIS by reference.

Arctic Risk Profile. An ongoing concern in the Arctic is the environmental effects of a very large oil spill on sensitive marine and coastal habitats that occur there within a land sea-ice biome that supports a traditional subsistence lifestyle for Alaska native populations and provides important habitats for migratory and local faunal populations. The ability to respond to and contain a very large discharge event under the extreme climatic conditions and seasonal presence of ice is of particular concern.

Loss of Well Control. While some formation properties of the Arctic OCS are expected to have pressures, temperatures, and volumes sufficient to produce a discharge that could result in catastrophic consequences, drilling risks associated with these formation characteristics are not directly related to issues of extreme cold and presence of ice. Instead, the fact that the Arctic OCS is largely a frontier geologic province contributes risk to Arctic drilling operations (USGS 2011).

Human error while working under extreme weather conditions on the Arctic OCS could increase the risk of loss of well control in certain circumstances where established procedures are not followed. However, when accounting for other Arctic specific variables, the incident rate of loss of well control is expected to be lower than for exploration and development operations in the GOM (Bercha et al. 2008).

To address some of the risk inherent in Arctic operations, the BOEM regulations include specific requirements for conducting operations in the Arctic, such as locating the BOP in a well cellar (a hole constructed in the sea bed) to position the top of the BOP below the maximum potential ice gouge depth, using special cements in areas where permafrost is present, enclosing or protecting equipment to assure it will function under subfreezing conditions, and developing critical operations and curtailment procedures which detail the criteria and process through which the drilling program would be stopped, the well shut in and secured and the drilling unit moved off location before environmental conditions (such as ice) exceed the operating limits of the drilling vessel.

Containment and Response. Much of risk from a catastrophic event that is particular to the extreme climate of the Arctic is associated with containment and response issues at the well site. The time needed to drill a relief well in the Beaufort Sea under the scenario varies from 60 to 300 days depending on the timing of the event relative to the ice free season, since the well site may become inaccessible when solid or broken ice is present. During that time, the ability to mount effective containment and response efforts under broken or solid ice conditions is a critical factor.

Fate and Consequence. Response away from the well site could also be hindered and/or aided by broken and solid ice. In addition, some options available to manage fates of spills have not been previously used in larger-scale operations the Arctic to fully evaluate their effectiveness, such as burning and dispersant use, although state-of-the art research on these response techniques suggest they could decrease the volume of oil in the water (SINTEF 2010).

In summary, the Catastrophic Discharge Scenarios developed for the Beaufort Sea estimates a discharge rate of 1.7 to 3.9 Mbbl over a duration of 60 to 300 days. Factors affecting duration are timing of the event relative to the ice free season and/or the availability of a rig to drill a relief well. The foundation for the analysis in Section 4.10.7 of this EIS is taken from the 2012-2017 OCS Oil and Gas Leasing Program Draft Programmatic EIS (BOEM 2011), which contains the first post-DWH event scenario for the Beaufort Sea. Summaries of this information are provided in the applicable resource discussions below. As allowed for by CEQ regulations in §1502.21, NMFS has incorporated the information presented in the Draft Programmatic EIS (BOEM 2011d) into this EIS by reference.

Summaries of information from the former MMS (now BOEM) Final Environmental Impact Statement (FEIS) for the Beaufort Sea Planning Area Oil and Gas Lease Sales 186, 195, and 202 (MMS 2003) are also provided in this EIS where applicable.

4.10.6 Chukchi Sea – Analysis of Very Large Oil Spill Impacts

The foundation of the analysis provided in Section 4.10.6 of this EIS is taken from the BOEM (2011b) analysis for Lease Sale 193. Summaries of this information are provided in the resource discussions below. As allowed for by CEQ regulations in §1502.21, NMFS has incorporated the information presented in the BOEM FSEIS into this EIS by reference. The specific sections from BOEM (2011b) that are referenced in this EIS are noted in the sections below. BOEM (2011b) is available online at: http://www.boem.gov/ak-eis-ea. Additional information pertinent to this project is presented in each resource section as well. The information taken from BOEM (2011b) is identified as "Existing Analysis," and the analysis beyond what was presented in that document is listed as "Additional Analysis."

The scenario in BOEM (2011b) is substantially similar to the discussion presented in the 2012-2017 OCS Oil and Gas Leasing Program Final Programmatic EIS (BOEM 2012). NMFS has incorporated the information presented in the BOEM Draft Programmatic EIS into this EIS by reference. The specific sections from BOEM (2011e) that are referenced in this EIS are noted in the sections below.

4.10.6.1 Physical Oceanography

4.10.6.1.1 Existing Analysis (BOEM 2011b and BOEM 2012)

BOEM uses an OSRA (Oil Spill Risk Analysis) model to simulate estimated oil spill trajectories; in other words, the OSRA model is a method for estimating where a VLOS may go. Input for the OSRA model includes calculated values of wind, ice, currents, vectors, and numerous other physical, social, and economic parameters. A summary of the OSRA model structure, input, and output are provided in Section IV.E.1 of BOEM (2011b), and are incorporated here by reference.

Section 4.2.3.2 of the BOEM (2012) analysis describes the effects of sea ice and currents on the movement and weathering of spilled oil in the Beaufort Sea planning area. This information is incorporated herein by reference.

4.10.6.1.2 Additional Analysis for Physical Oceanography

Phase 1 (Initial Event)

Impact producing factors associated with a well control incident, such as explosion, fire, and redistribution of sediment would have minor effects on physical ocean resources within the EIS project area. Uncontrolled combustion of petroleum hydrocarbons in the environment would result in an increase in water temperature in the immediate vicinity of the fire. It is difficult to quantify the increase in water temperature that would result from fire associated with a well control incident, but it is likely that the geographic extent of changes in water temperature would be limited to areas immediately adjacent to the fire, and the duration of such thermal effects would be temporary. Redistribution of seafloor sediments would have minor impacts on the seafloor topography in the immediate vicinity of the well control incident. Although effects resulting from redistribution of seafloor sediment would likely be permanent, the intensity of the effects would be low and the geographic extent would be limited. Sinking of the drilling rig to the sea floor would effectively create an artificial reef (BOEM 2011b), which would have permanent, local, low-intensity effects on the physical character of the EIS project area. If the rig were to sink in shallow water it could be considered a navigational hazard. Overall, effects of the initial well control incident on the physical character of the EIS project area would be minor.

Phase 2 (Offshore Oil)

Oil in the water from a VLOS event would affect the physical character of the sea surface in the EIS project area. An oil slick covering hundreds of square kilometers of ocean surface would influence ocean-atmosphere interactions, including exchange of gasses across the air-water interface and the generation of wind driven waves in the affected area. The presence of an oil slick at the sea surface would impede normal gas exchange across the air-water interface, but the impacts of such effects would likely be surpassed by the release of large quantities of methane, ethane, propane and other hydrocarbon gasses into the water column (Kessler et al. 2011). The natural gas mixture released into the water during a VLOS event would have temporary effects on the dissolved gas content of seawater in the affected area. The fate and effects of dissolved hydrocarbons are discussed in more detail in Section 3.1.7 (Water Quality) and Section 3.1.8 (Ecosystem Processes) of this EIS. The presence of an oil slick at the sea surface would likely lead to decreases in the magnitude of wind-driven waves in the affected area. Effects on waves resulting from a VLOS would be low intensity, local, and temporary. Such effects would decrease concurrently with clean-up or partitioning of the oil into environmental compartments other than the sea surface. Due to limited water depths on the Chukchi Sea shelf, most fractions of the released oil would float to the surface, and effects on the physical character of pelagic and epibenthic zones would be expected to be minor during this phase of the VLOS. However, effects of an oil slick on the viscosity of the sea surface would be high-intensity and regional. The sea surface could be considered an important physical resource within the EIS project area because of its critical role in myriad chemical, physical, and biological processes. Due to the viscosity and stickiness of spilled oil, the overall effects of offshore oil on the physical character of the ocean would be major. In addition, an oil slick would effectively decrease the freezing point of the affected seawater and may have impacts on the formation of sea ice in affected areas.

Phase 3 (Onshore Contact)

Spilled oil could adhere to the shoreline and affect the composition of beach substrates by creating oil and sediment conglomerates.

Phase 4 (Spill Response and Cleanup)

Spill cleanup operations could have adverse impacts on the physical character of the ocean and shoreline. Minor impacts due to differential shoreline erosion would be possible if the removal of contaminated substrates affects beach stability.

In situ burning of oil would result in high-intensity effects on sea surface temperature, but these effects would be temporary and spatially limited to the area of *in situ* burning operations. The use of dispersants would effectively move the impacts associated with spilled oil from the sea surface into the water column. Dispersed oil in the pelagic environment would affect the density and viscosity of the water, but these effects would be low-intensity and would decrease as the dispersed oil is weathered, diluted, and degraded.

Phase 5 (Long-term Recovery)

Long-term direct effects on the physical character of the ocean would be negligible. Oil is a mixture comprised mostly of volatile and hydrophobic compounds. As a result of its volatility and hydrophobicity, oil has a strong tendency to associate with non-aqueous phase materials. Oil associated with solid phase particles may remain on beaches and in sediments on the sea floor for extended periods of time, but the long-term effects of weathered oil in the environment are expected to be related to the chemical properties and potential toxicity of certain hydrocarbon compounds.

Conclusion

The overall effects of the VLOS on the physical character of the ocean would initially be high-intensity due to the viscosity and stickiness of oil floating at the sea surface. The duration of these impacts would be limited by the properties of oil that cause it to associate with non-aqueous phase materials. If *in situ* burning is used as a response technique, high-intensity short term impacts would occur to the physical character of the sea surface. The overall effects of the VLOS on the physical character of the ocean in the EIS project area would be high-intensity, temporary, and would affect an area of hundreds of square kilometers. Such effects are classified as moderate due to their high-intensity and temporary duration.

4.10.6.2 Geology

The geology of the continental shelf and OCS within the EIS project area is discussed in Section 3.1.3 of this EIS. For the purpose of this EIS, geological processes would not be altered by a VLOS; therefore geology as a resource is not carried forward for analysis in Chapter 4. In addition, naturally occurring phenomena like ice gouging and strudel scouring would not likely be affected by a VLOS, nor would these phenomena be expected to significantly affect response to a VLOS.

4.10.6.3 Climate and Meteorology

<u>4.10.6.3.1 Existing Analysis (BOEM 2011b and BOEM 2011d)</u>

Discussions on GHG emissions from BOEM (2011b, 2011e) can be found in Section 4.10.6.4 (Air Quality) of this EIS.

4.10.6.3.2 Additional Analysis for Climate and Meteorology

A VLOS within the U.S. Chukchi Sea has the potential to impact climate change, especially during Phases 1 (Initial Event) and 4 (Spill Response and Cleanup) of the oil spill scenario.

During Phase I of a VLOS, the fire associated with the initial explosion of gas and oil would emit CO_2 and black carbon. CO_2 is a GHG, and its emissions have been linked to climate change. Black carbon, which could result from soot particles as a consequence of the initial fire, could have a warming effect which could lead to accelerated melting of sea and land ice and snow, also called radiative forcing. This is due to reflective ice and snow being covered by the blackness of black carbon, which has a greater ability to absorb heat rather than reflect it (BOEM 2011b). Section 4.10.6.4 (Air Quality) of this EIS has more information on black carbon and radiative forcing.

During Phase 4, impacts to climate change would be associated with in-situ burning and emissions from cleanup response equipment. In-situ burning would result in a plume of black smoke containing air pollutants including CO_2. The use of offshore vessels, aircraft, and surface vehicles used for removal of spilled oil and support of oil removal operations could result in thousands of tons of air pollutants including the GHG, CO_2 (BOEM 2011b).

During Phase 5, support vessels may be required to assist in a long-term recovery effort which would emit CO_2. Emissions from this phase are expected to be lower than those resulting from Phases 1 and 4 (BOEM 2011b).

The magnitude of impacts is a function of the mass of GHGs and amount of reflective surface covered by heat absorbing black carbon. Although these values are not specifically quantified, it is surmised that the magnitude would be largest in Phase 4 for GHG emission and Phase 1 for radiative forcing. The magnitude of effects associated with radiative forcing would also depend on the amount of daylight and amount of ice and snow present that could be covered by black carbon. Since CO_2 emissions and black carbon deposition resulting from a VLOS would occur in a relatively short timeframe, the magnitude of effects is expected to be less than those associated with the actual oil exploration activities (see Section 4.5.1.2).

The duration of actual activities leading to climate change impacts (deposition of black carbon and CO_2 emissions) would be short-term or temporary, however, as mentioned in Section 4.5.1.2, GHGs could remain in the atmosphere for decades up to centuries, and their effects are considered long-term.

Extent of impacts to climate change would be the same as those identified for the actual oil exploration activities (Section 4.5.1.2), and therefore would be considered at a minimum state-wide but could extend beyond state boundaries.

The context of the impacts associated with climate change would be the same as those identified for the actual oil and gas exploration activities (Section 4.5.1.2), and are considered to be unique.

As mentioned in Section 4.4.1.2 of this EIS, any activity emitting GHGs would be expected to contribute to an increase in global warming which, in turn, is believed to contribute to climate change. Direct impacts of a VLOS are assumed to be minor, due to their low magnitude and low contribution to GHG emissions on a state level. Indirect effects are considered minor to moderate, since the outcome of activities associated with a VLOS could lead to a greater continued increase in GHG emissions which is not in alignment with the goal to reduce GHG sources and emissions in an effort to minimize impacts to global climate change.

4.10.6.4 Air Quality

4.10.6.4.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

Section IV.E.3 of BOEM (2011b) describes potential impacts to air quality during the five phases of a possible VLOS within the U.S. Chukchi Sea Planning Area. This information is incorporated herein by reference, and a summary of that information is provided here.

A VLOS could emit large amounts of regulated potentially harmful pollutants into the atmosphere. This will cause major air quality impacts during some phases of the event. The greatest impacts to air quality conditions would occur during Phase 1 and Phase 4, particularly if the spill occurs in the winter. Impacts continue for days during Phase 1 but could continue for months under Phase 4. Therefore, while the impacts are estimated to be major during these two phases, the emissions from the VLOS would be temporary and over time, air quality in the Arctic would return to pre-oil-spill conditions.

Likewise, Section 4.4.4.3.2 of the BOEM (2011e) analysis provides an analysis of the impacts of a catastrophic discharge event on air quality in the Chukchi Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that evaporation of oil from a catastrophic discharge event, and emissions from spill response and cleanup activities including in situ burning, if used, have the potential to affect air quality in Arctic Alaska. The greatest impacts on air quality would occur during the initial explosion of gas and oil and during spill response and clean up, particularly if the event occurs during the winter. Impacts could continue for days during the initial event and could continue for months during spill response and clean up. Therefore, while the impacts may be large during these two phases, overall, the emissions from a catastrophic discharge event would be temporary and, over time, air quality in Arctic Alaska would return to pre-oil spill conditions (BOEM 2011d).

4.10.6.4.2 Additional Analysis for Air Quality

The magnitude of pollutant emissions and resultant impact levels are the two basic measurements for assessing the level of effects of a project on air quality. The potential magnitude for pollutant emissions is greatest during both Phase 1 of the spill scenario (initial explosion emissions of PM and combustion products) and Phase 4 of the spill scenario (spill response and cleanup using large amounts of fuel burning equipment). Both of these phases have the potential for large amount of emissions which could have a major effect on air quality, at least during the event and in the vicinity of the emissions.

The duration of air pollution impacts is dependent on several factors, including duration of the emissions from the source, meteorological conditions (wind), and chemical transformations for specific pollutants. In general, there are no long-term, recurring effects from short-term releases, such as those associated with any of the potential VLOS phases. The expected short-term or temporary period of emissions from any of the phases indicates that the overall effects on air quality would also only be temporary and therefore considered minimal to moderate, even for phases with larger magnitudes of emissions.

The extent of air pollution impacts is dependent on several factors, including source location, duration of the emissions, and meteorological conditions. Increases in levels of air pollutants at different distances are attributed to the type of emissions, which are covered by the magnitude indicator. Typically, as a potential VLOS evolves, direct emissions from the spill itself are rapidly dissipated. The extent of emissions from Phase 4 activities may be more spread out, however the effects of this on overall air quality are expected to be only minimal to moderate as there would not be large concentrations of equipment emissions over the full extent of a potential spill.

As discussed in Section 3.1.5.2, there are no Class I air quality designations in or around the EIS project area. The potential for VLOS-related air quality effects at unique or sensitive locations would be attributed to Phase 4 activities, where equipment may be staged. Staging activities would include equipment transport and is expected to have low emissions and only a short-term occurrence. Therefore, the context of air quality effects is expected to be minimal.

Conclusion

Impacts to air quality resultant from a VLOS could be of minimal to moderate extent and duration, due to the short-term or temporary time frame when emissions would be strongest associated with the spill. There are no Class I air quality designations in or around the EIS project area, and overall effects on air quality would be temporary. Therefore, according to the criteria laid out in Section 4.1.3, the summary impact level could be minimal.

4.10.6.5 Acoustics

4.10.6.5.1 Existing Analysis (BOEM 2011d)

Section 4.4.5.4.2 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on the acoustic environment in the Chukchi Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The BOEM analysis concludes that the pressure wave and noise generated from an incident involving a loss of well control would affect marine mammals and could be large enough to harass or disturb them if they were close enough to the site of the event. In addition, accident response and support activities, including support aircraft and vessel activity, have the potential to cause noise impacts. These impacts would occur both at the site of the response activity and along the routes of support vessels and aircraft. The duration and magnitude of the impacts would depend on the volume, location, duration, and weather conditions during the catastrophic discharge event, and the response and cleanup activities (BOEM 2011d).

4.10.6.5.2 Additional Analysis for Acoustics

In the event of a VLOS, the acoustic environment could be changed by noise generating sources associated with the initial well control incident and with the subsequent cleanup effort.

Impact producing factors associated with the initial well control incident such as explosion and fire would have minor effects on the acoustic environment within the EIS project area. Although quantitative estimation of the sound pressure levels (SPLs) associated with an explosion is difficult, initial effects on the acoustic environment could be high-intensity. However, these effects would be restricted to areas in the immediate vicinity of the well control incident, and would be extremely temporary. Due to the limited geographic extent and temporary nature of the impacts, overall effects of the initial well control incident on the acoustic environment would be considered minor.

Increases in aircraft and vessel traffic associated with oil spill cleanup activities would result in impacts to the acoustic environment similar to those described in Section 4.5.1.4 of this EIS under 'Acoustic Footprints of Non-Airgun Sources.' Aircraft are used extensively during oil spill response to map and track real-time oil spill extent, to coordinate spill clean-up operations, to track marine wildlife affected by oil, and for deployment of dispersants. Fixed wing aircraft would typically be used for many of the more-offshore operations due to their extended flight capabilities. Helicopters would be used for near-shore operations and for personnel transport from shore to-and-from offshore vessels both near-shore and further offshore. Aircraft sounds are dominated by tonal harmonics of engine/turbine and blade rates and are largely within the frequency range of cetacean hearing. Due to limited sound transmissibility from air to water, except at steep incidence angles, aircraft underwater noise levels are low relative to vessel noise outside limited areas beneath the aircraft. The level of aircraft noise reaching the sea surface and transmitting into the water depends on the aircraft flight altitude and flight speed, with higher received levels at low flight altitudes and increased flight speed. Because aircraft travel at high speeds, the duration of aircraft noise events is typically just a few tens of seconds (Patenaude et al. 2002). However, aircraft involved in oil spill response duties may circle or remain in limited areas and thereby produce more prolonged noise than would straight-line flight paths.

Oil spill response would involve multiple vessels, including vessels for deploying booms, floating storage vessels, DP platforms for wellsite mechanical repair, observation vessels, drillships, tugs personnel transfer vessels and icebreakers. A response operation in the Chukchi or Beaufort seas could be limited to pre-purposed vessels due to the large amount of time required for other vessels to transit into the arctic. Section 4.5.1.4 provides information on the noise footprints of several vessel types. Standard support vessels could produce 120 dB re 1 µPa sound levels to distances near 1.6 km (1 mi) (see Table 4.5-12). Vessels or drillships on DP would produce higher noise emissions and would consequently have larger noise footprints with 120 dB re 1 µPa zones extending up to 10 km (6.2 mi) from the vessel. Ice breaking vessels would also produce high levels of sound due mainly to the very high thrust required to drive the vessel onto ice being broken. Icebreaker sound levels may be similar to or greater than large vessels on DP. Cosens and Dueck (1993) measured sound levels of three icebreakers during icebreaking activity. The measurements at 0.4 and 0.5 km range showed peak spectral levels near 110 dB re 1 $\mu Pa^2/Hz$ between 25 and 50 Hz. The broadband sound levels were not provided.

Impacts on the acoustic environment associated with spill response and cleanup would be medium-intensity, temporary, and regional. Due to the intensity, duration, and geographic extent associated with these impacts, the overall effects of spill response and cleanup on the acoustic environment would be considered moderate. In addition, impact producing factors associated with a VLOS could include the drilling of a relief well, which would result in effects on the acoustic environment similar to those described in Section 4.5.1.4 of this EIS.

4.10.6.6 Water Quality

4.10.6.6.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

Section IV.E.2 of BOEM (2011b) describes potential impacts to water quality resources during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

A VLOS and gas blowout would present sustained degradation of water quality from hydrocarbon contamination in exceedence of state and federal water and sediment quality criteria. These effects would be significant. Additional effects on water quality would occur from response and cleanup vessels, in-situ burning of oil, dispersant use, discharges and seafloor disturbance from relief well drilling, and activities on shorelines associated with clean-up, booming, beach cleaning, and monitoring.

Likewise, Section 4.4.3.3.2 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on water quality in the Chukchi Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event in either coastal or marine waters could present sustained degradation of water quality from hydrocarbon contamination in exceedence of state and federal water and sediment quality criteria, and that these effects could be significant depending upon the duration and area impacted by the spill. Additional effects on water quality could occur from response and cleanup vessels, in situ burning of oil, dispersant use, discharges and seafloor disturbance from relief well drilling, and activities on shorelines associated with cleanup, booming, beach cleaning, and monitoring (BOEM 2011d).

4.10.6.6.2 Additional Analysis for Water Quality

The effects of a 2.2 MMbbl oil spill on water quality in the Chukchi Sea would include sustained exceedences of state and federal water quality criteria due to the introduction of large quantities of petroleum hydrocarbons and associated compounds to the environment. The magnitude of the effects of a VLOS on water quality in the Chukchi Sea could be high. The duration of such effects could be long-term, and the geographic extent of the effects could be either regional or state-wide depending on the specific launch area, meteorological conditions at the time of the spill, and effectiveness of the response effort. Chemical response techniques, such as the use of dispersants, could result in additional degradation of water quality, which may or may not offset the benefits of dispersant use. Although water is generally considered a common resource, a VLOS could impact water quality in sensitive areas that are protected by legislation. Overall, a VLOS could have major effects on water quality in the Chukchi Sea.

4.10.6.7 Environmental Contaminants and Ecosystem Functions

4.10.6.7.1 Existing Analysis (BOEM 2011d)

Section 4.4.6.2.4 of the BOEM (2011e) analysis provides some information about the impacts of a catastrophic discharge event on ecosystem functions in the Chukchi Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The BOEM analysis states that sensitive benthic habitats could suffer long-term loss of ecological function because of both hydrocarbon toxicity and the subsequent cleanup activities. Hydrocarbons could persist at sublethal concentrations in sediments for decades, and sensitive habitats (i.e., kelp beds, intertidal zones; live-bottom and coral reef) damaged by a spill would likely recover slowly and possibly not recover at all. However, hydrocarbons would be broken down by natural processes, and most benthic habitats are likely to eventually recover. Pelagic habitats would eventually recover their habitat value as hydrocarbons broke down and were diluted. Recovery time would vary with local conditions and the degree of oiling. Overall, impacts on habitats from accidental hydrocarbon spills in open water could range from negligible to moderate, and impacts could be short term to long term; no permanent degradation of pelagic habitat would be expected (BOEM 2011d).

4.10.6.7.2 Additional Analysis for Environmental Contaminants and Ecosystem Functions

For the purposes of this section, ecosystem functions refer to the capacity of natural components and processes to provide goods and services that satisfy human needs directly or indirectly (DeGroot et al. 2002).

This section uses a typology for four classes of ecosystem functions proposed by DeGroot et al. (2002) to describe potential impacts that could occur to ecosystem functions as a result of a 2.2 million barrel oil spill in the Chukchi Sea. These classes include: regulation functions; habitat functions; production functions; and information functions, and were defined in Chapter 3, Section 3.1.8.

Phase 1 (Initial Event)

Regulation Functions

Impact producing factors resulting from the initial well control incident such as fire and explosion would have local effects on the ability of natural systems to maintain essential ecological processes. Inputs of heat and petroleum hydrocarbons would inhibit the use of water and nutrients by some organisms. The dampening capacity of the ecosystem in response to perturbation (i.e. resilience) would be overwhelmed in the immediate vicinity of the event. Trophic interactions would be disrupted, and the role of biota in the storage and cycling of nutrients would be perturbed in the vicinity of the event.

Release of large quantities of ethane, propane, and other hydrocarbon gasses into the water column would result in increased levels of respiration in microbial communities (Valentine et al. 2010). In response to perturbation, the respiration to biomass ratio (R/B) would increase, and production to respiration ratios (P/R) would decrease (Odum 1985). Efficiency of trophic transfers would decrease as a result of the initial well control incident. Valentine et al. (2010) reported oxygen depletion in plumes of oil and gas subsequent to the Deepwater Horizon oil spill caused by increased microbial respiration driven by hydrocarbon gasses. Propane and ethane were the primary drivers of microbial respiration in the plumes, resulting in local depletion of dissolved oxygen in the water. Low-diversity bacterial blooms resulted from biodegradation of some hydrocarbon fractions. Decreased diversity of microbial communities and reduced energy flow at higher trophic levels could be expected to occur in response to the initial well control incident (Valentine et al. 2010, Odum 1985).

Habitat Functions

Effects of the initial well control incident on habitat functions would be localized and high intensity. Spawning and refuge habitat functions would be affected for most communities in the immediate vicinity of the well control incident. The effects could be adverse with regard to habitat functions for most multi-celled organisms. However, the initial well control incident may have positive effects on habitat functions for bacteria with the ability to metabolize short-chain hydrocarbons (Valentine et al. 2010).

Production Functions

The initial well control incident would have both beneficial and adverse effects on production functions related to conversion of energy and nutrients into biomass. Levels of photosynthesis would likely decrease in the immediate vicinity of the event due to releases of heat and hydrocarbon compounds into the environment. In contrast, respiration would likely increase at the microbial level as a result of increased temperatures and bioavailability of carbon in the vicinity of the well control incident. Subsequent to the Deepwater Horizon oil spill, Hazen et al. (2010) reported enrichment of communities of hydrocarbon degrading bacteria in the vicinity of the oil spill. Metabolism of hydrocarbons would signify increased respiration in response to perturbation, and some measureable increases in biomass would likely occur in the vicinity of a VLOS in the Chukchi Sea. However, it is unlikely that the energy from hydrocarbons incorporated into lower trophic level organisms would be available for utilization by primary and secondary consumers due to toxic effects of petroleum hydrocarbon compounds at higher trophic levels (Peterson et al. 2003). Thus, the length of the food chain (or complexity of the food web) would decrease in response to inputs of oil and gas. Although some hydrocarbon compounds would be utilized as nutrients at lower trophic levels, flows of energy and nutrients would decrease at higher trophic levels in response to physical and chemical stress on primary and secondary consumers.

Information Functions

The effects of the initial well-control incident on information functions in the Chukchi Sea ecosystem would be related to impacts on social and cultural systems, and on human health, all of which are addressed in this EIS (see Sections 4.5.3.2 for Subsistence and 4.5.3.3 for Public Health).

Phase 2 (Offshore Oil)

Regulation Functions

Efficiency of trophic transfers would be impacted across regional scales. Hundreds of square kilometers of ocean area would be affected. Changes in the microbial community structure would occur in the oiled area. While populations of some bacteria would increase in response to the presence of offshore oil, transfer of nutrients and biomass to higher trophic levels would be impeded as a result of stress and physical effects on primary and secondary consumers. Species diversity would decrease in the affected area, resulting in decreases in food web complexity (Odum 1985).

It is likely that gas regulation functions (CO_2/O_2 balance) and climate regulation functions would be impacted (Kessler et al. 2011). Oxygen depletion was observed in large areas of the Gulf of Mexico as a result of metabolism of hydrocarbons released during the Deepwater Horizon oil spill (Valentine et al. 2010, Kessler et al. 2011). Although the impacts of this oxygen depletion are not likely to be measureable in the atmosphere, oxygen depletion would be likely to affect marine ecosystems in the Chukchi Sea. In addition, perturbation of the Chukchi Sea ecosystem could inhibit the growth of phytoplankton that produce dimethyl sulfide and other climate regulating gasses. Functions related to maintenance of water quality and assimilation of wastes would be adversely affected as a result of offshore oil and gasses released during a VLOS.

Habitat Functions

The effects of offshore oil on habitat functions would be high-intensity and regional in scale. Spawning and refuge habitats would be affected for most communities in the vicinity of the well control incident.

Production Functions

Offshore oil would have adverse effects on production functions in the Chukchi Sea. Photosynthesis would be limited by both a decrease in availability of light, as well as by chemical inhibition, both of which would result from exposure of primary producers to large quantities of petroleum hydrocarbons. Low concentrations of petroleum hydrocarbons could have a stimulatory effect on photosynthesis in some species of marine algae; however, photosynthesis would be inhibited at higher concentrations (Chan and Chiu 1985).

The effects of offshore oil on production functions associated with subsistence and cultural resources are discussed in other sections of this EIS.

Information Functions

The effects of offshore oil on information functions in the Chukchi Sea ecosystem would be related to impacts on social and cultural systems, and on human health, all of which are addressed in other sections of this EIS.

Phase 3 (Onshore Contact)

Regulation Functions

For planning purposes, the USCG estimates that 5 to 30 percent of the spilled oil (110,000 to 660,000 bbl) would reach the shore in the event of an offshore VLOS (BOEM 2011b). Coastlines, and especially coastal wetlands, are important areas for regulation functions, such as nutrient cycling, water regulation, and soil retention, and these areas generally support higher levels of biodiversity and species richness relative to either offshore or other onshore areas. Onshore contact of spilled oil would have adverse effects on regulation functions by impacting coastal biological communities and changing the natural patterns of nutrient cycling, water regulation, and soil retention to which biological communities are adapted.

Habitat Functions

Physical and chemical changes to the shoreline environment would impact spawning and refuge habitat functions for all shoreline communities; these impacts are discussed in other sections of this EIS.

Impacts to coastal wetlands, tidal flats, and sheltered beaches would generally be greater than impacts to exposed gravel or cobbled beaches (Gundlach and Hayes 1978), and the relative sensitivities of different shoreline types would be a consideration in establishing response priorities subsequent to a VLOS.

Production Functions

Impact producing factors associated with oil on the shoreline, such as contact with coastal wetlands and vegetation, would have long-term adverse effects on production functions. Marine algae and coastal vegetation respond variably to petroleum hydrocarbons. Presence of oil would likely inhibit the germination and growth of many species; however, in areas with persistent inputs of naturally-occurring hydrocarbons (e.g. natural oil seeps), some species of marine algae develop the ability to acclimate to the presence of otherwise toxic hydrocarbon compounds (Carrera-Martinez et al. 2011). Similarly, robust coastal plants such as Arctic Kelp (*Laminaria solidungula*) would be likely to recover subsequent to clean-up. Thus, overall levels of photosynthesis and primary production would decrease temporarily but would likely return to pre-VLOS levels within several years after the cessation of clean-up activity. Perturbations to community structure may result in *structural* changes to biological communities in nearshore areas, but functional properties of the system related to primary production and nutrient fixation would likely return to their pre-spill states within several years after cessation of clean-up activities.

Impacts of the VLOS on production functions related to subsistence and cultural resources (Sections 4.10.7.15 and 4.10.7.17, respectively) are discussed in other sections of this document, and those discussions are not duplicated here.

Information Functions

The effects of onshore contact of a VLOS event on information functions in the Chukchi Sea ecosystem would be related to impacts on social and cultural systems, and on human health, all of which are addressed in other sections of this document.

Phase 4 (Spill Response and Cleanup)

Regulation Functions

Activities associated with spill response and clean-up would have a variety of effects on regulation functions within the Chukchi Sea ecosystem. Effects on nutrient cycles, biological energy flows, and biological control of population cycles would depend heavily on the methods used to respond to spilled oil.

Dispersants would change the location of the impact of the spilled oil from the surface of the water to areas deeper in the water column. Application of dispersants would likely decrease the magnitude of impacts on the sea surface microlayer where gas exchange processes occur, leading to decreased impacts on gas regulation functions in the affected area. Distributing the oil deeper in the water column would also decrease the magnitude of impacts on marine nutrient cycles, which are largely driven by photosynthesis and respiration occurring in the photic zone (sunlit waters generally in the upper 50 m (164 ft) of the water column). Dispersion of oil out of the photic zone would limit the potential for phototoxic effects, which can occur as a result of sunlight driven photochemical reactions that increase the bioavailability and toxicity of certain petroleum hydrocarbon compounds including some PAHs and their derivatives. However, dispersants themselves would contribute to short term adverse effects on regulation functions by increasing the bioavailability of petroleum hydrocarbons, which could lead to increased respiration rates and oxygen depletion in some marine areas (Hazen et al. 2010). Some surfactants and solvents present in commercially available dispersant formulations would have toxic effects at high concentrations that could occur immediately after the application of the dispersants. Overall, dispersants would likely decrease the magnitude and duration of effects of spilled oil on regulation functions in the Chukchi Sea, although the intensity and spatial distribution of effects would be likely to increase for a short period of time immediately following dispersant application.

The effects of *in situ* burning on regulation functions would be similar to those described for dispersants. *In situ* burning would introduce large quantities of smoke and gasses into the atmosphere, which would result in temporary effects on gas regulation processes. Gasses released as products of the combustion reaction would also influence the climate regulation functions of the atmosphere; such effects are expected to be short-term and would become negligible as the released gasses become diluted in the atmosphere. Incomplete combustion of crude oil on the surface of the water would generate large quantities of toxic products; however, the impacts of the combustion products on regulation functions would be less than those of the greater quantities of unburned oil present prior to *in situ* burning.

Mechanical recovery in the offshore environment would have net positive impacts on regulation functions resulting from the removal of the spilled oil. However, beach cleaning could destabilize biological communities and physical substrates leading to temporary oscillations in the nutrient and energy cycles associated with regulation functions.

Application of fertilizer to enhance biodegradation of spilled oil would temporarily destabilize nutrient cycles in the treated area. By modifying nutrient stoichiometry (expressed as ratios of bioavailable carbon to nitrogen to phosphorus, or C:N:P) in the affected area, application of fertilizer would temporally concentrate assimilation of the oil into the environment. This assimilation of the spilled oil is itself an example of a regulation function. Rapid assimilation and detoxification of the oil resulting from augmented biodegradation processes would increase the intensity of effects on nutrient cycles in the affected area, but would decrease the duration of those effects.

Habitat Functions

Response and clean-up activities could have intense effects on habitat functions in sensitive areas. For example, the use of hot water hydraulic washing to clean oiled shoreline could destabilize physical substrates causing adverse impacts to spawning and refuge habitats for coastal species. Shoreline sensitivity indices would be used to establish oil spill response priorities and to help determine the most appropriate clean-up methods to be used in sensitive areas.

Production Functions

The effects of oil spill clean-up activities on production functions would depend on the particular response techniques used. As discussed above, the use of dispersants could effectively move oil out of the photic zone, thereby decreasing adverse effects on photosynthesis. Dispersants would also increase the bioavailability of the oil to organisms living deeper in the water column, leading to increased respiration in some classes of heterotrophs (Hazen et al. 2010), as well as toxic effects in most pelagic organisms. The use of dispersants would decrease the duration of VLOS impacts on production functions, but would increase the intensity of the effects.

In situ burning would have adverse effects on production functions. Release of heat and combustion products into the water would have adverse effects on primary producers. The duration of these effects would likely be short term. While cascades of indirect effects could lead to structural changes in biological communities over decadal timescales (Peterson et al. 2003), the functional properties of the ecosystem responsible for primary production would be expected to recover within several years after the cessation of cleanup activities.

Information Functions

The effects of spill cleanup operations on information functions in the Chukchi Sea ecosystem would be related to impacts on social and cultural systems, and on human health, all of which are addressed in other sections of this document.

Phase 5 (Long-term Recovery)

Regulation Functions

Regulation functions related to nutrient cycles, regulation of water and gasses, and waste assimilation would likely recover within several years of the cessation of clean-up activities. With regard to regulation functions at the system level, respiration to biomass ratios would likely return to pre-spill values within several years after the spill, and ratios of production to respiration would approach unity over a similar timescale. Species composition and community structure may change as a result of a VLOS in the Chukchi Sea, but the functions performed by interactions of biological communities with their chemical and physical environment would be more resistant to the stress associated with a VLOS event. Although the structural properties of the ecosystem may experience lasting effects, functional properties of the ecosystem would be expected to recover more rapidly from the effects of the perturbation (Odum 1985).

Recovery of biological control functions related to dynamic trophic interactions would be less certain. Fourteen years after the *Exxon Valdez* oil spill, Peterson et al. (2003) described ongoing impacts to biological control functions resulting from cascades of indirect effects triggered by the oil spill. The magnitude of natural oscillations in predator-prey population cycles would be expected to increase as a result of the VLOS event. For example, Peterson et al. (2003) report that cascades of indirect effects triggered by the *Exxon Valdez* oil spill were responsible for cyclic instability in the population cycles of several species in onshore communities. Although the species and habitats present in the EIS project area are different from those in Prince William Sound, the following account is useful for understanding how cascades of indirect effects may persist for decades following a VLOS event:

> *Indirect interactions lengthened the recovery process on rocky shorelines for a decade or more. Dramatic initial loss of cover by the most important biogenic habitat provider, the rockweed **Fucus gardneri**, triggered a cascade of indirect impacts. Freeing of space on the rocks and the losses of important grazing (limpets and periwinkles) and predatory (whelks) gastropods combined to promote initial blooms of ephemeral green algae in 1989 and 1990 and an opportunistic barnacle, **Chthamalus dalli**, in 1991. Absence of structural algal canopy led to declines in associated invertebrates and inhibited recovery of **Fucus** itself, whose recruits avoid desiccation under the protective cover of the adult plants. Those **Fucus** plants that subsequently settled on tests of **Chthamalus dalli** became dislodged during storms because of the structural instability of the attachment of this opportunistic barnacle. After apparent recovery of **Fucus**, previously oiled shores exhibited another mass rockweed mortality in 1994, a cyclic instability probably caused by simultaneous senility of a single-aged stand. The importance of indirect interactions in rocky shore communities is well established, and the general sequence of succession on rocky intertidal shores extending over a decade after the Exxon Valdez oil spill closely resembles the dynamics after the Torrey Canyon oil spill in the UK. Expectations of rapid recovery based on short generation times of most intertidal plants and animals are naıve and must be replaced by a generalized concept of how interspecific interactions will lead to a sequence of delayed indirect effects over a decade or longer* (Peterson et al. 2003).

Similar cascades of indirect effects could be expected to occur in both onshore and offshore communities in response to a VLOS in the Chukchi Sea. While most properties of the Chukchi Sea ecosystem responsible for performance of regulation functions could be expected to recover within several years of a VLOS event, the post-spill ecosystem would be less resilient to the effects of additional perturbations. Increased magnitude of oscillations in the populations of key species would likely destabilize the established system of trophic interactions in the Chukchi Sea ecosystem, putting the system at greater risk for major impacts from any subsequent perturbations.

Habitat Functions

Persistence of oil in sediments may have negative long-term effects on habitat functions within the affected area. Subsequent to the *Exxon Valdez* oil spill in Prince William Sound, Peterson et al. (2003) reported long-term impacts to habitat functions resulting from persistence of 3-5 ring PAHs (e.g. phenanthrene, anthracene, pyrene, triphenylene, and associated derivatives). Lighter non-aromatic hydrocarbon compounds released during a VLOS are more readily degraded in the environment as a result of physical weathering processes and biodegradation. Long-term effects on habitat functions would be limited to areas where oil may become trapped in sediments or other substrate, and shielded from weathering and degradation. Long-term effects on habitat functions would be local and medium intensity, but would have the potential to affect unique resources depending upon the location of the discharge and the efficacy of the response effort.

Changes in the structure of biological communities and food webs could result in long-term changes in habitat usage and resource utilization. Prediction of the direction and magnitude of such changes is problematic; however it is likely that small, short-lived organisms would begin to utilize habitat and resources that were previously used by larger, longer-lived organisms (Odum 1985).

Production Functions

Levels of primary production in the Chukchi Sea would be expected to return to pre-spill levels within several years of the cessation of clean-up activities associated with a VLOS event. However, lasting impacts on production functions at the system level would be related to human utilization of natural resources in the area. Long-term effects of a VLOS event on subsistence, cultural resources, and human health are discussed in other sections of this document.

Information Functions

The long-term effects of a VLOS event on information functions in the Chukchi Sea ecosystem would be related to impacts on social and cultural systems, and on human health, all of which are addressed in other sections of this document.

Conclusion

Effects of a VLOS on ecosystem functions in the Chukchi Sea would be high intensity, long-term, regional, and could affect unique resources. Overall, the effects of a VLOS on ecosystem functions in the Chukchi Sea would be considered major. However, with few exceptions, the ecosystem functions in the VLOS area would likely recover within several years of the cessation of clean-up activities. The functional properties of ecosystems described in this section, such as nutrient cycling and habitat functions, are more robust (i.e. resistant to stressors) than are species composition and other structural properties. As suggested by Peterson et al. (2003), a VLOS event would be likely to affect ecosystem structure over timescales of decades; ecosystem functions, from which humans derive value, would be likely to recover more quickly.

4.10.6.8 Lower Trophic Levels

4.10.6.8.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

Section IV.E.4 of BOEM (2011b) describes potential impacts to lower trophic levels resources during the five phases of a possible VLOS in the Chukchi Sea. In addition, Section 4.4.7.5.3 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on invertebrates and lower trophic levels in the Chukchi Sea. This information from these two documents is incorporated herein by reference, and a summary of that information is provided below.

A VLOS would likely have less than a one year effect on phytoplankton populations in the Chukchi Sea due to the influx of phytoplankton carried into the Chukchi Sea by the waters of the Gulf of Anadyr, the Bering Sea, and the Alaska Coastal currents that would supplement remaining endemic populations. However, short-term, local-level effects would have greater potential to affect local food webs. Severity of effects would be determined by duration of oil spill, weather patterns, and the resultant distribution and geographic coverage of surface oil slicks. Ice algae population effects would be determined by similar factors, as the presence of oil within polynyas and reaches, and if incorporated into first year ice would likely have at least a one-year effect on local populations due to effects on primary productivity and the probable inability of epontic communities reliant on ice algae to survive within oil-influenced ice.

Invertebrate populations within benthic, pelagic, and onshore environments are at greater risks from a VLOS due to their slower reproductive rate, longer life spans, and the potential of adult breeding populations being negatively affected by the VLOS and leading to a longer recovery rate. If population level effects resulting from a VLOS occur in breeding stocks of invertebrates of these Chukchi Sea environments, the recovery potential of populations would not be enhanced by the flow of Bering Sea and Anadyr waters as it is with phytoplankton populations. Phytoplankton and zooplankton populations extirpated by oil slicks that are constantly shifting and forming in new areas due to influences of wind, weather, and waves, would not be available to organisms that depend on them for food and survival. Food webs can be very short in the Arctic, with interactions between megafauna (i.e. whales, seals, walrus) and lower trophic organisms often comprising one or two trophic levels due to the tight benthic and pelagic coupling on the shallow continental shelf off the Alaskan Arctic coast (Dunton et al. 2005, Grebmeier et al. 2006). Bioaccumulation and biomagnification in these foodwebs is a concern. Long lived copepods (such as *Calanus glacialis*) may live two to three years, store lipids in the body cavity, undergo diapause (a form of hibernation), and be consumed by upper level predators (atlantic cod, bowhead whales, etc.) at a later date (USDOI, MMS, 2004). Toxicity studies carried out with benthic crabs and shrimp indicate they may not immediately die from toxins (living 24-96 hrs, depending on exposure and oil type), thus allowing greater opportunities for consumption by upper-level predators and biomagnification to occur (Brodersen, 1987). Phytoplankton themselves may not die immediately from the effects of exposure to oil; therefore, advective drift following bioaccumulation in their populations may allow them to be consumed by other organisms in locations away from contamination sites (Jiang et al., 2010). Recovery rates of one or more years may result from these effects on invertebrate populations.

4.10.6.8.2 Additional Analysis for Lower Trophic Levels

As outlined in the discussion in BOEM (2011b), a VLOS of approximately 2.2 MMbbl has the potential to adversely impact lower trophic levels. The scale of these impacts could vary greatly, depending on when, where, and how much oil would directly affect the given areas. The Oil Spill Trajectory Analysis described in BOEM (2011b) (Section IV.E.) provides an outline of various theoretical events, with detailed geographic summaries. The important conclusion is that oil has the potential to reach the entire EIS project area under certain conditions. Therefore, all lower trophic levels within the Chukchi Sea are vulnerable to long term impacts. The most likely impacts include:

- Mortality to all life stages resulting from pressure waves from an initial explosive event, toxicity to oil (acute and chronic), and coating with an oil layer;
- Impact to food web and resultant bioaccumulation and biomagnification as a result of the close interactions between megafauna (i.e. whales, seals, walrus) and lower trophic organisms (Dunton et al. 2005, Grebmeier et al. 2006) (see Section 4.10.6.11 for more information regarding the effects of bioaccumulation and biomagnification on marine mammals);
- Longer recovery rates due to species traveling outside the original contamination site or being consumed later, thereby prolonging the recovery, as a result of drift or diapause (a form of hibernation), respectively. This would delay recovery since these species surviving the initial incident would store toxins and be consumed at a later date by higher trophic level organisms (MMS 2004, Jiang et al. 2010, Brodersen 1987); and
- Habitat loss due to oiling of ice or benthic substrate and the resultant decrease in primary productivity or mortality events.

The magnitude of these impacts is dependent on a variety of factors. The primary factors influencing the level of impact include:

- Duration and volume of the spill;
- Distribution and geographic coverage of surface oil slicks;
- Persistence and dispersion of oil in the water column (epontic, pelagic, or benthic);
- Chemical composition of the oil;
- Efficacy of chemical dispersants;
- Incorporation of spill into first year ice; and
- Weather patterns, including hours of daylight and UV intensity, presence or absence of ice, presence or absence of polynyas, and reaches.

Depending upon the factors discussed above, the VLOS could have a summary impact level of major, should the spill persist in the environment or affect unique resources. However, should the spill not persist or affect unique resources, the impacts to the lower trophic levels would be of low to medium magnitude, temporary, local to regional geographic extent, and common context, with the exception of the time/area closures mentioned above. In this case, the impact criteria listed in Table 4.5-17 would lead to a summary impact level of moderate due to the shorter duration and regional impacts to common resources.

4.10.6.9 Fish and Essential Fish Habitat

<u>4.10.6.9.1 Existing Analysis (BOEM 2011b and BOEM 2011d)</u>

Fish

Section IV.E.5 of BOEM (2011b) describes potential impacts to fish and fish resources during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

The level of effects of a very large oil spill in the Chukchi Sea on a fish species and its population would depend on many factors including:

- life stage affected (egg, larvae, juvenile, adult);
- species distribution and abundance (widespread, rare);
- habitat dependence (ocean water column, sea surface, benthos, sea ice, estuarine, freshwater);
- life history (anadromous, migratory, reproductive behaviors and cycle, longevity, etc.);
- extent and location of spawning areas in the estuarine or riverine systems;
- species exposure and sensitivity to oil and gas (toxicology, swimming ability);
- effect on prey species; and
- location of the oil spill (nearshore, further offshore), depth at which the hydrocarbon release occurs (seafloor, mid-column or surface), ratio of the mixture of oil and gas released, and time of year the oil spill occurs.

Considering all these factors, some species or life stages of a species could be significantly affected (defined here as greater than three generations to return) at a population level.

In addition, Section 4.4.7.3.3 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on fish in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could have population-level consequences on some fish populations if vital habitat areas were affected or if the spill occurred in spawning areas or juvenile feeding grounds when fish populations are highly concentrated. In such cases, catastrophic spills could cause substantial reductions in population levels for one or more years. However, no permanent impacts on fish populations are expected (BOEM 2011d).

Essential Fish Habitat

Section IV.E.6 of BOEM (2011) describes potential impacts to EFH during the five phases of a possible VLOS in the Chukchi Sea. Likewise, Section IV.E.15 of BOEM (2011b) describes potential impacts to subsistence resources. This information is incorporated herein by reference, and a summary of that information is provided here.

The level of effects of a very large oil spill in the Chukchi Sea on EFH would depend on several factors including:

- location of the oil spill (nearshore, further offshore); depth at which the release occurs (seafloor, mid-column or surface), ratio of the mixture of oil and gas released, and time of year oil spill occurs;
- extent and location of spawning areas in the estuarine or riverine systems;
- species abundance and distribution (widespread, rare);
- the species and the sensitivity of their life stage affected (egg, larvae, juvenile, adult); and
- life history and reproductive cycle.

Considering these factors, EFH of some species' life stages could be significantly impacted by a VLOS.

Likewise, Section 4.4.6.4.3 of the BOEM (2011e) analysis provides an analysis of the impacts of a catastrophic discharge event on EFH in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could cause long-term declines of fish species that rely on shallow coastal, intertidal, and freshwater areas. Spills occurring under ice could result in long-term degradation of EFH because of the cleanup difficulties; severity of effects of accidental hydrocarbon spills on EFH would depend on the size of the spill, its location, environmental factors, and the uniqueness of the affected EFH (BOEM 2011d).

4.10.6.9.2 Additional Analysis for Fish and Essential Fish Habitat

As outlined in the discussion in BOEM (2011b), a VLOS of approximately 2.2 MMbbl has the potential to impact fish and fish resources. The scale of these impacts could vary greatly, which is primarily determined by the location of the spill. The Oil Spill Trajectory Analysis described by BOEM (2011b) (Section IV.E.1.) provides an outline of various theoretical events with detailed geographic summaries. The important conclusion from this exercise is that oil has the potential to reach the entire EIS project area under certain conditions. Therefore, all fish resources within the Chukchi Sea are vulnerable to impacts, potentially long term. The most likely impacts include:

- Mortality to all life stages resulting from pressure waves from an initial explosive event, toxicity to oil (acute and chronic), and coating with an oil layer;
- Reduction of individual fitness and survival due to physiological contaminant effects. These effects can, in turn, affect swimming, feeding, reproductive and migratory behaviors and the physiologic adjustment for anadromous fish as they move between freshwater and saltwater environments; and
- Onshore and offshore habitat loss due to oiling, resulting in displacement and stress. Displacement could result in blocked or impeded access to spawning, rearing, feeding, and migratory habitats important for survival.

The magnitude of these impacts is dependent on a variety of factors. The primary factors influencing the level of impact include:

- Location and time of year of the oil spill;
- Life stage affected (egg, larvae, juvenile, adult) and life history (anadromous, migratory, reproductive behaviors and cycle, longevity);
- Species distribution and abundance;
- Species exposure and sensitivity to oil and gas (toxicology, swimming ability); and
- Habitat dependence (marine vs. freshwater, onshore vs. offshore, location of spawning habitat, depth).

Based on the five oil spill phases, the greatest impacts could be felt during Phases 2 and 3, particularly in benthic and nearshore regions. The fish typically found in these areas are more susceptible to impacts from a VLOS due to their increased dependence on relatively limited habitat when compared to pelagic fish, or decreased swimming ability resulting in an inability to escape impacted areas. Most impacts to habitat could be short term in duration, with shoreline and substrate impacts lasting longer. The fish assemblages with an increased susceptibility include:

- Migratory and juvenile fish that use nearshore, shallow lagoons, estuaries, and bays;
- Benthic fish, which are typically poor swimmers; and
- Cryopelagic species such as Arctic cod, should the spill occur in winter or get entrained in seasonal pack ice.

Most fish and EFH within the EIS project area are important resources that are widespread and abundant. However, the impacts from a VLOS could be of high intensity, long term duration, and occur over a broad, regional extent. Therefore, according to the criteria laid out in Table 4.5-17, the summary impact level could be moderate.

4.10.6.10 Marine and Coastal Birds

4.10.6.10.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

Section IV.E.9 of BOEM (2011b) describes potential impacts to marine and coastal bird resources during the five phases of a possible VLOS in the Chukchi Sea. In addition, Section 4.4.7.2.3 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on birds in Arctic Alaska. The information from these two analyses is incorporated herein by reference, and a summary of that information is provided here.

A VLOS has the greatest potential for affecting large numbers of birds in part due to its toxicity to individuals and their prey and the amount of time these birds spend on the surface of marine and coastal waters. Under a hypothetical VLOS scenario, marine and coastal birds in key areas or at key times could experience a variety of negative effects from petroleum exposure and habitat loss. Key areas evaluated included:

- Kasegaluk Lagoon;
- Ledyard Bay;
- Peard Bay;
- barrier islands;
- the spring open-water lead systems;
- Cape Lisburne; and
- Cape Thompson.

All of the areas above provide important nesting, molting, or migration habitat to a variety of seabirds, waterfowl, and shorebirds. The Ledyard Bay Critical Habitat Unit is especially important to spectacled eiders that molt there in dense flocks from July to November.

A VLOS during periods of peak use could affect large numbers of marine and coastal birds, including listed eiders, loons, seabirds, and waterfowl. As a typical example, up to 45 percent of the estimated Pacific Flyway population of Pacific brant could be affected, if an oil spill reaches Kasegaluk Lagoon. Effects could range from direct mortality of approximately 60,000 brant to sublethal effects on an equal or smaller number of brant. The loss of up to 45 percent of the Pacific Flyway population would have conspicuous population-level effects. The situation with brant is similar to a wide variety of waterfowl and shorebirds that use similar areas of the Chukchi Sea.

A hypothetical VLOS could impact large numbers of murres, puffins, and kittiwakes at the Cape Lisburne and Cape Thompson colonies. The magnitude of potential mortality could result in significant adverse impacts to the colonies. Large-scale mortality could occur to migrating or molting concentrations of marine and coastal birds, including adult male and juvenile murres in the late summer molting area. Mortality from a hypothetical VLOS could result in population-level effects for most marine and coastal bird species that would take more than three generations to recover.

Large-scale mortality could occur with respect to pelagic distributions of auklets and shearwaters during the open-water period.

As a group, the Launch Areas (specifically LAs 8-13) affected by the deferral corridors contemplated in Alternatives III and IV tend to exhibit higher percentages of spill trajectories contacting sensitive nearshore and coastal habitats along the Chukchi Sea. These alternatives may offer protection to nearshore resources, spring lead systems and spring polynyas by decreasing the percentage of trajectories that would contact these resource areas. In this sense, the most protection to nearshore and coastal birds is afforded by the broadest coastal deferral, Alternative III. Deferrals may also afford more time for spill response and cleanup prior to a spill contacting nearshore resources. These benefits would not be expected to accrue to pelagic species of birds.

4.10.6.10.2 Additional Analysis for Marine and Coastal Birds

Direct and indirect exposure to oil is an impact producing factor that can adversely affect marine and coastal birds. The level of impact is dependent upon the timing of the VLOS, the seasonal effects of currents and subsequent advection of oil, timing and duration of the oil spill, presence or absence of fast or pack ice, location (within important habitat areas or outside), and general weather patterns (wind and storm events). If a VLOS occurs in important habitat areas, the magnitude of impacts to marine and coastal birds could be medium to high, with displacement from the area, impacts to prey resources and habitat quality, and a likelihood of injury or mortality from either direct contact with or ingestion of oil and associated contaminants. The duration of the impacts could be long-term to permanent because habitat areas could be abandoned or large portions of the population could be affected. The geographic extent could occur state-wide due to migrating, molting, and breeding bird populations. If the VLOS were to occur outside important habitat areas, the effects could be the same except the duration could be temporary to long-term rather than long-term to permanent. The chance of recovery could be greater due to less birds likely being affected, compared to a higher concentration of birds that could be found in many important habitat areas at certain periods of time.

Population level effects are likely, given the high concentration of migrating, molting, and breeding bird populations. The impacts from a VLOS could be of high intensity, long term duration, and occur over a broad, regional extent. Therefore, a VLOS in the Chukchi Sea during the lifetime of this EIS could result in a major impact to marine and coastal birds. This is due to the potential adverse effects to population levels, habitat, molting, and breeding areas, important habitat areas, toxicity to prey and individuals, and mortality of individuals.

Ledyard Bay Critical Habitat Area

The Ledyard Bay Critical Habitat Unit (LBCHU) was designated as a critical habitat for ESA-listed spectacled eiders in 2001 due to its importance for the persistence and recovery of spectacled eiders, its marine aquatic flora and fauna in the water column, and its abundant benthic community. The oil spill analysis from BOEM (2011b) reported the following model results for impacts to Ledyard Bay:

> ***Summer within 60 and 360 Days:*** *The OSRA model estimates that 38 percent and 22 percent of trajectories from a hypothetical VLOS originating from LA10 or LA11, respectively, could contact spectacled eiders molting in the LBCHU (ERA 10) during the summer within the 60 and 360 day periods.*
>
> ***Winter within 360 Days:*** *The OSRA model estimates that 16 percent and 10 percent of trajectories from a hypothetical VLOS originating from LA10 or LA11, respectively, could contact spectacled eiders molting in the LBCHU (ERA 10) during the winter within 360 days.*

Spectacled eiders make use of the spring lead system when they migrate from their wintering area in the Bering Sea. The spring lead system includes the LBCHU and typically has represented the only open-water area along their path. Once tundra nesting habitats are sufficiently melted to allow nesting (historically around June 10), most breeding pairs of spectacled eiders leave nearshore coastal areas to begin nesting on the Arctic Coastal Plain as far east as Canada. All three breeding populations of spectacled eiders molt in Ledyard Bay from July through October, including most females that nest on the

North Slope (Petersen et al. 1999). Many post-breeding male spectacled eiders slowly begin to converge in offshore aggregations in Ledyard Bay starting in July and begin an extended molt. While molting they are flightless for several weeks. Female spectacled eiders whose nests fail early on go to the coast and eventually end up in Ledyard Bay for flightless molt. Females with broods are the last to arrive at Ledyard Bay around the end of the first week of September, and they may be present into November. The post-breeding molt is an energetically demanding period and Ledyard Bay provides an abundant and accessible food supply with low levels of disturbance and predation.

Ledyard Bay is also important habitat for many other species of waterfowl and tundra nesting seabirds, including ESA-listed Steller's eider and ESA candidate species, yellow-billed loon and Kittlitz's Murrelet. Marine mammals are also important components of the ecosystem, with major migrations of bowhead whales and beluga whales coming through the area in spring. Ice seals and walrus are present all year but especially when sea ice is present. Spotted seals and walrus also use the coastline for haulouts.

Conclusion

Ledyard Bay is undoubtedly rich habitat for a variety of benthic invertebrates and fish species and it is an important habitat for many key marine mammal and bird species. It derives its special designation and protected status, however, from its tremendous importance to the threatened spectacled eider. All of the species from all taxa could be affected by a VLOS in Ledyard Bay to various degrees but the conclusion about the overall effect of a VLOS on this area is driven by the effects on spectacled eider. For this threatened species, Ledyard Bay is a unique habitat and one that is crucial to their continued existence because most of the population stages here in spring and spends their flightless molt period there in the fall. Molting eiders are especially vulnerable to oil spills because they cannot fly away. Molting eiders are present in Ledyard Bay from July through October, almost the entire open-water period when exploratory drilling and accidental spills are most likely to occur. Because of the potentially devastating effects on the world population of spectacled eiders, the overall effects of a VLOS on Ledyard Bay would be considered high in magnitude and intensity, permanent in duration (lasting more than five years), and state-wide in geographic extent. Similar but smaller effects could be expected for other populations of migrating birds and marine mammals. This would be considered a major effect on this important habitat area according to the criteria established in Table 4.5-17.

Kasegaluk Lagoon Time/Area Closure

Kasegaluk Lagoon is an estuary important to rearing fish, including out-migrating salmon smolts from the Kukpowruk, Kokolik, and Utukok rivers. Salmon, other fish, and abundant invertebrate populations are a major attractant for very large numbers of migratory birds that make use of Kasegaluk Lagoon during May to October. Threatened spectacled and Steller's eiders are among the many species of tundra-nesting waterfowl that stage in the lagoon in the spring and post-breeding periods. About half of the Pacific flyway population of brant use Kasegaluk Lagoon during the post-breeding period. Large numbers of phalaropes, dunlins, and other species of shorebirds also use the area during the open-water period. Concentrations of beluga whales use Kasegaluk Lagoon in the spring/summer for molting, where the relatively warm waters and gravelly substrate helps the process.

Conclusion

The effects of a VLOS on coastal vegetation and wetlands could involve hundreds of miles of shoreline and, if influenced by strong winds and waves, could be blown or washed some distance inland. Although barrier islands could protect lagoon areas to some extent, if oil entered a lagoon in substantial amounts, the barrier islands could inhibit weathering and flushing by waves, thereby leading to a more extended exposure of the lagoon environment to the oil than if it was on an outer coast. Kasegaluk Lagoon has a number of entrances to the open ocean and would thus be susceptible to oil spill penetration. BOEM (2011) VLOS analyses are prefaced with assumptions about when, where, and how much oil would directly affect given areas. Of great importance to biological resources is the timing of the spill and how it would overlap with migration and other critical life functions. If oil enters Kasegaluk Lagoon and persists for up to 10 years, as is projected in the BOEM model, most of the animals that use the area at any time of the year could be exposed at least one time and perhaps repeatedly over the years, with potentially permanent effects on all of the populations with intensive use of the lagoon, including many species of fish, waterfowl, shorebirds, beluga whales, and spotted seals. Kasegaluk Lagoon is a unique resource in the Chukchi Sea and the effects of a VLOS would be considered high in magnitude and intensity, permanent in duration (lasting more than five years), and state-wide in geographic extent because it would affect migrating populations of birds. This would be considered a major effect on this time/area closure location according to the criteria established in Table 4.5-17.

4.10.6.11 Marine Mammals

4.10.6.11.1 Existing Analysis (BOEM 2011b and 2011e)

Section 4.4.7.1.3 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on marine mammals in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event would impact marine mammals from direct contact, inhalation, and ingestion (either directly or indirectly through the consumption of oiled forage or prey species). These effects would be significant, causing a multitude of acute and chronic effects. Additional effects on marine mammals would occur from water and air quality degradation associated with response and cleanup vessels, in situ burning of oil, dispersant use, discharges and seafloor disturbances from relief well drilling, and activities on shorelines associated with cleanup, booming, beach cleaning, and monitoring. A catastrophic discharge event has the potential to increase the area and duration of an oil spill, thereby increasing the potential for population-level effects, or at a minimum, an increase in the number of individuals killed. For example, a catastrophic discharge event contaminating ice leads or polynyas in the spring could have devastating effects, trapping bowhead whales where they may encounter fresh crude oil. Beluga whales that also use the spring lead system to migrate would also be susceptible to a spill that concentrates in these leads (BOEM 2011d). Polar bears are most often found near open leads and polynyas where they hunt for seals, making them vulnerable to ingestion of oil through grooming or ingesting oiled prey.

Sections IV.E.7, IV.E.8, IV.E.10, and IV.E.11 of BOEM (2011b) describe potential impacts to marine mammal resources during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

Cetaceans

Direct contact with spilled oil resulting from a VLOS would have the greatest potential to adversely affect cetacean species when toxic fumes from fresh oil are inhaled at times and places where aggregations of cetaceans may be exposed. Cetaceans likely would avoid oil spill response and cleanup activities, potentially causing displacement from preferred feeding habitats, and could alter migratory paths for the duration of those activities. Presence of oil on and in the water may be avoided by some and not other cetaceans. Cetaceans as a general group would likely experience some loss of seasonal habitat, reduction of prey, and contamination of prey. Consumption of contaminated prey may adversely affect the health of cetaceans. Human activities brought about by implementation of Oil Spill Response Plans, i.e. cleanup and remediation, post-spill event follow-up treatment and research, and monitoring efforts, may displace cetaceans. A variety of adverse effects on cetaceans could result from contact with and exposure to a VLOS event ranging from simple avoidance to mortality of cetaceans depending on timing, location, cetacean species involved, and circumstances unique to a given spill event.

Bowhead Whale

Depending on the timing of the spill, bowhead whales could experience contact with fresh oil during summer and/or fall feeding event aggregations and migration in the Chukchi Sea and western Beaufort

Sea. Skin and eye contact with oil could cause irritation and various skin disorders. Toxic aromatic hydrocarbon vapors are associated with fresh oil. The rapid dissipation of toxic fumes into the atmosphere from rapid aging of fresh oil and disturbance from response related noise and activity limits potential exposure of whales to prolonged inhalation of toxic fumes. Exposure of aggregations of bowheads, especially if calves are present could result in mortality. Surface feeding bowheads could ingest surface and near surface oil fractions with their prey, which may or may not be contaminated with oil components. Incidental ingestion of oil factions that may be incorporated into bottom sediments can also occur during near-bottom feeding. Ingestion of oil may result in temporary and permanent damage to bowhead endocrine function and reproductive system function; and if sufficient amounts of oil are ingested mortality of individuals may also occur. Population level effects are not expected; however in a very low probability, high impact circumstance where large numbers of whales experience prolonged exposure to toxic fumes and/or ingest large amounts of oil, injury and mortality could potentially affect population growth rates.

Exposure of bowheads could occur in the spring lead system during the spring calving and migration period. Exposure to aged winter spill oil (which has had a portion or all of the toxic aromatic compounds dissipated into the atmosphere through the dynamic open water and ice activity in the polynya) presents a much reduced toxic inhalation hazard. Some inhalation, feeding related ingestion of surface and near surface oil fractions may occur during this period and may result in temporary and/or permanent effects on endocrine and reproductive performance. It is possible that a winter spill would result in a situation where toxic aromatic hydrocarbons would be trapped in ice for the winter period and released in toxic amounts in the spring polynya system when bowheads are migrating through in large numbers. In this low probability situation, calves could die and recovery from the loss of a substantial portion of an age class cohort and its contribution to recruitment and species population growth could take decades.

Bowhead whales could be exposed to a multitude of short and longer term additional human activity associated with initial spill response, cleanup and post event human activities that include primarily increased and localized vessel and aircraft traffic associated with reconnaissance, media, research, monitoring, booming and skimming operations, in-situ burning, dispersant application and drilling of a relief well. These activities would be expected to be intense during the spill cleanup operations and expected to continue at reduced levels for potentially decades post event. Specific cetacean protection actions would be employed as the situation requires and would be modified as needed to meet the needs of the response effort. The response contractor would be expected to work with NMFS and state officials on wildlife management activities in the event of a spill. The two aforementioned groups most likely would have a presence at the Incident Command Post to review and approve proposed activities and monitor their impact on cetaceans. As a member of the team, NFMS personnel would be largely responsible for providing critical information affecting response activities to protect cetaceans in the event of a spill.

Bowheads would be expected to avoid vessel supported activities at distances of several kilometers depending on the noise energy produced by vessel sound sources; drill rig; numbers and distribution, size and class of vessels. Migrating whales would be expected to divert up to as much as 20-30 km around relief well drilling operations and up to a few km around vessels engaged in a variety of activities. Temporary and non-lethal effects are likely from the human activities that would be related to VLOS response, cleanup, remediation, and recovery. Displacement away from or diversion away from aggregated prey sources could occur, resulting in important feeding opportunity relative to annual energy and nutrition requirements. Frequent encounters with VLOS activities and lost feeding opportunities could result in reduced body condition, reproductive performance, increased reproductive interval, decreased in vivo and neonatal calf survival, and increased age of sexual maturation in some bowheads. Effects from displacement and avoidance of prey aggregations and feeding opportunities as a result of human activities associated with spill response, clean-up, remediation and recovery are not expected to result in population level effects.

Beluga Whale

Beluga whales are vulnerable to contact with a VLOS when large aggregations are gathered in the lagoons and nearshore habitats along the Alaska Chukchi Sea coast during molting and nursing. The fate of beluga prey, especially Arctic cod and other Arctic fisheries, could affect seasonal habitat use, determine if toxic amounts of contaminated fish are ingested, or possibly change distribution of these whales until fisheries recovery occurs. Temporary and/or permanent injury and non-lethal effects could occur.

Belugas would come into contact with the human activities associated with cleanup operations when near shore, where localized intensive boom and skimming efforts to protect lagoons and other coastal resources occur. Avoidance behavior and stress to belugas (that have also experienced small boat supported subsistence hunting) in coping with concentrated cleanup activities could occur. Once offshore, belugas could inhale fumes of fresh spilled oil. Prolonged inhalation of toxic fumes or accidental inhalation of surface oil could result in temporary and/or permanent injury or mortality to some individuals. Displacement from or avoidance of important nearshore habitats could occur in subsequent years after a spill, and belugas could redistribute from the seasonal use of the Chukchi Sea nearshore areas to less optimal molting and nursing areas and potentially reduce population productivity and recruitment. Should cleanup activities occur in or near lagoons or nearshore feeding areas, molting, or birthing habitats, beluga could potentially abandon these areas for as long as spill related activities persisted. Post spill recovery of belugas to pre-spill abundance and habitat use patterns would be dependent upon the recovery periods necessary to restore pre-spill levels of prey populations and the quality of near-shore preferred habitats. Recovery would also depend on the level of human activity in and adjacent to preferred habitats.

Fin Whale

A few individual fin whales could experience similar effects as noted for bowheads above if contacted by oil during the ice free period. Fin whale prey (schooling forage fish and zooplankton) could be reduced or contaminated, leading to modified distribution of fin whales and/or ingestion of oil contaminated prey. Temporary and/or permanent injury and non-lethal effects could occur, but mortality or population level effects are considered to be unlikely because of the low density of animals in the areas.

Fin whales would likely avoid the noise related to VLOS response, cleanup and post-event human activities similar to that noted for bowhead whales.

Humpback Whale

A few individual humpback whales could experience effects similar to those noted for bowheads above if contacted by oil during the ice free period. Humpback whale prey (primarily schooling forage fish) could be reduced and/or contaminated, leading to modified distribution of humpback whales or ingestion of oil contaminated prey. Temporary and/or permanent injury and non-lethal effects could occur, but mortality or population level effects are considered unlikely because of the low density of animals in the areas. If prey populations, presence, productivity and distribution are reduced due to VLOS effects, humpback habitat value would be reduced unless the humpbacks in the Alaska Chukchi and Beaufort Seas originate from the Western North Pacific stock.

Humpback whales would likely avoid the noise related to VLOS response, cleanup and post-event human activities in a manner similar to that noted for bowhead whales.

Gray Whale

Gray whale aggregations have consistently occurred near shore along the Alaska Chukchi Sea coast from west of Wainwright to northeast of Barrow. This zone would likely be the location of much of the cleanup operations to protect the coastline, lagoons, and river mouths. Avoidance of these intense clean-up activities could displace gray whales from preferred feeding areas. Oil contamination of benthic sediments and/or mortality of benthic invertebrates that these whales require could result in abandonment of these primary summer feeding areas that provide the majority of the annual nutritional and energy requirement of these whales and potentially take years to recover. Reduction in body condition, and potential mortality from insufficient body energy to complete the long distance migration of this species to and from as far south as Mexico could occur. Reduction or loss of the portion of the Western North Pacific stock of gray whales using the Chukchi Sea would likely take three generations or more to recover. Population level adverse effects from loss or reduction of prey resources nearshore could result in changes in distribution, habitat use, and/or presence in the Chukchi Sea. Loss of food sources could be reflected in individual body condition and mortality during the long stressful migrations this species endures.

Minke Whale

Individual minke whales could experience similar effects as noted for bowheads above if contacted by oil during the ice free period. Minke whale prey could be reduced or contaminated, leading to a modified distribution of minke whales or ingestion of oil contaminated prey. Temporary and/or permanent and non-lethal effects are likely and mortality or population level effects are considered to be unlikely. Changes in distribution of minke whales in the Alaska Chukchi Sea are not likely.

Minke whales would likely avoid the noise related to VLOS response, cleanup, and post-event human activities they may encounter in a manner similar to that noted for bowhead whales.

Killer Whale

Individual killer whales could experience similar effects as noted for bowheads above if contacted by oil during the ice free period. Killer whale marine mammal prey abundance and distribution could be reduced, or contaminated, leading to modified distribution of killer whales and/or ingestion of oil contaminated prey. Temporary and/or permanent injury and non-lethal effects could occur, but mortality or population level effects are considered to be unlikely because of the low density of animals in the areas.

Killer whales would likely avoid the noise related to VLOS response, cleanup and post-event human activities they may encounter in a manner similar to that noted for bowhead whales.

Harbor Porpoise

Individual harbor porpoise could experience similar effects as noted for bowheads above if contacted by oil during the ice free period. Harbor porpoise prey could be reduced or contaminated, leading to modified distribution of harbor porpoise or ingestion of oil contaminated prey. Temporary and/or permanent injury and non-lethal effects could occur, but mortality or population level effects are considered to be unlikely.

Harbor porpoise would likely avoid the noise related to VLOS response, cleanup, and post-event human activities. The apparent distribution of the porpoises near shore and in the various lagoons where forage fish are abundant puts these animals at risk of frequent contact with spill clean up activities. Such activities are concentrated (to place booms and skim oil) near the mouths of rivers and near lagoons to protect coastline resources. A reduction of coastal fisheries could reduce the capacity of the Chukchi Sea near shore to support harbor porpoise and, consequently, redistribution of porpoises could occur. Ingestion of contaminated fish could reach toxic levels and result in impaired endocrine function, reproductive impairment, or mortality. A substantial reduction in the low numbers that occur in offshore Alaska Chukchi Sea may take greater than three generations to recover due to the remoteness of this part of their range and the pioneering behavior required to recover.

Ice Seals

Section IV.E.10 of BOEM (2011b) describes potential impacts to ice seals during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

In the event of a VLOS, ice seals could be adversely affected to varying degrees depending on habitat use, densities, season, and various spill characteristics.

Spotted seals are the only phocid species in the analysis area that habitually use shore-based haulouts. Their principle haulout locations that could be affected by a VLOS, ranked from largest to smallest, are Kasegaluk Lagoon, Kugrua Bay, Dease Inlet/Admiralty Bay, Smith Bay, and the Colville River Delta. Kasegaluk Lagoon is the largest haulout location that could be affected, and is several times larger than all of the others combined. Although spotted seals may forage for fishes in the open ocean, their presence is not known to be associated with the ice front. Consequently, their presence is associated with haulout areas and nearshore areas with open water.

In contrast, ribbon seals are the most pelagic seal species in the area, remaining in the open ocean for most of the year except for spring whelping and molting in the Bering and southern Chukchi Seas. Based on their very low presence in marine mammal surveys, BOEM concludes that they occur only in very low numbers spread across the Chukchi Sea and are virtually absent from the Beaufort Sea. Consequently, ribbon seal populations are not expected to be affected by a VLOS from any of the OSRA Launch Areas.

Both bearded and ringed seals closely associate with sea ice throughout the year, very rarely, if ever, coming ashore. Both species prefer to forage in proximity to the southern ice edge during the summer months, although some may be found in the open ocean away from areas of sea ice. Bearded seals feed on benthic organisms on the relatively shallow Chukchi continental shelf, while ringed seals forage for fishes and some invertebrates in the water column. These differences in food selection and foraging behavior help determine the presence or absence of each of these species in an area. Bearded seals are essentially restricted to areas over the continental shelf and the ice front where they can reach the seafloor to feed on benthic organisms. Ringed seals may be found under areas of solid ice as well as in the ice front where they predate fishes such as Arctic and saffron cod.

Presently there are no areas identified as important ringed, bearded, or ribbon seal habitat during the summer months. However, during the winter, conditions change drastically with the southward advance of sea ice, when only bearded and ringed seals persist in the Chukchi and Beaufort Seas. During winter, bearded seals loosely congregate around polynyas, and lead systems, generally avoiding areas of shorefast ice. Ringed seals, however, select shorefast ice zones as their primary habitat where they survive by making and maintaining breathing holes through the ice and by constructing subnivean lairs, particularly under pressure ridges where they are somewhat protected from predators. If lead systems or polynyas occur near the shorefast zone, ringed seals may often maintain a presence in proximity to the lead or polynya. However, because of their site fidelity and need for stable ice, they are strongly linked with stable shorefast ice. Any VLOS reaching a polynya or lead system could have serious effects on local ringed and bearded seal sub-populations, potentially oiling or even killing a number of bearded and/or ringed seals.

Pacific Walrus

Section IV.E.11 of BOEM (2011b) describes potential impacts to walrus during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

In the event of a VLOS, the OSRA model estimates most of the contact between oil and walrus habitat would occur on the U.S. side of the Chukchi Sea, while the bulk of the walrus population hauls out on the Russian side of the Chukchi Sea. Contact with oil on the U.S. side of the Chukchi Sea would be most likely to occur at Herald or Hanna shoals, or at coastal haulouts near Wainwright or Pt. Lay. Walrus are less vulnerable to injury from contact than are furred seals, but more likely to be subjected to long term chronic ingestion of hydrocarbons from eating benthic prey than are seals that eat fish. In the event of a VLOS, key habitats to protect for walrus would include the Herald and Hanna Shoal polynyas and the Wainwright and Pt. Lay areas. Significant impacts to the walrus population would be most likely to occur if large scale contamination of prey and habitat persisted for years.

The Pacific walrus population is currently estimated at a minimum of 129,000. If a VLOS were to occur and to contact large portions of habitat inhabited by walrus, calves of the year would most likely be at risk.

Polar Bears

Section IV.E.8 of BOEM (2011b) describes potential impacts to polar bears during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

In the event of a VLOS in this scenario, most of the contact between oil and polar bear habitat would occur on the U.S. side of the Chukchi Sea. The majority of the CBS stock is believed to den and come ashore on the Russian side of the Chukchi Sea, particularly at Wrangel Island. The majority of the SBS stock of polar bears come ashore and den further eastward in the Beaufort Sea. However there is a large area of overlap between the CBS stock and the SBS stock out on the sea ice in the northeastern portion of the Chukchi Sea. Both stocks are believed to be in decline. If a VLOS were to occur and if it resulted in the loss of large numbers of polar bears, particularly adult breeding age females, this would have a significant impact on the SBS and/or CBS stocks of polar bears. Contact with oil on the U.S. side of the Chukchi Sea would be most likely to occur along the U.S. Chukchi Sea coastline or the U.S. Chukchi Sea barrier islands. In the event of a VLOS, key habitats to protect for polar bears would include the barrier islands and shoreline.

4.10.6.11.2 Additional Analysis for Marine Mammals

Cetaceans

Conclusions regarding potential effects of a VLOS on cetaceans in the Chukchi Sea will be addressed separately for each species below. Narwhals, included in previous sections of this EIS, were omitted from BOEM (2011b) analysis. Narwhals in the Chukchi Sea are exceedingly rare. Because the co-occurrence of narwhals and a VLOS in the Chukchi Sea is highly unlikely this species is not considered in this additional analysis.

Bowhead Whale

Bowhead whales are most vulnerable to oil spills in the Chukchi Sea while feeding during late summer and fall and during the westward migration throughout the fall. A winter spill, or if oil persists in ice over winter, could impact bowheads migrating through the lead system during the spring.

Injury and mortality are most likely during Phase 1 (initial event) of a VLOS. Contact through the skin, eyes, or through inhalation and ingestion of fresh oil could result in temporary irritation or long-term endocrine or reproductive impacts, depending on the duration of exposure. Based on criteria described in Section 4.1.3, the magnitude of the resulting impact could be high. The duration of impacts could range from temporary (such as skin irritations or short-term displacement) to permanent (e.g. endocrine impairment or reduced reproduction) and would depend on the length of exposure and means of exposure, such as whether oil was directly ingested, the quantity ingested, and whether ingestion was indirect through prey consumption. Displacement from areas impacted by the spill due to the presence of oil and increased vessel activity is likely. If the area is an important feeding area, such as off Barrow, or along the migratory corridor, especially in the spring lead system, the impacts may be of higher magnitude. The extent of impact could be state-wide, given the migratory nature of bowhead whales. Bowhead whales are a unique resource, as they are a centerpiece of the Iñupiat subsistence lifestyle and listed as endangered under the ESA. Population level impacts are possible if a VLOS event coincided with and impacted a large feeding aggregation of bowhead whales during the open water season, particularly if calves were present. Mothers with young calves are also vulnerable to potential exposure to oil in the lead system during the spring migration. A VLOS could result in major impacts on bowhead whales.

Beluga Whale

Beluga whales of the eastern Chukchi Sea stock could be particularly vulnerable to a VLOS during June and July when congregating in the nearshore waters near Kasegaluk Lagoon and along the Alaskan Chukchi Sea coast. Belugas from this stock and the Beaufort Sea stock could encounter spilled oil during migrations through the Chukchi Sea in the spring and again later in the fall, although distribution is generally more dispersed during the fall. Impacts of a VLOS on beluga whales, especially while concentrated in lagoons and nearshore areas, are similar to those described for other cetaceans and include prey and habitat destruction and contamination, potential injury, illness, and mortality from contact with or ingestion of oil or dispersants, and displacement caused by avoidance of spills and clean-up activities. Using criteria described in Section 4.1.3, the magnitude of impacts could range from medium to high, depending on habitat and prey impairment and level of injury or mortality. Durations could range from temporary skin irritations to permanent endocrine or reproductive failure or long-term displacement, and the extent could be state-wide due to the migratory nature of belugas. Belugas are considered unique because of their importance as a subsistence resource. An impact to the eastern Chukchi Sea stock, particularly in the vicinity of Kasegaluk Lagoon and Point Lay, could substantially impact local subsistence hunters. Population level impacts would depend on the extent of the spill, damage to molting and calving areas and prey resources, how long it takes for resources to recover, and whether displacement from important habitat is long-term. A VLOS could have a major impact on beluga whales in the Chukchi Sea, particularly on the eastern Chukchi Sea stock.

Fin Whale

Fin whales are only present in the Chukchi Sea in small numbers during summer months. If, however, they were to encounter an oil spill during that time, physiological impacts of oiling may occur. Prey could also be impacted through reduced abundance or contamination that could lead to longer term habitat alterations, displacement, or contaminant loading in fin whales. In accordance with criteria established in Section 4.1.3 of this EIS, the magnitude of impacts to individual fin whales could be medium to high, with displacement from the area, impacts to prey resources and habitat quality, and a possibility of injury from either direct contact with or ingestion of oil or associated contaminants, such as dispersants. Duration could range from temporary to permanent, depending on the type of injury incurred or extent of habitat alteration. The geographic extent could be state-wide, since the fin whale is a migratory species and, as they are listed as endangered under the ESA, fin whales are considered a unique resource. Population level impacts are unlikely, given the low numbers of fin whales in the EIS project area, yet a VLOS could still result in a major impact to individual fin whales.

Humpback Whale

The impacts of a VLOS on humpback whales in the Chukchi Sea are anticipated to be similar to those described for fin whales.

The potential for population level impacts depends on the stock from which humpbacks in the Chukchi Sea originate. It is currently unknown whether they come from the Central North Pacific or the Western North Pacific stock. The Western North Pacific stock is more likely, given its known geographic range, and is a substantially smaller stock with an estimated minimum population estimate of 732 whales (Allen and Angliss 2010). As noted in BOEM (2011b) Section IV.E.7., recovery of the Western North Pacific stock from mortality resulting from a VLOS could take three or more generations. Therefore, the Western North Pacific stock of humpback whales could experience a major impact from a VLOS at the population level. BOEM further state that, if humpbacks in the Chukchi Sea Lease Sale 193 area originate from the Central North Pacific stock, then a negligible number would be expected to experience temporary and non-lethal effects from a VLOS. The Central North Pacific stock is more robust than the Western North Pacific stock, with an estimated minimum population of 7,469 whales (Allen and Angliss 2010). Population level impacts are, therefore, unlikely for this stock, but a VLOS could still result in a major impact to individual humpback whales.

Gray Whale

Gray whales may be particularly vulnerable to impacts from a VLOS in the Chukchi Sea. Summer feeding aggregations commonly occur nearshore between Wainwright and Barrow, where they are likely to experience displacement caused by increased vessel traffic in the aftermath of a spill, and/or physical impacts from direct contact with oil and contamination of benthic prey resources. The resulting impacts could be similar to those described for bowhead and fin whales. Reduced prey availability and loss of feeding habitat could have long-term impacts on body condition and fitness. Based on criteria described in Section 4.1.3, the magnitude of impact from a VLOS on gray whales could be medium to high, depending on level of injury or mortality. The duration could range from temporary (minor skin irritations) to permanent (loss of habitat), and impacts could extend state-wide, given that gray whales migrate well beyond the Chukchi Sea to as far south as Mexico. The species is no longer listed as endangered, so could be considered a common to important resource. Whether population level impacts occur depends on the extent of the spill and loss of nearshore prey resources and habitat, as well as availability of alternate habitat. A VLOS in the Chukchi Sea could have an overall moderate to major impact on gray whales.

Minke Whale

Minke whales are seen in low numbers and in small groups during the open water season in the Chukchi Sea. The likelihood of encountering a VLOS may, therefore, be low and would only occur in the event of a summer spill. If encountered, however, a VLOS could result in similar impacts to that described for bowhead, fin, and humpback whales. A difference in assessing overall impacts, as per the criteria in Section 4.1.3, would be that minke whales are not listed as depleted under the MMPA or listed under the ESA, so are not considered a unique resource. A population level impact is unlikely given the low sighting rate in the Chukchi Sea and apparent broad distribution in the North Pacific. The overall impact of a VLOS on minke whales could be moderate.

Killer Whale

Killer whales occur in the Chukchi Sea during the open water season. If they were to encounter an oil spill during that time, they could experience impacts similar to that described for other cetaceans. Duration of impacts resulting from consuming contaminated prey could be prolonged through bioaccumulation of toxins through the food chain, since killer whales in the Chukchi Sea are mammal-eating transients and considered apex predators. Killer whales are not listed as depleted under the MMPA or listed under the ESA, so, in accordance with criteria of Section 4.1.3 of this EIS, are not considered a unique resource. A population level impact of a VLOS on killer whales is unlikely given the low occurrence rate in the Chukchi Sea. The overall impact of a VLOS on killer whales could, therefore, be moderate.

Harbor Porpoise

Harbor porpoise are present in the Chukchi Sea during the open water season and have been sighted with increasing frequency in both the nearshore and offshore areas in recent years. This may indicate a range extension (Funk et al. 2010). Increasing frequency of occurrence may leave harbor porpoise more susceptible to an encounter with a VLOS and subsequent clean-up activities at the point of origin offshore, if the spill trajectory included nearshore waters, and nearshore clean-up activities. Impacts on harbor porpoise could be similar to that described for other cetaceans – displacement due to prey loss and vessel activity, potential injury, illness or mortality from contact with oil, consuming oiled prey, or otherwise consuming oil and associated chemicals. Impacts on individual porpoises, based on criteria described in Section 4.1.3 of this EIS, could range from medium to high intensity and from temporary to permanent duration, depending on level of injury or mortality, as well as long-term impacts on prey resources through reduced availability or contamination. The extent could be broad, reaching to the level of state-wide, given that harbor porpoise seasonally occur in the area and are a migratory species. Harbor porpoise, however, are not listed under the ESA so would be considered a common resource. Population level impacts are not likely, although BOEM (2011) states in Section IV.E.7., that recovery from a major reduction in numbers of harbor porpoise in the offshore waters of the Chukchi Sea may take longer than three generations. This may curtail the range extension but not necessarily the population as a whole. A VLOS could have a moderate impact on harbor porpoise in the Chukchi Sea.

Ice Seals

The impact of a VLOS on ice seals in the Chukchi Sea could vary by habitat requirements, prey preferences, and seasonality of occurrence in the area, among other factors. Potential impacts are, therefore, discussed separately for each species.

Bearded Seal

Bearded seals occur in the Chukchi Sea year round and could, thus, be vulnerable to impacts from fresh oil and overwintering residual oil from a VLOS. Direct contact with oil could result in injury or mortality events, particularly if it occurred in a polyna or lead system in which bearded seals aggregated (BOEM 2011b). Bearded seals are benthic feeders and are restricted to shallow shelf areas for feeding. Damage to these areas and prey resources could cause long-term displacement and possible loss of fitness due to inadequate prey availability. Based on criteria described in Section 4.1.3, impacts of a VLOS on bearded seals could be of medium to high intensity and of temporary to permanent duration, depending on extent of habitat loss, injury, or level of mortality. The geographic extent could be regional to state-wide, depending on how far bearded seals could be displaced or need to search for alternative habitat. Bearded seals are a unique resource in the Chukchi Sea due to their importance as a subsistence resource for coastal communities and recent proposal to be listed as threatened under the ESA. Population level impacts are possible if large portions of important benthic habitat are unavailable and if contact with a VLOS occurred in areas of high concentrations of seals. A VLOS in the Chukchi Sea could have a major impact on bearded seals.

Ringed Seal

Ringed seals may also occur in the Chukchi Sea year round, where they are closely associated with sea ice. During the open water season, they spend more time in the water foraging, leaving them vulnerable to impacts of a VLOS during that time of the year. During winter and spring, they associate with shorefast ice where ice entrained oil may persist. The intensity, duration, and extent of impacts of a VLOS on ringed seals are similar to those anticipated for bearded seals. A large-scale impact on prey resources could result in displacement, at a minimum, or even compromised fitness. Ringed seals are hunted for subsistence by Alaska Natives from communities along the coasts of the northern Bering, Chukchi and Beaufort seas, so are considered a unique resource. Population level impacts are possible if large portions of important habitat and prey are unavailable and if contact with a VLOS occurred in areas of high concentrations of seals. Based on criteria described in Section 4.1.3 of this EIS, a VLOS in the Chukchi Sea would have a major impact on ringed seals.

Ribbon Seal

Ribbon seals are infrequently seen in the northern or eastern Chukchi Sea and, based on satellite tags, disperse broadly with retreating sea ice. This leaves them less vulnerable to a VLOS in the Chukchi Sea. A small proportion of individuals that do contact oil from a VLOS could die (BOEM 2011b). On an individual level, impacts could be similar in intensity, duration, and extent to that described for other ice seals, but population level impacts are unlikely. Ribbon seals are harvested by Alaska Native subsistence hunters, primarily from villages along the Bering Strait and to a lesser extent at villages along the Chukchi Sea coast, so are considered a unique resource, based on criteria described in Section 4.1.3. As a result, a VLOS could result in a major impact on individual ribbon seals.

Spotted Seal

Spotted seals are particularly vulnerable to impacts of a VLOS, as they are the only ice seal species in the Chukchi Sea that regularly hauls out on shore and concentrates nearshore in lagoons, such as Kasegaluk Lagoon. Spotted seals could be susceptible to impacts of floating oil in foraging areas in open water, oil that came ashore the Chukchi Sea coast, and the multitude of activities associated with clean-up, from boom deployment to vessels and airplanes. Displacement from important habitat areas is possible, as is direct impacts from contact with oil and dispersants. Based on criteria described in Section 4.1.3, impacts of a VLOS on spotted seals could be of medium to high intensity and of temporary to permanent duration, depending on extent of habitat loss, injury, or level of mortality and whether oil reached nearshore haul out concentrations. The geographic extent could be state-wide, given the migratory behavior of spotted seals. Spotted seals are an important species for Alaskan subsistence hunters, primarily in the Bering Strait and Yukon-Kuskokwim regions, so are considered a unique resource. Population level impacts are possible if large portions of important habitat are unavailable and if contact with a VLOS occurred in areas of high concentrations of seals. A VLOS in the Chukchi Sea could have a major impact on spotted seals.

Pacific Walrus

Pacific walrus are most susceptible to impacts of a VLOS during the summer months and can be impacted at sea, on ice floes, or onshore. In recent years, walrus have been hauling out in large numbers (up to >15,000 animals [Clarke et al. 2011a]) between Wainwright and Point Lay during late summer to early fall. Disturbance to such a large concentration could result in stampedes and subsequent trampling deaths and injury caused by increased overflights and vessels during spill response efforts. Oil coming ashore where walrus are densely concentrated could also impact large numbers of animals, including young of the year, through physical contact with the skin and membranes, inhalation of fumes, and impacts on benthic prey. Impacts of oil and dispersants on benthic prey resources (such as contamination or mortality) could have lasting impacts on prey and habitat availability for walrus in the Chukchi Sea. Based on criteria described in Section 4.1.3 of this EIS, impacts of a VLOS on Pacific walrus could be of medium to high intensity, with intensity greatest if the VLOS and subsequent clean-up activities coincide with dense aggregations of walrus, duration could range from temporary displacement to long term injury or displacement from important habitat, the geographic extent could be state-wide due to the migratory behavior of walrus and potential for decreased fitness and a need to seek alternate forage locations of benthic habitat and prey are severely altered. Walrus are an important subsistence species for several communities along the Bering and Chukchi Sea coasts of Alaska and the coast of Chukotka (Russia), so are considered a unique resource. Population level impacts are possible if young of the year are impacted or access to important habitat is curtailed. A VLOS in the Chukchi Sea could have major impacts on Pacific walrus.

Polar Bear

Polar bears are vulnerable to impacts of a VLOS in the Chukchi Sea, particularly if it occurred during the summer open water period or the broken ice period during the fall; most denning occurs on either the Russian side of the Chukchi Sea or in the Beaufort Sea. Polar bears are listed as threatened and critical habitat was recently designated in December 2010 along the Chukchi Sea coastline and barrier islands. Oil from a VLOS in the Chukchi Sea could foul these areas and impact critical habitat. A VLOS in the Chukchi Sea could involve either the Southern Beaufort Sea stock (SBS) or Chukchi/Bering Seas stock (CBS) in the region of overlap near Point Lay and the northeastern Chukchi Sea, but CBS are most likely to be impacted by a spill in the Chukchi Sea either nearshore, on land, at sea, or on offshore ice floes. Both populations are small and apparently not increasing. Based on criteria described in Section 4.1.3, impacts of a VLOS on polar bears could be of medium to high intensity, particularly if the fur were sufficiently fouled to result in loss of insulation, if oil were ingested, or if displacement from critical habitats affected overall fitness. Duration of impacts could range from temporary displacement to permanent habitat loss, reproductive impairment, or even death. Contamination and toxic impacts from either directly consuming oil or through consuming marine mammal prey in which contaminants accumulated could be long-lasting. The geographic extent of impacts could be state-wide, given the migratory movements of bears and possible need to relocate if local habitats are severely altered. It is also possible that, if the oil discharge were widespread, denning areas could be impacted. Polar bears are considered unique due to their threatened status and importance as a subsistence resource. Population level impacts are possible and dependent on numbers of polar bears directly injured or killed, extent of habitat loss, and chronic long-term impacts on reproduction and survival. Impacts of a VLOS on polar bears in the Chukchi Sea could be major.

4.10.6.12 Terrestrial Mammals

4.10.6.12.1 Existing Analysis (BOEM 2011b and BOEM 2012)

Section IV.E.12 of BOEM (2011b) describes potential impacts to terrestrial mammals during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

Terrestrial mammals should not be significantly affected by a VLOS event. Caribou are the only species occurring onshore in the proposal area that might be affected in numbers greater than 1,000; however, this level of impact is unlikely. If a worst case scenario was to occur and several thousand caribou were to succumb to the effects of oil contamination, the herd sizes are sufficient to recover from losses within one and no more than two years. Grizzly bears in the Alaskan Arctic require extremely large home ranges to meet their needs. Consequently a VLOS is unlikely to involve more than a few bears at most. If those bears were to die as a result of consuming an oiled marine mammal carcass, contaminated salmon, or through grooming oiled fur, their home ranges could be reoccupied by other bears within that same season, and the population recovery would most likely occur within a year or two.

Effects on local muskox populations should also be small since they do not occur in large numbers, spending much of their time inland and away from the coast. The effects on furbearers such as foxes, wolves and wolverines would also be short-term since they either produce large litters (foxes), or occur in very low densities (wolverines, wolves). Any losses to fox populations would quickly be replenished, while the low population density and large home-ranges of wolverines and wolves would act to prevent more than a very few individuals from being exposed to a VLOS.

The presence of oil spill cleanup crews and the associated oil spill response activity (aircraft, landing craft, nearshore boats, etc.) should effectively haze most terrestrial mammal species from contaminated areas or sites. By unintentionally disturbing the animals, responders may provide a positive benefit by forcing those animals away from the spill and potential contamination.

In addition, Section 4.4.7.1.3 of the BOEM (2012) analysis provides a discussion of the impacts of a catastrophic discharge event on terrestrial mammals in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event would result in sustained degradation of water quality, shoreline terrestrial habitats, and, to a lesser extent, air quality that could impact terrestrial mammals from direct contact, inhalation, and ingestion. These effects could be severe where persistent, heavy oil makes contact with important habitat and prey base, causing a multitude of acute and chronic effects (BOEM 2011d).

4.10.6.12.2 Additional Analysis for Terrestrial Mammals

There are approximately 30 species of terrestrial mammals within the vicinity of the EIS project area (Table 3.2-5). Among these species, it is expected that only barrenground caribou (*Rangifer tarandus* *granti*) may experience interactions with oil and gas exploration activities associated with this EIS during critical periods of their life cycle; therefore, this analysis will focus solely on caribou. Descriptions of distribution, life cycle, and habitat characteristics of other species are not included in this EIS.

The effects of a VLOS would be of medium intensity, temporary duration, local extent, and common context. While there could be a perceptible change to the caribou population, it would likely be temporary in duration, with a localized impact, and the caribou population would be expected to recover within one to two years even with a direct loss of several thousand animals (BOEM 2011b). For more information regarding the impact to subsistence or recreational hunting see Sections 4.10.6.15 and 4.10.6.20 in this EIS, respectively. Utilizing the impact criteria listed in Section 4.1.3, there would be a summary impact level of minor to moderate, depending on the magnitude and duration of the VLOS.

4.10.6.13 Time/Area Closure Locations

A low probability, high impact VLOS could affect marine mammals and marine and coastal birds in areas recommended for time/area closure in the Chukchi Sea. Discussion of impacts to marine mammals in Hanna Shoal and Kasegaluk Lagoon can be found in Section 4.10.6.11 and impacts to marine and coastal birds in Ledyard Bay Critical Habitat Area and Kasegaluk Lagoon can be found in Section 4.10.6.10.

Hanna Shoal Time/Area Closure

Hanna Shoal is a relatively shallow area of the offshore Chukchi Sea that is rich in marine life and adjacent to many existing oil lease areas. Phytoplankton, amphipods, polychaete worms, crab larvae, fish larvae, and other benthic invertebrates form the foundation of the marine food web and are abundant in the muddy substrate of Hanna Shoal. Numerous species of seabirds and waterfowl spend time feeding in Hanna Shoal at some point during the year, especially during post-breeding and fall migration periods.

Gray whales have historically used Hanna Shoal to feed on mud-dwelling benthic invertebrates. However, surveys in the last few years indicate they may not be using the area as much as in the past (Clarke et al. 2011a). Bearded and ringed seals are common in the area during summer, feeding on benthic invertebrates and fish. Pacific walrus are also common when the ice edge is near Hanna Shoal in either spring or fall. In the winter, walrus and bearded seals concentrate along leads and polynya regions, including Hanna Shoal. If oil collects or migrates into these small open-water areas in the ice, most if not all of the seals in the area could be adversely affected by direct contact, ingestion, and contamination of prey. Walrus are less vulnerable to injury from contact than are furred seals but more likely to be subjected to long term chronic ingestion of hydrocarbons from eating more sedentary benthic prey than are seals that eat fish.

Hanna Shoal is one of several areas in the Chukchi Sea that forms consistent polynyas in the winter and leads in the pack ice crucial to marine mammals and some seabird species. The closeness of Hanna Shoal to existing lease areas means it has relatively high probabilities for exposure to oil in BOEM's VLOS modeling exercise (BOEM 2011b). The majority of seabird species would be most susceptible to effects of a spill during the open-water season. The effects on marine mammals, especially Pacific walrus, bearded seals, and ringed seals would be much greater if the spill occurred in or persisted into the winter than if it was only in the summer, due to the concentration of these animals in polynyas and leads. Young of the year would be especially vulnerable. Benthic invertebrate species favored by walrus and diving seabirds could become contaminated and become a source of chronic exposure for years after a spill. Hanna Shoal is an important resource in the Chukchi Sea. If a VLOS occurred in or persisted into the winter, the effects would be considered high in magnitude and intensity due to effects on Pacific walrus and ice seals, long-term in duration (lasting more than five years), and state-wide in geographic extent because it would affect migrating populations of birds and marine mammals. A VLOS would be considered to have major effects on Hanna Shoal according to the criteria established in Section 4.1.3.

Kasegaluk Lagoon

Kasegaluk Lagoon is an estuary important to rearing fish, including out-migrating salmon smolts from the Kukpowruk, Kokolik, and Utukok rivers. Salmon, other fish, and abundant invertebrate populations are a major attractant for very large numbers of migratory birds that make use of Kasegaluk Lagoon during May to October. Concentrations of beluga whales use Kasegaluk Lagoon in the spring/summer for molting, where the relatively warm waters and gravelly substrate helps the process. Spotted seals haul out along the shores of Kasegaluk Lagoon in the summer and feed in nearby waters.

The effects of a VLOS on coastal vegetation and wetlands could involve hundreds of miles of shoreline and, if influenced by strong winds and waves, could be blown or washed some distance inland. Although barrier islands could protect lagoon areas to some extent, if oil entered a lagoon in substantial amounts, the barrier islands could inhibit weathering and flushing by waves, thereby leading to a more extended exposure of the lagoon environment to the oil than if it was on an outer coast. Kasegaluk Lagoon has a number of entrances to the open ocean and would thus be susceptible to oil spill penetration. BOEM (2011b) VLOS analyses are prefaced with assumptions about when, where, and how much oil would directly affect given areas. Of great importance to biological resources is the timing of the spill and how it would overlap with migration and other critical life functions. If oil enters Kasegaluk Lagoon and persists for up to 10 years, as is projected in the BOEM model, most of the animals that use the area at any time of the year could be exposed at least one time and perhaps repeatedly over the years, with potentially permanent effects on all of the populations with intensive use of the lagoon, including many species of fish, waterfowl, shorebirds, beluga whales, and spotted seals. Kasegaluk Lagoon is a unique resource in the Chukchi Sea and the effects of a VLOS would be considered high in magnitude and intensity, permanent in duration (lasting more than five years), and state-wide in geographic extent because it would affect migrating populations of birds and marine mammals. This would be considered a major effect on this time/area closure location according to the criteria established in Section 4.1.3.

4.10.6.14 Socioeconomics

4.10.6.14.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

Section IV.E.14 of BOEM (2011b) describes potential impacts to socioeconomic resources during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

A VLOS event of 2.2 MMbbl would generate several thousand direct, indirect, and induced jobs, and millions of dollars in personal income associated with oil spill response and cleanup in the short run. The effects would be significant in the short term. The expectation is that employment of cleanup workers to increase rapidly during Phase 2 and Phase 3, and to peak during Phase 4. Revenue impacts from a VLOS event include additional property tax revenues accruing to NSB from any additional onshore oil spill response infrastructure, and any potential decline in Federal, State, and local government revenues from displacement of other oil and gas production. A VLOS could also have significant adverse impacts on economic activity that does not currently take place in the area but could exist in the future, such as commercial fishing, recreational fishing, tourism, and increased Arctic marine shipping.

Section 4.4.13.3.2 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on sociocultural systems in the Alaskan Arctic. This information is incorporated herein by reference, and a summary of the information is provided. The analysis notes that while local villagers would be employed in the cleanup for a catastrophic discharge event, it is likely that many additional workers would be necessary, placing stress on village facilities. An influx of outsiders is likely to result in some cultural conflict, stressing the local sociocultural systems. As is evident from the EVOS event, such cleanup efforts can be disruptive socially, psychologically, and economically for an extended period of time (BOEM 2011d).

4.10.6.14.2 Additional Analysis for Socioeconomics

The socioeconomic effects of historical oil spills provide indicators for estimating the future impact in a very large oil spill scenario. The Chukchi VLOS described in this hypothetical worst-case scenario would be 2.2 MMbbl and 1.8 Bcf of gas. The 1989 EVOS was 240,000 bbl. The socioeconomic effects researched after EVOS can serve as good indicators, but are of a different magnitude than this analysis.

Public Revenue & Expenditures

The BOEM (2011b) analysis describes potential new NSB revenues associated with property taxes assessed for the construction of worker infrastructure, as well as potential lost NSB, NAB, state and federal revenues due to permitting delays, or exploration moratoria. Local and state agencies may also increase expenditures associated with the administration of oil spill response and social services related to the influx of new workers.

Employment & Personal Income

The BOEM (2011b) analysis provides an estimate for the number of workers needed for spill clean-up, but does not estimate the number or percent of these workers that would be local from NSB and NAB. It is likely that a spill in the Chukchi Sea could induce some local employment.

A major impact to subsistence would occur after a VLOS (described in Section 4.10.6.15) and could change the components of the non-cash economy. Households could require cash to supplement the loss of subsistence resources. NSB and NAB residents may be able to access emergency assistance or employment in the short-term, but there could be long-term public health and environmental justice impacts related to a loss of subsistence opportunity. This is discussed further in the Environmental Justice Section 4.10.6.22 and Public Health Section 4.10.6.16 of this EIS.

Demographic Characteristics

The BOEM (2011b) sociocultural analysis, discussed in Section 4.10.6.16 of this EIS, describes that new oil spill clean-up employment opportunities could be generated from a VLOS. However, it is not likely that workers originating from elsewhere would relocate permanently to the region. The BOEM (2011b) sociocultural analysis indicates that an outmigration of residents did not take place in the case of the EVOS so it would not be expected in the case of a VLOS in the Chukchi Sea. However, a study in Northeast NPR-A states that: "workforce changes and demographic changes could occur through consolidation of households to save money, placement of dependents with relatives beyond the village, and outmigration of wage earners in search of employment" when subsistence-harvest patterns are disrupted for multiple years (BLM 2008a, BOEM 2011b).

Social Organizations & Institutions

The influx of clean-up workers would create a short to long-term demand on institutions and social services in North Slope communities. Regional and local non-profit organizations such as the AEWC and Eskimo Walrus Commission that mediate between industry and subsistence users would be impacted. BOEM (2011b) described "fears" about the:

> *…lack of local resources to mobilize for advocacy and activism with regional, state, and federal agencies; the lack of personal and professional time…capacity to interact with regional, state, and federal agencies…responding repeatedly to questions and information requests posed by researchers and regional, state, and federal outreach staff; and having to employ and work with lawyers to draft litigation in attempts to stop proposed development" (MMS 2007a:279, in BOEM 2011b).*

Fears about institutional capacity would be well-founded and it is likely that the quality of local community services would be diminished or halted in the short to long-term to respond to agencies, researchers, and litigation.

Private companies and regional corporations may be beneficially impacted in the short-term (Phases 1 to 4) through the sale of goods and services to spill response companies.

Conclusion

Employment and local revenues associated with VLOS would be high intensity, long-term in duration, statewide to national in extent, and unique in context. The impact to the non-monetary economy is discussed in detail in Section 4.10.7.15 (Subsistence), but would be high intensity, long-term in duration, regional in extent, and unique in context. Therefore, the summary impact level for socioeconomics would be major.

4.10.6.15 Subsistence

Existing Analysis (BOEM 2011b and BOEM 2011d)

Section IV.E.15 of BOEM (2011b) describes potential impacts to subsistence resources during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

If a VLOS occurred and affected any part of the bowhead whale's migration route, it could taint this culturally important resource. Any actual or perceived disruption of the bowhead whale harvest from oil spills and any actual or perceived impacts anywhere during the bowhead's spring migration, summer feeding, and fall migration could disrupt the bowhead hunt for an entire season even though whales still would be available. In fact, even if whales were available for the spring and fall seasons, traditional cultural concerns of tainting could make bowheads less desirable and alter or stop the subsistence harvest in Barrow, Wainwright, Point Lay, and Point Hope, and the beluga whale hunt in Point Lay for at least two seasons. Concerns over the safety of subsistence foods could persist for many years past any actual harvest disruption. This would be a significant adverse effect. In terms of other species, this same concern also would extend to walrus, seals, polar bears, fish, and birds.

A spill originating within the Chukchi Sea region could produce indirect impacts felt by communities remote from the sale area and far removed from the spill. Essentially, concerns about subsistence harvests and subsistence food consumption would be shared by all Iñupiat and Yup'ik Eskimo communities in the Chukchi (including indigenous people on the Russian Chukchi Sea coast) and Bering seas adjacent to the migratory corridor used by whales and other migrating species. Major impacts are expected from a VLOS when contamination of the shoreline, tainting concerns, cleanup disturbance, and disruption of subsistence practices are factored together (USDOI, MMS, 2009).

In addition, Section 4.4.13.3.2 of the BOEM (2011e) analysis provides some information about the impacts of a catastrophic discharge event on subsistence harvest in the Alaskan Arctic regions. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that as the result of a catastrophic discharge event, the economically, socially, and culturally important bowhead whale hunt could be disrupted, as could the beluga harvest and the more general and longer hunt for walrus west of Barrow. Animals could be directly oiled, or oil could contaminate the ice floes or onshore haulouts they use on their northern migration. Such animals could be more difficult to hunt because of the physical conditions. Animals could be spooked and/or wary, either because use of the spill itself or because of the hazing of marine mammals, which is a standard spill-response technique in order to encourage them to leave the area affected by a spill. Oiled animals are likely to be considered tainted by subsistence hunters and would not be harvested, as occurred after the EVOS. This would also apply to terrestrial animals, such as bears that scavenge oiled birds and animals along the shore, or caribou that seasonally spend time along the shore or on barrier islands seeking relief from insects. The loss of subsistence harvest resources, particularly marine mammals, would have significant effects on Alaska native culture and society (BOEM 2011d).

4.10.6.16 Public Health

4.10.6.16.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

Sections IV.E.15 Subsistence Harvest Patterns and IV.E.16 Sociocultural Systems of BOEM (2011b) describe potential impacts to public health from the potential for contamination of subsistence resources and disruption of sociocultural systems during the five phases of a possible VLOS in the Chukchi Sea. In addition, Section 4.3.2.4.2 of the BOEM (2011e) analysis provides some information about the impacts of a catastrophic discharge event on human health in the Alaska Arctic regions. This information is incorporated herein by reference, and a summary of that information is provided here.

The effects of a VLOS on sociocultural systems could cause significant adverse effects via chronic disruption to sociocultural systems for several years with a tendency for additional stress on the sociocultural systems. Longer term disruptions to subsistence resources and practices would impact sharing networks, subsistence task groups, and crew structures, as well as cause disruptions of the central Iñupiat cultural value: subsistence as a way of life (USDOI, MMS, 2007a).

These disruptions could cause breakdowns in family ties, a community's sense of well-being, and damage sharing linkages with other communities and could seriously curtail community activities and traditional practices for harvesting, sharing, and processing subsistence resources—a major impact on sociocultural systems. The effects of disruption to sociocultural systems would last beyond the period of oil-spill cleanup and could lapse into a chronic disruption of social organization, cultural values, and institutional organization with a tendency to displace existing social patterns. The accommodation response of Iñupiat culture in itself to the impacts of a VLOS could represent major impacts to social systems (USDOI, MMS, 2003a, 2006a, 2007a; USDOI, BLM and MMS, 2003). Similar to Subsistence Harvest-Patterns, the potential for significant impacts could be reduced by implementing larger a larger deferral area under Alternative IV or, to a greater extent, Alternative III.

4.10.6.16.2 Additional Analysis for Public Health

The above section describes in detail some of the effects of a VLOS on sociocultural systems, with subsequent impacts on health by way of disruptions in social organization, cultural values, and institutional organization. In addition to the long-term impacts on sociocultural systems, the short-term strain resulting from a large influx of outside workers following a VLOS would have a number of other health impacts. The presence of migratory workers in isolated areas is associated with the spread of infectious disease, particularly sexually transmitted infections (STIs) (Goldenberg 2008). Rates of Chlamydia, gonorrhea, and other STIs would be expected to increase during Phase 4 of a VLOS, as the population of extra-regional workers surges. Similarly, the population increase in response to a VLOS will strain the already limited capacity of the local health care system, particularly if the response results in temporary settlement of workers in villages outside of Barrow or Deadhorse. Additional strain on the health care system could result from increased burden of disease, starting with potential respiratory illness in the immediate post-spill environment and persisting through changes in chronic disease and social pathology resulting from long-term alterations in subsistence activities and sociocultural systems.

The impact of a VLOS on air quality is described in detail in Section 4.10.6.4. Potentially harmful emissions of several EPA criteria pollutants are likely to occur, likely resulting in severe levels of nitrogen dioxide (NO_2), carbon monoxide (CO), sulfur dioxide (SO_2), particulate matter (PM_{10} and $PM_{2.5}$), and volatile organic compounds (VOC). The impact is likely to be greatest during Phase 1, following the initial explosion and fire, and during Phase 4 due to the use of burning, dispersants and as a result of emissions from aircraft and offshore vessels operating during clean-up. The effect for both phases would be greater if the spill were to occur during winter. Respiratory irritation, asthma, and exacerbations of chronic obstructive lung disease are likely to increase in areas where concentrations of the pollutants are greatest. Pre-existing lung disease and prolonged exposure to respiratory irritants will be the greatest risk for exposed individuals.

The greatest and most persistent impacts to public health following a VLOS are likely to result from stress, anxiety, and changes to subsistence harvest patterns. Impacts on subsistence are described in detail in Section 4.10.6.15 and are likely to result from a combination of factors including diversion of hunters to jobs in the clean-up response; contamination and perception of contamination of food sources; and displacement and/or mortality of marine mammal stocks. The experience of the EVOS demonstrated that changes in consumption patterns may persist in some communities long after species themselves recover. Persistent changes in diet and nutrition are likely to result in increases in the rate of food insecurity and increased prevalence of diabetes and related chronic disease. To the degree to which contamination enters the food system, increases in cancer may occur.

Social pathology, including alcohol use and subsequent alcohol-related problems, is likely to occur following a VLOS as a result of stress, alterations in the social environment, and support networks and the influx of outside workers. These impacts are described in the Environmental Justice Section (4.10.6.22).

Conclusion

The magnitude of adverse impacts to public health is expected to be medium to high. Many predicted public health effects would be treatable and/or transient, which would be associated with a magnitude of medium. However, some impacts may be irreversible and thus should be classified as high. Duration of impacts would range from temporary to permanent, with some effects only lasting for a brief period associated with the influx of workers during the Phase 4 clean-up period. However, health effects resulting from changes in subsistence patterns would likely persist for many years. The extent would be regional, and the context would be unique, as a VLOS would affect two or more minority or low-income communities in the EIS project area. Therefore, the summary impact on public health of a VLOS in the Chukchi Sea is expected to be moderate to major depending on the size, nature, and location of the spill.

4.10.6.17 Cultural Resources

4.10.6.17.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

Section IV.E.17 of BOEM (2011b) describes potential impacts to cultural and archaeological resources during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

The greatest impacts on archaeological resources from a very large oil spill would be to onshore archaeological sites from oil-spill-cleanup activities. The potential for effects increases with oil-spill size and associated cleanup operations. Primary oil-spill impacts from cleanup activities would be expected on both prehistoric and historic archaeological sites. Following the EVOS, the greatest effects came from vandalism, because more people knew about the locations of the resources and were present at the sites. Offshore resources are at greatest risk from bottom-disturbing activities, notably anchoring and anchor dragging.

Although it is not possible to predict the precise numbers or types of sites that would be affected, contact with archaeological sites would probably be unavoidable and the resulting loss of information would be irretrievable. The magnitude of the impact would depend on the significance and uniqueness of the information lost. It is difficult to draw a distinct correlation between the potential for archaeological impacts from a VLOS under the different action alternatives. Because impacts to archaeological resources would not vary under the different action alternatives, additional information about the location of currently unknown resources is not essential to a reasoned choice among lease sale alternatives.

The most effective way to avoid adverse impacts from a VLOS would be to focus on effective surveying of potential exploration sites and the various mitigating measures used to protect archaeological sites while cleaning up oil spills. The latter category should include avoidance (preferred), site consultation and inspection, onsite monitoring, site mapping, scientific collection of artifacts, and programs to make people aware of cultural resources (Haggarty et al., 1991; USDOI, MMS 2007a, 2009).

In addition, Section 4.4.15.3.2 of the BOEM (2011e) analysis provides some information about the impacts of a catastrophic discharge event on archaeological resources in Alaskan Arctic regions. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could result in extensive impacts on a large number of archaeological and historic resources. Due to the large area affected by a catastrophic event some resources such as coastal historic sites that are sensitive to prolonged contact with oil could be heavily impacted. Cleanup crews would be needed in a greater number of locations. This could allow oil to be in contact with resources for a significant amount of time before cleanup efforts could be applied, which could result in impacts to these resources. A greater threat to archaeological and historic resources during a catastrophic discharge event would result from the larger number of response crews being employed. A catastrophic discharge event would result in large impacts to numerous archaeological and historic resources from response activities (BOEM 2011d).

4.10.6.17.2 Additional Analysis for Cultural Resources

Given the limited data related to historic and prehistoric resources in the Chukchi Sea, it is difficult to determine how many historic properties might be located in areas affected by a VLOS event. The presence of oil and the various oil-spill response and cleanup activities could potentially impact both prehistoric and historic archaeological resources, including submerged prehistoric sites and historic shipwrecks, as well as onshore prehistoric and historic resources, including camps, village sites, artifact scatters, historic structures, and World War II and Cold War era facilities.

Offshore Prehistoric and Historic Resources

As discussed in Chapter 3, Section 3.3.4, the presence of offshore prehistoric resources in the EIS project area is difficult to assess. In the event of a VLOS, submerged prehistoric and historic resources adjacent to a blowout could be damaged by the high volume of escaping gas, buried by large amounts of dispersed sediments, crushed by the sinking of the rig or platform, destroyed during relief well drilling, or contaminated by hydrocarbons (BOEM 2011b). Oil settling to the seafloor could contaminate organic materials associated with archaeological sites, resulting in erroneous dates from standard radiometric dating techniques (e.g. 14C-dating), and accelerate the deterioration of wooden shipwrecks and artifacts on the seafloor (BOEM 2011b). However, offshore resources are at greatest risk from bottom-disturbing activities, notably anchoring and anchor dragging. The potential to impact archaeological resources increases as the density of anchoring activities in these areas increases (BOEM 2011b). The anchoring of VLOS response and support vessels near a blowout site and in shallow water could result in damage to both known and undiscovered archaeological sites.

Onshore Prehistoric and Historic Resources

Archaeological resources have been recorded in greater numbers in the Chukchi Sea area, and unknown resources are more likely to be present. The greatest impacts on archaeological resources from a VLOS would be to onshore archaeological sites from oil-spill-cleanup activities. Cleanup activities could impact beached shipwrecks, or shipwrecks in shallow waters, and coastal historic and prehistoric archaeological sites. Any onshore activity (cleanup or otherwise) that brings development in contact with remote areas has the potential to expose archaeological resources to disturbance from construction or from vandalism. Historic sites, such as hunting, fishing, and whaling camps, or structures associated with settlements or the Distant Early Warning (DEW) Line (a system of radar stations) could be affected by increased cleanup activity in remote areas and increased vandalism. Prehistoric sites, though often not as visible as historic sites, also might be subjected to increased vandalism, as well (MMS 2007a, MMS 2009, BLM 2008a). As Bittner (1993) described in her summary of the 1989 EVOS, “Damage assessment revealed no contamination of the sites by oil, but considerable damage resulted from vandalism associated with cleanup activities, and lesser amounts were caused by the cleanup process itself" (MMS 2007a, 2009).

4.10.6.18 Land and Water Ownership, Use, and Management

4.10.6.18.1 Existing Analysis (BOEM 2011d)

Section 4.4.10.3.2 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on land use, development patterns, and infrastructure in the Alaskan Arctic. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could have both direct and indirect effects on land use, depending on the type, size, location, and duration of the incident. Impacts generally would be more intense in areas with little infrastructure in place to handle accidents and where a greater reliance is placed on coastal activities for subsistence (BOEM 2011d).

4.10.6.18.2 Additional Analysis for Land and Water Ownership, Use, and Management

Land and Water Ownership

Because the response efforts to a VLOS would not require any change in existing leasing rights, or the sale or transfer of any federal, state, or Native land or waters, no change in underlying land or water ownership would be anticipated in the Chukchi Sea. This includes federal waters (from 3 to 200 nm) and the federal lands National Petroleum Reserve-Alaska, Alaska Maritime National Wildlife Refuge, and Cape Krusenstern National Monument, state waters (shore to the three-mile limit), state lands and state selected lands, Native village lands and village selections and Native allotments, lands owned by the NSB and NAB, and municipal conveyed and selected lands.

Land and Water Use

A spill of this magnitude in the Chukchi Sea would impact some land uses. The presence of oil accumulation along the shoreline and in tidal zones could affect existing land uses by making it difficult to access land, creating a real or perceived change to the resources and values that support specific land uses, and discouraging pursuit of traditional land use in areas affected by a spill. Examples of these uses include subsistence, other traditional land uses, and recreation.

Industrial land may experience increased usage to support additional vessels, aircraft, vehicles and materials used in responding to a VLOS. This could require the construction or expansion of docks, warehouses, airstrips and/or storage facilities. It is unlikely that new permanent facilities would be constructed for spill response. Response support crews would need to be housed, affecting residential land uses. This could be accommodated through the construction of temporary worker camps, most likely in the vicinity of Prudhoe Bay or in the villages of Wainwright or Barrow. Depending on the location of industrial and commercial lands in the immediate vicinity of spill response activities, some temporary industrial land use may occur in new areas. Remote lands currently designated for natural resource protection might experience increased levels of human activity or disturbance for habitat restoration along shorelines where oil may accumulate. This would have similar effects to those discussed above, regarding access, damage to land and resource values, and interest in using the area. The duration of potential effects on land use would depend on the amount of oil that reaches shoreline and intertidal areas, the nature and duration of response activities, and the success in cleanup and restoration activities.

Land and Water Management

Current management plans within the EIS project area do not include contingencies for a VLOS. It is assumed that in the event of a VLOS, federal and state management plans that include coastal areas may require additional approvals for response and cleanup activities to accommodate heightened levels of human access for habitat restoration and oil cleanup efforts. Federal and state waters would be managed in the short term with an intense focus on response and clean-up of oil. Any management plan policies that are modified for a VLOS event would most likely be temporary, but could lead to plan updates to address any potential change in land and resource values, actions needed to promote recovery of affected resources, or address the potential for response activities in the unlikely event that they are needed.

Conclusion

The magnitude of impact would be low for land and water ownership because no change would be expected. The magnitude of impact would be high for land and water use for areas affected by a spill that have seen historical or current use for subsistence, other traditional land uses, and recreation, due to the potential change in resource/use values, and the level of activity associated with spill response and cleanup. The magnitude of impact would be medium for land and water management if management plans must result in new approvals to accommodate response efforts or a spill results in a change in resource or land values. The duration of impact would be long term because response efforts may extend up to several years, although the impact could be permanent if in the unlikely event construction of a new facility or infrastructure to accommodate spill response activities. The extent of impacts would be regional because the spill would affect large expanses of water and has the potential to come into contact with land along an extensive area of shoreline in and near the EIS project area. The context of impact would generally be common because the areas of land and water affected are extensively available, unless some special, rare, or unique characteristics associated with specific subsistence and recreation areas are affected. In summary, the effects of a VLOS would be major because of the possibility for high intensity and long term impact to land use and land management.

4.10.6.19 Transportation

4.10.6.19.1 Existing Analysis (BOEM 2011b and BOEM 2011d)

No specific analysis of the potential effects of a VLOS on transportation was provided in either the BOEM (2011b) or (2011e) discussions.

4.10.6.19.2 Additional Analysis for Transportation

The transportation systems among the Chukchi Sea communities would experience increased levels of air, vessel and surface traffic associated with containment, recovery, and cleanup activities for a VLOS that would involve hundreds of workers and vessels, aircraft, and onshore vehicles operating over an extensive area for one to two years. BOEM (2011b) predicted that in the event of a VLOS, offshore vessels such as skimmers, workboats, barges and icebreakers involved with cleanup would be used to remove oil from a spill area that occurs at sea and to drill a new well. Aircraft (fixed wing) would also likely be engaged in application of dispersants.

A VLOS may require up to 1,600 diesel-powered oil-skimming vessels, and other marine equipment such as ice breakers, over the course of time to confine and remove oil from the ocean surface (BOEM 2011b). The amount and type of vessels used during cleanup efforts could vary depending on seasonal and ice conditions:

> *In the event that response efforts continue into the winter season, small vessel traffic would come to a halt once the forming ice begins to cover the ocean surface. Larger skimming vessels could continue until conditions prevent oil from flowing into the skimmers. At this point, operations could shift to in-situ burning if sufficient thicknesses are encountered. The lack of daylight during winter months would increase the difficulties of response. As ice formation progresses, the focus of the response would shift to placing tracking devices in the forming ice sheet to follow the oil as it is encapsulated into the ice sheet. Once the ice sheet becomes solid and stable enough, recovery operations could resume by trenching through the ice to recover the oil using heavy equipment. This would most likely occur in areas closer to shore because the ice would be more stable. In late spring and early summer, as the ice sheet rots, larger ice-class vessels could*

> *move into the area and begin recovery or in-situ burning operations as the oil is released from the ice sheet. The ice would work as a natural containment boom keeping the oil from spreading rapidly. As the ice sheet decays, oil encapsulated in the ice would begin surfacing in melt pools at which time responders would have additional opportunities to conduct in-situ burn operations. Smaller vessels could eventually re-commence skimming operations in open leads and among ice flows, most likely in a free skimming mode (without boom) along the ice edge*.

Small boats and aircraft could also be involved with beach cleaning activities at oiled beaches (including booming) at marine and freshwater shorelines.

Aircraft could be used to apply dispersants used to decrease the size of the oil slick on the surface in the event of a VLOS. In addition, BOEM (2011b) noted that "during the response and cleanup process other aircraft may be needed for personnel and equipment transport, including helicopters, small piston-powered aircraft, and large commercial jets."

Aircraft used during spill response in the Chukchi Sea would likely be deployed from existing airport facilities including the airports of Barrow, Wainwright, Point Lay, Point Hope, Kivalina and Kotzebue, and other suitable airstrips (BOEM 2011b). Small vessels and surface vehicles would also be used during response operations at onshore areas.

As indicated in BOEM (2011b):

> *Aircraft and vessel operations would support many short-term efforts during the initial spill response as well as throughout the spill containment and treatments to minimize volume, spread, and environmental consequences. These include a wide variety of surveillance missions, placement of transmitter equipped buoys (to track spill edge in real time), media coverage, monitoring wildlife, dispersant application, treatments to shorelines and waters, as well as various activities associated with spill research, monitoring, and evaluation.*

Even after spill response and cleanup has occurred "aircraft and vessel operations would be supporting many longer term efforts for monitoring the recovery of resources, fate of oil and/or dispersants in the Arctic environment, and research and monitoring on the effectiveness of various cleanup and restoration practices" (BOEM 2011b). The effects and impacts of aircraft and vessels disturbance causes during response to a VLOS to seabirds, marine mammals and terrestrial mammals is described in Sections 4.10.6.10 through 4.10.6.12 and the affects to subsistence hunters is described in Section 4.10.6.15.

Local modes of transportation between communities by aircraft, vessels and surface means would be affected by a VLOS in nearshore and coastal areas. In the event of a VLOS, responders and additional response equipment would likely be transported to the airports of the Chukchi Sea communities. The Barrow airport could serve as a center for distributing responders and equipment to the smaller airports. As response efforts continue, the levels of air traffic to the areas affected in the Chukchi Sea would experience an increase in the numbers of flights arriving as additional response crews and supplies are transported to the affected areas. Air transportation within the state could also be indirectly affected as higher demand would occur for air travel to the spill area connecting from the Anchorage and Fairbanks airports. Increased levels of aircraft associated with spill response would affect local transportation systems for the duration of the response to a VLOS. Use of local airports associated with spill response activities (resupply, transport of spill response crews) could strain local transportation infrastructure.

Vessels and equipment associated with response would be present in increased numbers. It is likely that local tug/barge and small vessel traffic between communities would be affected during the spill due to the increased numbers of response and support vessels present in nearshore areas. Increased levels of response and support vessels associated with spill response would affect local transportation systems for the duration of the response to a VLOS. Local nearshore areas normally used for marine transportation between communities would experience and encounter vessels associated with spill response activities.

This could strain the local patterns of existing transportation. It is likely that in response to a VLOS there would be impairment of normal operations with deployment of response workers, vessels and equipment affecting the exiting levels of transportation along the coastline of the Chukchi Sea communities.

Surface transportation in the summer months could also be interrupted in the event of a VLOS that reaches the nearshore areas and coastlines. Local modes of surface transportation (e.g. off-road vehicles) used by residents during subsistence activities along the coasts may also become oiled if traveling within these areas.

Conclusion

The conclusions for impacts to transportation in the Chukchi Sea would be of high intensity (potentially year round), and long term in duration lasting one to two years or more during response and surveillance monitoring during recovery. The extent would be regional to statewide extent, and important in context. In summary, the impact of a VLOS on transportation would be moderate to major.

4.10.6.20 Recreation and Tourism

4.10.6.20.1 Existing Analysis (BOEM 2011d)

Section 4.4.12.3.2 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on recreation and tourism in the Chukchi Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that effects from a catastrophic discharge event would likely include beach and coastal access restrictions, including restrictions on visitation, fishing, or hunting while cleanup is being conducted, and aesthetic impacts associated with the event itself and with cleanup activities. These impacts are expected to be temporary, with the magnitude dependent on the location and size of the event and the effectiveness of cleanup operations. Longer-term impacts may also be substantial if tourism were to suffer as a result of the real or perceived impacts of the event, or if there were substantial changes to tourism and recreation sectors in the region as a result of the event (BOEM 2011d).

4.10.6.20.2 Additional Analysis for Recreation and Tourism

Recreation and tourism occur at generally low levels of use in the Chukchi Sea. The effects of a VLOS for recreation and tourism will be described by setting and activities. It is important to distinguish between recreation and subsistence uses. The vast majority of fishing, hunting, and boating that occurs in the EIS project area are *subsistence*-based, managed completely apart from recreation-based activities, with separate rights and privileges (see Section 4.10.6.15, Subsistence for further discussion). This section discusses only recreation-based activities, a small portion of the human uses in the area.

The setting for recreation and tourism could be impacted by a VLOS, primarily the visitor experience of the recreation setting. If visitors recreating in the Chukchi Sea are expecting a fairly isolated and undeveloped recreation setting, the presence of response vessels, aircraft and support crews could alter the experience of the setting or the sense of place (Williams & Stewart 1998), as expectations of a pristine, isolated setting would not be met. The expectation for an isolated and undeveloped setting could be held by people traversing the area in personal pleasure boats or yachts, and recreationists using the coastal areas. Visual impacts are discussed in further detail in Section 4.10.6.21. The setting would also be adversely impacted by the physical presence of oil on the water and shoreline. The impact of the oil on the recreation setting would increase in effect as it spreads and reaches coastal areas. The appearance of water and coastline would be altered, presence or abundance and distribution of wildlife could change, and natural sounds could be supplanted by human-induced noise for spill response.

A VLOS could have a potential impact on the recreation setting including impacts on existence and bequest values (Schuster et al. 2005). Existence value refers to the knowledge that a particular resource exists and an emotional attachment to the resource, even if the place is never visited in person (Cordell et al. 2003, Rolston 1985) and bequest value refers to a desire to bequeath a natural resource to future generations (Cordell et al. 2003, Rolston 1985). A person who does not physically recreate in the Chukchi Sea could hold existence or bequest values related to the Arctic environment. A VLOS would alter the recreation setting from a natural setting to a setting impacted by oil and response vessels. The experience of the recreation setting would also likely be altered, including the experience of recreationists that hold existence and bequest values related to the Arctic environment.

The main activities that would be affected by a VLOS are offshore and coastal activities. Offshore wildlife viewing may be adversely impacted by the presence of the response efforts if wildlife avoids these vessels or industrial sites. If wildlife populations decrease as a result of the VLOS, that would also impact wildlife viewing through decreased sitings. Nearshore activities are generally engaged in by residents of local communities, and levels of activity are low; but those that exist would have noticeable impacts. Recreation activities could also be displaced; recreationists may avoid the affected areas, choosing instead to recreate someplace else to avoid the VLOS areas as publicity of the spill increases.

Conclusion

Based on the criteria given in Section 4.1.3, the intensity of the VLOS on recreation and tourism is expected to be high; the VLOS would noticeably alter recreation in the study area. Offshore and coastal settings would be altered by the amount of vessels, aircraft, and support for response. As the oil moves from the offshore setting to the coastal setting, recreation resources would be highly impacted from the oil. Most recreation in the area occurs in or near the water, and activities would be affected by the presence of the response teams, and the oil; particularly wildlife viewing, fishing and yachting. The recreation setting and activities would be altered for long-term duration, by the response teams and by the physical oil which could take over a year to clean or disperse, as well as impacts to existence and bequest values, which may last several years. Direct impacts to visitor setting and activities would be regional and could affect up to the entirety of the EIS project area. Indirect impacts to existence and bequest values would be considered state-wide based on the criteria because recreationists beyond the Chukchi Sea could hold existence and bequest values for the area.

The Alaska Maritime National Wildlife Refuge and Cape Krusenstern National Monument are within the EIS project area in the Chukchi Sea. Because these areas are federally designated and management includes public use, there is a perception of high recreation sensitivity in the area. Even though recreation opportunities across the Chukchi Sea are not scarce and not protected by legislation, the potential to impact recreation settings and activities in a national monument and public use of a national wildlife refuge, the context is considered important.

The impacts would be high intensity, long term duration, regional to statewide in extent, and important in context. In summary, the impact of a VLOS on recreation and tourism would be major.

4.10.6.21 Visual Resources

4.10.6.21.1 Existing Analysis (BOEM 2011b and 2011e)

No analysis of impacts specific to visual resources is presented in the BOEM (2011b) or BOEM (2011e) documents.

4.10.6.21.2 Additional Analysis for Visual Resources

A VLOS occurring in within the Chukchi Sea portion of the EIS project area has the potential to impact scenic quality and visual resources during Phases 2, 3, and 4 of the spill scenario. Potential impacts to scenic quality and visual resources are based on information presented in Section IV.D.2. (VLOS Scenario), Section IV.E.1 (OSRA Model [Oil Spill Trajectories]), and Section IV.E.2 (Water Quality) of the LS 193 FSEIS (BOEM 2011b). Direct effects could include views of the incident observed from local on-land or at-sea vantage points, or from images displayed in various forms of image-based media (e.g.

television, newspapers, and magazines). Indirect effects may include psychological/social distress from witnessing the incident first hand, or observing accounts of the incident through the same image-based media described above. The intensity, duration and extent of impacts will depend on the on the magnitude of the release (i.e. how much oil was released, and for how long) and the timing (seasonality) and location of the event. For example, a spill that occurred in closer proximity to the shoreline would have less time to weather before reaching nearshore and shoreline areas, thereby increasing potential for impacts to these areas. Oil released from a spill occurring during the fall season would have a greater likelihood of being sequestered under forming ice pack, and consequently may be transported across large geographic areas through moving ice. For the purposes of this analysis, potential impacts to scenic quality and visual resources are discussed by Phases 1 to 4 of the spill scenario. It is further assumed that the constituency of sensitive viewers would expand beyond the local population, tourist, and/or recreators in the area to include a broader public exposed to the VLOS via national (and international) media coverage. For this reason, this analysis assumes high visual sensitivity among all potential affected viewer groups.

Phase 1 (Initial Event)

The magnitude of impacts to scenic quality and visual resources is expected to be high during Phase 1 of the VLOS scenario. The explosion and resulting fire may be seen by individuals situated on marine vessels or those engaged in offshore subsistence activities. It is expected that air and marine traffic would be mobilized immediately to the location of the incident, resulting in a perceptible change in movement and activity in local communities (spill response and clean-up discussed further in Phase 4). Phase 1 impact to visual resources would be localized and temporary; resulting in short-term direct impacts to scenic quality and visual resources. Indirect effects, such as psychological/social distress are expected to occur among a broad public as a result of viewing images of the explosion and fire.

Phase 2 (Offshore Spill)/Phase 3 (Onshore Contact)

The magnitude of impacts to scenic quality and visual resources is expected to be high during Phase 2 and Phase 3 of the VLOS scenario. Direct impacts are expected to result from first-hand observation or media-based observation of images of oil on the water surface and in contact with onland areas. Indirect effects could include psychological/social distress from viewing oil on the water surface. The geographic extent and degree to which an offshore spill would affect on- and offshore locations outside of the EIS project area would depend on how far surface oil traveled (i.e. sequestration in moving ice, spreading through wind and wave action), and the amount that reached the shoreline. Although the duration of impacts under the VLOS scenario are expected to be short-term, potential direct and indirect impacts resulting from Phase 2 and 3 scenarios could be long-term depending on the persistence of oil, extent of affected area, and the degree to which seasonality influenced clean-up efforts.

Phase 4 (Spill Response and Cleanup)

The magnitude of impacts to scenic quality and visual resources is expected to be high during Phase 4. Direct impacts are expected to result from witnessing first-hand or through media outlets the perceptible change in activity level due to the presence of vessels, aircraft, skimmers, boomers, and actions associated with in-situ burning, animal rescue, introduction of dispersants, bioremediation, beach cleaning, and drilling of the relief well. Indirect effects could include psychological/social distress from viewing response efforts, again either first hand or through media outlets. The duration of impacts under the VLOS scenario 4 is expected to be short-term; long-term response efforts are discussed below (Phase 5).

Phase 5 (Long-Term Recovery)

The magnitude of impacts to scenic quality is expected to depend largely on the intensity, duration, and extent of Phases 2 and 3, and the effectiveness of efforts described in Phase 4. The magnitude of effects is expected to be highest in areas where oil is still visible on the surface of the water or on land, or where efforts to remediate water quality are underway. Indirect effects, such as psychological/social distress from witnessing (viewing) the spill and subsequent response is expected to attenuate in Phase 5 – although, the degree to which such indirect effects are reduced is again dependent on the visibility of oil and the level of response still underway. Such indirect effects may persist due to knowledge or fear of contamination, regardless of whether evidence of such contamination is visible to viewers. It is assumed that media coverage would not continue at levels experienced in Phases 1 to 4, thereby reducing direct and indirect effects to sensitive viewers located outside of Alaska.

Conclusion

In conclusion, major direct and indirect impacts to visual resources are expected to result from a VLOS scenario. Impacts would be of high intensity, short- to long-term in duration, regional to state-wide in geographic extent, and would affect an important resource.

4.10.6.22 Environmental Justice

4.10.6.22.1 Existing Analysis (BOEM 2011b and 2011e)

Section IV.E.18 of BOEM (2011b) describes potential impacts to environmental justice during the five phases of a possible VLOS in the Chukchi Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

Environmental Justice impacts on Inupiat Natives could occur because of their reliance on subsistence foods, and oil-spill impacts would affect subsistence resources and harvest practices, sociocultural systems, and human health. Depending on the trajectory of the VLOS, the Inupiat communities of Barrow, Wainwright, Point Lay, and Point Hope, as well as the subsistence communities on the Russian Arctic Chukchi Sea coast, would all experience adverse impacts to varying degrees.

In the event of a VLOS in the Chukchi Sea, the Environmental Justice-related impacts described above would produce disproportionate, high, adverse effects in the Inupiat subsistence-oriented communities of Barrow, Wainwright, Point Lay, and Point Hope and in Russian subsistence communities along the Chukchi Sea coastline.

In addition, Section 4.4.14.3.2 of the BOEM (2011e) analysis provides some information about the impacts of a catastrophic discharge event on environmental justice in Alaska Arctic regions. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that many of the long-term impacts of a catastrophic discharge event on low-income and minority communities are unknown. Different cultural groups would likely possess varying capacities to cope with catastrophic events, with some low-income and/or minority groups more reliant on subsistence resources and/or less equipped to substitute contaminated or inaccessible subsistence resources with those purchased in the marketplace. Because lower income and/or minority communities may live near and be directly involved with catastrophic discharge event cleanup efforts, the vectors of exposure can be higher for them than for the general population, increasing the potential risks of long-term health effects (BOEM 2011d).

4.10.6.22.2 Conclusion

The impacts to subsistence foods and human health in the Iñupiat subsistence-oriented communities of Barrow, Wainwright, Point Lay, and Point Hope would be high intensity, long-term in duration, regional in extent, and unique in context. Therefore the summary impact level for environmental justice is major; there would be a disproportionate adverse effect to minority populations.

4.10.7 Beaufort Sea – Analysis of Impacts

The foundation for the analysis in Section 4.10.7 of this EIS is taken from the 2012-2017 OCS Oil and Gas Leasing Program Draft Programmatic EIS (BOEM 2011d), which contains the first post-DWH event scenario for the Beaufort Sea. Summaries of this information are provided in the applicable resource discussions below. As allowed for by CEQ regulations in §1502.21, NMFS has incorporated the information presented in the Draft Programmatic EIS (BOEM 2011d) into this EIS by reference.

Summaries of information from the former MMS (now BOEM) FEIS for the Beaufort Sea Planning Area Oil and Gas Lease Sales 186, 195, and 202 (MMS 2003) are also provided in this EIS where applicable. As allowed for by CEQ regulations in §1502.21, NMFS has incorporated the information from BOEM's FEIS into this document by reference. The specific sections from MMS (2003) that are referenced in this EIS are noted in the appropriate sections of this document.

Analysis beyond what was presented in BOEM (2011e) and MMS (2003) pertinent to this EIS is presented in each resource section. The information taken from BOEM (2011e) and MMS (2003) is identified as "Existing Analysis," and the analysis beyond what was presented in those documents is listed as "Additional Analysis."

4.10.7.1 Physical Oceanography

4.10.7.1.1 Existing Analysis (BOEM 2011d and MMS 2003)

Section 4.2.3.2 of the BOEM (2011e) analysis describes the effects of the movement and weathering of spilled oil on sea ice and currents in the Beaufort Sea planning area. This information is incorporated herein by reference.

Section IV.I.1 of MMS (2003) describes the behavior of spilled oil from a possible VLOS in the Beaufort Sea under various oceanographic conditions. This information is incorporated herein by reference, and a summary of that information is provided here.

4.10.7.1.2 Additional Analysis for Physical Oceanography

The direction and rate of movement of a VLOS originating in the narrow (15 to 40 km [9 to 25 mi]) Beaufort OCS would depend largely upon the wind direction in the spill area. Winds in the narrow area where exploration activities would occur are predominantly from the northeast and would facilitate wind driven transport of oil westward along the Beaufort Sea coast. Under such conditions, Ekman transport would tend to move spilled oil north, away from the shore. In contrast, westerly winds would tend to move oil closer to shore. Barrier islands would provide some protection to the mainland shoreline from a VLOS event originating outside of the barrier islands.

Phase 1 (Initial Event)

Impact producing factors associated with a well control incident, such as explosion, fire, and redistribution of sediment would have minor effects on physical ocean resources within the EIS project area. Uncontrolled combustion of petroleum hydrocarbons in the environment would result in an increase in water temperature in the immediate vicinity of the fire. It is difficult to quantify the increase in water temperature that would result from fire associated a well control incident, but it is likely that the geographic extent of changes in water temperature would be limited to areas immediately adjacent to the fire, and the duration of such thermal effects would be temporary. Redistribution of seafloor sediments would have minor impacts on the seafloor topography in the immediate vicinity of the well control incident. Although effects resulting from redistribution of seafloor sediment would likely be permanent, the intensity of the effects would be low and the geographic extent would be limited to the immediate vicinity (probably within 1 km) of the well control incident. Sinking of the drilling rig to the sea floor would effectively create an artificial reef, which would have permanent, local, low-intensity effects on the physical character of the EIS project area. If the rig were to sink in shallow water it could be considered a navigational hazard. Overall, effects of the initial well control incident on the physical character of the EIS project area would be minor.

Phase 2 (Offshore Oil)

Oil in the water from a VLOS event would affect the physical character of the sea surface in the EIS project area. An oil slick covering hundreds of square kilometers of ocean surface would influence ocean- atmosphere interactions including exchange of gasses across the air-water interface and the generation of wind driven waves in the affected area. The presence of an oil slick at the sea surface would impede normal gas exchange across the air-water interface, but the impacts of such effects would likely be surpassed by the release of large quantities of methane, ethane, propane and other hydrocarbon gasses into the water column. The natural gas mixture released into the water during a VLOS event would have temporary effects on the dissolved gas content of seawater in the affected area. The presence of an oil slick at the sea surface would likely lead to decreases in the magnitude of wind-driven waves in the affected area. Effects on waves resulting from a VLOS would be low intensity, local, and temporary. Such effects would decrease concomitant with clean-up or partitioning of the oil into environmental compartments other than the sea surface. Due to limited water depths on the Beaufort Sea shelf, most fractions of the released oil would float to the surface and effects on the physical character of pelagic and benthic zones are expected to be minor during this phase of the VLOS. However, effects of an oil slick on the viscosity of the sea surface would be high-intensity and regional. The sea surface could be considered an important physical resource within the EIS project area because of its critical role in myriad chemical, physical and biological processes. Due to the viscosity and stickiness of spilled oil, the overall effects of offshore oil on the physical character of the ocean would be major. In addition, an oil slick would effectively decrease the freezing point of the affected seawater, and may have non-negligible impacts on the formation of sea ice in affected areas.

Phase 3 (Onshore Contact)

Exposure to oil would affect the physical character of the shoreline for reasons similar to those described above. Spilled oil would adhere to the shoreline and affect the composition of beach substrates.

Phase 4 (Spill Response and Cleanup)

Spill cleanup operations could have adverse impacts on the physical character of the ocean and shoreline. Minor impacts due to differential shoreline erosion would be possible if the removal of contaminated substrates affects beach stability.

In situ burning of oil result in high-intensity effects on sea surface temperature, but these effects would be temporary and spatially limited to the area of *in situ* burning operations. The use of dispersants would effectively move the impacts associated with spilled oil from the sea surface into the water column. Dispersed oil in the pelagic environment would affect the density and viscosity of the water, but these effects would be low-intensity, and would decrease as the dispersed oil is weathered, diluted, and degraded.

Phase 5 (Long-term Recovery)

Long-term direct effects on the physical character of the ocean would be negligible. Oil is a mixture comprised mostly of volatile and hydrophobic compounds. As a result of these properties, oil has a strong tendency to associate with non-aqueous phase materials. Oil associated with solid phase particles may remain on beaches and in sediments on the sea floor for extended periods of time, but the long-term effects of weathered oil in the environment are expected to be related to the chemical properties and potential toxicity of certain hydrocarbon compounds.

Conclusion

The overall effects of the VLOS on the physical character of the ocean would initially be high-intensity due to the viscosity and stickiness of oil floating at the sea surface. The duration of these impacts would be limited by the properties of oil that cause it to associate with non-aqueous phase materials. If *in situ* burning is used as a response technique, high-intensity short term impacts would occur to the physical character of the sea surface. The overall effects of the VLOS on the physical character of the Beaufort Sea in the EIS project area would be high-intensity, temporary, and would affect an area of hundreds of square kilometers. Overall impacts to physical oceanography would be classified as moderate due to their high-intensity and temporary duration.

4.10.7.2 Geology

The geology of the continental shelf and OCS within the proposed action area is discussed in Section 3.1.3 of this EIS. For the purpose of this EIS, geological processes would not be altered by a VLOS; therefore geology as a resource is not carried forward for analysis in Chapter 4. In addition, naturally occurring phenomena like ice gouging and strudel scouring would not likely be affected by a VLOS, nor would these phenomena be expected to affect response to a VLOS.

4.10.7.3 Climate and Meteorology

4.10.7.3.1 Existing Analysis (BOEM 2011d)

Discussions on GHG emissions in the existing BOEM (2011e) analysis can be found in Sections 4.10.7.4 (Air Quality) of this EIS.

4.10.7.3.2 Additional Analysis for Climate and Meteorology

The VLOS scenario in the Beaufort Sea has the potential to impact climate change, especially during Phases 1 and 4 of the oil spill and cleanup scenario. These impacts are considered to be of the same nature and magnitude of those that could occur as a result of a VLOS in the Chukchi Sea (Section 4.10.6.3). The level of the impacts are expected to be of low magnitude, long-term duration, a minimum extent of state-wide, and unique in context. Therefore, the overall impact rating would be considered moderate.

4.10.7.4 Air Quality

4.10.7.4.1 Existing Analysis (BOEM 2011d)

Section 4.4.4.3.2 of the BOEM (2011e), provides an analysis of the impacts of a catastrophic discharge event on air quality in the Beaufort Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that evaporation of oil from a catastrophic discharge event, and emissions from spill response and cleanup activities including in situ burning, if used, have the potential to affect air quality in Arctic Alaska. The greatest impacts on air quality would occur during the initial explosion of gas and oil and during spill response and clean up, particularly if the event occurs during the winter. Impacts could continue for days during the initial event and could continue for months during spill response and clean up. Therefore, while the impacts may be large during these two phases, overall, the emissions from a catastrophic discharge event would be temporary and, over time, air quality in Arctic Alaska would return to pre-oil spill conditions (BOEM 2011d).

4.10.7.4.2 Additional Analysis for Air Quality

As described above, a VLOS has the potential to temporarily impact air quality in localized areas in the Beaufort Sea. However, the MMS 2003 information is based on a smaller potential VLOS; the magnitude, extent, and duration of effects on air quality would likely be larger for a larger spill, with higher initial emissions and more cleanup activities required. The potential VLOS-related air quality impacts are expected to be the same (similar levels of effect) in the Beaufort Sea as in the Chukchi Sea. Therefore, based on the more detailed information provided in Section 4.10.6.4, a VLOS has the potential to impact air quality, particularly during Phases 1 and 4 of the oil spill and cleanup scenario.

4.10.7.5 Acoustics

4.10.7.5.1 Existing Analysis (BOEM 2011d)

Section 4.4.5.4.2 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on the acoustic environment in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The BOEM analysis concludes that the pressure wave and noise generated from an incident involving a loss of well control would affect marine mammals and could be large enough to harass or disturb them if they were close enough to the site of the event. In addition, accident response and support activities, including support aircraft and vessel activity, have the potential to cause noise impacts. These impacts would occur both at the site of the response activity and along the routes of support vessels and aircraft. The duration and magnitude of the impacts would depend on the volume, location, duration, and weather conditions during the catastrophic discharge event, and the response and cleanup activities (BOEM 2011d).

4.10.7.5.2 Additional Analysis for Acoustics

In the event of a VLOS, the acoustic environment could be changed by noise generating sources associated with the initial well control incident and with the subsequent cleanup effort. The impacts of a VLOS in the Beaufort Sea would be considered to be of the same nature and magnitude (minor to moderate) of those that could occur as a result of a VLOS in the Chukchi Sea, discussed in Section 4.10.6.5.

4.10.7.6 Water Quality

4.10.7.6.1 Existing Analysis (BOEM 2011d)

Section 4.4.3.3.2 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on water quality in the Beaufort Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event in either coastal or marine waters could present sustained degradation of water quality from hydrocarbon contamination in exceedence of state and federal water and sediment quality criteria, and that these effects could be significant depending upon the duration and area impacted by the spill. Additional effects on water quality could occur from response and cleanup vessels, in situ burning of oil, dispersant use, discharges and seafloor disturbance from relief well drilling, and activities on shorelines associated with cleanup, booming, beach cleaning, and monitoring (BOEM 2011d).

4.10.7.6.2 Additional Analysis for Water Quality

The above analysis of effects of a VLOS on water quality in the Beaufort Sea (MMS 2003) is based on a potential VLOS flow rate of 15,000bbl per day over 15 days totaling 225,000bbl, of which 20 percent evaporates, leaving 180,000 bbl spilled on an artificial island and surrounding Beaufort Sea waters. The VLOS scenario analyzed for the Chukchi Sea uses a spill size of 2.2MMbbl, which would have similar effects on water quality in the Beaufort Sea analysis (MMS 2003). If a VLOS event were to originate outside the barrier islands in the Beaufort Sea, the islands could afford some level of protection to nearshore water quality in sensitive areas. If a VLOS event were to originate inside the barrier islands, the geographic extent of the affected area could be constrained to some extent by the effects of the islands on transport of spilled oil. However, sensitive areas inshore of the barrier islands would be likely to experience high-intensity effects on water quality in the event of an oil spill occurring inside of the islands.

A spill of 2.2 MMbbl in the Beaufort Sea would result in elevated concentrations of petroleum hydrocarbons and related compounds in the water. Those concentrations would exceed both state and federal water quality criteria over large areas and for extended periods of time. A VLOS in the Beaufort Sea would have high-intensity effects on water quality. The duration of such effects could be long-term, and the geographic extent of the effects could be either regional or state-wide depending on the specific launch area, meteorological conditions at the time of the spill, and effectiveness of the response effort. Chemical response techniques, such as the use of dispersants, could result in additional degradation of water quality, which may or may not offset the benefits of dispersant use. Although water is generally considered a common resource, a VLOS in the Beaufort Sea could impact water quality in sensitive areas that are protected by legislation. Overall, a VLOS would have major effects on water quality in the Beaufort Sea.

4.10.7.7 Environmental Contaminants and Ecosystem Functions

4.10.7.7.1 Existing Analysis (BOEM 2011d)

Section 4.4.6.2.4 of the BOEM (2011e) analysis provides some information about the impacts of a catastrophic discharge event on ecosystem functions in the Beaufort Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The BOEM analysis states that sensitive benthic habitats could suffer long-term loss of ecological function because of both hydrocarbon toxicity and the subsequent cleanup activities. Hydrocarbons could persist at sublethal concentrations in sediments for decades, and sensitive habitats (i.e., kelp beds, intertidal zones; live-bottom and coral reef) damaged by a spill would likely recover slowly and possibly not recover at all. However, hydrocarbons would be broken down by natural processes, and most benthic habitats are likely to eventually recover. Pelagic habitats would eventually recover their habitat value as hydrocarbons broke down and were diluted. Recovery time would vary with local conditions and the degree of oiling. Overall, impacts on habitats from accidental hydrocarbon spills in open water could range from negligible to moderate, and impacts could be short term to long term; no permanent degradation of pelagic habitat would be expected (BOEM 2011d).

4.10.7.7.2 Additional Analysis for Environmental Contaminants and Ecosystem Functions

Impacts to ecosystem functions potentially resulting from a VLOS in the Beaufort Sea would be very similar to those described for the Chukchi Sea in Section 4.10.6.7 of this EIS, with several exceptions that are described below.

Potential locations for exploratory drilling activities are generally located closer to shore in the Beaufort Sea compared to the Chukchi Sea portion of the EIS project area. Due to the proximity of potential VLOS launch locations to sensitive nearshore habitats, a VLOS in the Beaufort Sea would have greater impacts on habitat functions relative to a similar event in the Chukchi Sea. Spawning and refuge habitats would be affected for most communities in the vicinity of the well control incident as discussed in other sections of this document. Impacts to coastal wetlands, tidal flats, and sheltered beaches would generally be greater than impacts to exposed gravel, cobbled beaches, or offshore areas (Gundlach and Hayes 1978). The effects of a VLOS on habitat functions in the Beaufort Sea would be high-intensity and regional scale. Overall impact of a VLOS on habitat functions in the Beaufort Sea would be major.

Response and clean-up activities could have intense effects on habitat functions in sensitive areas. For example, the use of hot water hydraulic washing to clean oiled shoreline could destabilize physical substrates causing adverse impacts to spawning and refuge habitats for coastal species.

Persistence of oil in sediments may have negative long-term effects on habitat functions within the affected area. Long-term effects on habitat functions would be limited to areas where oil may become trapped in sediments or other substrates, and shielded from weathering and degradation. Long-term effects on habitat functions would be local and medium intensity, but would have the potential to affect unique resources depending upon the location of the discharge and the efficacy of the response effort. Due to the prevalence of barrier islands in the Beaufort Sea portion of the EIS project area that shelter the coastline from wave action and weathering processes, it is probable that long- term adverse effects of a

VLOS on habitat functions would persist over greater geographic areas in the Beaufort Sea relative to the Chukchi Sea. In addition, presence of oil would be likely to affect production functions by inhibiting the germination and growth of many species in the Beaufort Sea area. However, robust primary producers such as Arctic Kelp (*Laminaria solidungula*), which dominates the Boulder Patch community in Stefansson Sound, would be likely to recover rapidly subsequent to clean-up. Thus, overall levels of photosynthesis and primary production would decrease temporarily, but would likely return to pre-VLOS levels within several years after the cessation of clean-up activity.

Conclusion

Effects of a VLOS on ecosystem functions in the Beaufort Sea would be high intensity, long-term, regional, and could affect unique resources. Overall, the effects of a VLOS on ecosystem functions in the Beaufort Sea would be considered major. However, with few exceptions, the ecosystem functions in the VLOS area would likely recover within several years of the cessation of clean-up activities. The functional properties of ecosystems described in this section, such as nutrient cycling and habitat functions, are more robust (i.e. resistant to stressors) than are species composition and other structural properties. As suggested by Peterson et al. (2003), a VLOS event would be likely to affect ecosystem structure over timescales of decades; ecosystem functions, from which humans derive value, would be likely to recover more quickly.

4.10.7.8 Lower Trophic Levels

4.10.7.8.1 Existing Analysis (BOEM 2011d and MMS 2003)

Section 4.4.7.5.3 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on invertebrates and lower trophic levels in the Beaufort Sea. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could affect a large number of benthic and pelagic invertebrates and their habitats. The location of the spill and the season in which the spill occurred would be important determinants of the impact magnitude of the spills. Hydrocarbon releases contacting the Stefansson Sound Boulder Patch community could have direct impacts on organisms inhabiting the area. The magnitude of impacts to the Boulder Patch would depend on the location and severity of the spill (BOEM 2011d).

Section IV.1.2.b of MMS (2003) describes potential impacts to lower trophic level organisms during a possible VLOS in the Beaufort Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

Large-scale effects on marine plants from oil spills have been observed in the intertidal and subtidal zones of other regions. Because of the predominance of shorefast ice in the affected area, there is no resident marine flora in waters less than 6 feet deep; therefore, there would be no effects. The oil spill also is not expected to have any measurable effect on subtidal marine plants (such as those of the Boulder Patch kelp habitat), because they live below the zone where toxic concentrations of oil can reach them.

A very large oil spill probably would affect half of the planktonic organisms in about half of the sound, or a total of about one-quarter of the Stefansson Sound plankton. Because of their wide distribution, large numbers, and rapid rate of regeneration (12 hours), there would be only a temporary, local effect on the planktonic community. The recovery of the community would be complete within 1-2 weeks (the estimated flushing time for Stefansson Sound).

Some lower trophic-level organisms on the shorelines would be adversely affected. Use of dispersants on a spill near benthic kelp communities would mix the oil farther down into the water column and could affect the kelp community. However, the use of dispersants is not essential for spill response; their use would require further approval by the Coast Guard.

4.10.7.8.2 Additional Analysis for Lower Trophic Levels

The oil spill discussion in MMS (2003) analyzed the effects of an oil spill of 180,000 bbls, but for the purposes of this EIS, a VLOS of 2.2 MMbbls occurring over a 74 day period is considered for the Beaufort Sea. Although the impacts to lower trophic levels would be similar regardless of the size of the spill, the magnitude, duration, and extent would be substantially greater with a larger spill.

The existing leases in the Beaufort Sea are much closer to shore than those in the Chukchi Sea, with most leases within 56 km (35 mi) of the shore, and in shallower waters. A VLOS could therefore have a greater impact on nearshore habitats, although some impacts could be mitigated by the extensive barrier islands protecting the Beaufort Sea coastline. These islands may protect many of the bays and lagoons in the nearshore habitat from exposure to oiling. Although MMS (2003) determined that up to half of the coastline could be oiled in an 180,000 bbl spill, a larger spill could impact more coastline. No modeling was performed for the Beaufort Sea analysis, but prevailing winds are generally easterly through mid-July, and then shift to westerly in August. Over the course of a 74 day spill, there would likely be a net westerly movement, blowing the oil onshore and affecting any portion of the coastline.

As the lower trophic level organisms in the Chukchi and Beaufort seas are very similar, the extensive analysis performed by BOEM (2011) for the Chukchi Sea (Section 4.10.6 of this EIS) can be largely applied to the Beaufort Sea. The most likely impacts to lower trophic levels include:

- Mortality to all life stages resulting from pressure waves from an initial explosive event, toxicity to oil (acute and chronic), and coating with an oil layer;
- Impact to food web through bioaccumulation and biomagnification as a result of the close interactions between megafauna (i.e. whales, seals, walrus) and lower trophic organisms (Dunton et al. 2005, Grebmeier et al. 2006) (see Section 4.10.6.11 for more information regarding the effects of bioaccumulation and biomagnification on marine mammals);
- Longer recovery rates due to species traveling outside the original contamination site or being consumed later, thereby prolonging the recovery, as a result of drift or diapause (a forma of hibernation), respectively. This would delay recovery since these species surviving the initial incident, would store toxins and be consumed at a later date by higher trophic level organisms(MMS 2004, Jiang et al. 2010, Brodersen 1987); and
- Habitat loss due to oiling of ice or benthic substrate and the resultant decrease in primary productivity or mortality events.

The magnitude of these impacts is dependent on a variety of factors. The primary factors influencing the level of impact include:

- Duration and volume of the spill;
- Distribution and geographic coverage of surface oil slicks;
- Persistence and dispersion of oil in the water column (epontic, pelagic, or benthic);
- Chemical composition of the oil;
- Efficacy of chemical dispersants;
- Incorporation of spill into first year ice; and
- Weather patterns, including hours of daylight and UV intensity, presence or absence of ice, presence or absence of polynyas and reaches

Depending upon the factors discussed above, a VLOS in the Beaufort Sea could have a summary impact level of major, should the spill persist in the environment or affect unique resources. However, should the spill not last a long time or affect unique resources, the impacts to the lower trophic levels would be of low to medium magnitude, short-term duration, local to regional geographic extent, and common context.

In this case, the impact criteria listed above would lead to a summary impact level of moderate due to the shorter duration and regional impacts to common resources.

4.10.7.9 Fish and Essential Fish Habitat

4.10.7.9.1 Existing Analysis (BOEM 2011d and MMS 2003)

Section 4.4.7.3.3 of the BOEM (2011e), provides an analysis of the impacts of a catastrophic discharge event on fish in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could have population-level consequences on some fish populations if vital habitat areas were affected or if the spill occurred in spawning areas or juvenile feeding grounds when fish populations are highly concentrated (e.g., the Arctic cisco population concentrated near the Colville River). In such cases, catastrophic spills could cause substantial reductions in population levels for one or more years. However, no permanent impacts on fish populations are expected (BOEM 2011d).

Sections IV.1.2.c and IV.I.2.d of MMS (2003) describe potential impacts to fish and essential fish habitat during a possible VLOS in the Beaufort Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

Fish

Fish distribution in the Beaufort Sea varies seasonally as many species move from offshore to nearshore environments. Therefore, a VLOS that reached the shore would have a much greater effect in summer and autumn when these fish species are nearshore feeding and spawning than in winter when many of these species are once again offshore. Based on the Oil-Spill-Risk Analysis model (Table IV.I-9a), the nearshore areas of highest chance of contact include Land Segments 31-37. If a 180,000-barrel oil spill occurred, these land segments would have a 0.5-8% chance of being contacted in 30 days. According to Tables IV.I-6a and IV.I-6b, a 180,000-barrel oil spill would contact about 300 kilometers of coastline, which is about seven times that estimated for the 4,600-barrel oil spill associated with Alternative I for Sales 186, 195, and 202. However, the combined probability of one or more spills occurring and contacting the nearshore area is very low (less than 0.5%). If it did occur, some marine and migratory fish might be harmed or killed. The number affected would depend on the size of the area affected, the concentration of petroleum present, the time of exposure, and the stage of fish development involved (eggs, larva, and juveniles are most sensitive). If lethal concentrations were encountered, or sublethal concentrations were encountered over a long-enough period, fish mortality would be likely to occur. However, mortality due to petroleum-related spills is seldom observed outside of the laboratory environment. This is because the zone of lethal toxicity is very small and short lived under a spill, and fishes in the immediate area typically avoid that zone. Mortality would be expected only in cases where fishes were somehow trapped in a lethal concentration and could not escape. Because this would be very unlikely outside of the laboratory environment, little to no mortality due to lethal concentrations would be expected.

If oil were to reach the shore and become buried in intertidal and/or subtidal sediments, it likely would be released back into the water column at a later time. However, the amounts of oil released in that manner are likely to be relatively small over time, and fish density in Beaufort Sea coastal waters also is relatively low most of the year. While a 180,000-barrel oil spill would be expected to affect about 300 kilometers of nearshore waters and coastline, it would be likely to have mostly sublethal effects (for example, changes in growth, feeding, fecundity, and temporary displacement) on marine and migratory fish. Juvenile fish (for example, arctic cod), which are common in the nearshore area during summer, or nearshore spawners (for example, capelin) are among those most likely to be adversely affected. Some fish in the immediate area of a spill may be killed; however, it is not expected to be a measurable effect on marine and migratory fish populations. Recovery of the number of fish harmed or killed would be expected within 10 years.

Oil-spill-cleanup activities, whether on ice or for oil entrained in the ice, are not expected to adversely affect fish populations. It is possible that a containment boom could trap some oil in a shoreline area and temporarily contaminate that area long enough to affect fishes or their food resources. In general however, reducing the amount of oil in the marine environment is expected to have a beneficial effect on fishes, because it reduces the possibility of hydrocarbons contacting them and their food resources. The extent of that benefit would depend on the actual reduction in the amount of oil contacting fish and their food resources, as compared to that of not reducing the amount of contact.

Essential Fish Habitat

Section 4.4.6.4.3 of the BOEM (2011e) analysis provides a discussion of the impacts of a catastrophic discharge event on EFH in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could cause long-term declines of fish species that rely on shallow coastal, intertidal, and freshwater areas. Spills occurring under ice could result in long-term degradation of EFH because of the cleanup difficulties; severity of effects of accidental hydrocarbon spills on EFH would depend on the size of the spill, its location, environmental factors, and the uniqueness of the affected EFH (BOEM 2011d).

4.10.7.9.2 Additional Analysis for Fish and Essential Fish Habitat

The most likely impacts to fish resulting from a VLOS are:

- Mortality to all life stages resulting from pressure waves from an initial explosive event, toxicity to oil (acute and chronic), and coating with an oil layer;
- Reduction of individual fitness and survival due to physiological contaminant effects. These effects can, in turn, affect swimming, feeding, reproductive and migratory behaviors and the physiologic adjustment for anadromous fish as they move between freshwater and saltwater environments; and
- Onshore and offshore habitat loss due to oiling, resulting in displacement and stress. Displacement could result in blocked or impeded access to spawning, rearing, feeding, and migratory habitats important for survival.

The magnitude of these impacts is dependent on a variety of factors. The primary factors influencing the level of impact include:

- Location and time of year of the oil spill;
- Life stage affected (egg, larvae, juvenile, adult) and life history (anadromous, migratory, reproductive behaviors and cycle, longevity);
- Species distribution and abundance;
- Species exposure and sensitivity to oil and gas (toxicology, swimming ability); and
- Habitat dependence (marine vs. freshwater, onshore vs. offshore, location of spawning habitat, depth).

Based on the five oil spill phases described in BOEM (2011), the greatest impacts in the Beaufort Sea could be felt during Phases 2 and 3, particularly in benthic and nearshore regions. The fish typically found in these areas are more susceptible to impacts from a VLOS due to their increased dependence on relatively limited habitat when compared to pelagic fish, or decreased swimming ability resulting in an inability to escape impacted areas. Most impacts to habitat could be short term in duration, with shoreline and substrate impacts lasting longer. The fish assemblages with an increased susceptibility include:

- Migratory and juvenile fish that use nearshore, shallow lagoons, estuaries, and bays;

- Benthic fish, which are typically poor swimmers; and
- Cryopelagic species such as Arctic cod, should the spill occur in winter or get entrained in seasonal pack ice.

In general, the leases in the Beaufort Sea are much closer to shore than those in the Chukchi Sea, with most less than 56 km (35 mi) from shore, and in shallower waters. A spill could therefore have an even greater impact on nearshore habitats, although it could be mitigated to some degree by the extensive barrier islands protecting the Beaufort Sea coastline. These islands may protect many of the bays and lagoons in the nearshore habitat to their landward side from exposure to oiling. Although MMS (2003) determined that up to half of the shoreline could be oiled in a 180,000 bbl spill, a larger spill could impact more shoreline. No modeling specific to the Beaufort Sea was performed, but prevailing winds are generally easterly through mid-July, and then shift to westerly from August onward. Over the course of a 74 day spill, there would likely be a net westerly movement, blowing the oil onshore. There is a possibility that any portion of the coast could be affected by a spill, but not the whole coast at one time.

The EFH described by NMFS in the Beaufort Sea is very similar to that in the Chukchi Sea, except that there is no opilio crab EFH in the Beaufort Sea. Therefore, it is likely that the types of effects to EFH would be very similar to those described in Section 4.10.6.9. The biggest concern for fish resources is not oil in the open ocean, but in nearshore waters and along the coast, where it can interfere with juveniles and spawning habitat. It can also be very disruptive in estuaries, lagoons, and bays, where many fish congregate and are not able to escape as easily as their pelagic counterparts can in the open ocean.

Most fish and EFH within the EIS project area are important resources that are widespread and abundant. However, the impacts from a VLOS could be of high intensity, long term duration, and occur over a broad, regional extent. Therefore, according to the criteria laid out in Section 4.1.3, the overall summary impact level of a VLOS could be moderate.

4.10.7.10 Marine and Coastal Birds

4.10.7.10.1 Existing Analysis (BOEM 2011d and MMS 2003)

Section 4.4.7.2.3 of the BOEM (2011e) analysis and Section IV.I.2 of MMS (2003) describe potential impacts to marine and coastal birds during a possible VLOS in the Beaufort Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

A catastrophic discharge event is expected to cause spectacled eider mortality, if females with recently fledged young contact stranded oil in coastal habitats, or flocks of adult eiders or females with young feeding in lagoons and offshore waters are contacted by a spill sweeping over thousands of square kilometers. A winter spill released from the ice in spring could contact eiders concentrated in open water of river deltas. Substantial mortality that could result from such a large spill would represent a significant loss for the relatively small Arctic Coastal Plain spectacled eider population, requiring many generations for recovery. Recovery is not likely to occur while the regional population is in declining status. Any mortality, or decreased fitness or productivity from indirect effects such as decreased availability of food organisms or physiological effects from oil ingestion would be additive to the loss of oiled individuals. Although Fish and Wildlife Service survey data do not show a significant decline in the coastal plain spectacled eider population, the potential exists for a significant adverse effect from an oil spill on this regional population. Mortality of a few Steller's eiders also would represent a significant loss to its small regional population.

A 180,000-barrel oil spill in open water assumed for this analysis is expected to result in the loss of thousands of broodrearing and young waterfowl and shorebirds if they contact stranded oil along a substantial proportion of the affected shoreline. In lagoon habitats, observed high densities of long-tailed ducks suggest that on some occasions, tens of thousands of molting individuals could be contacted by a spill sweeping over thousands of square kilometers, representing a significant loss from the regional population. Likewise, contact of substantial numbers of postbreeding common eiders in the vicinity of barrier islands or Ross' gulls in the vicinity of Point Barrow, August through September could result in significant losses. Recovery is not expected to occur while specific populations are in declining status. A winter spill entering the environment after the ice melts in the spring could contact loons and other migrant waterfowl concentrated in open water near river deltas. Any mortality, or decreased fitness or productivity from indirect effects such as decreased availability of food organisms or physiological effects from oil ingestion would be additive to the losses of oiled individuals.

4.10.7.10.2 Additional Analysis for Marine and Coastal Birds

Direct and indirect exposure to oil is an impact producing factor that can affect marine and coastal birds. The increase from a 180,000 bbl oil spill to a 2.2MMbbls spill could cause adverse effects to marine and coastal birds that may be longer in duration and cover a larger area then those explained above in the MMS (2003) analysis. The level of effect is dependent upon the timing of the VLOS, the seasonal effects of currents and subsequent advection of oil, timing, and duration of the oil spill, presence or absence of fast or pack ice, location (within important areas or outside) and general weather patterns (wind and storm events). In accordance with criteria established in Section 4.1.3 of this EIS, if a VLOS occurs in critical habitat areas, the magnitude of impacts to marine and coastal birds could be medium to high, with displacement from the area, impacts to prey resources and habitat quality, and a likelihood of injury or mortality from either direct contact with or ingestion of oil and associated contaminants. The duration of the impacts could be long-term to permanent, because critical habitat areas could be abandoned or large portions of the population could be affected. The geographic extent could be state-wide due to migrating, molting and breeding bird populations. See Section 4.10.6.14 for more information about critical habitat areas. If the VLOS would occur outside critical habitat areas the effects could be the same except the duration could be temporary to long-term rather than long-term to permanent. The chance of recovery could be greater due to less birds likely being affected, compared to a higher concentration of birds that could be found in many important habitat areas at certain periods of time.

Population level effects are likely, given the high concentration of migrating, molting and breeding bird populations, a VLOS in the Beaufort Sea during the lifetime of this EIS could result in a major impact to marine and coastal birds. This is due to the potential adverse effects to population levels, habitat, molting and breeding areas, important habitat areas, toxicity to prey and individuals, and mortality of individuals.

4.10.7.11 Marine Mammals

4.10.7.11.1 Existing Analysis (BOEM 2011d and MMS 2003)

Section 4.4.7.1.3 of BOEM (2011e) provides an analysis of the impacts of a catastrophic discharge event on marine mammals in Arctic Alaska. The PEIS analyzes a catastrophic discharge event of 1.7 to 3.9 million bbl for the Beaufort Sea. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event would impact marine mammals from direct contact, inhalation, and ingestion (either directly or indirectly through the consumption of oiled forage or prey species). These effects would be significant, causing a multitude of acute and chronic effects. Additional effects on marine mammals would occur from water and air quality degradation associated with response and cleanup vessels, in situ burning of oil, dispersant use, discharges and seafloor disturbances from relief well drilling, and activities on shorelines associated with cleanup, booming, beach cleaning, and monitoring. A catastrophic discharge event has the potential to increase the area and duration of an oil spill, thereby increasing the potential for population-level effects, or at a minimum, an increase in the number of individuals killed. For example, a catastrophic discharge event contaminating ice leads or polynyas in the spring could have devastating effects, trapping bowhead whales where they may encounter fresh crude oil. Beluga whales that also use the spring lead system to migrate would also be susceptible to a spill that concentrates in these leads (BOEM 2011d).

Section IV.I.2.e(1) Bowhead Whales and IV.I.2.g Marine Mammals of MMS (2003) describes potential impacts to marine mammals during a possible VLOS in the Beaufort Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

Bowhead Whales

It is likely that some bowhead whales would experience temporary, nonlethal effects, including one or more of the following symptoms:

- oiling their skin, causing irritation
- inhaling hydrocarbon vapors
- ingesting oil-contaminated prey
- fouling of their baleen
- losing their food source
- temporary displacement from some feeding areas

Some whales could die as a result of contact with spilled oil, particularly if there is prolonged exposure to freshly spilled oil, such as in a lead. The extent of the effects would depend on how many whales contacted oil, the duration of contact, and the age/degree of weathering of the spilled oil. The number of whales contacting spilled oil would depend on the location, size, timing, and duration of the spill and the whales' ability or inclination to avoid contact. If oil got into leads or ice-free areas frequented by migrating bowheads, a large portion of the population could be exposed to spilled oil. Under some circumstances, some whales could die as a result of contact with spilled oil. Prolonged exposure to freshly spilled oil could kill some whales, but the number likely would be small.

Based on conclusions from studies that have looked at the effects of oil spills on cetaceans, exposure to spilled oil is unlikely to have serious direct effects on baleen whales. Most individuals exposed to spilled oil are expected to experience temporary, nonlethal effects from oiling of the skin, inhaling hydrocarbon vapors, ingesting contaminated prey, fouling of their baleen, reduced food source, and displacement from feeding areas. Exposure of bowhead whales to spilled oil could result in lethal effects to some individuals.

Marine Mammals (Pinnipeds, Polar Bears, and Beluga and Gray Whales)

The effects from activities associated with Beaufort Sea oil and gas exploration and development are estimated to include the loss from [a large] oil spill (0.11 percent chance) of small numbers of pinnipeds (perhaps 300 ringed seals but probably fewer than 10-20 spotted and 30-50 bearded seals and small numbers [fewer than 100] walrus), polar bears (6-10 bears), and beluga and gray whales (fewer than 10), with populations recovering (recovery meaning the replacement of individuals killed as a consequence of exploration and development) within about 1 year.

The effect of a very large oil spill is expected to be fairly long term (1-2 generations, about 15 years) on pinnipeds and polar bears and short term (about 1 year) on beluga whales.

4.10.7.11.2 Additional Analysis for Marine Mammals

The introduction to Section 4.10.5 describes the approach used to extrapolate the estimated spill volume from a VLOS of 180,000 bbls discussed in MMS (2003) to 2.2 MMbbls considered in this EIS and in the following conclusions. With at least an order of magnitude increase in the volume of oil spilled in the current scenario, it can be assumed that the area impacted by such a spill and the volume persisting over time will greatly exceed that calculated by MMS (2003).

Cetaceans

Conclusions regarding potential effects of a VLOS on cetaceans in the Beaufort Sea will be addressed separately for each potentially affected species. Fin whales, humpback whales, minke whales, killer whales, harbor porpoise, and narwhals were omitted from the above MMS (2003) analysis and the following additional analyses due to their absence from or rarity in the Alaskan Beaufort Sea.

Bowhead Whale

Bowhead whales are vulnerable to oil spills in the Beaufort Sea while feeding during late summer and fall and during the westward migration across the region throughout the fall. If the spill occurs in the winter, or if oil persists in ice over winter, bowheads migrating through the lead system during the spring could be impacted.

If injury and/or mortality were to occur, it would most likely occur during the oil spill phase of a VLOS. Contact through the skin, eyes, or through inhalation and ingestion of fresh oil could result in temporary irritation or long-term endocrine or reproductive effects, depending on the duration of exposure. Multiple injuries or mortalities may result from exposure to aggregations, such as feeding aggregations, of bowhead whales during the summer or fall. The nearshore areas from Harrison Bay to Kaktovik are habitat areas of particular concern, as this is the region of highest concentration of active oil leases and an important late-summer and fall feeding, milling, and migration corridor for bowhead whales (Clarke et al. 2011b). Bowhead mothers and calves congregated in the nearshore waters of Camden Bay in disproportionate numbers in 2008 (Koski and Miller 2009) although this has not been seen in the last few years. The bowhead whale feeding “hot spot” that regularly forms during late summer and fall northeast of Point Barrow to Smith Bay is another area of high concentrations of bowhead whales that could be substantially impacted by a VLOS in the Beaufort Sea. This area is to the west of the majority of the federal leases but in close proximity to state leases in Smith Bay. Westerly winds late in the season may limit the initial movement of oil into this area, but easterly winds could do otherwise. In addition, oil persisting months to years after the initial spill either in sediments or sea ice, could have long-term ramifications on habitat quality and prey resources in these important fall feeding areas. Direct mortality of zooplankton may occur, and accumulation of toxins in the lipids of copepods could, through ingestion, bioaccumulate in bowhead whales. Bowhead whales that feed at or near the seafloor could continue to contact and ingest oil and dispersants that settled on and persist in seafloor sediments (see BOEM 2011 Section IV.E.7 in Section 4.10.6.11 of this EIS).

The entire population of Western Arctic bowhead whales passes through the Beaufort Sea at least twice each year while migrating from and to the Bering Sea and eastern Beaufort Sea and Amundson Gulf. The whales are dependent on lead systems during spring migration, which leaves them susceptible to oil entrained in sea ice that melts out the following spring. The fall migration corridor is less well defined, with some whales migrating near shore and others offshore. Those travelling farther offshore and not stopping to feed in the areas noted above may avoid contact with oil and associated clean-up activities. The remainder could encounter at least some portion of a VLOS were one to occur in the Beaufort Sea. Bowhead whales are exceedingly long-lived (150+ years [George et al. 1999]), increasing the chances of continued exposure to oil, contaminants, and clean-up activities that persist for years after an initial spill.

Based on criteria established in Section 4.1.3, the magnitude of the resulting impact from a VLOS in the Beaufort Sea could be high. The duration of effects could range from temporary (such as skin irritations or short-term displacement) to permanent (e.g. endocrine impairment or reduced reproduction) and would depend on the length of exposure and means of exposure, such as whether oil was directly ingested, the quantity ingested, and whether ingestion was indirect through prey consumption. Displacement from areas impacted by the spill due to the presence of oil and increased vessel activity is likely. If the area is an important feeding area, such as off Barrow, or along the migratory corridor, the effects may be of higher magnitude. The extent of impact could be state-wide, given the migratory nature of bowhead whales. Bowhead whales are a unique resource, as they are a centerpiece of the Iñupiat subsistence lifestyle and listed as endangered under the ESA. Population level effects are possible if a VLOS event coincided with and impacted a large feeding aggregation of bowhead whales during the open water season, particularly if calves were present. Mothers with young calves are also vulnerable to potential exposure to oil in the lead system during the spring migration. A VLOS could result in major impacts on bowhead whales.

Beluga Whale

Beluga whales from both the eastern Chukchi Sea and Beaufort Sea stocks are most vulnerable to a VLOS in the Beaufort Sea during spring and fall migrations. They are largely absent from the area during summer months. Suydam et al. (2005) found that use of the inshore waters within the Beaufort Sea OCS lease sale area was rare during that time. Most of the fall migration occurs offshore of the oil lease areas in the Beaufort Sea. The Beaufort Sea stock migrates westward in September from the eastern Beaufort Sea either far offshore of the Alaskan coastal shelf, on the shelf edge, or near the continental slope (Richard et al. 2001). Beluga whales regularly sighted during September-October surveys of the Alaska Beaufort Sea coast are distributed offshore along the shelf-break and slope areas, including in Barrow Canyon (Clarke et al. 2011b, 2011c). Under conditions of prevailing easterly winds, oil from a VLOS could disperse offshore where contact with belugas is possible. If prevailing dispersal is shoreward, most belugas could be outside of and avoid the areas of greatest impact. Oil concentrated in the spring lead system could impact the Beaufort stock as they migrate eastward during the spring through direct contact or ingestion of oil. Belugas could also be affected through secondary contamination of prey.

In accordance with criteria of Section 4.1.3 of this EIS, the magnitude of impacts on individual beluga whales could range from medium to high, depending on the extent of oil dispersal and level of injury or mortality resulting from contact. The duration of impacts could range from temporary skin irritations to permanent endocrine or reproductive failure if ingested, and the extent could be state-wide due to the migratory nature of belugas. Belugas are considered unique because of their importance as a subsistence resource. Lasting population level impacts could depend on the extent of the spill. The entire Beaufort Sea stock migrates through the Beaufort Sea twice annually and, if contact with a spill were unavoidable, a large portion of the stock could be impacted. A VLOS could have a major impact on beluga whales in the Beaufort Sea.

Gray Whale

Gray whales may be vulnerable to direct impacts from a VLOS in the Beaufort Sea if the spill extends sufficiently westward. Most summer feeding aggregations of gray whales are on the Chukchi Sea side of Point Barrow. Gray whales are observed feeding in late-summer and fall on the Beaufort Sea side of Point Barrow, although rarely east of Smith Bay (Clarke et al. 2011b, 2011c). MMS (2003) estimated a 0.5 to 6 percent chance that oil spilled in the Beaufort Sea lease area during the open water season would move sufficiently westward to contact the feeding area used by gray whales. Given that, small numbers of gray whales may encounter a VLOS, although larger aggregations will likely be outside of the impact area. Based on criteria of Section 4.1.3 of this EIS, the magnitude of impact from a VLOS on individual gray whales in the Beaufort Sea could be medium to high, depending on level of injury or mortality. Duration could range from temporary (minor skin irritations) to long-term (loss of habitat), and extend state-wide, given that gray whales migrate well beyond the Beaufort Sea to as far south as Mexico. The species is no longer listed as endangered, so it could be considered an important resource. A population level impact is unlikely, assuming oil from a VLOS in the Beaufort Sea remains within the Beaufort Sea. A VLOS in the Beaufort Sea could have a moderate to major impact on individual gray whales.

Ice Seals

The impact of a VLOS on ice seals in the Beaufort Sea may vary by habitat requirements, prey preferences, and seasonality of occurrence in the area, among other factors. Potential impacts are, therefore, discussed separately for each species. Ribbon seals are omitted from this section due to their rarity in the Beaufort Sea.

Bearded Seal

Bearded seals may occur in the Beaufort Sea year round and are commonly sighted throughout the Beaufort Sea shelf area (Clarke et al. 2011b, 2011c). They could, thus, be vulnerable to impacts from encountering fresh oil in open water and residual oil in sea ice, leads, and polynas, as well as associated VLOS clean-up activities. Direct contact with oil could result in large-scale injury or mortality events, particularly if it occurred in a polyna or lead system in which bearded seals aggregate. Bearded seals are benthic feeders and are restricted to shallow shelf areas for feeding. Damage to these areas and prey resources could cause long-term displacement and possible loss of fitness due to inadequate prey availability. Based on criteria of Section 4.1.3 of this EIS, impacts of a VLOS on bearded seals could be of medium to high intensity and of temporary to permanent duration, depending on extent of habitat loss, injury, or level of mortality. The geographic extent could be regional to state-wide, depending on how far bearded seals could be displaced or need to search for alternative habitat. Bearded seals are a unique resource in the Beaufort Sea due to their importance as a subsistence resource for coastal communities, as well as a recent proposal to list the species as threatened under the ESA. Population level impacts are possible if large portions of important benthic habitat are unavailable and if contact with a VLOS occurred in areas of high concentrations of seals, resulting in large-scale injury or mortality. A VLOS in the Beaufort Sea could have a major impact on bearded seals.

Ringed Seal

Ringed seals occur in the Beaufort Sea year round, where they are closely associated with sea ice. Ringed seals are the most commonly sighted pinniped during fall aerial surveys of the Beaufort Sea shelf and are broadly distributed across the area (Clarke et al. 2011b, 2011c). During the open water season, they spend more time in the water foraging, leaving them vulnerable to impacts of a VLOS during that time of the year. During winter and spring, they associate with shorefast ice where ice entrained oil may persist. The intensity, duration, and extent of impacts of a VLOS on ringed seals are similar to that anticipated for bearded seals (see above). Ringed seals are so are considered a unique resource because they are hunted for subsistence by Alaska Natives from communities along the coasts of the northern Bering, Chukchi, and Beaufort Seas. Population level impacts are possible if large portions of important habitat and prey are unavailable, and if contact with a VLOS occurred in areas of high concentrations of seals resulting in large scale injury or mortality. Based on criteria of Section 4.1.3 of this EIS, a VLOS in the Beaufort Sea could have a major impact on ringed seals.

Spotted Seal

Spotted seals may be vulnerable to impacts of a VLOS in the Beaufort Sea, where they are known to occur in nearshore areas and occasionally haul out. Spotted seals could be susceptible to impacts of floating oil in foraging areas in open water, oil that washes ashore in coastal areas, and the multitude of activities associated with clean-up, from boom deployment to vessels and airplanes. Displacement from important habitat areas is possible, as are direct impacts from contact with oil and dispersants. Based on criteria of Section 4.1.3 of this EIS, impacts of a VLOS on spotted seals could be of medium to high intensity and of temporary to permanent duration, depending on the extent of habitat loss, injury, or level of mortality. The geographic extent could be state-wide given the migratory behavior of spotted seals. Spotted seals are an important species for Alaskan subsistence hunters, so are considered a unique resource. Population level impacts are possible if large portions of important habitat are unavailable and if contact with a VLOS occurred in areas of high concentrations of seals. A VLOS in the Beaufort Sea could have a major impact on spotted seals.

Pacific Walrus

Pacific walrus are most susceptible to impacts of a VLOS during the summer months and can be affected at sea, on ice floes, or onshore. Walrus distribution in the Beaufort Sea is generally limited to waters north and east of Point Barrow, in the vicinity of Barrow Canyon, and only occasionally east of Smith Bay (Clarke et al. 2011b). There have been no large onshore aggregations of walrus in the Beaufort Sea as are seen along the Chukchi Sea coast. The likelihood of walrus contacting a VLOS in the Beaufort Sea is similar to that described above for gray whales. Assuming that impacts of a VLOS occurring in the Beaufort Sea remain in the Beaufort Sea, small numbers of walrus could be affected (e.g. of the 32 sightings (281 individuals) of walrus during BWASP surveys, 2006 to 2009, only three were east of Barrow Canyon [Clarke et al. 2011b, 2011c]). The larger aggregations in the Chukchi Sea will likely be outside of the impact area. Walrus that do encounter a VLOS could experience impacts associated with physical contact with the skin and membranes, inhalation of fumes, and impacts on benthic prey. Impacts of oil and dispersants on benthic prey resources (such as contamination or mortality) could have lasting impacts on prey and habitat availability for walrus in the Beaufort Sea. Based on criteria established in Section 4.1.3 of this EIS, impacts of a VLOS on individual Pacific walrus could be of medium to high intensity, duration could range from temporary displacement to long term injury or displacement from important habitat, and the geographic extent could be state-wide due to the migratory behavior of walrus. Walrus are an important subsistence species for several communities along the Bering and Chukchi Sea coasts of Alaska and the coast of Chukotka (Russia), so are considered a unique resource. Population level impacts are unlikely, unless oil disperses into the Chukchi Sea areas where large aggregations haul-out and feed. A VLOS in the Beaufort Sea could have major impacts on individual Pacific walrus.

Polar Bear

A VLOS in the Beaufort Sea could involve either the CBS or the SBS during the open-water season and the SBS stock at other times of the year, including during denning. Polar bears are vulnerable to impacts of a VLOS in the Beaufort Sea across a range of habitats and VLOS-related activities. They could directly contact oil in offshore areas during the summer open water period or the broken ice period during the fall, as it comes ashore on barrier islands and coastal regions, and experience disturbance impacts of clean-up activities originating from onshore localities. Polar bear occurrence onshore increased in recent years, likely in response to retreating ice conditions offshore (Schliebe et al. 2006). Polar bears are common in the fall near or onshore between Cape Halkett and Kaktovik (Clarke et al. 2011b, 2011c), the area that encompasses most of the active leases in the Beaufort Sea. Polar bears from the SBS stock den on both sea ice and in snow drifts on land, with an increasing percentage now denning on land (Fischbach et al. 2007). Primary terrestrial denning areas include barrier islands from Barrow to Kaktovik and coastal areas up to 25 miles inland, including ANWR to Peard Bay (Allen and Angliss 2010). Critical habitat was recently designated along the Beaufort Sea coastline that includes sea ice critical habitat, barrier islands critical habitat, and onshore denning critical habitat. Critical habitats could be impacted and suitability for use compromised by direct contamination from oil or chemical dispersants or by access being hindered by floating oil and subsequent clean-up activities (including disturbance caused by increased vessel and aircraft activity).

Based on criteria of Section 4.1.3 of this EIS, impacts of a VLOS on polar bears could be of medium to high intensity, particularly if the fur were sufficiently fouled to result in loss of insulation, if oil were ingested, or if displacement from critical habitats affected overall fitness. Duration of impacts could range from temporary displacement to permanent habitat loss, reproductive impairment, or even death. Contamination and toxic impacts from either directly consuming oil or through consuming marine mammal prey in which contaminants accumulated could be long-lasting. The geographic extent of impacts could be state-wide, given the migratory movements of bears and possible need to relocate if local habitats are severely altered. It is also possible that, if the oil discharge were widespread, denning areas on barrier islands could be impacted. Shore-based clean-up activities could lead to disturbance or displacement, including during den excavation in the fall or emergence from dens in the spring. Polar bears are considered unique due to their threatened status and importance as a subsistence resource. Population level impacts are possible and dependent on numbers of polar bears directly injured or killed, extent of habitat loss (including denning areas), and chronic long-term impacts on reproduction and survival. A VLOS could have major impacts on polar bears in the Beaufort Sea.

Kaktovik Time/Area Closure

The coastal area off Kaktovik provides habitat for a number of marine and anadromous fish, shorebirds and waterfowl, and marine mammals. MMS (2003) did not calculate the risk of a VLOS affecting Kaktovik in particular, but it did calculate the risk of oil reaching the coastline of the Arctic National Wildlife Refuge, which includes Kaktovik and lands eastward to Canada. The analysis stated that:

> *The coastline would be vulnerable to offshore spills mainly during the summer open-water period; during the rest of the year, the coastline probably would be buffered from offshore spills by the band of landfast ice. The Oil-Spill-Risk Analysis conditional probabilities for summer (Tables A.2-85 through A.2-90) indicate that the risk to the Refuge would be highest, of course, for any inshore spill in the eastern Alaskan Beaufort Sea. The specific probability that a spill from various offshore locations would contact the Refuge's coastline within 30 days is given in Table A.2-87. The table shows that the probability would be 38 percent or less from all hypothetical launch areas except one in Launch Area 18, which corresponds with the nearshore lease tracts in the eastern Alaskan Beaufort Sea. A summer spill in that area is estimated to have a 49 percent probability of contacting the Refuge's coastline within 30 days (Table A.2-87).*

Large numbers of bowhead whales move past Kaktovik from late August into October. Females with calves are common and some animals feed on concentrations of zooplankton. Several other marine mammal and bird species can be found near Kaktovik.

The primary reason this area is considered for time/area closure in this EIS is because of its importance to marine mammals and subsistence hunters from Kaktovik. The consequences of a 2.2 MMbbl VLOS impacting the waters in and around Kaktovik should be considered much greater than what was identified in the MMS (2003) 180,000 bbl VLOS analysis. No specific risk calculations were made for most of the biological components of the waters around Kaktovik but, because so many important species are migratory, impacts to them anywhere along the migration route would affect their status in this portion of the Beaufort Sea. Using more generalized analyses, the potential effects are likely to be of highest magnitude and duration on birds and marine mammals (see Sections 4.10.7.10 and 4.10.7.11). The effects on certain bird and marine mammal species, many of which are crucial for subsistence cultures, dominate the conclusion about the effects of a VLOS in this time/area closure. These effects are considered to be of high magnitude and intensity, long-term, and of state-wide geographic scope because they affect migrating birds and marine mammals. A VLOS could have major effects on the Kaktovik time/area closure according to the criteria established in Section 4.1.3.

Barrow Canyon and Adjacent Beaufort Shelf and Shelf Break Time/Area Closure

Barrow Canyon, a deep submarine canyon to the west of Point Barrow separates the shallow Beaufort and Chukchi sea shelves (Pickart and Stossmeiser 2008). The Alaskan Beaufort Sea shelf is approximately 80 km (50 mi) wide and extends approximately 500 km (311 mi) from Point Barrow to the Canadian border (Weingartner 2008). Bottom topography varies little along the shelf except for Barrow Canyon, which has steep walls and reaches depths of 200 to 250 m (656 to 820 ft). Outside and north of the barrier islands, water depths increase gradually to the shelf break approximately 64 km (40 mi) offshore (Shell 2011a). Neither MMS (2003) nor BOEM (2011) calculated the risks of a VLOS impacting Barrow Canyon and adjoining areas in particular.

Physical and oceanographic features of Barrow Canyon, coupled with favorable wind conditions promote the formation of an important recurring feeding area for bowhead whales near Point Barrow in late summer and fall. A strong shelf-break front forms along the southeastern edge of Barrow Canyon when shelf-break currents are directed onto the Beaufort shelf or along the edge of the canyon in response to weak winds. The front is absent when winds are moderate to strong from the east. The shelf-break front promotes the concentration and retention of euphausiids and copepods on the western Beaufort shelf and, consequently, a bowhead whale feeding "hotspot" (Okkonen et al. 2011).

Barrow Canyon is also an important habitat for beluga whales. During light to moderate ice years, beluga whale sightings are often highest in Barrow Canyon and offshore shelf break and slope areas (Clarke et al. 2011b, 2011c; Moore et al. 2000). Ringed, spotted, and bearded seals are also common year round, especially when ice is present. Many species of tundra-nesting seabirds, shorebirds, and waterfowl use the Barrow Canyon area, especially the nearshore areas, for feeding and staging during migration. These include ESA-listed Steller's and spectacled eiders and candidate species yellow-billed loon and Kittlitz's murrelet.

The primary reason Barrow Canyon and the adjacent seas are considered a time/area closure location in this EIS is because of their importance to marine mammals and subsistence hunters from Barrow and Wainwright. The risk of a 2.2 MMbbl VLOS impacting Barrow Canyon should be considered much greater than what was identified in the MMS (2003) 180,000 bbl VLOS analysis. No specific risk calculations were made for most of the biological components of the Barrow Canyon system but, because so many important species are migratory, impacts to them anywhere along the migration route would affect their status in Barrow Canyon. The potential effects are likely to be of highest magnitude and duration on birds and marine mammals (see Sections 4.10.7.10 and 4.10.7.11). The effects on certain bird and marine mammal species, many of which are crucial for subsistence cultures, dominate the conclusion about the effects of a VLOS on the Barrow Canyon and adjacent Beaufort Sea shelf and shelf break time/area closure, which is considered a unique resource because of its the combination of oceanographic features that concentrate biological resources and proximity to nearby subsistence cultures. These effects are considered to be of high magnitude and intensity, long-term, and of state-wide geographic scope because of impacts to migrating birds and marine mammals. A VLOS could have major effects on the Barrow Canyon and adjacent Beaufort Sea shelf and shelf break areas according to the criteria established in Section 4.1.3.

4.10.7.12 Terrestrial Mammals

4.10.7.12.1 Existing Analysis (BOEM 2011d and MMS 2003)

Section 4.4.7.1.3 of BOEM (2011e) provides an analysis of the impacts of a catastrophic discharge event on terrestrial mammals in Arctic Alaska. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event would result in sustained degradation of water quality, shoreline terrestrial habitats, and, to a lesser extent, air quality that could impact terrestrial mammals from direct contact, inhalation, and ingestion. These effects could be severe where persistent, heavy oil makes contact with important habitat and prey base, causing a multitude of acute and chronic effects (BOEM 2011d).

Section 4.1.2.h of MMS (2003) describes potential impacts to marine and coastal birds during a possible VLOS in the Beaufort Sea. This information is incorporated herein by reference, and a summary of that information is provided here.

The potential effect of a very large oil spill (180,000 barrels) on caribou, muskoxen, grizzly bears, and arctic foxes is likely to be limited to caribou groups occurring during the spring and during the insect relief periods in coastal waters near shorelines with extensive oil contamination. Although the oil spill is estimated to contact over 480 kilometers of shoreline and muskoxen, grizzly bears, and arctic foxes frequenting coastal areas from Pitt Point east to about the Canning River Delta, the majority of the coastline contamination would occur between Oliktok Point (Land Segment 36) east to about the Staines River delta (Land Segment 42) (Table IV.I-9c, LA12, 30 days). Caribou groups that belong to the Central Arctic, Teshekpuk Lake Herd, and Porcupine herds are the assemblages of caribou likely to encounter oil while in coastal waters or on the beaches.

Heavily oiled caribou might die from absorption and/or inhalation of toxic hydrocarbons. Several hundred caribou of the Central Arctic, Teshekpuk Lake, and Porcupine herds could die from the oil spill.

Small numbers of muskoxen, grizzly bears, and arctic foxes may encounter oil and be adversely affected. Potential losses would represent a short-term effect, with populations recovering within about one year.

The effects of a very large oil spill on caribou, muskoxen, grizzly bears, and arctic foxes are expected to be short term (recovery expected within about one year).

4.10.7.12.2 Additional Analysis for Terrestrial Mammals

There are approximately 30 species of terrestrial mammals within the vicinity of the EIS project area (Table 3.2-5). Among these species, it is expected that only barrenground caribou (*Rangifer tarandus granti*) may experience interactions with oil and gas exploration activities during critical periods of their life cycle; therefore, this analysis will focus solely on caribou. Descriptions of distribution, life cycle, and habitat characteristics of other species are not included in this EIS.

The oil spill discussion in MMS (2003) analyzed the effects of an oil spill of 180,000 bbl, and for the purposes of this EIS, a VLOS of 2.2 MMbbl occurring over a 74 day period is considered. Although the impacts to caribou would be similar regardless of the size of the spill, the magnitude, duration, and extent would be substantially greater with a larger spill.

The effects of a VLOS would be of medium intensity, temporary duration, local extent and common context because while there is a perceptible change to the caribou population, it is likely to be temporary, with a localized impact, and the caribou population can recover within one to two years even with a loss of several thousand animals (BOEM 2011b). For more information regarding the impact to subsistence or recreational hunting, see Sections 4.10.7.15 and 4.10.7.20, respectively. Utilizing the impact criteria listed in Section 4.1.3, a summary impact level of minor to moderate would result for caribou, depending on the magnitude and duration of the VLOS.

4.10.7.13 Time/Area Closures

A low probability, high impact VLOS could affect marine mammals and marine and coastal birds in time/area closure locations in the Beaufort Sea. Discussion of impacts to marine mammals in the waters off Kaktovik and Barrow Canyon and Adjacent Beaufort Shelf and Shelf Break can be found in Section 4.10.7.11 and impacts to marine and coastal birds can be found in Section 4.10.6.10.

4.10.7.14 Socioeconomics

4.10.7.14.1 Existing Analysis (BOEM 2011d)

Section 4.4.13.3.2 of BOEM (2011e) provides an analysis of the impacts of a catastrophic discharge event on sociocultural systems in the Alaska Arctic regions. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could employ local villagers during the cleanup, it is likely that many additional workers would be necessary, placing stress on village facilities. An influx of outsiders is likely to result in some cultural conflict, stressing the local sociocultural systems. As is evident from the EVOS, such cleanup efforts can be disruptive socially, psychologically, and economically for an extended period of time (BOEM 2011d).

4.10.7.14.2 Additional Analysis for Socioeconomics

The MMS (2003) estimate of employment associated with oil spill clean-up activities was based on the most relevant historical experience of an oil spill in Alaskan waters, the EVOS of 1989. That spill was 240,000 bbls, while the Beaufort Sea VLOS described in this hypothetical VLOS scenario, would be 2.2 MMbbls. The socioeconomic effects described in MMS (2003) would be more intense due to the larger quantities of oil reaching the shore, the larger magnitude of the spill, and the longer duration of clean-up effort. The BOEM (2011) analysis described in Section 4.10.6.14 contains estimates that relate to an event in the Chukchi Sea, but are relevant to a scenario in the Beaufort Sea as well.

Public Revenue & Expenditures

Under a VLOS, there would be loss of future federal and state revenues due to a potential moratorium on future oil and gas production, or other disruptions. A Natural Resource Damage Assessment conducted by NOAA would determine compensation for natural resource service values. Local revenues would be generated in the communities staging clean-up response through the sale of goods and services to workers. NSB would receive property taxes if an enclave were developed to house the clean-up equipment and workers.

Employment & Personal Income

The MMS (2003) analysis provides an estimate for the number of workers needed for spill clean-up, but the VLOS scenario in the Beaufort Sea would be for a larger spill, thereby increasing the estimate for numbers of workers by an order of magnitude. The number of cleanup workers needed is unknown but the VLOS could induce some local employment.

The purchase of goods and services stemming from the disposable income of clean-up workers would have a positive, though short-term local economic impact. MMS (2003) and BOEM (2011) describe that after EVOS, numerous local residents quit their jobs to work on the cleanup, often accepting positions with considerably higher wages. This generated a sudden and substantial inflation in the local economy, a short to long-term economic impact. Economic impacts would be smaller for NSB than those that occurred during EVOS due to the likelihood that cleanup activities, including administrative personnel and spill-cleanup workers, would be located in Prudhoe Bay's existing enclave-support facilities (Cohen 1993:261 in BOEM 2011b).

Other major impacts related to the long-term disruption of the non-cash/subsistence economy are described in the Environmental Justice Section 4.10.6.22 and Public Health Section 4.10.6.16. The BOEM (2011b) analysis does not detail the level and extent of disaster funding to temporarily replace subsistence activity, but it mentions the redirection from subsistence activities to cash activities.

Demographic Characteristics

New oil spill clean-up employment opportunities described in MMS (2003) are not likely to cause a permanent demographic shift. The potential for outmigration due to the disruption of the subsistence activities is not analyzed in the BOEM (2011) analysis.

Social Organizations & Institutions

The influx of clean-up workers would create a long-term demand on institutions and social services in Barrow. Regional and local non-profit organizations that mediate between industry and subsistence users and social organizations would be impacted. BOMRE (2011) describes requests for temporary assistance from various institutions.

Private companies and regional corporations may be positively impacted in the short-term through the sale of goods and services to spill response companies.

Conclusion

Employment and local revenues associated with VLOS clean-up in the Beaufort Sea would be high intensity, long-term in duration, regional to national in extent, and unique and important in context. The impact to the non-monetary economy is discussed in detail in Section 4.10.7.15 (Subsistence), and are summarized as major negative impacts (classified as high intensity, long-term to permanent in duration (lasting more than five years), regional to statewide in extent because it would affect local and Alaskan residents, workers and businesses, and unique and important in context). Therefore, the summary impact level to socioeconomics would be major according to the direct and indirect impacts criteria established in Section 4.1.3.

4.10.7.15 Subsistence

4.10.7.15.1 Existing Analysis (BOEM 2011d)

Section 4.4.13.3.2 of BOEM (2011e) provides some information about the impacts of a catastrophic discharge event on subsistence harvest in the Alaska Arctic regions. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that as the result of a catastrophic discharge event, the economically, socially, and culturally important bowhead whale hunt could be disrupted, as could the beluga harvest. Animals could be directly oiled, or oil could contaminate the ice floes or onshore haulouts they use on their northern migration. Such animals could be more difficult to hunt because of the physical conditions. Animals could be spooked and/or wary, either because use of the spill itself or because of the hazing of marine mammals, which is a standard spill-response technique in order to encourage them to leave the area affected by a spill. Oiled animals are likely to be considered tainted by subsistence hunters and would not be harvested, as occurred after the EVOS. This would also apply to terrestrial animals, such as bears that scavenge oiled birds and animals along the shore, or caribou that seasonally spend time along the shore or on barrier islands seeking relief from insects. The loss of subsistence harvest resources, particularly marine mammals, would have significant effects on Alaska native culture and society (BOEM 2011d).

4.10.7.15.2 Additional Analysis for Subsistence Resources

Based on the criteria of Section 4.1.3 of this EIS, the intensity of the VLOS on subsistence resources and subsistence harvest in the Beaufort would be of high intensity and cause a year round change in subsistence use patterns. Subsistence harvests of marine mammals, fish, migratory birds, and caribou that occurs in or along the coastlines and lagoons would be affected by oiling and fouling and by the presence of the response equipment and personnel. Subsistence harvests could be altered long-term to permanent in duration. The perception that food is tainted and/or contaminated could be long-lasting or permanent among the Iñupiat communities of the Beaufort Sea (see Section 4.10.7.16, Public Health of this EIS). As observed after EVOS, the interruption of two to three years of training youth in subsistence harvest practices changed the balance of the subsistence economy for a period persisting well beyond the spill itself.

Impacts to subsistence harvests and sharing of resources would be regional to state-wide and may extend throughout the EIS project area and impact the non-wage regional economy of the communities of the Beaufort and Chukchi seas (Section 4.10.7.14, Socioeconomics of this EIS). Impacts from a VLOS to subsistence harvest of ESA protected bowhead whales and polar bears are considered unique in context. Impacts from a VLOS to subsistence harvest of beluga whales, seals, walrus, fish, birds, and caribou are considered important in context.

The impacts of a VLOS in the Beaufort Sea would be high intensity, long-term to permanent in duration, regional to statewide in extent, and affecting resources that are unique and important in context. In summary, the impact of a VLOS on subsistence harvest would be major.

4.10.7.16 Public Health

4.10.7.16.1 Existing Analysis (BOEM 2011d)

Section 4.3.2.4.2 of BOEM (2011e) provides some information about the impacts of a catastrophic discharge event on public health in the Alaska Arctic regions. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that major areas of concern related to a catastrophic discharge event would include impacts on subsistence resources, air quality, and oil spill cleanup (BOEM 2011d).

4.10.7.16.2 Additional Analysis for Public Health

The effects on public health associated with a VLOS in the Beaufort Sea are anticipated to be similar to those associated with a VLOS in the Chukchi Sea. The overall effects could range from moderate to major depending on the size, nature and location of the spill.

4.10.7.17 Cultural Resources

4.10.7.17.1 Existing Analysis (BOEM 2011d)

Section 4.4.15.3.2 of BOEM (2011e) provides some information about the impacts of a catastrophic discharge event on archaeological resources in Alaska Arctic regions. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could result in extensive impacts on a large number of archaeological and historic resources. Due to the large area affected by a catastrophic event some resources such as coastal historic sites that are sensitive to prolonged contact with oil could be heavily impacted. Cleanup crews would be needed in a greater number of locations. This could allow oil to be in contact with resources for a significant amount of time before cleanup efforts could be applied, which could result in impacts to these resources. A greater threat to archaeological and historic resources during a catastrophic discharge event would result from the larger number of response crews being employed. A catastrophic discharge event would result in large impacts to numerous archaeological and historic resources from response activities (BOEM 2011d).

4.10.7.17.2 Additional Analysis for Cultural Resources

This section describes potential impacts to both offshore and onshore prehistoric and historic resources from a VLOS event in the Beaufort Sea.

Given the limited data related to historic and prehistoric resources in the Beaufort Sea area, it is difficult to determine how many historic properties might be located in areas affected by a VLOS event. The presence of oil and the various oil-spill response and cleanup activities could potentially impact both prehistoric and historic archaeological resources, including submerged prehistoric sites and historic shipwrecks, as well as onshore prehistoric and historic resources, including camps, village sites, artifact scatters, historic structures, and World War II and Cold War era facilities.

Offshore Prehistoric and Historic Resources

In the event of a VLOS, submerged prehistoric and historic resources adjacent to a blowout could be damaged by the high volume of escaping gas, buried by large amounts of dispersed sediments, crushed by the sinking of the rig or platform, destroyed during relief well drilling, or contaminated by hydrocarbons (BOEM 2011b). Oil settling to the seafloor could contaminate organic materials associated with archaeological sites, resulting in erroneous dates from standard radiometric dating techniques (e.g. 14C-dating), and accelerate the deterioration of wooden shipwrecks and artifacts on the seafloor (BOEM 2011b). However, offshore resources are at greatest risk from bottom-disturbing activities, notably anchoring and anchor dragging. The potential to impact archaeological resources increases as the density of anchoring activities in these areas increases (BOEM 2011b). The anchoring of VLOS response and support vessels near a blowout site and in shallow water could result in damage to both known and undiscovered archaeological sites.

Onshore Prehistoric and Historic Resources

The greatest impacts on archaeological resources from a VLOS would be to onshore archaeological sites from oil-spill-cleanup activities. Cleanup activities could impact beached shipwrecks, or shipwrecks in shallow waters, and coastal historic and prehistoric archaeological sites. Any onshore activity (cleanup or otherwise) that brings development in contact with remote areas has the potential to expose archaeological resources to disturbance from construction or from vandalism. Historic sites, such as hunting, fishing, and whaling camps, or structures associated with settlements or the World War II and Cold War era Navy, Air Force, and Army facilities could be affected by increased cleanup activity in remote areas and increased vandalism. Prehistoric sites, though often not as visible as historic sites, also might be subjected to increased vandalism, as well (MMS 2007a, 2009; BLM, 2008). As Bittner (1993) described in her summary of the 1989 EVOS:

> *Damage assessment revealed no contamination of the sites by oil, but considerable damage resulted from vandalism associated with cleanup activities, and lesser amounts were caused by the cleanup process itself* (MMS 2007a, 2009).

4.10.7.18 Land and Water Ownership, Use, and Management

4.10.7.18.1 Existing Analysis (BOEM 2011d)

Section 4.4.10.3.2 of BOEM (2011e) provides an analysis of the impacts of a catastrophic discharge event on land use, development patterns, and infrastructure in the Alaskan Arctic. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that a catastrophic discharge event could have both direct and indirect effects on land use, depending on the type, size, location, and duration of the incident. Impacts generally would be more intense in areas with little infrastructure in place to handle accidents and where a greater reliance is placed on coastal activities for subsistence (BOEM 2011d). The Alaska Coastal Management Program was not reauthorized by the Alaska Legislature and is not in effect at this time.

4.10.7.18.2 Additional Analysis for Land and Water Ownership, Use, and Management

An oil spill that reaches the Beaufort Sea coastline has the potential to affect land use and management. In addition, activities associated with oil spill response and clean-up also have the potential to affect land use and management. The following analysis provides a discussion of these potential affects. Impacts to land and water ownership, use, and management related to a VLOS event in the Beaufort Sea would be similar to those occurring in the Chukchi Sea, the only difference being that existing leases in the Beaufort Sea lie closer to shore, making the likelihood of oil contacting the coastline more likely. Taking this into account, the impacts discussed in Section 4.10.6.18 for the Chukchi Sea are applicable to the Beaufort Sea as well.

Land and Water Ownership

Because the response efforts to a VLOS would not require any change in existing leasing rights, or the sale or transfer of any federal, state, or native land or waters, no change in underlying land or water ownership would be anticipated in the Beaufort Sea.

Land and Water Use

A spill of this magnitude in the Beaufort Sea would impact some land uses. Should an oil spill result in oil accumulating along the shoreline and in tidal zones, the presence of oil could affect existing land uses by making it difficult to access land, creating a real or perceived change the resources and values that support specific land uses, and discouraging pursuit of traditional land use in areas affected by a spill. Examples of these include subsistence, other traditional land uses, and recreation.

Industrial land may experience increased usage to support additional vessels, aircraft, vehicles and materials used in responding to a VLOS. This could require the construction or expansion of docks, warehouses, airstrips and/or storage facilities. It is unlikely that new permanent facilities would be constructed for spill response. Response support crews would need to be housed, affecting residential land uses. This could be accommodated through the construction of temporary worker camps, most likely in the vicinity of Prudhoe Bay or in the villages of Kaktovik, Nuiqsut and Barrow. Depending on the location of industrial and commercial lands in the immediate vicinity of spill response activities, some temporary industrial land use may occur in new areas. Remote lands currently designated for natural resource protection might experience increased levels of human activity or disturbance for habitat restoration along shorelines where oil may accumulate. This would have similar effects to those discussed above, regarding access, damage to land and resource values, and interest in using the area. The duration of potential effects on land use would depend on the amount of oil that reaches shoreline and intertidal areas, the nature and duration of response activities, and the success in cleanup and restoration activities.

For a discussion of the impacts from a VLOS event in the Beaufort Sea, see Section 4.10.7.15 (Subsistence) and Section 4.10.7.20 (Recreation).

Land and Water Management

Current management plans do not include contingencies for a VLOS. It is assumed that in the event of a VLOS, federal and state management plans that include coastal areas may require additional approvals for response and cleanup activities to accommodate heightened levels of human access for habitat restoration and oil cleanup efforts. Federal and state waters would be managed in the short term with an intense focus on response and clean-up of oil. Any management plan policies that are modified for a VLOS event would most likely be temporary, but could lead to plan updates to address any potential change in land and resource values, actions needed to promote recovery of affected resources, or address the potential for response activities in the unlikely event that they are needed.

Conclusion

Based on Table 4.4-2 and the analysis provided above, the impacts of land and water use caused by a VLOS are described as follows. The magnitude of impact would be low for land and water ownership because no change would be expected. The magnitude of impact would be high for land and water use for areas affected by a spill that have seen historical or current use for subsistence, other traditional land uses, and recreation, due to the potential change in resource/use values, and the level of activity associated with spill response and cleanup. The magnitude of impact would be medium for land and water management if management plans must result in new approvals to accommodate response efforts or a spill results in a change in resource or land values. The duration of impact would be long term because response efforts may extend up to several years, although the impact could be permanent if in the unlikely event construction of a new facility or infrastructure to accommodate spill response activities. The extent of impacts would be regional because the spill would affect large expanses of water and has the potential to come into contact with land along an extensive area of shoreline in and near the project area. The context of impact would generally be common because the areas of land and water affected are extensively available, unless some special, rare, or unique characteristics associated with specific subsistence and recreation areas are affected. In summary, the effects of a VLOS would be major due to the possibility for high intensity and long term impact to land use and land management.

4.10.7.19 Transportation

4.10.7.19.1 Existing Analysis (BOEM 2011d)

The BOEM (2011e) analysis did not specifically analyze impacts to transportation associated with an oil spill scenario.

4.10.7.19.2 Additional Analysis for Transportation

Setting

The transportation systems among the communities of Kaktovik, Nuiqsut and Barrow and the Prudhoe Bay area would experience increased levels of air, vessel and surface traffic associated with containment, recovery, and cleanup activities for a VLOS that would involve hundreds of workers and vessels, aircraft, and onshore vehicles operating over an extensive area for one to two years. In the event of a VLOS, vessels such as skimmers, workboats, barges and icebreakers involved with cleanup would be used to remove oil from a spill area that occurs at sea and to drill a new well. Aircraft (fixed wing) would also likely be engaged in application of dispersants. Equipment involved with clean up and response would vary based on seasonal conditions as described in Section 4.10.6.19. In the event that response efforts continue into the winter season, small vessel traffic would come to a halt once the forming ice begins to cover the ocean surface. Larger skimming vessels could continue until conditions prevent oil from flowing into the skimmers. Small boats and aircraft would also be involved with beach cleaning activities at oiled beaches (including booming) at marine and freshwater shorelines.

In addition aircraft could be used to apply dispersants used to decrease the size of the oil slick. Additional aircraft would also be used for transporting response personnel and equipment, including helicopters, small piston-powered aircraft, and large commercial jets affecting these communities. Aircraft could also be used to map the extent of an oil spill and for surveillance. Surface vehicles would also be used during response operations onshore.

Activities

Local modes of transportation between communities by aircraft, vessels and surface means would be affected by a VLOS in nearshore and coastal areas. Impacts to the transportation system along the Beaufort Sea coast would be similar as discussed for the Chukchi Sea (Section 4.10.6.19). In the event of a VLOS response, additional equipment would likely be delivered to the Prudhoe Bay area via surface transportation on the Dalton Highway. Air traffic to Deadhorse/Prudhoe Bay would increase from Anchorage and air traffic between the communities of Kaktovik, Nuiqsut and Barrow would increase in the event of a VLOS. The airport at Deadhorse/Prudhoe Bay could be a logistical center for distributing incoming responders and equipment to the airports at Barrow, Nuiqsut and Kaktovik. During the initial response phase the spill equipment that is already staged at local communities would be rapidly deployed via aircraft and support vessels. As response efforts continue the levels of air traffic to the areas affected of the Beaufort Sea would increase in the numbers of flights arriving as additional response crews and supplies are transported into the affected area. In the event of a VLOS air transportation within Alaska could also be indirectly affected as higher demand would occur for air travel to the spill area connecting from the Anchorage and Fairbanks airports. The increased levels of aircraft associated with spill response would affect local transportation systems for the duration of the response to a VLOS. Use of local airports associated with spill response activities (resupply, transport of spill response crews and equipment) could strain the local and regional air transportation infrastructure.

Vessels and equipment associated with response would be present in increased numbers in the nearshore areas. Prudhoe Bay and spill response facilities at West Dock near Prudhoe Bay would be expected to experience high levels of activity as potential areas where response vessels and equipment would be staged and refuel. It is likely that local tug/barge and small vessel traffic between communities would be affected during the spill due to the increased numbers of response and support vessels present in nearshore areas. Increased levels of response and support vessels associated with spill response would affect local transportation systems for the duration of the response to a VLOS. Local nearshore areas normally used for marine transportation between communities would experience and encounter vessels associated with spill response activities. This could strain the local patterns of existing marine transportation. It is likely that in response to a VLOS there would be impairment of normal operations with deployment of response workers, vessels and equipment affecting the exiting levels of transportation along the coastline of the Beaufort Sea communities. In addition skiffs and small vessels used locally in nearshore waters may be come oiled. Skiffs and small vessels used locally in nearshore waters may be come oiled.

Surface transportation in the summer months could also be interrupted in the event of a VLOS that reaches the nearshore areas and coastlines. Local modes of surface transportation, including four wheelers/off road vehicles, used by residents during subsistence activities along the coasts may also become oiled.

The effects and impacts of aircraft and vessels disturbance caused during response to a VLOS to seabirds, marine mammals and terrestrial mammals is described in Sections 4.10.7.10 through 4.10.7.12 and the affects to subsistence hunters is described in Section 4.10.7.15.

Conclusion

The conclusions for impacts to transportation in the Beaufort Sea would be of high intensity (potentially year round), and long term in duration lasting one to two years or more during response and surveillance monitoring during recovery. The extent would be regional to state-wide, and important in context. In summary, the impact of a VLOS on transportation would be moderate to major.

4.10.7.20 Recreation and Tourism

4.10.7.20.1 Existing Analysis (BOEM 2011d)

Section 4.4.12.3.2 of BOEM (2011e) provides an analysis of the impacts of a catastrophic discharge event on recreation and tourism in the Beaufort Sea planning area. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that effects from a catastrophic discharge event would likely include beach and coastal access restrictions, including restrictions on visitation, fishing, or hunting while cleanup is being conducted, and aesthetic impacts associated with the event itself and with cleanup activities. These impacts are expected to be temporary, with the magnitude dependent on the location and size of the event and the effectiveness of cleanup operations. Longer-term impacts may also be substantial if tourism were to suffer as a result of the real or perceived impacts of the event, or if there were substantial changes to tourism and recreation sectors in the region as a result of the event (BOEM 2011d).

4.10.7.20.2 Additional Analysis for Recreation and Tourism

Impacts to the recreation setting and activities in the Beaufort Sea would be similar as discussed for the Chukchi Sea (Section 4.10.6.20), except impacts to the setting of the Beaufort Sea would be magnified along the coast of the Arctic National Wildlife Refuge (ANWR) due to the sensitivity of visitors to that area. Visitors to ANWR are expecting an isolated and undeveloped setting here more than the rest of the Beaufort Sea because the area is managed to maintain wilderness characteristics and there is no oil and gas exploration or drilling activities in the coastal area. The area is perceived as an undeveloped setting for recreation with a high sensitivity to impacts to wilderness characteristics. Even though recreation opportunities across the Beaufort Sea are not scarce and not protected by legislation, the potential to impact recreation settings and activities in a National Wildlife Refuge that is managed to maintain wilderness characteristics, the context is considered unique.

Conclusion

The conclusions for impacts to recreation and tourism discussed earlier for the Chukchi Sea are also applicable to the Beaufort Sea. The impacts would be high intensity, long term duration, regional to state-wide extent, and unique in context. In summary, the impact of a VLOS on recreation and tourism would be major.

4.10.7.21 Visual Resources

4.10.7.21.1 Existing Analysis (BOEM 2011d)

No analysis of impacts specific to visual resources is presented in the BOEM (2011e) document.

4.10.7.21.2 Additional Analysis for Visual Resources

Based on the scenario described in the spectacled and Steller's Eider, and the Vegetation and Wetland Habitat sections of the MMS (2003) analysis, a VLOS event is expected to temporarily impact scenic quality and visual resources within the Beaufort Sea. The behavior, and hence visibility, of released oil is expected to change depending on the presence and condition of ice. The magnitude and extent of direct impacts expected to scenic quality and visual resources is also expected to change based on the presence and condition of ice. For example, a spill that occurred on solid ice is not expected to enter the water. In such a scenario, the magnitude of impacts to scenic quality and visual resources is expected to be high; however impacts are expected to be of short duration and local extent. In contrast, should a VLOS scenario occur during open water, the intensity of impacts is expected to remain high; however the extent of impacts could be of regional extent due to the lack of containment of oil by ice. Additional direct impacts are expected to result from the perceptible change in the level of marine vessel and air traffic due to response and clean-up efforts. In all cases, indirect effects, including psychological/social distress among viewers, is expected to occur from witnessing oil slicks on the surface of near- or on-shore areas either in person or through media outlets. As in the analysis of the Chukchi VLOS scenario, both local and off-site viewers in the Beaufort Sea are expected to be sensitive to potential affects to scenic quality and visual resources.

The scenario described above is based on an 180,000 bbl VLOS. The magnitude, extent, and duration of impacts to scenic quality and visual resources are expected to be larger for a larger spill, such as that described for a 2.2 MMbbl VLOS. Should a 2.2 MMbbl VLOS scenario occur in the Beaufort Sea, similar impacts are expected to result from Phases 1 and 5 of the oil spill and cleanup scenario as that described in Section 4.10.6.21. The greatest change would likely be observed in the magnitude, duration, and extent of impacts to shoreline and on-land areas.

Conclusion

In conclusion, major direct and indirect impacts to visual resources are expected to result from a VLOS scenario. Impacts would be of high intensity, short- to long-term in duration, regional to state-wide in geographic extent, and would affect an important resource.

4.10.7.22 Environmental Justice

4.10.7.22.1 Existing Analysis (BOEM 2011d)

Section 4.4.14.3.2 of BOEM (2011e) provides some information about the impacts of a catastrophic discharge event on environmental justice in Alaska Arctic communities. This information is incorporated herein by reference, and a summary of the information is provided. The analysis concludes that many of the long-term impacts of a catastrophic discharge event on low-income and minority communities are unknown. Different cultural groups would likely possess varying capacities to cope with catastrophic events, with some low-income and/or minority groups more reliant on subsistence resources and/or less equipped to substitute contaminated or inaccessible subsistence resources with those purchased in the marketplace. Because lower income and/or minority communities may live near and be directly involved with catastrophic discharge event cleanup efforts, the vectors of exposure can be higher for them than for the general population, increasing the potential risks of long-term health effects (BOEM 2011d).

4.10.7.22.2 Additional Analysis for Environmental Justice

The above text recognizes that Iñupiat Alaska Natives are the predominant residents of the affected area and a VLOS would affect subsistence resources and harvest practices, therefore having disproportionately high adverse effects.

For a description of the character and intensity of impacts to subsistence resources and harvests and human health, the reader should also refer to the Subsistence (Section 4.10.7.15) and Public Health (Section 4.10.7.16) discussions in this EIS.

MMS (2003) states that potential effects to subsistence resources and subsistence harvests could be mitigated to some extent. The BOEM (2011e) Environmental Justice analysis is more specific about mitigation techniques and limitations, but concludes that there are "significant and perhaps irrevocable adverse impacts."

Conclusion

The impacts to subsistence foods and human health in the Iñupiat subsistence-oriented communities of Kaktovik, Nuiqsut and Barrow would be high intensity, long-term in duration, regional in extent, and unique in context. Therefore the summary impact level for environmental justice is major; there would be a disproportionate adverse effect to minority populations.

4.11 Cumulative Effects

An EIS must include an analysis of the potential cumulative effects of a proposed action and its alternatives and consider those cumulative effects when determining environmental impacts. The analysis of cumulative effects in this EIS employs the definition of cumulative impacts found in the CEQ regulations (40 CFR 1508.7 and 1508.25(a)(2)):

> *Cumulative impact is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.*
>
> *To determine the scope of environmental impact statements, agencies shall consider…cumulative actions, which when viewed with other proposed actions have cumulatively significant impacts and should therefore be discussed in the same impact statement.*

Cumulative effects are assessed by aggregating the potential direct and indirect effects of the proposed action with the impacts of past, present, and reasonably foreseeable future actions in the vicinity of the project. The ultimate goal of identifying potential cumulative effects is to provide for informed decisions that consider the total effects (direct, indirect, and cumulative) of the project alternatives. As suggested by the CEQ handbook *Considering Cumulative Effects Under the National Environmental Policy Act* (1997), the following basic types of cumulative effects are also considered:

- additive – the sum total impact resulting from more than one action;
- countervailing – adverse impacts that are offset by beneficial impacts; and
- synergistic – when the total impact is greater than the sum of the effects taken independently.

Cumulative effects may result from the incremental accumulation of similar effects or the synergistic interaction of different effects. Repeated actions may cause effects to build up over time, or different actions may produce effects that interact to produce cumulative impacts greater than (or less than) the sum of the effects of the individual actions.

As directed by CEQ's NEPA regulations (40 CFR 1502.16), direct and indirect impacts on specific physical, biological, and social resources are discussed in combination with varying levels of effects, ranging from negligible to major. The cumulative effects analysis focuses on impacts to long-term productivity and sustainability of valued ecosystem components.

4.11.1 Methodology for Identifying Cumulative Impacts

The methodology used for cumulative effects analysis in this EIS consists of the following steps:

- *Identify issues, characteristics, and trends within the affected environment that are relevant to assessing cumulative effects of the action alternatives.* Include discussions on lingering effects from past activities, and demonstrate how they have contributed to the baseline condition for each resource. This information is summarized in Chapter 3.
- *Describe the potential direct and indirect effects of oil and gas exploration activities.* This information is presented in detail in Sections 4.4 to 4.9 of this EIS.
- *Define the spatial (geographic) and temporal (time) frame for the analysis.* This timeframe may vary between resources depending on the historical data available and the relevance of past events to the current baseline.
- *Identify past, present, and reasonably foreseeable external actions such as other types of human activities and natural phenomena that could have additive or synergistic effects.* Summarize past and present actions, within the defined temporal and spatial timeframes, and also identify any reasonably foreseeable future actions (RFFAs) that could have additive, countervailing, or synergistic effects on identified resources.
- *Use specific methodology to screen all of the direct and indirect effects, when combined with the effects of external actions, to capture those synergistic and incremental effects that are potentially cumulative in nature.* Both adverse and beneficial effects of external factors are assessed and then evaluated in combination with the direct and indirect effects for each alternative on the various resources to determine if there are cumulative effects.
- *Evaluate the impact of the potential cumulative effects using the criteria established for direct and indirect effects, and assess the relative contribution of the action alternatives to cumulative effects.*
- *Discuss rationale for determining the impact rating, citing evidence from the peer-reviewed literature, and quantitative information where available.* The term "unknown" can be used where there is not enough information to determine an impact level, and the information cannot be readily obtained in a timely or cost effective manner. However, under CEQ guidelines, the effect of missing information on the decision to be made must be addressed in the EIS.

The advantages of this approach are that it closely follows CEQ guidance, employs an orderly and explicit procedure, and provides the reader with the information necessary to make an informed and independent judgment concerning the validity of the conclusions.

4.11.2 Past, Present, and Reasonably Foreseeable Future Actions

Relevant past and present actions are those that have influenced the current condition of the resource. For the purposes of this EIS, past and present actions include both human-controlled events, such as subsistence harvest and commercial whaling, and natural events, such as climate change. The past and present actions applicable to the cumulative effect analysis have been either presented in Chapter 3, or are discussed below. Additional past actions were identified using agency documentation, NEPA documentation, reports and resource studies, peer-reviewed literature, and best professional judgment. Table 4.11-1 lists a summary of relevant past and present actions.

Past, present, and RFFAs and activities considered for the cumulative effects analysis include: oil and gas exploration, development, and production activities; scientific research; mining exploration, development, and production; military facilities and training exercises; air and marine transportation; major community development projects; subsistence activities; recreation and tourism; and climate change. Commercial whaling in the late 19th century is also a past effect specific to bowhead whales that still influences population levels.

Recent environmental reports, lease sale documents, surveys, research plans, NEPA compliance documents, and other source documents have been evaluated to identify these actions. RFFAs were assessed to determine if they were speculative and would occur within the analytical timeframe of the EIS. Some specific assumptions include:

- Oil and gas exploration activities identified within this time frame cannot be foreseeably expected to result in discovery and production, primarily due to commercial uncertainty and regulatory timeframes.
- Potential oil and gas activities in the Canadian and Russian offshore Arctic were also researched and assessed if deemed applicable, given the potential to influence migratory marine mammal populations. Publically available information on the specific timing and nature of these activities is limited;
- Present oil and gas production activities are expected to continue at current levels, with the potential to contribute to cumulative effects through actions associated with both production and resupply;
- Mining activities occur primarily onshore but may involve air and marine support activities;
- Military activities with the potential to result in synergistic and additive effects include major construction or demolition projects and major training exercises;
- Community development activities with the potential to result in synergistic and additive effects include major construction projects such as the Kaktovik Airport and annual sealift resupply for fuel and commercial goods;
- Subsistence activities are evaluated primarily for their cumulative effect on populations of wildlife, such as fish and marine mammals.

Past, present and future actions for consideration in the cumulative impacts analysis are listed below. For the purposes of this EIS, present actions are those that are ongoing and have activities that contribute to potential cumulative effects. Future actions are those that are reasonably foreseeable within the next five to ten years. General categories of past, present and RFFAs are summarized in Table 4.11-1. For each of the general categories, a second set of detailed tables has been developed listing specific actions/activities that will be taken into consideration (Tables 4.11-2 through 4.11-10). Figures 4.1 and 4.2 show general locations of relevant past, present, and future actions for the Beaufort and Chukchi seas.

Table 4.11-1 General Categories of Relevant Past, Present, and Reasonably Foreseeable Future Actions

Category	Area	Type of Action
Oil and Gas Exploration, Development and Production	Offshore Waters[1] (Beaufort and Chukchi seas) Onshore North Slope (Beaufort Sea) Nearshore waters[2] (Beaufort Sea) Canadian Arctic Russian Chukchi Sea	Seismic surveys Coastal/nearshore ice roads Construction Maintenance Exploratory drilling Production Transportation (pipelines, aircraft, marine, ice roads)
Scientific Research	Nearshore waters (Beaufort and Chukchi seas) Offshore waters (Beaufort and Chukchi seas) Onshore North Slope	Oceanographic surveys Biological surveys Geophysical surveys
Mining	Western Brooks Range/foothills (Chukchi Sea) Red Dog/Red Dog Port (Chukchi Sea)	Coal mining Minerals mining

Category	Area	Type of Action
Military	Various coastal sites (Northwest Alaska, Gulf of Alaska, North Slope) Offshore waters (Beaufort and Chukchi seas)	DEW Line Sites USCG Icebreaker presence Aircraft overflights Submarine traffic
Transportation (separate from oil and gas, mining)	Marine (Beaufort and Chukchi seas) Onshore North Slope	Marine vessel traffic Roads and vehicular traffic Aircraft traffic Utility pipelines
Community Development Projects	North Slope Borough Northwest Arctic Borough	Village expansions Water and sewage projects Airport construction/improvements
Subsistence Activities	Kaktovik, Nuiqsut, Barrow, Wainwright, Point Lay, Point Hope, Kivalina, Kotzebue, and adjacent areas (offshore Beafort, Chukchi Seas, onshore)	Hunting (e.g. caribou, birds) Fishing Trapping Whaling Sealing Traveling
Recreation and Tourism	Arctic National Wildlife Refuge Various locations (Beaufort and Chukchi seas)	Wildlife viewing Sport/commercial hunting and fishing Recreation activities Cruise ships and commercial vessels
Commercial Whaling	Range of bowhead whales	Commercial harvest and mortality
Climate Change	Global	Changes in temperature, ice conditions, ocean circulation patterns, and other atmospheric, cryosperic, and coean processes
Persistent Contaminants	Offshore waters (Beaufort and Chukchi seas) Nearshore waters (Beaufort and Chukchi seas) Shoreline (Beaufort and Chukchi seas)	Accumulation of contaminants from multiple sources that have the potential for impact to wildlife (including benthos), and contamination of subsistence resources with human health implications

1 – Offshore waters are consideral federal waters for the purpose of this analysis

2 – Nearshore waters are consideral state waters for the purpose of this analysis

4.11.2.1 Oil and Gas Exploration, Development and Production

4.11.2.1.1 Existing Oil and Gas Production and Pipeline Facilities

Oil and gas development is the main agent of industrial-related change within the EIS project area. There are a number of other past, present, and ongoing oil and gas projects that contributed to past and present cumulative effects (Table 4.11-2). Among the cumulative effects issues associated with these activities are effects on marine mammals, subsistence, borough and state fiscal characteristics, and air and water quality. The majority of exploration activities and all of the production and transportation systems have occurred in the central Beaufort Sea portion of the EIS project area. Although oil from seepages was used as fuel by Iñupiat people prior to western contact, the first modern program of oil and gas exploration on the North Slope was conducted by the U.S. Navy and the United States Geological Survey (USGS) during the 1940s and 1950s. Federal leasing on the North Slope began in 1958 and led to several industry-sponsored exploration programs. The discovery of oil at Prudhoe Bay in 1968, followed by discoveries at Kuparuk, West Sak, and Milne Point in 1969, marked the beginning of commercial oil development in the region (NRC 2003). Completion of the Trans-Alaska Pipeline System (TAPS) in 1977 allowed year-round transport of North Slope oil to the marine terminal in Valdez and efficient export to market. Leasing of state and federal offshore continental shelf (OCS) areas began in 1979, and offshore discoveries were made at Endicott, Sag Delta, Point McIntyre, Niakuk, and Northstar (NRC 2003). The Point McIntyre and Niakuk pools, as well as the more recently discovered Liberty field, are located mostly in the offshore area; the Point McIntyre and Niakuk production facilities are located either onshore or on existing nearshore production facilities (MMS 2008). Several additional developments including Nikaitchuq, Northstar, and Oooguruk operate in nearshore areas of the Beaufort Sea. TAPS throughput peaked in 1988, at nearly 2.1 million barrels per day, but has since declined to about 630,000 barrels per day in 2011 (Alyeska 2011). Currently there are 35 fields and satellites producing oil on the North Slope and in nearshore areas of the Beaufort Sea, and additional discoveries are under development.

Table 4.11-2 Specific Past, Present, and Reasonably Foreseeable Future Actions Related to Oil and Gas Development and Production in the EIS Project Area

Category	Geographic Area/Unit	Action/Project	Activities	Timing Open Water	Timing Winter	Past	Present	Future
Oil/Gas Development Onshore Offshore	1- Beaufort Sea Coastal – Badami Unit	Badami	Production currently 1,500 bopd, pipeline to Endicott, additional exploration ongoing, winter sea ice road access		X	X	X

4.11.2.1.2 Oil and Gas Exploration Activities

Oil and gas exploration activities have also occurred over the last 60 years throughout the EIS project area, but unless they lead to development of a project, are generally limited in time to a specific seasonal period over the course of one or two years, and are individually limited in geographic extent. As a result, the impacts from exploration activities tend to be limited in duration and occur in the immediate vicinity of exploration activities and transportation support routes. Exploration activities are similar to those discussed in Chapter 2 of this EIS, including seismic exploration (on land, over ice, open water) and exploratory drilling (onshore gravel pads and ice pads, offshore drillships and artificial islands). By far, the majority of onshore and offshore exploration activities have taken place in the Beaufort Sea and have occurred on a regular basis since the late 1960s, although some military programs date back to the 1940s. More limited and intermittent exploration activities have taken place in offshore areas of the Chukchi Sea since the 1980s. However, it should be noted that barge traffic to and from the Prudhoe Bay area passes through the Chukchi Sea in early summer, returning in late fall.

A small refined fuel spill (typically less than 48 bbls) from G&G refueling operations at sea or at docks could occur during exploration activities as well.

Oil and gas exploration has also occurred in the Canadian Arctic, specifically in the eastern Beaufort Sea, off the Mackenzie River Delta, Mackenzie Delta and in the Arctic Islands. Characteristics are similar to exploration activities in Alaska (shallow hazards, site clearance, 2D and 3D seismic surveys, exploratory drilling), except that the majority of support is provided by road access and coastal barges. Oil and gas exploration has also occurred in offshore areas the Russian Arctic and in areas around Sakhalin Island to the south of the Bering Straits. Sakhalin Island is located approximately 3,220 km (2,000 mi) from Kotzebue at a latitude approximately the same as British Columbia.

From the perspective of cumulative effects, multiple exploration activities that may occur over a large geographic area, with some level of activity going on from year to year, raise concerns about disturbance to fish and wildlife and response in behavior and distribution. The potential geographic extent of exploration activities, along with air and marine support, implies that sound producing activities are occurring across much of the range of many marine mammal species. In addition, the availability of fish and wildlife for subsistence harvest based on response to exploration activities and interference with subsistence hunting is also of concern to North Slope Natives.

There are currently no State of Alaska leases in the Chukchi Sea, and no onshore oil and gas production along the Chukchi Sea coast. The State of Alaska has scheduled lease sales that would offer exploration rights in certain regions including the Beaufort Sea nearshore areas. Activities in these areas are considered reasonably foreseeable, however, the exact locations and amount of acreage available for leasing are yet to be determined. The NSB plans to drill exploration and development wells in their East Barrow, South Barrow, and Walakpa gas fields during 2011-2012 (Petroleum News 2011a). In its most recent five-year plan, the State of Alaska does not intend to hold lease sales in the nearshore waters of the Chukchi Sea (ADNR 2013).

There are a number of onshore and nearshore exploration wells being proposed on State oil and gas leases in the Beaufort Sea region. State lease sales in this region, as well as BLM lease sales for the NPR-A, are proposed for 2012. However, these prospects are primarily onshore or inshore with little potential for affecting the proposed area.

Internationally but within the geographical scope of the proposed area, there are a number of past, present, and reasonably foreseeable future activities related to oil and gas exploration, development, and production located in Canadian and Russian waters. There is little information on specific plans, but the effects of Canadian and Russian activities are expected to be similar to those resulting from activities occurring in the Alaska Arctic OCS.

4.11.2.1.3 Large-Scale Future Oil and Gas Projects in Alaska

Activities related to natural gas development in the EIS project are reasonably foreseeable, assuming a market is found for the gas, and a gas pipeline is constructed to transport the gas (see discussion of the Alaska Pipeline Project below). Such activities may include the construction and installation of a gas pipeline to shore from existing offshore production facilities in the Beaufort Sea, and expansion of existing offshore and shore-based facilities to accommodate natural gas production.

The following project descriptions are five major oil and gas development projects proposed in the Beaufort Sea that are reasonably foreseeable within the next five years. Although the majority of project activities and facilities would take place on shore, there are marine components that would contribute to potential cumulative effects.

Alaska Pipeline Project

The schedule for this project has been delayed. The initial plans were altered, when on July 30, 2012, the Alaska Pipeline Project (APP) announced that it would conduct a non-binding public solicitation of interest in securing capacity on a potential new pipeline system to transport Alaska's North Slope gas in the fall of 2012. The solicitation of interest was conducted to identify parties potentially interested in making future capacity commitments on a pipeline system from the Alaska North Slope to a gas liquefaction (LNG) terminal at a tidewater location in south-central Alaska or to an interconnection point near the border of British Columbia and Alberta in Canada. APP's previous project plans, which were described in the 2011 DEIS are now on hold. APP received a two-year filing extension until fall 2014.

Point Thomson Project

ExxonMobil is proposing to produce gas and hydrocarbon liquids (condensate and oil) from the Thomson Sand reservoir and delineate other hydrocarbon resources in the Point Thomson area on the North Slope of Alaska. This project is located to the east of the existing Badami field, and west of ANWR. Produced fluids will be processed on site, with condensate and oil being transported by pipeline to existing common carrier pipelines at Badami that supply the Trans Alaska Pipeline System (TAPS). The primary activities that would contribute to cumulative effects include marine and air traffic associated with construction and operation, and an increased level of construction activity on the shoreline over a three-year period.

These project components include three production pads, process facilities, an infield road system, an export pipeline, infield gathering lines, and an airstrip.

The hydrocarbon reservoir lies mainly offshore. To avoid offshore development and potential adverse impacts on the marine environment, onshore drilling pads close to the shore have been selected to directionally drill into the offshore portions of the reservoir.

Offloading sealift modules without installing a solid fill causeway or dock would represent the primary marine component of the project.

Sealift by ocean-going barges direct to the Point Thomson location was selected as the option for moving heavy loads, such as process modules, to the site. Module transportation to the project site is scheduled for the summer of 2013 and would take place over three open water seasons (2013 through 2015). It is anticipated that the large ocean barges will be in place at the Point Thomson site for approximately 14 days, providing adequate time to dock and offload cargo. Once offloaded, the barges will leave the site. The method of barge access will be utilized for up to three construction seasons (2013 through 2015), with barges passing through the Chukchi Sea to and from offloading.

A bulkhead and five offshore mooring dolphins (pilings driven into the sea floor) are necessary for landing and securing the ocean barges, which require several feet of draft and cannot directly access the beach. The bulkhead (referred to as the high bulkhead) will be located above the Mean High Water (MHW) line on the beach. Mooring dolphins are needed to ensure an accurate alignment of the barges for offloading operations and will be left in place for future use. To better accommodate landing and offloading of the smaller coastal barges, an adjacent lower bulkhead (low bulkhead) will also be constructed above the MHW line on the beach, with an associated gravel ramp constructed to the Central Pad. Air traffic would be associated with construction and operations.

Alpine Unit CD-5 and CD-6 Projects

Permits applications for construction of Alpine CD-5 were submitted several years ago, but were delayed due to regulatory challenges resulting in denial of permits. These challenges were resolved in late 2011, with production now anticipated to begin in 2016. Construction of CD 5 and 6 would involve constructing a bridge across the Colville River to access the production pad; road connections to the Prudhoe Bay Kuparuk road system would be limited to seasonal ice roads. Barge support for construction would be based out of Prudhoe Bay, with modules and other construction material transported by gravel/ice roads. Air traffic would be associated with construction and operations. The primary areas of nexus with offshore exploratory activity would involve barge sealifts through the Chukchi and Beaufort seas, and offloading activity at West Dock.

Liberty Project

The Liberty Project is located on the eastern end of the Prudhoe Bay area in nearshore waters. It was initially conceived as an offshore production island, but has been redesigned as directional drilling from a location at the Endicott Satellite drilling island. Exploratory drilling was suspended in 2010. Development within the next five years is possible. Road access would be provided through the existing Prudhoe Bay road system; barge support for construction would be based out of Prudhoe Bay, with modules and other construction material transported by gravel roads. Air traffic would use the existing Prudhoe Bay air facilities. The primary areas of nexus with offshore exploratory activity would involve barge sealifts through the Chukchi and Beaufort seas, and offloading activity at West Dock.

Continuation of Badami Production

The Badami project is located approximately 20 miles east of Prudhoe Bay on the Beaufort Sea coast. It is connected by pipeline to Endicott, but there are no all-season road connections; Badami has a gravel causeway barge dock. The facility went into production around 2001, but was suspended in 2007 after production results were less than expected. In 2010, production was temporarily restarted. Additional winter exploratory drilling is currently being conducted; depending on results, production could be resumed on a continuing basis within a couple of years. Some improvements to the dock and other facilities may be needed. The primary areas of nexus with offshore exploratory activity would involve barge sealifts through the Chukchi and Beaufort seas, and offloading activity at Badami (Bradner 2011, Petroleum News 2011b).

4.11.2.2 Scientific Research

There are a number of scientific research programs that take place in offshore areas of the Beaufort and Chukchi seas. This section cannot be exhaustive in the listing of all studies funded by BOEM and other federal and industry partners in these waters. The following is a representative sample of the number and types of studies that have been and continue to be pursued in Alaskan Arctic waters. These activities involve vessel, air, and over-ice support which may contribute to cumulative effects through disturbance of marine mammals and impacts to subsistence harvest through marine vessel and aircraft traffic, and disturbance of bottom sediment through sampling. BOEM supports a variety of research programs aimed at understanding the Arctic OCS environment and associated ecosystems. BOEM Alaska OCS regional research in 2013 includes physical oceanography studies, habitat and ecology studies including mapping the distribution of marine mammals, shorebirds, fish, benthic, and epifaunal communities in the northern Chukchi Sea and central and eastern Beaufort Sea, studies designed to understand the rate and effects of climate change, modeling of weather and changing patterns of ice formation and loss, atmospheric effects from increased economic development, and effects of development and climate change on native subsistence and cultures. These studies include the Hanna Shoal Ecosystem Study and the Synthesis of Arctic Research study, both designed to attempt synthesizing past and future information being collected in the Alaskan Arctic. Included are marine mammal research studies such as the Bowhead Feeding Variability in the Western Alaska Beaufort Sea, as well as the Chukchi Offshore Monitoring in Drilling Area (COMIDA) program to establish an integrated knowledge of the Chukchi Sea ecosystem. These programs conduct studies to understand bowhead whale population and migration structures and include a range of biological, chemical, and physical processes. These include collections to establish baseline data sets for benthic infauna and epifauna, organic carbon and sediment grain size, radioisotopes for down core dating, trace metals in sediments, biota and suspended particles, as well as associated parameters. The program operates annually in the Chukchi Sea. In addition, the BOEM research vessel, the 36-foot Launch 1273, will be underway supporting research in the Beaufort Sea during the 2013 open water season. In the past, the ANIMIDA and (c)ANIMIDA Projects operated during the summers of 2004, 2005, 2006, and 2007. An explicit goal of the (c)ANIMIDA Project is to examine temporal and spatial changes in chemical and biological characteristics of the oil and gas exploration and development area of the Alaskan Beaufort Sea and to determine if any observed changes are related to the Northstar development and production operations. From 1997 through 2008, BOEM developed and conducted 31 projects directly related to improving equipment and processes for the prompt identification and removal of oil from harsh Arctic environments. Since 2000, the ANIMIDA project has been monitoring and attempting to understand the geographical extent of the Boulder Patch, a geographically isolated hard-bottom kelp community that exists in the Stefansson Sound south and east of the Prudhoe Bay and Liberty developments.

The NMFS National Marine Mammal Laboratory has contracted with the NSB to provide services related to the Bowhead Head Whale Feeding Ecology study (BOWFEST) through April 2013. The purpose of BOWFEST is to document patterns and variability in the timing and locations of bowhead whales feeding in the western Beaufort Sea and to estimate temporal and spatial patterns of habitat use by bowhead whales within the EIS project area. Local Iñupiat hunters conduct boat-based surveys of the study area to gather information on bowhead whale behavior and movement. The study is based around Barrow. In addition, the bowhead whale satellite tagging study operates annually in the Beaufort and Chukchi seas. The purpose of the project is to understand migration routes, migration timing, feeding areas, diving behavior, and time spent in areas within the spring and summer ranges of bowhead whales. Fifteen satellite tags were deployed on bowhead whales in Alaska and Canada in 2009. In August, eight bowhead whales were tagged near Barrow, Alaska, and three were tagged in Canada near Atkinson Point on the Tuktoyaktuk Peninsula. One gray whale was also tagged in Canada. Four more bowheads were tagged near Barrow in October 2009. The study has been operating since at least 2006, and between two and fifteen tags have been deployed on bowhead whales during each of those years.

The Russian-American Long-term Census of the Arctic (RUSALCA) is funded by NOAA and the NSF Arctic Observing Network Program (ARC-0855748) to understand and ultimately predict the effects of climate change in the northern Bering and Chukchi seas. To this end, the RUSALCA program collects information related to changes in physical and biogeochemical processes, and alteration of biomass and productivity of organisms and their associated marine food webs. The census involves a series of biophysical moorings in the western Bering Strait, CTD transects conducted across the Herald Shelf Valley, and a series of shipboard projects aimed at understanding biogeochemical processes that influence climate and ecosystem dynamics in the study area. RUSCLA appears to operate annually during the open water season and overlaps with the EIS project, in particular, in the Chukchi Sea near Cape Lisburne and Point Hope, and in the northern Beaufort Sea.

The Alaskan Ocean Observing system (AOOS) has various sensors and monitors deployed throughout the EIS project area to measure and record meteorological conditions and other environmental variables. AOOS also coordinates a seabird monitoring network in the proposed action area.

The Western Arctic Shelf Basin Interactions (SBI) project, sponsored by the NSF and the Office of Naval Research, was a multi-year, interdisciplinary program aimed at investigating the impact of global change on physical, biological and geochemical processes over the Chukchi and Beaufort Sea shelf basin region in the Western Arctic Ocean. The goal was to improve understanding of shelf-basin exchange, and to improve predictions of global change impacts in the Arctic. The SBI program includes both field and modeling studies (http://www.eol.ucar.edu/projects/sbi/). The project collected data during the 2002 to 2004 field seasons. In addition, NSF plans to conduct seismic surveys in northwest corner of U.S. EEZ, Chukchi Sea within the foreseeable future.

Finally, Chukchi baseline studies funded by ConocoPhillips Alaska, Inc (CPAI), Statoil, and Shell include physical oceanography, benthic, zooplankton, fish, acoustics, and ice studies in the Chukchi Sea.

Past, present, and reasonably foreseeable future actions related to scientific research in the EIS project area are summarized in Table 4.11-3.

4.11.2.3 Mining

Mining takes place in onshore areas of the Chukchi Sea portion of the EIS project area. While the majority of mining activities take place onshore, marine and air transportation could contribute to potential cumulative effects through the disturbance of marine mammals and impacts to the subsistence harvest. The world's largest known zinc resources are located in the western Brooks Range. As much as 25 million tons of high-grade zinc is estimated to be present near Red Dog Mine, approximately 40 mi from the southwest corner of the NPR-A (Schoen and Senner 2003). The Red Dog Mine port site may also become the port facility for a very large proposed coal mining operation adjacent to the Chukchi Sea. In addition, coal mining prospecting proposals for the Brooks Range have been submitted to ADNR, Division of Mining, Land and Water (DMLW) for approval. Past, present and reasonably foreseeable future activities related to mining activities within the EIS project area are summarized in Table 4.11-4.

4.11.2.4 Military

Military activity in the Arctic is thought to have increased in recent years, and it may be reasonable to expect that military activity will continue to increase in the foreseeable future. Military activities in the proposed action area include the transit of military vessels through area waters, as well as submarine activity, aircraft overflights, and related maneuvers. However, very little public information is available about future military activity in the region. Military vessel, submarine, and aircraft traffic could contribute to cumulative effects through the disturbance of marine mammals and effects to the subsistence harves, and the potential for marine fuel spills.

The Distant Early Warning Line, also known as the DEW Line, was a system of 63 radar stations located across the northern edge of the North American Continent, roughly along the 69th parallel. The radar stations were constructed between 1954 and 1957, and decommissioned during the 1990s. A runway operated by NSB (Kaktovik airport) presently active at the former Barter Island DEW Line site. The Bullen Point site is currently managed by the U.S. Air Force and has a gravel airstrip and a small radar system.

Submarines are valuable platforms for a wide variety of research activities including passive and active acoustic studies. Although the U.S. Navy (and other organizations) are likely to continue to use submarines within the proposed action area, detailed information about future military actions is not publicly available.

Past, present and reasonably foreseeable future activities related to military activities within the EIS project area are summarized in Table 4.11-5.

4.11.2.5 Transportation

In addition to marine and air transportation associated with the previously mentioned activities, there is frequent marine and air traffic associated with coastal communities on the North Slope and in Northwest Alaska. Marine and air transportation could contribute to potential cumulative effects through the disturbance of marine mammals and impacts to the subsistence harvest. It is reasonable to assume that trends associated with transportation to facilitate the maintenance and development of coastal communities will continue. In some specific cases, described below, transportation and associated infrastructure in the proposed activity area may increase as a result of increased commercial activity in the area. Past, present and reasonably foreseeable future activities related to transportation activities within the EIS project area are summarized in Table 4.11-6.

Vessel Traffic. Vessel traffic through the Bering Strait has risen steadily over recent years according to USCG estimates, and Russian efforts to promote a Northern Seas Route for shipping may lead to continued increases in vessel traffic adjacent to the western portion of the EIS project area. An analysis done by Shell Oil as part of a Revised Outer Continental Shelf Lease Exploration Plan for the Chukchi Sea (Shell 2011a) indicated that barge traffic passing through the Chukchi Sea during the month of July through October has increased from roughly 2000 miles of non-seismic vessel traffic in 2006 to roughly 11,500 miles of non-seismic vessel traffic in 2010. In comparison, the same analysis estimated that vessel miles associated with seismic surveys in 2006 were roughly 70,000 miles, compared to roughly 30,000 miles in 2010.

Vessel traffic within the EIS project area can currently be characterized as traffic to support oil and gas industries, barges or cargo vessels used to supply coastal villages, smaller vessels used for hunting and local transportation during the open water period, military vessel traffic, and recreational vessels such as cruise ships and a limited number of ocean-going sailboats. Barges and small cargo vessels are used to transport machinery, fuel, building materials and other commodities to coastal villages and industrial sites during the open water period. For example, villages along the Beaufort and Chukchi sea coasts are serviced by vessels from Crowley Alaska and or Northern Transportation Company. Additional vessel traffic supports the Arctic oil and gas industry, and some activity is the result of emergency-response drills in marine areas.

In addition, research vessels, including NSF and USCG icebreakers, also operate in the EIS project area. USCG anticipates a continued increase in vessel traffic in the Arctic. Changes in the distribution of sea ice, longer open-water periods, and increasing interest in studying and viewing Arctic wildlife and habitats may support an increase in research and recreational vessel traffic in the proposed action area regardless of oil and gas activity.

	Beaufort and Chukchi Seas - Offshore	Marine Vessel Traffic	Vessel traffic	X		X	X	X
		Aircraft Traffic	Aircraft Traffic	X	X	X	X	X

Aircraft Traffic. Industry uses helicopters and fixed wing aircraft to support routine activities within the EIS project area. In addition, at least four companies operate passenger and air cargo services between North Slope communities and population centers, flying inland and along the coast. These may involve several scheduled flights daily using small propeller-driven aircraft. The majority of air travel and freight hauling between Arctic coastal communities involves small commuter-type aircraft, and government agencies and researchers often charter aircraft for travel and research purposes. These activities are expected to continue, and the level of aircraft traffic within the EIS project area may increase as a result of climate change and/or increased industrial activity and community development.

4.11.2.6 Community Development Projects

Community development projects in Arctic communities involve both major infrastructure projects, such as construction of airports and response centers, as well as smaller projects (e.g. construction of a new washeteria). These projects could result in construction noise in coastal areas, and could generate additional amounts of marine and aircraft traffic to support construction activities. Marine and air transportation could contribute to potential cumulative effects through the disturbance of marine mammals and impacts to the subsistence harvest. Keeping in mind that "it is not practical to analyze how the cumulative effects of a proposed action interact with the universe (CEQ 1997)," this section will focus only on past, present, and reasonably foreseeable community development projects that are truly meaningful within the context of the cumulative effects analysis.

Major community development projects that are foreseeable at the present time include the construction of a new airport at the village of Kaktovik, and potentially a new emergency response facility at Wainwright.

Past, present and reasonably foreseeable future activities related to community development project activities within the EIS project area are summarized in Table 4.11-7.

Table 4.11-7 Past, Present, and Reasonably Foreseeable Future Actions Related to Community Development Projects in the EIS Project Area

4.11.2.7 Subsistence

Subsistence activities occur in coastal and offshore portions of the EIS project area. Subsistence hunters primarily use boats and snowmachines for access. In addition to the harvest and mortality of marine mammals, boat and snowmachine traffic could lead to the disturbance of marine mammals as well. The types of subsistence uses and activities that were described in Chapter 3 are expected to continue into the future. Current and past hunting, gathering, fishing, trapping subsistence activities would be similar in the types of activities and areas utilized for the communities associated with the EIS project area in the future.

Past, present and reasonably foreseeable future activities related to subsistence activities within the EIS project area are summarized in Table 4.11-8.

4.11.2.8 Recreation and Tourism

Recreation and tourism activities are generally pursued by non-residents of the EIS project area. Marine and coastal vessel and air traffic could contribute to potential cumulative effects through the disturbance of marine mammals or impacts to the subsistence harvest. With the exception of adventure cruise ships that transit the Beaufort and Chukchi sea coasts in small numbers, much of the air sightseeing traffic is concentrated in ANWR. The types of recreation and tourism activities that were described in Chapter 3 are expected to continue into the future. Current and past sport hunting and fishing, or other recreation or tourism-related activities would be similar in the types of activities and areas utilized for the communities associated with the EIS project area in the future.

Past, present and reasonably foreseeable future activities related to recreation and tourism activities within the EIS project area are summarized in Table 4.11-9.

4.11.2.9 Climate Change

Climate change is an ongoing factor in the consideration of cumulative environmental effects on the Arctic region (NOAA 2011). It has been implicated in changing weather patterns, changes in the classification and seasonality of ice cover, and the timing and duration of phytoplankton blooms in the Beaufort Sea. Climate conditions in the EIS project area have been undergoing remarkable changes, particularly over the past 20 years (USGS 2011). Warmer air and water temperatures result in earlier spring snowmelt, decreased ice thickness during the winter, and accelerated rates of coastal erosion and permafrost degradation (USGS 2011). In addition, due to the changing extent and thickness of sea ice, resulting from changes in the temperature regime, there is more open water during the summer season. The lack of sea ice also leads to the creation of wind driven waves, which in turn contribute to coastal erosion. These changes have been attributed to rising CO_2 levels in the atmosphere and corresponding increases in CO_2 levels in the waters of the world's oceans. These changes have also led to the phenomenon of ocean acidification (IPCC 2007). This phenomenon is often called a sister problem to climate change, because they are both attributed to human activities that have resulted in increased CO_2 levels in the atmosphere. Ocean acidification in high latitude seas is happening at a more advanced rate compared to other areas of the ocean. The capacity of the Arctic Ocean to uptake CO_2 is expected to increase in response to increased levels as a result of climate change (Bates and Mathis 2009). This is due to the loss of sea ice that increases the open water surface area of the Arctic seas. Exposure of cooler surface water lowers the solubility (or saturation) of calcium carbonate within the water, which in turn leads to lower available levels of the minerals needed by shell-producing organisms (Fabry et al. 2009).

Climate change could affect the habitat, behavior, distribution, and populations of marine mammals, fish, and other wildlife within the EIS project area. Climate change could also affect the availability of, or access to, subsistence resources, particularly spring hunts for bowhead whales and other marine mammals. Climate change also affects the length of seasons that ice roads are operable, potentially leading to more reliance on marine access.

Past, present and reasonably foreseeable future activities related to climate change activities within the EIS project area are summarized in Table 4.11-10.

4.11.3 Alternative 1 – No Action

Under Alternative 1, NMFS would not issue any ITAs under the MMPA for seismic surveys or exploratory drilling in the Beaufort and Chukchi seas, and BOEM would not issue G&G permits or ancillary activity notices for activities in the Beaufort and Chukchi seas. There would be no potential for a VLOS under Alternative 1. As discussed in Section 4.4.1, there would be no direct or indirect effects to resources as a result of Alternative 1, other than to socioeconomics and land and water use, management, and ownership. Therefore, there would be no cumulative effects to resources outside of socioeconomics and land and water use, management, and ownership under Alternative 1.

Over the past several years, there has been a certain level of oil and gas exploration activity that has been permitted by NMFS and BOEM in the Beaufort and Chukchi seas. This level of activity is greater than what is associated with Alternative 1 (no activity permitted), but less than what is associated with Alternative 2. Therefore the impacts analyzed for Alternative 1 would be less than the status quo for oil and gas exploration activities in the Beaufort and Chukchi seas, and is within the range of activities evaluated in this EIS.

4.11.3.1 Socioeconomics

4.11.3.1.1 Summary of Direct and Indirect Effects

The magnitude of the direct and indirect socioeconomic effects from Alternative 1 is generally negative, due to potential lost opportunity for offshore oil and gas development. There would be no net change to the non-monetary (subsistence) economy. The potential impact to local employment and sales tax is low in magnitude because total personal income and local employment rates would not have increased by more than five percent. The duration of the local socioeconomic impacts would be temporary because it is not year-round, however, the activity would have occurred over a fixed number of years. The likelihood of exploration resulting in production cannot be predicted therefore the magnitude of potential unrealized revenue for state and federal governments is unknown. These potential negative economic impacts of the activity would be statewide and even national in extent. The context of the socioeconomic impacts, the people that would experience the potential for local employment and tax revenue, are unique in that Iñupiat communities would primarily be affected.

The summary impact level of direct and indirect effects from the No Action Alternative for Socioeconomics is moderate, not exceeding the significance threshold.

4.11.3.1.2 Past and Present Actions

As described in Chapter 3, oil and gas exploration, development, production, and transportation are major contributors to the economy of Alaska, the communities within NSB, and to a lesser degree for Northwest Arctic Borough.

Public Revenue & Expenditures

The predominant source of NSB revenue comes from property sold or leased by the oil industry (MMS 2008). The Northwest Arctic Borough generates a large portion of its revenue from payment in lieu of taxes from the Red Dog Mine and the remainder from state and federal government sources (EPA 2009c).

Approximately 90 percent of all state tax revenue is paid by the oil and gas industry, but the proposed action involves exploration activities on federal lands which generate no state revenue (ADCCED 2011a). Federal royalty revenue associated with offshore leases is a small portion of the total U.S. budget, but Federal spending in Alaska is first based on per capita (ADCCED 2011a). Onshore oil production has been declining, resulting in declining revenues to Borough and state governments.

Employment & Personal Income

The extraction of natural resources from remote rural Alaska produces only modest direct economic benefit in the form of jobs, household income, business purchases, and public revenue for most residents (Goldsmith 2007). North Slope oil field operations provide employment to over 5,000 people who are not residents of NSB (ADCCED 2011c). Direct employment in the oil and gas industry makes up just four percent of the total state employment (Fried 2011). Employment rates in NSB and Northwest Arctic Borough are much lower than state or national averages and have shown further decline in the period between 2000 and 2009 (U.S. Census 2009). However, indirect benefits of oil and gas development are substantial. The majority of employment in these areas is from state and local government, which receive operating revenues from taxes on oil and gas facilities and production. Over time, oil and gas exploration and production have decreased from historic levels; however, oil and gas and mining continue to contribute to local employment and income.

Demographic Characteristics

The middle range for the State of Alaska and EIS project area borough population growth projections are just under one percent annual increase per year; for the EIS project area regions annual growth is about 0.9 percent per year (ADLWD 2011d). The population for the State of Alaska in 2020 is projected to be 766,231; the North Slope Borough projected population for 2019 is 7,140; the Northwest Arctic Borough projected population for 2019 is 7,709; and Nome Census Area projected population for 2019 is 9,911 (ADLWD 2011d). North Slope Borough population has grown since it started to be tracked in the 1960 Census from 2,133 to 9,430 today (ADCCED 2011c).

In- and out-migration are more substantial and uncertain components of population change in Alaska than natural births and deaths. In certain years, net out-migration was strong enough to reverse the trend of annual growth.

Social Organizations & Institutions

Cultural values are reflected in governmental and tribal (governmental) bodies in the EIS project area (see Table 3.3-6) to ensure that economic development and social services address the needs of local communities appropriately. Social organizations and institutions will remain important in meeting community needs and preserving community culture, with regard to issues associated with resource development and trends in federal, state, and local revenue.

4.11.3.1.3 Reasonably Foreseeable Future Actions

There are numerous categories of reasonably foreseeable future actions that have an impact on public revenue and expenditures, employment and personal income, and social organizations and institutions. These include: onshore oil and gas exploration, development and production; mining exploration, development and production; military, transportation, community development projects, subsistence activities (as they affect the non-cash economy), and recreation and tourism. These categories of socioeconomic impact would likely to be not at a magnitude, like the discovery of oil in Prudhoe Bay (1968) and construction of TAPS or the oil price drop of 1985, to impact state and local revenue, employment, and demographic characteristics.

Public Revenue & Expenditures

If oil and gas production activities continue at current levels, the State of Alaska would continue to collect the majority of state tax revenue from the oil and gas industry, although this is expected to decline without major new discoveries, facility development and production. The vast majority of produced oil in Alaska depends on TAPS for transport to market and any OCS oil contribution would extend its commercial life. This would continue state and local royalty oil revenue that otherwise would end immediately upon a shutdown of TAPS.

Oil and gas revenue represented 90 percent of state tax revenue in 2009 during a period of high oil prices (ADCCED 2011a). For the EIS project area, the enacted FY 2012 State Capital Budget is $75.5 million divided between infrastructure ($67.1 million), education ($8.1 million), and ($0.3 million) public safety and health projects (OMB 2011). $52.5 million of this capital budget for the Arctic area comes from the federal government. Revenue generated for the NSB would follow similar trends, including declines in revenue without major new discoveries and subsequent development. Declines in state and borough revenue would be reflected in declines in capital project funding, levels of government services, and public sector employment.

Employment & Personal Income

Government bodies (boroughs, other municipal governments, and school districts) would remain the largest employer in the NSB and Northwest Arctic Borough (ADLWD 2005, NSB 2005). Foreseeable oil and gas and mining activity would contribute to maintaining current employment and income levels, but would not result in major increases. Increases in scientific research, military activity, transportation, and recreation and tourism would have a minor to negligible impact to local employment because current levels of these activities create very little direct employment. Expansion and continued development at Red Dog will contribute to the employment and income opportunities in Nome and Northwest Arctic Borough residents; however, a decline in oil and gas development on the North Slope would contribute to a decline in private and public sector employment and personal income.

Demographic Characteristics

Reasonably foreseeable future actions are likely to be of a scale and dispersed geographic nature to maintain current demographic levels and characteristics based on employment and revenue opportunities. As indicated previously, there is nothing foreseeable that would result in large-scale state or regional in-migration and change in demographic characteristics.

Social Organizations & Institutions

It is assumed social organizations and institutions will function at their current levels in the future, subject to available funding, which could be affected by any declines in federal, state, and borough revenue. Modest population growth would increase the demand on institutions and social services to some degree.

4.11.3.1.4 Contribution of Alternative to Cumulative Effects

The No Action Alternative is expected to contribute a low intensity, temporary adverse impact to the region due to the lost opportunity for revenue. Although there would be no impact to the local non-monetary economy, new local employment would also not be realized and there would be no OCS oil contribution to extend the commercial life of TAPS. Therefore the contribution to cumulative effects of socioeconomics would be negligible to minor.

If Alternative 1 results in the inability of a lessee to lawfully explore for oil and gas, the federal government could be required to buy back the leases from the lessees, which could cost tax payers several billions of dollars. A buy back of the leases would result in lost lease rentals to the federal government and delay/lose of any production, royalties, employment, and taxes from any petroleum that might have been produced.

4.11.3.1.5 Conclusion

The direct and indirect effects of Alternative 1 would be adverse and negligible to minor due to the lost opportunity for employment and generation of public revenue. The contribution to the socioeconomic cumulative effects would be adverse and negligible to minor.

4.11.3.2 Land and Water Ownership, Use, Management

4.11.3.2.1 Summary of Direct and Indirect Effects

Land and Water Ownership

Based on Table 4.4-2 and the analysis provided in Section 4.4.1.2, the impacts on land and water ownership under Alternative 1 would be high in magnitude, long term in duration, regional in extent, and important in context. In total, the direct and indirect impacts on land ownership are considered to be major, and result in changes of federal, state, and private development rights by effectively preventing exploration for oil and gas resources in compliance with federal regulations.

Land and Water Use

Based on Table 4.4-2 and the analysis provided in Section 4.4.1.2 the impacts on land and water use under Alternative 1 would be high in magnitude, long term in duration, important in context, and regional in extent, although some changes in land use could occur in support areas out of the region, in areas that provide support services such as Nome and Dutch Harbor. In total, the direct and indirect impacts on land use are considered to be major; they result in changes of federal, state, and private development rights by effectively preventing exploration for oil and gas resources in compliance with federal regulations. Refer to Sections 4.10.3.14 and 4.10.3.19 for impacts on subsistence and recreation.

Land and Water Management

Based on Table 4.4-2 and the analysis provided in Section 4.4.1.2, the impacts on land and water management under Alternative 1 would be high in magnitude, long term in duration, important in context, and regional in extent, although some changes in land use could occur in support areas out of the region. In total, the direct and indirect impacts on land and water management are considered to be major; they would result in changes of federal and state land and water management by effectively preventing exploration for oil and gas resources in compliance with federal regulations.

4.11.3.2.2 Past and Present Actions

Ownership patterns in Alaska were primarily influenced by Alaska statehood in 1959, ANCSA in 1971, North Slope oil development facilitated by the TransAlaska Pipeline in 1973, and ANILCA in 1980. Land management plans and lease sale documents were developed for public land at the federal and state level, while comprehensive plans, zoning, subdivision and other regulations were developed at the municipal level. In turn, physical land and water use generally reflects these policies and regulations. Specific land uses that have affected the EIS project area in the past include oil and gas leasing, development, production, and transportation; subsistence uses, discussed in Section 4.10.3.14; the development of Red Dog Mine, and land uses associated with local communities. Much of the current industrial, transportation, and commercial land and water uses have resulted directly and indirectly from the oil and gas industry. The level of impact of past and present actions would be moderate due to the wide-spread and long term effects of the onshore oil and gas and mining industries.

4.11.3.2.3 Reasonably Foreseeable Future Actions

Lease sales would be likely to continue on state and federal lands, but would not occur and affect ownership in offshore areas. Oil and gas production at existing facilities is expected to continue through the term of the EIS, and additional oil and gas development projects are foreseeable. These will have a continuing influence on land and water use on the North Slope.

Additional land could be required for mining if new or expanded coal and mineral mining operations occur at Red Dog Mine, the Brooks Range, or the Ambler Mining District. This would affect land and water use in the vicinity of specific projects, but would not likely result in changes on a regional scale.

Small community development projects take place, such as village expansions or infrastructure projects, which may require zoning changes. These land use changes would be incrementally small and geographically dispersed, and thus would not have combined effects creating cumulative impacts on land ownership, use, or management.

4.11.3.2.4 Contribution of Alternative to Cumulative Effects

Under Alternative 1, the direct and indirect effects on land ownership would be minor, and on land use and management would be major due to the inability to explore and develop offshore leases in state and federal waters in compliance with federal regulations. The incremental contribution of these impacts to those caused by other reasonably foreseeable future actions would be to place restrictions on the ability of private oil companies to explore and develop leases in federal and state waters that would not otherwise be present. Therefore, the contribution of Alternative 1 to cumulative effects on land use and management would be major.

4.11.3.2.5 Conclusion

Under Alternative 1, because direct, indirect and cumulative impacts are considered major and cumulative impacts are major, the overall level of impact for land ownership, use and management would be considered major.

4.11.4 Alternative 2 – Authorization for Level 1 Exploration Activity

4.11.4.1 Physical Oceanography

4.11.4.1.1 Summary of Direct and Indirect Effects

The effects of Alternative 2 on physical ocean resources would be medium intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. Changes in water depth from discharged material would have minor effects on the physical resource character of the EIS project area. Construction of artificial islands, which could occur in nearshore state waters of the Beaufort Sea at a rate of one island per year under Alternative 2, would result in medium-intensity, permanent, localized effects on nearshore currents in the waters adjacent to the artificial islands. Over the life of this EIS, those effects would be minor and would occur only if artificial islands are constructed to support exploratory drilling activities. The effects of Alternative 2 on sea ice would be medium-intensity, local, temporary, and would affect a resource that is common in the EIS project area. The overall effects of Alternative 2 on physical ocean resources in the EIS project area would be minor, particularly with the implementation of additional mitigation measures related to reducing or eliminating certain discharge streams.

4.11.4.1.2 Past and Present Actions

Oil and gas development is the main agent of industrial related change in the EIS project area. Past and present actions related to oil and gas development have affected physical ocean resources in the Beaufort and Chukchi seas. Present actions are considered those that will occur during the life of this EIS. Several artificial gravel islands have been constructed to support oil and gas activities, and these artificial gravel islands have effects on water depth and local circulation patterns within the EIS project area. For instance, the Endicott development, located approximately 16 km (10 mi) northeast of Prudhoe Bay in the Beaufort Sea, consists of two man-made gravel islands connected by a 2.5 km (1.6 miles) man-made gravel causeway. The construction and existence of such structures influence water depth and currents in the EIS project area. The effects are medium intensity, permanent, and localized in the waters adjacent to the artificial islands.

Several nearshore developments in the Beaufort Sea (see Table 4.10-2), including the Northstar development, are connected to the Trans-Alaska Pipeline System (TAPS) via subsea pipelines, which have low-intensity, permanent, local impacts on the physical character of the ocean.

Barging and docking facilities at Barrow and Prudhoe Bay also influence the physical character of the nearshore ocean within the EIS project area.

4.11.4.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions with the potential to impact physical ocean resources in the proposed EIS project area include dredging and screeding associated with sealift barging to support future oil and gas development in the region (see Section 4.10.2). Dredging, screeding, and construction of docking facilities associated with reasonably foreseeable future development would have minor impacts on the physical character of the ocean within the EIS project area.

Expansion of Red Dog Port could result in effects to nearshore physical ocean resources in the EIS project area. Such effects would likely be medium-intensity, permanent, and localized to the areas in the immediate vicinity of the Red Dog Port development.

Climate change has the potential to affect water temperatures, sea levels, stream and river discharge, and ice dynamics throughout the EIS project area. These changes could impact the physical character of the ocean in the EIS project area, and could influence the effects of naturally occurring phenomena (e.g. sea ice and storm conditions) on human safety. Due to the changing extent and thickness of sea ice resulting from changes in the temperature regime, there could be more open water during the summer season. The reduced coverage of sea ice would also lead to the creation of larger wind driven waves, which in turn could contribute to increased coastal erosion (USGS 2011). However, over the lifespan of this EIS climate-related changes to physical ocean resources in the EIS project area are expected to be negligible (see Section 4.5.1.1).

4.11.4.1.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 2 would cause localized minor impacts to physical ocean resources in the EIS project area. While some actions associated with Alternative 2, such as the construction of man-made gravel islands, would interact in a synergistic fashion with past, present, and reasonably foreseeable future actions to influence physical ocean resources in the EIS project area, the impacts resulting from such synergies would represent only a small fraction of foreseeable cumulative impact.

4.11.4.1.5 Conclusion

The incremental contribution of activities associated with Alternative 2 to cumulative effects on physical ocean resources in the EIS project area would be minor.

In the event of a VLOS, the overall effects on the physical character of the ocean in the EIS project area would be high-intensity, temporary (with the exception of potential for long-term contamination of sediments with entrained oil), and would affect an area of hundreds of square kilometers. There would be moderate additive effects on the physical character of the ocean resulting from a VLOS in either the Beaufort or Chukchi Sea.

4.11.4.2 Climate & Meteorology

4.11.4.2.1 Summary of Direct and Indirect Effects

As described in Section 4.5.1.2, direct impacts from Alternative 2 to climate are anticipated to be low magnitude, long-term duration, and could affect unique resources on a global scale. Overall, these impacts are assumed to be minor, due to their low contribution to GHG emissions on a state level. Indirect effects are estimated to have a low to medium magnitude, long-term duration, and could affect unique resources on a global scale. Indirect effects are considered minor to moderate, since the outcome of activities associated with Alternative 2 could lead to a greater continued increase in GHG emissions.

4.11.4.2.2 Past and Present Actions

Since pre-industrial times, global anthropogenic GHG emissions have been continually increasing. GHG emissions have increased by 70 percent from 1970 to 2004. The majority of these GHG emissions (77 percent) are CO_2. The amount of GHGs in the atmosphere is the cumulative result of past and present emissions (and removals) of GHGs from human and natural processes. Over time GHGs are removed from the atmosphere due to natural, chemical processes. The removal rate varies between the different GHGs and can also vary based on conditions such as gas concentration in the atmosphere, changes in vegetation coverage, temperature, or other background chemical conditions (Solomon et al. 2007). Carbon dioxide, methane, and nitrous oxide are considered long-lived GHGs and can remain in the atmosphere from a decade to centuries or more. Due to these properties, cumulative effects to climate change from GHG emissions are both additive and synergistic in nature. The effects are additive because the more GHGs that are emitted, the higher the GHG atmospheric concentrations, and consequently the higher the ability to warm the planet which leads to other climate change impacts (see Section 3.1.4.4 for specific examples). The effects are also synergistic because as the concentration of GHGs in the atmosphere increases, it also affects the ability for GHGs to be removed or absorbed by the atmosphere. Therefore, GHG atmospheric concentrations will continue to increase, and perhaps accelerate, because of the continued increase in emissions and the potential decrease in the removal rate of these gases from the atmosphere (Solomon et al. 2007). However, a January 2012 U.S. Energy Information Administration report indicates that with improved efficiency of energy use and a shift away from the most carbon-intensive fuels, CO_2 emissions related to U.S. energy projects could remain at least five percent below 2005 levels through 2040 (EIA 2012).

According to the IPCC, CO_2 is considered the most important GHG due to its dominant atmospheric concentration. Burning fossil fuels is the largest contributor to CO_2 emissions, accounting for approximately two-thirds of the total since 1750 (Solomon et al. 2007). Scientists have identified specific climate trends that are attributed to these human-caused GHG emissions, including increases in air temperature, decrease in snow and ice extent, sea level rise, and decrease in ice thickness, as described in Section 3.1.4.4 under Changes in the Arctic. The past GHG emissions are expected to lead to warming and climate change in the future, even if GHG emissions were to halt (Solomon et al. 2007).

4.11.4.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions that would cumulatively contribute to global climate change impacts include the continued use of fossil fuels. Fossil fuel are used in the EIS project area for activities associated with oil and gas exploration and production, community power generation and space heating, transportation, and subsistence activities. The continued exploration and development of oil and gas reserves would continue to provide a supply of fossil fuels, however, it is not likely that there will be any oil or gas production in the Beaufort or Chukchi seas during the life of this document. When burned, these fossil fuels would emit GHGs and add to the cumulative concentration of GHGs in the atmosphere.

If atmospheric concentrations of GHGs were to stabilize, future warming and other interrelated climate change impacts would still be expected to occur. Therefore, past, present, and future actions within the next five to ten years could continue to impact climate change for years to come. Estimates by the IPCC indicate that air temperatures could increase by approximately 1.1 to 6.4 deg. Celsius (3.0 to 11.5 deg. Fahrenheit) and sea levels could rise by approximately 0.2 to 0.6 m (0.7 to 2.0 ft) within the next century. However, dramatic changes would not be seen within the life of this EIS. A number of factors including population, energy use, amount of renewable energy use, and natural climatic influences are represented by the range in estimates (IPCC 2000).

4.11.4.2.4 Contribution of Alternative to Cumulative Effects

In general, GHG emissions from a single project do not have a large impact on climate change. However, once added with all other GHG emissions in the past and present, they combine to create a perceptible change to climate including specific changes to the Arctic climate that are discussed in Section 3.1.4.4. Due to the extended amount of time that GHGs remain in the atmosphere, any amount of GHG emissions can be reasonably expected to contribute to future climate change impacts. Activities that promote fossil fuel use or make them more accessible, such as oil and gas exploration activities, could result in sustained and even increased use of fossil fuels and GHG emissions in the future. As described in Section 4.5.1.2, potential indirect effects associated with Alternative 2 include this sustained and/or increased fossil fuels use. These indirect effects are expected to have a larger contribution to climate change cumulative impacts than the direct effects since they could add to the largest contributor to atmospheric GHG concentrations, CO_2 emissions from fossil fuel combustion, for years to come. There are many sources of fossils fuels throughout the world, so the contribution of this project by itself may not lead to an observable increase in GHG emissions on a global scale. However when viewed cumulatively, all projects involving and promoting the sustained or increased use of fossil fuels such as this project, would result in an observable increase in GHG emissions and global climate changes. These observable, global changes would be long-term and could affect unique resources as discussed in Section 4.5.1.2 under Project-Related Effects to Climate Change.

4.11.4.2.5 Conclusion

The direct and indirect use of fossil fuels associated with offshore exploration and drilling is relatively small. Due to the additive and synergistic nature of GHG emissions on climate change impacts, if offshore exploration activities were to make the use of fossil fuels more accessible, Alternative 2 could contribute to a moderate to major cumulative impact to climate change. However, it cannot be foreseen that exploration activities being analyzed in this EIS would result in the production of oil and gas within the timeframe being analyzed.

If a VLOS were to occur, as described in Section 4.10, the associated GHG emissions and radiative forcing from black carbon would also contribute to climate change. However, since these impacts are expected to be temporary and of lower intensity than the direct and indirect effects associated with Alternative 2, they are expected to result in minor additive effects to climate change.

4.11.4.3 Air Quality

4.11.4.3.1 Summary of Direct and Indirect Effects

Under Alternative 2, Level 1 Exploration Activity, potential air pollutant emissions are expected to be moderate. These emissions would be short in duration, extent, and content. The overall effect on air quality is expected to be moderate. Indirect effects of this alternative may include increased use of other resources, such as additional personnel travel and resource transport which may have an effect on air quality. These indirect effects are unknown, but are expected to be negligible to minor, and would occur at locations outside of the EIS project area.

4.11.4.3.2 Past and Present Actions

Of the action categories presented in Table 4.10-1, oil and gas exploration, development, and production is the primary source category for air emissions in the EIS project area. Past actions are unlikely to have any effect on current (or future) air quality; emissions of air pollutants are assumed to have ceased, and physical and chemical transport would have dissipated any impacts to air quality. Present actions related to exploration, development, or production have the potential to affect air quality in the area due to the use of combustion equipment. Any present activities in this category are expected to be permitted and have potential emissions that meet air quality standards. Oil and gas production activities generating air emissions are concentrated in the area between Prudhoe Bay and the Colville River to the west. Other actions with lesser effects on air quality in the EIS project area include: scientific research; military; transportation; community development projects; subsistence activities; recreation and tourism; and subsistence whaling. These actions may include the use of combustion sources. The actions that include onshore activities (such as transportation and community development projects) also have the potential to create air pollution from ground-disturbing sources.

Oil and gas exploration, development, and production is the primary source of air emissions in the EIS project area. As shown in Table 4.11-2, there are several present allowable exploration, development, and production activities. Each of these has potential activity in the immediate vicinity of the project EIS area, therefore effects of air quality could overlap with the direct effects from Alternative 2. The effects from these activities are expected to be minor to moderate in magnitude, potentially long-term (for development and production facilities), and localized in the areas surrounding the specific activities. Present transportation actions (barges and air traffic) could also overlap in the vicinity of the EIS project area. The effects from transportation activities are expected to be minor in magnitude, short term in duration, and localized in the areas surrounding the specific activities.

4.11.4.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions with the potential to impact air quality in the proposed EIS project area include the same categories as present actions; oil and gas exploration, development, and production would be the primary future source category for air emissions in the EIS project area. Any future actions would require permitting to demonstrate compliance with air quality standards. Actions that have lesser potential to affect air quality are similar to those described above for present actions.

4.11.4.3.4 Conclusion

Alternative 2 has the potential to contribute to cumulative effects on air quality when activities occur in the vicinity of other sources of air pollution, primarily oil and gas exploration, development, and production actions. Due to distance between activities, and the mobile and intermittent source activities, the cumulative effects are expected to be less than the sum of each, likely remaining moderate in magnitude. Because of the short time duration for activities, cumulative effects would be highly dependent on actual meteorological conditions at the time, and the relative location of Alternative 2 activities to any of the other air pollution generating actions. The largest cumulative effects would occur when sources are directly upwind or downwind of each other. However, due to dispersion, the cumulative effects would be less than additive (lower than the sum of the total maximum effects). There are no accumulative or synergistic effects associated with air quality. Due to the short duration of the Level 1 Exploration Activity, cumulative effects with transportation actions (also mobile and, therefore, short in duration at any one location) are expected to be unlikely, however, if occurring, would also have the potential to be moderate in magnitude.

As identified in Sections 4.10.6.4 and 4.10.7.4, in the event of a VLOS, the overall effects on air quality in the EIS project area would potentially be high in magnitude, but only temporary in duration and primarily located in the vicinity of the cleanup activities. There would be moderate additive effects on air quality resulting from a VLOS within either the Arctic OCS.

4.11.4.4 Acoustics

4.11.4.4.1 Summary of Direct and Indirect Effects

Direct injurious effects of noise on marine fauna are discussed in Sections 4.5 to 4 to 4.8. NMFS currently applies pulse SPL thresholds of 190 and 180 dB re 1 µPa (rms) as conservative criteria for evaluating onset of auditory system injury for pinnipeds and cetaceans respectively. The largest potential zones of auditory system injury are produced by deep-penetration 2-D and 3-D seismic surveys performed in the 15 to 42 m (50 to 130 ft) depth range (Section 4.5.1.4). These zones can reach almost 3 km in radius although they are typically 2.0 to 2.5 km (1.2 to 1.5 mi) (Section 4.5.1.4 and Table 4.5-11).

Seismic surveys performed in shallow coastal waters and shallow hazards surveys using smaller airgun arrays produce smaller zones of ensonification (Table 4.5-10), where the term *zone of ensonification* here refers generally to the spatial areas exposed to sound levels greater than disturbance or injury effects criteria. Auditory system injury from continuous noise produce by vessels and drilling rigs is not believed to be a risk (Southall et al. 2007).

NMFS's current criteria for marine mammal disturbance are pulse SPL of 160 dB re 1 μPa (rms) and continuous (non-pulsed) noise SPL of 120 dB re 1 μPa. Deep penetration 2 and 3-D seismic survey disturbance zones for offshore surveys typically have radii greater than 10 km (6 mi) (Table 4.5-10). Transiting vessels typically have smaller disturbance zone radii under 2 km (1.2 mi) (Section 4.5.1.). Vessels on DP produce higher sound levels and larger disturbance zone radii; a measurement of a Shell vessel on DP in the Chukchi Sea estimated the 120 dB re 1 μPa threshold occurred at 5.6 km (3.5 mi) range (Chorney et al. 2011). Limited measurements of noise from jack-up drill rigs are available but their disturbance zones are expected to be less than 1 km (0.6 mi) due to acoustic isolation of the noise-producing equipment from the water. Anchored drillships may produce relatively large disturbance zones nearly 10 km (6 mi) radius during high-noise activities in the Beaufort and Chukchi seas, although anchor setting by tugs could produce short bursts of higher noise with even larger resulting disturbance zones (Section 4.5.1.4). The overall impact rating for direct and indirect effects to the acoustic environment under Alternative 2 would be moderate.

4.11.4.4.2 Past and Present Actions

Existing vessel and barge traffic supplies goods to communities along the Beaufort and Chukchi coasts, including Canadian communities. Barge traffic also supplies equipment to existing oil and gas operations near Prudhoe Bay and Point Thomson. Oil and gas exploration programs in the Canadian Beaufort Sea require vessel traffic along the Beaufort and Chukchi coasts. These vessel transits produce relatively small acoustic footprints in vicinity of the transiting vessels and barges, similar to those from oil and gas exploration support vessels (see Section 4.5.1.4).

Seismic survey exploration activities have occurred both inside and outside (but nearby) the EIS project area. The seismic surveys performed in the EIS project area since 2006 are listed in Table 4.5-9. The collaborative United States Geological Survey (USGS) – Geological Survey of Canada (GSC) seismic survey program in the Canada Basin has been active for several years and is expected to continue. Oil and gas exploration programs by several companies have occurred in the Canadian Beaufort Sea in recent years and these remain active. Noise generated by these seismic surveys has exposed marine mammals that are protected under the MMPA. Noise from these external surveys has propagated over long distances into the Beaufort EIS project area where it is sometimes detectable above background levels; acoustic recorders deployed in the U.S. Beaufort Sea in 2007 recorded seismic survey noise from surveys performed off the Mackenzie Delta in Canadian waters with per-pulse SEL levels sometimes exceeding 120 dB re 1 μPa^2 sec (Blackwell et al. 2009). These measurements were made 100 to 300 km (60 to 180 miles) from the seismic survey locations. At these large distances the pulse rms levels are expected to be numerically similar to SEL values (though the measurement units are different). Higher seismic survey noise levels could be present in the eastern part of the Beaufort Sea EIS project area when Canadian surveys occur close to the U.S.-Canada border. Seismic survey noise from surveys in the Russian Chukchi Sea has not been identified on autonomous acoustic recorders deployed almost continuously since 2007 in the Alaskan Chukchi Sea (Martin et al. 2010). Several Russian seismic projects have been underway during this time period, but those have occurred far enough west that little survey noise has propagated into the Alaskan Chukchi Sea. This situation is likely to change if the Russian surveys move closer to the U.S.-Russia border.

Military activities in the EIS project area, including vessel, submarine and ice breaker transits may generate underwater noise; however, year-round acoustic monitoring in the Alaskan Chukchi Sea has not identified significant military noise sources (Martin et al. 2010).

4.11.4.4.3 Reasonably Foreseeable Future Actions

As discussed above, vessel and barge traffic for supply of coastal communities and existing and future oil and gas facilities will continue to generate anthropogenic noise along vessel transit routes. It is reasonable to expect that seismic surveys will continue in the Canada Basin and in the Canadian Beaufort Sea. These surveys could generate substantial nearfield sound levels that could impact nearby marine mammals, and they will also generate noise that propagates over long distances into the EIS project area.

4.11.4.4.4 Contribution of Alternative to Cumulative Effects

Cumulative exposures to noise from anthropogenic activities both inside and outside the EIS project area might lead to indirect and cumulative effects. At present the effects of low-level cumulative exposures on marine fauna are poorly understood. However, a recent report by an expert panel has suggested criteria for auditory system injury based on cumulative SEL from multiple impulsive sounds received over 24 hours (Southall et al. 2007). The approach includes frequency-weighting of the received noise signals according to functions based on the hearing sensitivity of five marine mammal groups. The M-weighting functions are illustrated in Figure 3.1-8. Proposed thresholds for auditory system injury under this approach are 198 dB re 1 $\mu Pa^2 s$ for cetaceans and 186 dB re 1 $\mu Pa^2 s$ cumulative M-weighted SEL. Cumulative M-weighted SEL have been computed for single survey line transects for seismic surveys in the Chukchi Sea (e.g. O'Neill et al. 2010). These results appear to indicate that, for single-line seismic surveys in the Chukchi Sea EIS project area, the Southall et al. criteria are more conservative than the current rms criteria for estimating effects on pinnipeds, and less conservative for estimating effects on cetaceans (meaning that injury zones computed using the SEL thresholds are greater for pinnipeds and smaller for cetaceans than the respective zones computed using the current rms thresholds). Alternate survey geometries might produce different results. NMFS is considering the Southall et al. report and its proposed cumulative SEL metric for possible inclusion in future criteria, but the rms thresholds discussed above remain the present criteria for defining marine mammal exclusion zones (based on auditory system injury) near seismic survey and other impulsive sources, and disturbance zones near both impulsive and non-inpulse noise sources.

While the assessment of cumulative effects is difficult, cumulative exposures to noise from multiple activities over time, sometimes referred to as aggregate exposure, can be estimated for certain species. Few analyses of this type have been attempted due to the inherent uncertainty of where and when animals have or will be exposed to anthropogenic noise. A recent study by University of California under a grant from BP America is underway to evaluate methods for estimating cumulative noise exposures (Fleishman and Streever 2011; Racca et al. 2011). A study test case considers seismic survey noise exposures of bowhead whales in the Beaufort Sea. This study involves, as a first step, using an acoustic model to predict the temporally and spatially varying noise levels produced by seismic survey exploration activities. The second step of the study, now in progress, passes simulated bowhead migration paths through the predicted noise field. The paths are computed by a specialized algorithm that incorporates information about bowheads' migration corridor, timing and behavior, and estimated avoidance reactions to seismic survey noise. A cumulative sound exposure metric is calculated by integrating the time-dependent sound level received by each simulated bowhead as it traverses the seismic survey area. Frequency weighting such as proposed by Southall et al. can be included in this approach.

A final cumulative effect that is worth noting is habituation. Animals that have previously been exposed to anthropogenic noise may be less inclined to avoid similar noise on subsequent exposures. Habituation to anthropogenic noise may cause animals to approach loud noise sources more closely than they otherwise would, and as a result become exposed to higher and perhaps injurious noise levels.

Alternative 2 includes multiple 2D and 3D seismic surveys and shallow hazards surveys. It is reasonable to expect that some of these surveys would be concurrent and individual marine mammals could be exposed at relatively close-range to more than one survey in a relatively short time (perhaps less than 24 hours). While the disturbance zones based on 160 dB re 1 μPa (rms) would be unlikely to overlap, animals could have difficulty navigating between these zones. If a cumulative SEL criterion for auditory system injury similar to that proposed by Southall et al. (2007) were adopted, it is likely that some animals would receive substantially more exposure than would occur if only a single survey were present.

The inclusion of ice-breaking and one on-ice winter seismic survey would not be expected to generate significant cumulative effects due to their temporal separation from most other anthropogenic activities. These operations would also occur at a time of year when fewer marine mammals are present, thereby reducing exposures.

4.11.4.4.5 Conclusion

Under Alternative 2, the presence of multiple seismic surveys could lead to greater exposures of marine mammals to disturbance noise levels than from a single survey if the surveys are concurrent and/or with limited spatial separation. This is a more noteworthy issue in the Beaufort Sea EIS project area than in the Chukchi Sea; marine mammal migration corridors are narrower in the Beaufort and pass more directly through the primary oil and gas exploration areas. Exposures to potentially injurious cumulative sound levels might also occur with higher likelihood in the Beaufort as marine mammals could be exposed to noise from more than one seismic survey within relatively short time periods. The potential for this type of cumulative effect is not presently accounted for by current NMFS criteria for auditory system injury that are based on per-pulse rms sound levels.

Impacts on the acoustic environment associated with VLOS response and cleanup would be medium-intensity, temporary, and regional. Due to the intensity, duration, and geographic extent associated with these impacts, the overall effects of spill response and cleanup on the acoustic environment in the EIS project area would contribute a moderate additive effect on acoustics.

In addition, impact producing factors associated with a VLOS could include the drilling of a relief well, which would result in effects on the acoustic environment similar to those described in Section 4.5.1.4 of this EIS.

4.11.4.5 Water Quality

4.11.4.5.1 Summary of Direct and Indirect Effects

Actions associated with Alternative 2 would have a variety of direct and indirect effects on water quality in the EIS project area. Discharges from exploratory drilling operations would increase the temperature and salinity of seawater in the immediate vicinity of the discharge. Ocean-bottom cable surveys, anchor handling activities, and discharges from exploratory drilling activities would affect turbidity and concentrations of total suspended solids in the immediate vicinity of the activities. Effects on water quality resulting from increases in salinity, temperature, turbidity and/or total suspended solids would be low-intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1. Offshore exploratory drilling activities and associated shore-based and ice-based activities would influence concentrations of metals and organic contaminants in the water, which could affect water quality in the EIS project area. After mitigation, the effects of Alternative 2 on water quality are expected to be low-intensity, temporary, and local. Although applicable water quality criteria have not been established for some of the compounds present in discharged drilling fluids, the overall effects of Alternative 2 on water quality are expected to be minor.

4.11.4.5.2 Past and Present Actions

Over the past three decades, numerous onshore and offshore oil exploration and development projects have influenced water quality in the EIS project area (Brown et al. 2010; see Table 4.10-2). Activities that affect water quality include the construction of gravel islands and causeways, and discharges of materials (NRC 2003b). Due to past development and existing anthropogenic effects, existing water quality in the proposed action area cannot currently be considered “pristine” from a chemical perspective

(NRC 2003b, Brown et al. 2010). Certain organic pollutants tend to accumulate and persist in cold climates due to low mobility and slow degradation rates at low temperatures. Organic pollutants and other contaminants, such as heavy metals, have been deposited in the EIS project area as a result of both long-range transport processes and local activities.

NPDES-permitted discharges have included drill cuttings and used drilling fluids, cement slurry, drainage waters, and domestic wastewaters, which have been discharged after treatment according to the conditions and limitations of various NPDES permits. Discharges have generally been small, local, and infrequent, and the effects of discharges and spills on water quality have not accumulated (NRC 2003b). Water quality in the Beaufort and Chukchi seas is presently within the EPA criteria for the protection of marine life, and existing influences on water quality generally do not result in changes to ecosystem diversity or productivity, changes in the stability of biological communities, threats to human health, or loss of aesthetic, recreational, scientific, or economic values.

4.11.4.5.3 Reasonably Foreseeable Future Actions

Impacts to water quality in the EIS project area are expected to continue over the reasonably foreseeable future as a result of both long-range transport processes and local activities. It is reasonable to expect that NPDES permits including restrictions and monitoring requirements will be issued in the future. Discharges from existing industrial developments are expected to continue. Increases in marine vessel traffic (especially large vessels, such as cruise ships), military activities, and atmospheric deposition of pollutants could impact water quality in the Beaufort and Chukchi seas. Reasonably foreseeable increases in marine vessel traffic in the EIS project area would result in increased potential for introducing invasive species such as those contained in ballast water.

Changes in the acidity and alkalinity of the world's oceans are expected to continue and accelerate over the reasonably foreseeable future (USGS 2011). Concentrations of CO_2 dissolved in seawater are expected to increase as a result of increased concentrations of CO_2 in the atmosphere. Dissolution of CO_2 in seawater results in the formation of carbonic acid, which decreases the pH of the seawater causing ocean acidification. However, over the lifespan of this EIS, climate change and ocean acidification are expected to have negligible effects on water quality in the EIS project area.

4.11.4.5.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 2 would cause temporary local impacts to water quality such as increases in temperature, turbidity, and concentrations of pollutants. Some actions associated with Alternative 2, such as discharges of cooling water and waste material, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to water quality. These interactions would be local and temporary and would represent only a negligible cumulative impact.

4.11.4.5.5 Conclusion

The incremental contribution of activities associated with Alternative 2 to cumulative effects on water quality in the EIS project area would be minor.

In the event of a VLOS, the cumulative effects on water quality in the EIS project area would be high-intensity, long-term, and would affect an area of hundreds of square kilometers. There would be major additive effects on water quality resulting from a VLOS in either the Beaufort or Chukchi Sea.

4.11.4.6 Environmental Contaminants and Ecosystem Functions

4.11.4.6.1 Summary of Direct and Indirect Effects

Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 2 would be medium-intensity, temporary, and local. Regulation functions such as nutrient cycling and waste assimilation, which depend on biota and physical processes to facilitate storage and recycling of nutrients and breakdown or assimilation of contaminants, would be affected within the EIS project area, but the geographic extent of such impacts would be extremely limited. Habitat functions, particularly those related to benthic habitats, would be locally impacted as a result of activities and discharges associated with exploratory drilling. Production functions including primary productivity and subsequent transfers to higher trophic levels could potentially be impacted as a result of activities associated with Alternative 2, while the effects of Alternative 2 on information ecosystem functions would depend upon interrelationships between impacts to cultural resources, social resources, and aesthetic resources, which are addressed in other sections of this EIS. Overall direct and indirect effects of Alternative 2 on ecosystem functions are expected to be minor.

4.11.4.6.2 Past and Present Actions

A variety of past and present actions have affected the distribution of environmental contaminants in the EIS project area. Oil and gas exploration, development, and production have occurred in the area for several decades (see Table 4.10-2). Drilling operations generate waste muds and cuttings, produced water, and associated wastes, which typically contain a variety of organic pollutants and toxic metals (NRC 2003). Until recently, waste materials from the drilling of wells, including muds and cuttings, crude oil, spill materials, and other substances were disposed in open bermed areas called ‘reserve pits’ (NRC 2003). Historical practices within the EIS project area have also involved the disposal of muds and cuttings onto landfast ice in nearshore areas (Brown et al. 2010). Some materials from reserve pits have leached into the surrounding tundra, and the historical practice of applying reserve pit fluids to roads as a dust control measure has contaminated some terrestrial areas (NRC 2003). An agreement reached between industry and environmental groups has resulted in the remediation of most historical reserve pit sites, and injection of the contaminated materials into subsurface formations (NRC 2003). Current practices for the disposal of wastes generated from oil and gas exploration, development, and production activities usually involve injection wells used to dispose of wastes into subsurface formations thereby limiting the impact of present activities on the distribution of environmental contaminants within the EIS project area. Discharges from present developments have generally been small, local, and infrequent such that the effects from such discharges have not accumulated (NRC 2003). In addition to environmental contaminants originating from local sources, some organic pollutants and other contaminants are deposited in the EIS project area as a result of long-range transport processes. Oceanic currents and atmospheric transport processes currently contribute to the overall contaminant loads in the EIS project area and are considered in combination with actions that may lead to cumulative impacts.

Other past and present actions likely to influence ecosystem functions include vessel traffic and aircraft traffic within the EIS project area. Existing barging and docking facilities at Prudhoe Bay have the potential to influence ecosystem functions in the nearshore ocean within the EIS project area.

4.11.4.6.3 Reasonably Foreseeable Future Actions

As discussed in Section 4.4.1.4, anthropogenic materials are introduced to the Beaufort and Chukchi seas from a variety of sources, including influx from the Bering Sea, river runoff, coastal erosion, and atmospheric deposition, as well as from local and distant industrial activities (Woodgate and Aagaard 2005). Due to their hydrophobicity (non-polar molecular structure), persistence in the environment, and temperature-dependent volatility, certain contaminants originating from temperate environments would continue to contribute to the total contaminant loads of habitats and organisms in the Beaufort and Chukchi seas ecosystems. These impacts are likely to continue at varying rates and are considered in combination with actions that could lead to impacts in the cumulative case.

Future oil and gas development within the EIS project area would also contribute to cumulative impacts (see Table 4.10-2). Dredging, screeding, and construction of docking facilities associated with reasonably foreseeable future development would have minor impacts on ecosystem functions within the EIS project area.

Discharges from existing industrial developments are expected to continue. Increases in marine vessel traffic (especially large vessels, such as tug and barge fleets and cruise ships), military activities, and atmospheric deposition of pollutants could impact ecosystem functions in the Beaufort and Chukchi seas. The term "Sealift" refers to the annual supply of materials to the existing oilfields by tug and barge. During the next five years it is reasonably foreseeable that the size and number of Sealifts will increase as activities associated with the Alaska Pipeline Project and Point Thomson increase. Reasonably foreseeable increases in marine vessel traffic in the EIS project area would result in increased potential for introduction of invasive species such as those contained in ballast water.

Climate conditions in the EIS project area have been undergoing noticeable changes, particularly over the past 20 years (USGS 2011). Warmer air and water temperatures result in earlier spring snowmelt, decreased ice thickness during the winter, and accelerated rates of coastal erosion and permafrost degradation (USGS 2011). These changes and others are expected to continue over the reasonably foreseeable future and could aggregate with the effects of industrial activity to impact ecosystem functions. In addition to changes in air and water temperatures, changes in the acidity of the world's oceans are expected to continue and accelerate over the reasonably foreseeable future (USGS 2011). Ocean acidification may have substantial impacts on valued ecosystem components in the Beaufort and Chukchi seas, and must be considered in combination with actions that may lead to cumulative impacts in the proposed action area (USGS 2011).

4.11.4.6.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 2 would cause localized minor impacts to ecosystem functions within the EIS project area. Some actions associated with Alternative 2, such as discharges from exploratory drilling operations, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to ecosystem functions. The impacts resulting from such interactions would represent only a small fraction of foreseeable cumulative impact, and the accumulation of impacts is unlikely to be substantial.

4.11.4.6.5 Conclusion

The incremental contribution of activities associated with Alternative 2 to cumulative effects on ecosystem functions in the EIS project area would be minor.

A VLOS would likely have substantial accumulating effects on ecosystem functions as a result of high-intensity, long-term impacts to multiple ecosystem components over large geographic areas. Structural properties of the EIS project area ecosystem could be permanently affected as a result of a VLOS, and effects on ecosystem functions would be classified as major due to their high-intensity, long-term duration, and regional geographic extent, as discussed in Sections 4.10.6.7 and 4.10.7.7. There would be major additive effects on ecosystem functions resulting from a VLOS in either the Beaufort or Chukchi Sea.

4.11.4.7 Lower Trophic Levels

4.11.4.7.1 Summary of Direct and Indirect Effects

As discussed under Direct and Indirect Effects in Section 4.5.2, oil and gas exploration activities under Alternative 2 incorporate the use of a variety of small and large support vessels and icebreakers. Included in these efforts are seismic airgun arrays, and associated gear such as hydrophones and sensor arrays on cables deployed in the water column and ocean bottom. Drilling rigs, helicopters, fixed-wing aircraft, and on-shore support facilities are also associated with exploration activities. All of these can directly and indirectly cause behavioral disturbance, injury and mortality, and/or habitat loss/alteration, which in turn would affect lower trophic level organisms in the EIS project area.

The effects discussed above would likely be low in intensity, temporary to long-term in duration, of local extent and would affect common resources; resulting in a summary impact level of minor. The only exception to these levels of impacts would be the introduction of an invasive species due to increased vessel traffic, which could be of medium intensity, long-term or permanent duration, of regional geographic extent, and affect common or important resources; thereby causing a summary impact of moderate.

4.11.4.7.2 Past and Present Actions

Lower trophic levels in the EIS project area have been exposed to activities that may have impacted them in the past and will continue in the reasonably foreseeable future. The biggest impact on lower trophic levels results from activities that disturb the ocean floor; other impacts result from the discharge of drilling muds and cuttings, or habitat loss. Past and present actions that contribute some of these disturbances include oil and gas development and exploration, and the introduction of persistent contaminants. Offshore exploratory drilling activities in the Arctic have historically used systems such as artificial islands, which directly impact the sea floor and have caused direct injury and mortality to lower trophic level organisms, and also cause habitat loss and disturbance. The discharge of drilling muds and cuttings also pose a threat to the benthic community's habitat; sediment and cuttings sink to the bottom and cause mortality and injury by burying benthic organisms. The Beaufort Sea is shallower and experiences less circulation than the Chukchi Sea, so discharges pose a greater threat to the benthos in these calmer waters. Mortality and injury is also be caused by the introduction of toxins and sediments into the water column due to drilling discharges. These toxins may pose a threat to pelagic and benthic organisms. Habitat loss can also result from oil and gas exploration activities that require ice breaking efforts, forcing organisms to relocate.

The effects from past and present actions on lower trophic levels tend to be localized to the modest areas near the activity, and so are geographically dispersed, as are exploration activities, in the EIS project area. For this reason, overall effects of past and present actions are minor.

4.11.4.7.3 Reasonably Foreseeable Future Actions

All of the same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that have affected lower trophic levels in the past are likely to continue in the future. Offshore oil and gas exploration and development is likely to increase in Arctic waters of other countries (i.e. Russia and Norway) as the ice pack recedes and allows access to previously ice-covered areas. These activities would add to the risk of ocean floor disturbance that impact lower trophic habitat across large areas potentially reaching into the EIS project area. The continuation of offshore oil and gas exploration is expected to continue the accumulation of persistent contaminants from multiple sources and has the potential to affect lower trophic levels in the reasonably foreseeable future.

The influences of climate change on lower trophic levels are discussed in Section 3.2.1.3. In summary, the decrease of the extent of the Arctic ice pack impacts the epontic community, and subsequently, the pelagic and benthic communities (MMS 2007c). Warming ocean temperatures associated with climate change may increase zooplankton growth rates and generation times in the Beaufort and Chukchi seas.

The effects from oil and gas activity in the reasonable foreseeable future on lower trophic levels tend to be localized to the modest areas near the activity, and so are geographically dispersed, as are exploration activities, in the EIS project area. Although the effects of climate change will be long-term, the effects that would occur in the upcoming five years are not expected to considerably impact lower trophic levels. Therefore the overall impact from reasonably foreseeable future actions is minor.

4.11.4.7.4 Contribution of Alternative to Cumulative Effects

Under Alternative 2, the direct and indirect effects to lower trophic levels would be minor. The exploration activities authorized under Alternative 2 would add incrementally to the disturbance of lower trophic levels from increased sea floor disturbance. Discharge of drilling muds and small accidental spills would contribute a small amount to habitat change but such changes would be localized and very small. The resource would not be stressed to a point that would cause an irreversible impact. In the absence of a very large oil spill (see below), the exploration activities authorized under Alternative 2 would have moderate contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on lower trophic levels.

4.11.4.7.5 Conclusion

Alternative 2 would have a minor contribution to cumulative effects on lower trophic organisms.

In the event of a VLOS, the impact could be expected to be major should the spill persist in the environment or affect unique resources. However, should the spill not last a long time or not affect unique resources, the impacts could lead to a summary impact level of moderate due to the shorter duration and regional impacts to common resources. In the event of a VLOS, there would be moderate additive effects on lower trophic levels in the EIS project area; there would be major additive effects should the spill persist in the environment or affect unique resources.

4.11.4.8 Fish and Essential Fish Habitat

4.11.4.8.1 Summary of Direct and Indirect Effects

The overall impact of Alternative 2 on fish resources and EFH is minor. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 2, there would be no measurable effect on the resource.

Of the noise sources introduced by Alternative 2, most have been shown to have no long term impact on fish or fish resources. Because marine fish are widely dispersed and are largely unrestricted in their movements, noises associated with these activities are not expected to have a measurable effect on marine fish populations. All fish assemblages could potentially be exposed to noise, although pelagic and cryopelagic species are more likely to be affected, mainly through behavioral disturbance. However, the transient nature of the noise sources associated with seismic surveys, vessel traffic and icebreaking minimize the exposure to fish and fish resources, with standard ramp up procedures allowing further opportunity for mobile fish to escape the area of impact before any detrimental effects are felt. For more stationary noises associated with exploratory drilling, habituation provides a mechanism for fish to eliminate any effects from displacement. Therefore, the effect on juvenile and adult fish would be negligible. Based on the small footprint of the seismic surveys relative to the amount of habitat over the entire EIS project area, the effect would be minor, as a mechanism for population change exists, but no measurable change would result.

The opportunity for habitat loss or alteration resulting from Alternative 2 is very small. Direct effects to nearshore and offshore demersal fish and fish habitats from exploratory drilling, gravel island construction, icebreaking, and anchoring would be restricted to very limited areas, particularly when compared to the total area of benthic habitat available. Therefore, the adverse impacts are considered minor.

Of the activities described in Alternative 2, only those resulting in potential habitat loss or alteration are relevant to EFH. Effects to fish habitat from exploratory drilling, gravel island construction, and anchoring would be restricted to very limited areas, particularly when compared to the total area of benthic habitat available. Icebreaking would impact a small percentage of ice, which is essential for arctic cod. Salmon species spend much of their adult life at sea and therefore require feeding habitat. Saffron cod spend their entire lives in the marine environment and require spawning, rearing, or feeding habitat. Saffron cod also occurs in nearshore and estuarine environments (Wolotira 1985, Cohen et al. 1990). As with the analysis for marine fish, the opportunity for habitat loss or alteration resulting from

Alternative 2 is very small. Most impacts would be of such low intensity and of such small geographic extent that the effects would be considered minor.

4.11.4.8.2 Past and Present Actions

Past and present actions that have impacted or currently impact fish and EFH within the project EIS area include oil and gas development, transportation, military activity, scientific research, and subsistence activities. Primary issues of concern to fish and EFH include localized injury and mortality, impediments to fish passage and nearshore movement, and loss of habitat. Although the range of activities listed above have impacted fish resources, the scope of these impacts are difficult to quantify, but are considered to be negligible on a regional scale.

Oil and gas exploration and development activities have been occurring on the Arctic Coastal Plain since the 1960s. Much of the activity has been land-based, with fewer offshore elements. However, support for the North Slope development has relied on marine transportation, and continues to do so. Vessel traffic related to the oil and gas industry includes sealifts of large infrastructure pieces, barge deliveries, limited dredging, development (construction), and exploration activities (including seismic). Project-dependent traffic is infrequent and seasonally-dependent, occurring during the brief summer when the routes to the North Slope are ice-free. Exploration activities similar to those addressed in this EIS have also been ongoing within the EIS project area, but their limited scope is considered to have resulted in negligible impacts to fish. Seismic surveys are currently being undertaken in both Canadian and Russian Arctic waters, but are not considered to have any bearing on the fish resources with the EIS project area. Impacts from seismic surveys to fish resident in Canadian or Russian waters would be independent of the fish resources within the project EIS area; however, some species of fish, such as Arctic cisco, regularly migrate back and forth between the Canadian Beaufort Sea and U.S. Beaufort Sea. These type of migratory species could experience effects in both nations and therefore are not independent. The potential effects on fish from the oil and gas exploration and development activities listed here are the same as what is described in Section 4.4.2.2.

Arctic communities rely heavily on sea-going barges to transport consumer goods such as fuel and food to their remote locations. Barge traffic is slow-moving, infrequent, and seasonally dependent, resulting in no negligible impacts to fish.

Scientific research is ongoing within the EIS project area, and is driven by several factors. Although widespread and broadly focused, the cumulative impacts of these studies on fish resources are negligible, as the amount and scope of research is so limited.

Subsistence activities have been a vital part of northern life for as long as humans have lived in the region. Although subsistence patterns have changed over the years, and will likely continue to evolve in the future, it is not anticipated that any adverse impacts have occurred, or are occurring, to fish. Harvest of whitefish and salmon occurs across the coastal plain, but in small enough numbers to limit impacts. A detailed management regime has ensured that fish populations are maintained at viable levels, and fish resources are expected to be closely monitored into the future.

4.11.4.8.3 Reasonably Foreseeable Future Actions

Environmental changes associated with Arctic climate change have the greatest potential to impact fish resources within the EIS project area, and throughout the entire Arctic. Warming air and water has resulted in earlier spring snowmelt, decreased ice thickness, and permafrost degradation (USGS 2011). Studies have also documented a northern expansion of species. Pacific cod, walleye pollock, other groundfish are suspected to be expanding their range, based on the comparison of historical records. As the waters warm, productivity is likely to increase, thereby creating more favorable fish habitat throughout the Arctic.

This northward expansion of commercially viable species has renewed interest in a commercial fishery in the Arctic, which is currently not permitted in U.S. Arctic waters. The 2009 Arctic Fisheries Management Plan outlines the NPFMC's approach to "prohibit commercial harvest of all fish resources of the Arctic Management Area until sufficient information is available to support the sustainable management of a commercial fishery" (NPFMC 2009). No timeline has been set for such a decision to be made, but any decision would be highly dependent on climatic and financial factors.

The reduction in sea ice is anticipated to impact cryopelagic species such as Arctic cod. As the cryopelagic community is centered around sea ice, reduced sea ice result in habitat loss. Warming waters and decreases in ice cover also have the potential to alter prey and predator distributions and concentrations, thereby impacting fish.

Ocean acidification is a phenomenon associated with climate change that has recently begun to receive more scientific attention. Fish can be impacted by this phenomenon through several pathways including: reduction in calcifying prey organisms (e.g. pteropods for pink salmon); effects on calcium-carbonate structures in fish such as otoliths and some types of scales; alteration of carbonate based habitats that provide structural habitat; alteration of sound propagation causing increased exposure of fish to sound; effects on the olfactory sense leading to decreased ability of fish larvae to detect adult settling sites; and acidification acting synergistically with other climate change processes in influencing the risk of dispersal of non-native invasive species (BOEM 2011e).

With sea ice across the arctic gradually declining, vessel traffic is expected to increase throughout the region in coming years. However, even an exponential rise in vessel traffic would not be anticipated to have any measurable impact on fish, as the number of vessels would still be low enough to avoid.

Future mining activities are anticipated in the Arctic. Prospecting for zinc and coal in the western Brooks Range is on the horizon, but are unlikely to have any nexus with fish populations impacted by the activities proposed in this EIS. There would be no anticipated interactions with marine species.

Increased interest in the Arctic has resulted in an increase in scientific research, which could significantly increase the scientific understanding of fish resources within the EIS project area. This incremental increase in Arctic research activities will allow for an increasingly refined analysis of impacts on arctic resources, including fish, but will have a negligible impact on fish populations.

4.11.4.8.4 Contribution of Alternative to Cumulative Effects

Climate change is the only past, present, or reasonably foreseeable future action that is anticipated to have any measurable effects on fish and EFH within the EIS project area, and those effects are likely to be beneficial. As Arctic waters warm, productivity is likely to increase, thereby creating more favorable fish habitat throughout the region. The lack of measurable direct or indirect effects on fish and EFH resulting from the implementation of Alternative 2 would represent a negligible contribution to cumulative effects.

4.11.4.8.5 Conclusion

Most direct and indirect impacts resulting from Alternative 2 on fish and EFH would be of such low intensity and of such small geographic extent that the effects would be considered minor. The incremental contribution of activities associated with Alternative 2 to cumulative effects on fish would be negligible.

As described in Sections 4.106 and 4.10.7, in the event of a VLOS, there would be a moderate additive effect on fish and EFH within the EIS project area.

4.11.4.9 Marine and Coastal Birds

4.11.4.9.1 Summary of Direct and Indirect Effects

As discussed in Section 4.5.2.3, the effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. In summary, the impact of Alternative 2 on marine and coastal birds would be considered negligible to minor.

4.11.4.9.2 Past and Present Actions

Section 3.2.3 provides a brief description of the bird species that occur in the project area, including ESA-listed and candidate species, with references to conservation concerns from interactions with human activities and natural factors. The many marine species have been all exposed to a wide variety of marine vessel traffic and some species have been attracted to lights and collided with ship structures. Coastal species and nesting marine species may be affected by disturbance and loss of habitat from construction and some species, such as waterfowl, have been susceptible to collisions with power lines and communications structures. There have been no commercial or subsistence fishing operations in the Arctic seas large enough to affect their prey base or to threaten them with accidental entanglements but many species migrate through the Bering Sea, Gulf of Alaska, and other seas where there are large fisheries which may have adverse effects. Fixed-wing and helicopter traffic in nearshore areas has caused disturbance of marine and coastal birds. All species have been exposed to man-made and potentially toxic chemical compounds in the water and the food web that have been transported to the Arctic from around the world through the atmosphere, water currents, and migrating animals (AMAP 2010). Waterfowl and a few other species are also subject to subsistence hunting in various parts of their ranges, including the coastal communities adjacent to the Beaufort and Chukchi seas. Changes in sea-ice distribution, ocean acidification, and ocean dynamics due to climate change could have adverse effects on the some species and beneficial effects on others.

4.11.4.9.3 Reasonably Foreseeable Future Actions

All of the same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that have affected marine and coastal birds in the past are likely to continue in the future. Offshore oil and gas exploration and development is likely to increase in Arctic waters of other countries (i.e. Russia and Norway) as the ice pack recedes and allows access to previously ice-covered areas. These activities would add to the risk of oil spills and other contamination that could affect the same species of marine birds as occur in Arctic Alaska. Large spills from other areas could also be transported into Alaska waters by currents and ice. On-shore oil and gas exploration and production activities are also expected to continue on the Alaskan North Slope, which would contribute to disturbance and habitat loss for coastal and nesting marine species. Reasonably foreseeable natural gas development projects (the Point Thomson production unit and the Alaska Pipeline Project) could affect marine and coastal birds through disturbance associated with marine vessel traffic and habitat loss from on-shore facility construction. Potentially toxic compounds will continue to be produced around the world and many will find their way to the Arctic with potentially adverse effects on all species. Hunting along migration paths and in Arctic breeding areas will likely continue to be the largest source of direct human-induced mortality on waterfowl. Climate change could affect marine and coastal bird habitats through changes in sea-ice distribution, water quality, seasonality and characteristics of tundra vegetation, and ocean acidification. Some habitat changes could be adverse for some species and beneficial for others.

4.11.4.9.4 Contribution of Alternative 2 to Cumulative Effects

The exploration activities authorized under Alternative 2 would add incrementally to the disturbance of birds from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Vessels and on-shore structures could also contribute to the risk of injurious or fatal collisions. Discharge of drilling muds and small accidental spills would contribute a small amount to habitat change but such changes would be localized and very small compared to the contribution from climate change. The exploration activities authorized under Alternative 2 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds.

4.11.4.9.5 Conclusion

The direct and indirect effects of Alternative 2 on marine and coastal birds would be considered negligible to minor, given the temporary and localized nature of potential effects. Alternative 2 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds.

There would be a remote chance of a VLOS occurring during exploratory drilling under Alternative 2 (Sections 4.10.6.10 and 4.10.7.10). The implications for birds would depend on the amount and distribution of the accidental spill and to how quickly and thoroughly it could be cleaned up, especially in relation to areas and times when birds are in dense congregations during migration and post-breeding molt. If a very large spill occurred in the Chukchi Sea and impacted the Ledyard Bay/Kasegaluk Lagoon area, the population of spectacled eiders could be severely impacted because of their concentration in this area during spring migration and post-breeding molt and the high risk of mortality from exposure to oil. Other species could also be severely impacted and many could have population-level effects if the spill coincided with their staging areas during spring or fall migration. Areas in the Beaufort Sea within the barrier islands would be particularly sensitive because they are high use areas for a variety of birds. Contamination of coastal and benthic habitats could persist for many years and have chronic effects on the health and reproductive success of birds. A very large oil spill could also contribute substantially to the cumulative effects of disturbance on birds because of the large number of marine vessels and aircraft that would be involved in any clean-up effort, which would likely extend for more than one year and involve a large area. If a VLOS were to occur, there would be a major additive effect to the cumulative effects on many species of marine and coastal birds.

4.11.4.10 Marine Mammals

4.11.4.10.1 Bowhead Whales

4.11.4.10.1.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 2 on bowhead whales are described in detail in Section 4.5.2.4.9 and are summarized here. Potential direct and indirect effects of oil and gas exploration activities on bowhead whales are primarily disturbance and behavioral changes from noise exposure and, possibly, injury or mortality from ship strikes, and habitat degradation. Oil and gas exploration activities authorized under Alternative 2 would likely cause varying degrees of disturbance to feeding, resting, or migrating bowhead whales. Disturbance could lead to displacement from and avoidance of areas of exploration activity to distances up to 20 to 30 km (12.4 to 18.6 mi) (Miller et al. 1999, Richardson et al. 1999), as well as changes in calling behavior (Blackwell et al. 2010b). The EIS project area encompasses a large portion of bowhead whale habitat between the Bering Strait and Canadian border, so leaving the area entirely to avoid impacts is not an option. Duration of disturbance is expected to be short-term; long term effects of disturbance are not well understood. Surveys utilizing ice breakers could cause avoidance and displacement over a larger radius with the additional noise input from the icebreaking activities, but the period of time over which this activity would overlap with bowhead whales is much shorter. Multiple exploration activities occurring simultaneously or overlaping to varying degrees temporally and/or spatially would increase the footprint of the cumulative activities and also potentially increase impacts to bowhead whales as a result. Although bowhead whales react to approaching vessels at greater distances than they react to most other activities, most observed disturbance reactions to vessels and aircraft appear to be short-term. The extent of disturbance effects will depend on the number of exploration activities and associated support vessels in an area, but, for individual sound sources, impacts are expected to be localized.

Incidence of injury and mortality due to ship strikes appears low, but could rise with increasing vessel traffic. Only three ship-strike injuries to bowhead whales were documented from 1976 to 1992 (George et al. 1994).

Potential impacts to bowhead whale habitat from oil and gas exploration activities permitted under Alternative 2 would mostly affect the area immediate adjacent to the site of impact, whether it be discharges, sediment disruption, or icebreaking. Most impacts would also be temporary, although longer-term and regional effects could occur through the process of bioaccumulation through the food chain.

Sub-lethal impacts on bowhead whale health (such as hearing impairment or increased stress) cannot currently be measured. There is no information on TTS or PTS thresholds specific to bowheads, and the likelihood of obtaining the information is low. Hearing and hearing damage can only be readily analyzed in smaller cetaceans, primarily in captivity, or through studying ears of dead whales. Because bowhead whales respond behaviorally to loud noise and generally move away from the sound source, they are less likely to suffer hearing loss from increased noise. However, and Richardson and Thomson (2002) note that bowhead whales are less responsive to seismic airguns when engaged in certain activities, such as feeding.

In terms of the impact criteria identified in Table 4.5-17, most effects of individual exploratory activities authorized under Alternative 2 are of medium intensity and temporary in duration. Potential long-term effects from repeated disturbance over time or over a broad geographic range are unknown. Individually, the various activities may elicit localized effects on bowhead whales, yet the area and extent of the population over which effects would be felt would increase with multiple activities occurring simultaneously or consecutively throughout much of the summer-fall range of this population. Since the EIS project area extends across most of the spring and fall migratory path of bowhead whales in U.S. waters, the combined oil and gas exploration activities could result in regional level effects on bowhead whales. Bowhead whales are listed as endangered and are an essential subsistence resource for Iñupiat and Yupik Eskimos of the Arctic coast, which places them in the context of being a unique resource. Evaluated collectively, and with consideration given to reduced adverse impacts through the imposition of the required standard mitigation measures, the overall effect of activities authorized under Alternative 2 on bowhead whales is likely to be moderate.

4.11.4.10.1.2 Past and Present Actions

Commercial whaling was the single greatest historical source of mortality for bowhead whales. An estimated 60 percent of the pre-whaling population was harvested by the late nineteenth century (Braham 1984). Commercial whaling for bowheads ended in the early twentieth century. Subsistence harvests are currently the primary source of mortality for bowhead whales, with an average of about 40 takes per year (Suydam et al. 2011). The subsistence harvest is well-managed and regulated through a quota system by the IWC (Section 3.3.2). In addition to direct injury or mortality from subsistence whaling, non-targeted bowheads in the vicinity of a struck whale may experience acoustic disturbance from motorized skiffs (especially during the fall hunt) and the explosive sounds of a whale bomb detonating when a whale is harpooned.

Offshore oil and gas exploration, development and production activities have occurred in State waters or on the OCS in the Beaufort and Chukchi seas since 1979. Seismic surveys have been conducted in the Chukchi and Beaufort seas since the late 1960s and early 1970s (MMS 2006a). Most of this activity has occurred in the Beaufort Sea (Table 4.11-2). The Western Arctic stock of bowhead whales has been exposed to these activities for several decades. These offshore activities and their known and potential effects on bowhead whales were discussed in Section 4.5.2.4.9, including ice management vessels, seismic sources, exploratory drilling, aircraft (fixed wing and helicopter) for crew transport and monitoring, and other associated vessels. What is currently known of effects–particularly relating to acoustic disturbance—was derived from studies of bowhead whales coincident to these past and presently occurring activities. Although bowhead whales appear to avoid or be temporarily displaced from an area of oil and gas activity by as much as 20 to 30 km (12.4 to 18.6 mi) (see Section 4.5.2.4.9 for details), there is no evidence of long-term population level effects on the health, status, or population recovery due to these past and present activities (MMS 2006a).

Bowhead whales are exposed to other marine vessel traffic including large ocean-going barges, industrial container ships, icebreakers and other vessels used for scientific and commercial purposes throughout their range, including many vessels used to supply on-shore oil and gas developments on the Prudhoe Bay area. In addition to acoustic disturbance from icebreaking and engine noise from vessel traffic, ship strikes are possible. However, only three ship-strike injuries of bowhead whales were documented from 1976 to 1992. The low number is likely due to relatively few vessels passing through most of the bowhead's range or because bowheads struck by ships do not survive and are, therefore, not accounted for (George et al. 1994).

Bowhead whales are also exposed to man-made and potentially toxic chemical compounds in the water and the food web that have been transported to the Arctic from around the world through the atmosphere, water currents, and migrating animals (AMAP 2010). Since bowhead whales feed on lower trophic level organisms (zooplankton), they are considered at lower risk of bioaccumulation of contaminants, such as persistent organic compounds, than higher level consumers. Levels of persistent organic compound concentrations in samples collected from bowhead whales in Alaska are low compared to other marine mammals (O'Hara and Becker 2003).

Bowhead whales may be sensitive to current and ongoing effects of climate change in the Arctic. It is not, however, currently possible to make reliable predictions of the effects of changes in weather, sea-surface temperatures, or sea ice extent on bowheads. Research and models suggest that, at least in the short term, reduced sea ice cover may actually increase prey availability for bowhead whales and result in improved body condition (Moore and Laidre 2006, George et al. 2006, cited in Allen and Angliss 2010). The loss of sea ice is also opening new habitat and the possibility of exchange between Atlantic and Pacific populations that were previously separated by sea ice. Satellite-tagged bowhead whales from Alaska and West Greenland recently entered the Northwest Passage from opposite directions and spent roughly ten days in the same general area. This is the first documented overlap of these two populations (Heide-Jørgensen et al. 2011).

Bowhead whales in the EIS project area, thus far, appear resilient to the level of human-caused mortality and disturbance that has occurred within their range since the end of commercial whaling (MMS 2006b). Since bowhead whales may live 150+ years (George et al. 1999), many individuals in this population may have already been exposed to numerous disturbance events during their lifetimes. The subsistence harvest levels (approximately 0.1 to 0.5 percent of the population per year [Philo et al. 1993b]) appear to be sustainable. With the Western Arctic stock of bowhead whales continuing to increase at an estimated 3.4 percent per year (George et al. 2004), there is no indication that the combined effects of past or present noise and disturbance-causing factors (e.g. oil and gas activities, shipping, subsistence hunting, and research activities), habitat alterating activities (e.g. gravel island construction, port construction), or pollutants has had any long-lasting physiological, or other adverse effect(s) on the population (MMS 2006b).

4.11.4.10.1.3 Reasonably Foreseeable Future Actions

The factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that affected bowhead whales in the past and present are likely to continue into the future. Subsistence hunting will likely continue to be the greatest source of mortality for bowhead whales. The oil and gas exploration activities likely to occur during the next five years are the subject of this EIS and their potential impacts on bowhead whales are described in Sections 4.5.2.4.9, 4.6.2.4.1, 4.7.2.4.1 and 4.8.2.4.1. Offshore oil and gas exploration and development is also likely to increase in Arctic waters of neighboring countries, such as Russia and Canada. Increased traffic and industrial activity in the Russian Chukchi Sea and Canadian Beaufort could affect bowhead whales at different stages of migration or during summer feeding in the eastern Beaufort Sea and Amundsen Gulf.

On-shore oil and gas exploration and production activities are also expected to continue on the Alaskan North Slope. Reasonably foreseeable future natural gas development projects (e.g. the Point Thomson production unit and the Alaska Pipeline Project) could affect bowhead whales during the open-water season marine transport of processing facilities and materials for the construction phases and development of nearshore structures.

Potentially toxic compounds may be accidentally discharged coincident to some of the above mentioned industrial activities, as well as continue to be produced around the world and potentially end up in the Arctic food web.

Continued Arctic warming trends and the resulting changes in sea ice conditions could impact bowhead whales in several ways, including prey productivity and shifting migratory patterns based on the presence of sea ice. Whether the short-term beneficial increases in prey productivity will continue in the long-term is unknown. Climate change would affect the entirety of the bowhead whales' range, although the nature and extent of habitat changes may differ by area.

Marine vessel traffic may increase with continued retreat of summer sea ice due to climate change. Increased commercial shipping, fishing, and tourism could occur. Increased vessel traffic in the Beaufort and Chukchi Seas could increase disturbance effects on feeding and migrating bowhead whales and lead to a higher incidence of ship strikes. Expansion of commercial fisheries into Arctic waters may also occur coincident to retreating ice extent and result in additional acoustic disturbance, incidental takes, or entanglement in fishing gear. Coast Guard activities and icebreaker traffic may also increase coincident to growth in shipping and exploration activities during longer ice-free periods. The influence of climate change on marine mammals is further discussed in Section 3.2.4.4.

4.11.4.10.1.4 Contribution of Alternative to Cumulative Effects

The direct and indirect effects of oil and gas exploration activities authorized under Alternative 2 are detailed in Section 4.5.2.4.9 and summarized above. The primary impacts of these activities derive from increased acoustic disturbance in several areas across the summer and fall range of the Western Arctic stock of bowhead whales. Since the EIS project area extends across most of the migratory path of bowhead whales in U.S. waters, the combined oil and gas exploration activities could result in regional level effects on bowhead whales and a minor to moderate additive contribution to cumulative acoustic effects. The spatial and temporal extent of disturbance depends on the spatial and temporal distribution of exploration activities relative to bowhead whale distribution and behavior (e.g. feeding, resting, or migrating). The geographic area and percent of the population over which effects would be felt would increase with multiple activities—including activities external to oil and gas exploration authorized under Alternative 2-- occurring simultaneously or consecutively throughout much of the summer-fall range of this population.

Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the likelihood of occurrence is relatively low. The contribution of this source of mortality to overall mortality levels for this stock of bowhead whales would be negligible compared to the annual level of mortality incurred through the subsistence harvest.

Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds and contaminants. Most of these effects would be localized and short-term and, relative to the potential ecosystem-wide climate change effects of extensive sea ice loss and ocean acidification on habitat, seemingly minor. However, there is a great deal of uncertainty regarding future impacts of Arctic climate change and adequately assessing potential additive or synergistic effects of combined habitat impacts is not feasible.

The contribution of the direct and indirect impacts resulting from Alternative 2, when combined with the past, present, and reasonably foreseeable future actions would be minor to moderate, with most potential impacts due to acoustic disturbance that could, at least temporarily, disrupt or displace bowhead whales.

4.11.4.10.1.5 Conclusion

Under Alternative 2, the direct and indirect effects to bowhead whales would be moderate. Overall, Alternative 2 would have a minor to moderate contribution to cumulative effects on bowhead whales.

There would be a remote chance of a VLOS occurring during exploratory drilling under Alternative 2 (Sections 4.10.6.11 and 4.10.7.11). A very large oil spill would contribute substantially to cumulative effects of disturbance, injury and mortality, and habitat alterations. The duration of effects could range from temporary (such as skin irritations or short-term displacement) to permanent (e.g. endocrine impairment or reduced reproduction) and would depend on the length of exposure and means of exposure, such as whether oil was directly ingested, the quantity ingested, and whether ingestion was indirect through prey consumption. Displacement from areas impacted by the spill due to the presence of oil and increased vessel activity is likely. If the area is an important feeding area, such as off Barrow or Kaktovik, or along the migratory corridor, the effects may be of higher magnitude. The extent of impact could be state-wide, given the migratory nature of bowhead whales. Population level effects are possible if a very large oil spill coincided with and impacted large feeding aggregations of bowhead whales during the open water season, particularly if calves were present. If a VLOS were to occur, there would be a major additive effect to the cumulative effects on bowhead whales.

4.11.4.10.2 Beluga Whales

4.11.4.10.2.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 2 on beluga whales are described in Section 4.5.2.4.10 and are summarized here. The oil and gas exploration activities proposed in Alternative 2 could directly and indirectly affect beluga whales by causing noise disturbance, habitat degradation, and potential ship strikes. Beluga whales disturbed by oil and gas exploration activities may move away from important habitats. The scale of the avoidance depends on the number and relative proximity of the surveys. Numerous simultaneous seismic activities could cause avoidance over large distances. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

Direct and indirect effects on beluga whales from Alternative 2 would be low to medium intensity, short-term duration, local to regional extent, and would affect a unique resource. The summary impact level of Alternative 2 on beluga whales would be considered moderate.

4.11.4.10.2.2 Past and Present Actions

The historical baseline for beluga whales in Arctic Alaska is described in Section 3.2.4.2 and is summarized here. The primary source of human caused mortality in beluga whales has been and continues to be subsistence hunting. The annual subsistence take of Beaufort Sea stock belugas by Alaska Natives averaged 26 belugas during the five-year period from 2005-2009 (Allen and Angliss 2012b). The average annual subsistence take by Alaska Natives averaged 94 belugas from the eastern Chukchi stock during 2005-2009 (Allen and Angliss 2012b).

Beluga whales are exposed to marine vessel traffic including small skiffs and skin umiaqs operating close to shore, large ocean-going barges, industrial container ships, and icebreakers used for scientific and commercial purposes throughout their range. Fixed-wing and helicopter traffic in nearshore areas may cause temporary disturbance of belugas. Beluga whales are also exposed to man-made and potentially toxic chemical compounds in the water and the food web that have been transported to the Arctic from around the world through the atmosphere, water currents, and migrating animals (AMAP 2010). Since beluga whales feed on higher trophic level organisms they are considered at higher risk of bioaccumulation of contaminants, such as persistent organic compounds, than lower level consumers.

The best available abundance estimate for the Beaufort Sea stock is 39,258. The current population trend of the Beaufort Sea stock of beluga whales is unknown (Allen and Angliss 2010).

The most reliable estimate for the eastern Chukchi Sea stock continues to be 3,710 whales derived from 1989-91 surveys. There is currently no evidence that the eastern Chukchi Sea stock of beluga whales is declining (Allen and Angliss 2010).

Neither the Beaufort Sea stock nor the eastern Chukchi Sea stock is listed as depleted under the MMPA or threatened or endangered under the Endangered Species Act.

4.11.4.10.2.3 Reasonably Foreseeable Future Actions

The same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that affected beluga whales in the past and present are likely to continue into the future. Subsistence hunting will likely continue to be the primary source of human-caused mortality for beluga whales. Marine vessel traffic is expected to increase with continued retreat of summer sea ice due to climate change. Increased commercial shipping, fishing, and tourism are likely as a result. Offshore oil and gas exploration and development is also likely to increase in Arctic waters of other countries, such as Russia and Canada. Coast Guard activities and icebreaker traffic may also increase coincident to growth in shipping and exploration activities.

On-shore oil and gas exploration and production activities are also expected to continue on the Alaskan North Slope. Reasonably foreseeable natural gas development projects (the Point Thomson production unit and the Alaska Pipeline Project) could affect beluga whales during construction phases that involve large sea lifts of processing facilities and material during the open-water season and development of nearshore structures. Potentially toxic compounds will continue to be produced around the world and many will find their way to the Arctic food web.

Continued Arctic warming trends and the resulting changes in sea ice conditions could impact beluga whales throughout the entirety of their range, although the nature and extent of habitat changes may differ by area.

4.11.4.10.2.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 2 would add to the acoustic disturbance of beluga whales from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible. The exploration activities authorized under Alternative 2 would therefore have minor to moderate additive contributions to the cumulative effects on beluga whales.

4.11.4.10.2.5 Conclusion

As stated above, most exploration activities authorized under Alternative 2 would result in minor to moderate contributions to cumulative effects on beluga whales.

There would be a small chance of a VLOS occurring during exploratory drilling under this alternative (Section 4.10.7.11). A VLOS would contribute substantially to cumulative effects of disturbance, injury and mortality, and habitat alterations. The duration of effects could range from temporary (such as skin irritations or short-term displacement) to permanent (e.g. endocrine impairment or reduced reproduction) and would depend on the length of exposure and means of exposure, such as whether oil was directly ingested, the quantity ingested, and whether ingestion was indirect through prey consumption. Displacement from areas impacted by the spill due to the presence of oil and increased vessel activity is likely. If the area is an important feeding area, such as the Shelf Break of the Beaufort Sea, or along the migratory corridor, the effects may be of higher magnitude. The extent of impact could be state-wide, given the migratory nature of beluga whales. Population level effects are possible if a very large oil spill coincided with and impacted large feeding aggregations of beluga whales during the open water season, particularly if calves were present. If a VLOS were to occur, there would be a major additive effect to the cumulative effects associated with Alternative 2 on beluga whales.

4.11.4.10.3 Other Cetaceans

4.11.4.10.3.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 2 on cetaceans are described in Section 4.5.2.4.11 and are summarized here. In general, potential direct and indirect effects on other cetaceans resulting from exploration activities in the Beaufort and Chukchi seas authorized under Alternative 2 are similar to those on bowhead whales and beluga whales. The primary direct and indirect effects on other cetaceans would result from noise exposure. Potential noise sources include 2D/3D seismic survey equipment (airgun arrays), CSEM electromagnetic signals, echosounder and sonar devices associated with site clearance and shallow hazards surveys, support, monitoring and receiving vessels associated with these surveys, icebreaking activities, on-ice vibroseis seismic surveys (Beaufort Sea only), exploratory drilling, and helicopter and fixed wing aircraft associated with the different programs.

Direct and indirect effects arising from ship strikes and habitat degradation are also possible. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

Direct and indirect effects on other cetaceans from Alternative 2 would be of low to medium intensity, of temporary or short-term duration, local to regional in extent, and would affect a unique resource. The summary impact level of Alternative 2 on other cetaceans would be considered minor.

4.11.4.10.3.2 Past and Present Actions

The historical baseline for cetaceans in Arctic Alaska is described in Section 3.2.4.2 and is summarized here. In the past, commercial whaling was the single greatest source of mortality for cetaceans, primarily mysticetes. Humpback, fin, and gray whales were all taken in large numbers up until the cessation of commercial whaling activities in the twentieth century. Commercial whaling for gray whales was banned after 1946, humpbacks were protected worldwide in 1965 and fin whales were commercially taken in the North Pacific until 1976 (Perry et al. 1999, Rice et al. 1984). Since then, subsistence hunting has provided the only whaling pressure to Arctic species. Bowhead whales are the primary target, with only sporadic and occasional takes of gray, humpback and minke whales by Alaskan and Russian Natives. A single humpback whale was taken in Norton Sound in 2006, but that is the only reliable record of a subsistence humpback whale take by Alaska Natives (Allen and Angliss 2010). During the period of 1950 to 1980, 47 gray whales were taken by Alaskan subsistence hunters from 12 villages (Marquette and Braham 1982). Only two gray whales were taken in the 1990s, both in 1995 (Angliss and Outlaw 2005). The annual subsistence take by Russian Natives was 122 during the five-year period from 1999 to 2003 (Angliss and Outlaw 2005). All subsistence takes are within the limits set by the International Whaling Commission (Angliss and Outlaw 2005). No other cetaceans within the EIS project area are affected by subsistence whaling.

All cetaceans are exposed to marine vessel traffic including small skiffs operating close to shore, large ocean-going barges, industrial container ships, and icebreakers used for scientific and commercial purposes throughout their range. Fixed-wing and helicopter traffic in nearshore areas may cause temporary disturbance. Gray whales and harbor porpoises, being the most abundant and regularly encountered of the non-beluga and -bowhead cetaceans throughout the EIS project area, are likely exposed to the most potential disturbance. Any disturbance is negligible.

Cetaceans are also exposed to man-made and potentially toxic chemical compounds in the water and the food web that have been transported to the Arctic from around the world through the atmosphere, water currents, and migrating animals (AMAP 2010). Most mysticetes, such as gray, humpback, and fin whales, feed primarily on amphipods, euphasiids, and other lower trophic level benthic organisms. However, toothed whales, such as harbor porpoise and narwhals, feed on higher trophic level organisms and are therefore considered at higher risk of bioaccumulation of contaminants, such as persistent organic compounds.

Cetaceans may be sensitive to current and ongoing effects of climate change in the Arctic. It is not, however, currently possible to make reliable predictions of the effects of changes in weather, sea-surface temperatures, or sea ice extent on any specific species. Research and models suggest that, at least in the short term, reduced sea ice cover may actually increase prey availability for bowhead whales and result in improved body condition (Moore and Laidre 2006, George et al. 2006, cited in Allen and Angliss 2010). This conclusion could be expected to hold true for other mysticetes, and likely for odontocetes as Arctic warming is thought to be resulting in the northern expansion of fish ranges and abundances. The loss of sea ice is also opening new habitat and the possibility of exchange between Atlantic and Pacific populations that were previously separated by sea ice.

4.11.4.10.3.3 Reasonably Foreseeable Future Actions

The same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that affected cetaceans in the past and present are likely to continue into the future. Subsistence hunting will likely continue to be a source of mortality for gray whales. Marine vessel traffic is expected to increase with continued retreat of summer sea ice due to climate change. Increased commercial shipping, fishing, and tourism are likely, as a result. Offshore oil and gas exploration and development is also likely to increase in Arctic waters of other countries, such as Russia, Canada, and Norway. Marine military activity in the region is also on the rise, as both the U.S. Coast Guard and U.S. Navy have stated their interest in increasing their presence and response capabilities in the Arctic. As a result, Coast Guard activities and icebreaker traffic may also increase coincident to growth in shipping and exploration activities.

On-shore oil and gas exploration and production activities are also expected to continue on the Alaskan North Slope. Reasonably foreseeable natural gas development projects include the Point Thomson production unit and the Alaska Pipeline Project. These projects could affect cetaceans during their construction phases through increased vessel traffic in the form of sea lifts and barge transport during the open-water season and development of nearshore structures.

Continued Arctic warming and the resulting changes in sea ice conditions are likely to continue to impact cetaceans throughout the EIS project area. Whether the short-term beneficial increases in prey productivity will continue into the long-term is unknown. Any impacts are difficult to quantify. There is no indication of long-term adverse effects on the population from extensive seismic surveys and exploration drilling in previous decades.

4.11.4.10.3.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 2 would add to the acoustic disturbance of other cetaceans from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible.

None of the past, present, or reasonably foreseeable future actions described above are expected to have any substantial impact on cetacean populations within the EIS project area. Populations for most species are stable or increasing, and climate change is likely to add nominal beneficial impacts in the future. The exploration activities authorized under Alternative 2 would therefore have minor additive contributions to the cumulative effects on other cetaceans.

4.11.4.10.3.5 Conclusion

As stated above, most exploration activities authorized under Alternative 2 would result in minor contributions to cumulative effects on other cetaceans.

There would be a small chance of a VLOS occurring during exploratory drilling under this alternative (Section 4.10.7.11). A VLOS would contribute substantially to cumulative effects of disturbance, injury and mortality, and habitat alterations. Some species would be impacted more than others, depending on species abundance within the area affected by the spill, and the location and magnitude of the VLOS. Gray whales and harbor porpoises would be more likely to be impacted than other species in this group because of their higher relative abundance.

The duration of effects could range from temporary (such as skin irritations or short-term displacement) to permanent (e.g. endocrine impairment or reduced reproduction) and would depend on the length of exposure and means of exposure, such as whether oil was directly ingested, the quantity ingested, and whether ingestion was indirect through prey consumption. Displacement from areas impacted by a spill due to the presence of oil and increased vessel activity would be likely. If the area was an important feeding area, such as the Shelf Break of the Beaufort Sea, or along a migratory corridor, the effects would be of higher magnitude. Population level effects would not be likely given the sporadic and seasonal distribution of most cetaceans throughout the EIS project area. However, the extent could be regional, given the migratory nature of many cetaceans. If a VLOS were to occur, there would be a major additive effect to the cumulative effects associated with Alternative 2 on other cetaceans.

4.11.4.10.4 Ice Seals

4.11.4.10.4.1 Summary of Direct and Indirect Effects

There are four species of seals considered in this section that are often collectively called “ice seals”; ringed seal, spotted seal, ribbon seal, and bearded seal. The direct and indirect effects of Alternative 2 on ice seals are described in Section 4.5.2.4.12 and are summarized here. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past offshore oil and gas exploration activities in the Alaskan Beaufort and Chukchi seas and would likely be affected more frequently by exploration activities authorized under Alternative 2 than either ribbon or spotted seals. Data from observers on board seismic source vessels and monitoring vessels indicate that seals tend to avoid on-coming vessels and active seismic arrays but they do not appear to react strongly even as ships pass fairly close with active arrays. They also do not appear to react strongly to icebreaking or on-ice surveys, keeping their distance or moving away at some point to an alternate breathing hole or haulout, but the scope of these behavioral responses appears to be within their natural abilities and responses to their naturally dynamic environment. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and they would be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are protected under the MMPA, have unique ecological roles in the Arctic, and are important subsistence resources and are therefore considered to be unique resources. Given the standard mitigation measures that have been required in the past, the effects of exploration activities that could be authorized under Alternative 2 on ice seals would likely be low in magnitude, distributed over a wide geographic area, and temporary to short-term in duration. The effects of Alternative 2 would therefore be considered minor for all ice seal species according to the criteria established in Section 4.1.3.

4.11.4.10.4.2 Past and Present Actions

Each species of ice seal has a unique set of ecological and seasonal distribution characteristics that help determine their exposure to anthropogenic and natural forces within the EIS project area. These species are all highly dependent on sea ice for critical life functions and their seasonal distributions are heavily influenced by seasonal ice movement in Arctic waters. They are all exposed to marine vessel traffic ranging from small skiffs operated close to shore to large ocean-going barges, industrial container ships, and icebreakers used for scientific and commercial purposes. Vessel traffic associated with oil and gas development projects in the Prudhoe Bay area has made up a large percentage of total marine traffic in the past, with all of the large equipment and materials barges traversing the Beaufort and Chukchi seas in both directions between southern ports and Prudhoe Bay. Fixed-wing and helicopter traffic in nearshore areas has caused disturbance of seals on the ice and on shore-based haulouts. There have been no commercial or subsistence fishing operations in the Arctic seas large enough to affect their prey base, although large fisheries in the Bering Sea may affect the winter prey base of migrating seals. They are all exposed to man-made and potentially toxic chemical compounds in the water and the food web that have been transported to the Arctic from around the world through the atmosphere, water currents, and migrating animals (AMAP 2010). Each species is also subject to subsistence hunting in various parts of their ranges, primarily near coastal communities adjacent to the Beaufort and Chukchi seas but also in the Bering Sea during winter.

In 2010, NMFS determined that some of the DPS for ringed seals, spotted seals, and bearded seals should be listed as threatened under the ESA, primarily based on the likelihood of sea-ice habitat modification due to climate change and marine habitat modification due to ocean acidification. NMFS determined that ribbon seals did not warrant listing under the ESA in 2008.

4.11.4.10.4.3 Reasonably Foreseeable Future Actions

All of the same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that have affected ice seals in the past are likely to continue in the future. Marine vessel traffic is expected to increase as the ice pack recedes due to climate change, primarily involving large international commercial ships. Offshore oil and gas exploration and development is also likely to increase in Arctic waters of other countries (i.e. Russia and Canada) as the ice pack recedes and allows access to previously ice-covered areas. On-shore oil and gas exploration and production activities are also expected to continue on the Alaskan North Slope, with many of them requiring large sea barges to transport equipment and material from southern ports to the Prudhoe Bay area. Reasonably foreseeable natural gas development projects (the Point Thomson production unit and the Alaska Pipeline Project) could affect ice seals during their construction phases which involve large sea lifts of processing facilities and material during the open-water season and development of nearshore structures. Potentially toxic compounds will continue to be produced around the world and many will find their way to the Arctic. Subsistence hunting will likely continue to be the largest source of direct human-induced mortality on ice seals. The greatest concern for ice seals in the reasonably foreseeable future is the continued Arctic warming trends and the resulting deterioration of sea ice conditions that are so important to these species. Most of the other factors that could affect ice seals would have more localized effects but climate change affects the entire ranges of these species and could adversely affect every life stage. It is not clear how or when this issue will be addressed or when the deterioration of ice seal habitat will be reversed.

4.11.4.10.4.4 Contribution of Alternative 2 to Cumulative Effects

The exploration activities authorized under Alternative 2 would add to the disturbance of ice seals from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary and localized. Very small numbers of ringed seals could be exposed to exploration activities during the denning season (winter-spring) when females with young are more susceptible to disturbance. Exploration activities would contribute negligible risk of additional mortality to any species, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 2 would therefore have negligible to minor contributions to the cumulative effects on the four species of ice seals considered.

4.11.4.10.4.5 Conclusion

The direct and indirect effects of Alternative 2 on pinnipeds would be considered minor. Alternative 2 would have negligible to minor contributions to the cumulative effects on the four species of ice seals.

There would be a small chance of a VLOS occurring during exploratory drilling under Alternative 2 (Section 4.10.7.11). The implications for ice seals would depend on the amount and distribution of the accidental spill, especially in relation to the ice pack, and how quickly and thoroughly it could be cleaned up. However, ice seals have the ability to purge their bodies of hydrocarbons through renal and biliary pathways and are not dependent on their fur to keep them warm so they are not as susceptible to spilled oil as are birds or polar bears. Although they can get lesions on their eyes and some internal organs from contacting crude oil, studies have indicated that many of the physiological effects self-correct if the duration of exposure is not too great (Engelhardt et al. 1977, Engelhardt 1982, Engelhardt 1983, Engelhardt 1985, Smith and Geraci 1975, Geraci and Smith 1976a, Geraci and Smith 1976b, St. Aubin 1990). A VLOS could contribute substantially to the cumulative effects of disturbance on ice seals because of the large number of marine vessels and aircraft that would be involved in any clean-up effort, which would likely extend for more than one year and involve a large area. It could also contribute to injury and mortality of seals, especially young animals and those with poor health, although the numbers of animals involved is unlikely to be very large given their physiological resistance to acute oil toxicity. The contribution to habitat effects could be long-term because of the potential for spilled oil to be captured in the food web and to persist on shore-based haulouts for greater than five years. If a VLOS were to occur, there would be a minor to moderate additive effect to the cumulative effects associated with Alternative 2 on the four species of ice seals considered in this EIS.

4.11.4.10.5 Walrus

4.11.4.10.5.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 2 on walrus are described in Section 4.5.2.4.13 and are summarized here. Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. These data indicate that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest sounds generated by the ships. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of calf and juvenile mortality from stampedes. Walrus are protected under the MMPA, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for NEPA purposes. For the level and type of exploration activities that would be authorized under Alternative 2, given the mitigation measures that would be required by USFWS LOAs and NMFS as considered in this EIS, the effects on Pacific walrus would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 2 would therefore be considered minor for walrus according to the criteria established in Table 4.5-17.

4.11.4.10.5.2 Past and Present Actions

Pacific walrus are considered to be one population that ranges from Russia to Alaska in the Bering and Chukchi seas. Population trends have fluctuated substantially due to historic periods of heavy commercial and subsistence harvest alternating with conservation efforts. Joint U.S.-Russia surveys have been conducted since the 1970s but inconsistencies between methodologies, survey periods, and extent of area surveyed have yielded estimates of abundance that vary widely and the USFWS does not consider these surveys sufficient to establish the current population abundance or trend, although advances in thermal imaging and satellite telemetry could improve this situation (USFWS 2011c). In February 2011 the USFWS determined that Pacific walrus should be listed as either endangered or threatened under the ESA but higher priorities precluded the action and the species was put on the list of candidate species awaiting future action (USFWS 2011c). The listing action was determined to be warranted primarily based on the likelihood of sea-ice habitat modification due to climate change and marine habitat modification due to ocean acidification.

Pacific walrus are highly dependent on sea ice for critical life functions and their seasonal distribution is heavily influenced by seasonal ice movement in Arctic waters. They typically remain in close proximity to the pack ice as it recedes north in summer and south in the winter. Relatively few walrus have been exposed to the many exploration and shipping vessels traversing the Arctic seas in the past because these large ships tend to stay away from the ice edge if possible. However, the number of walrus encountered by vessels in the open water has increased in recent years, primarily in the fall when the ice pack recedes beyond the shelf break into water too deep for walrus to forage. The ice pack has been receding further north and sooner than it has in the past due to climate change. This change in the pack ice distribution has forced thousands of walrus to swim to shore-based haul outs along the Chukchi coast where they are more exposed to vessel and aircraft traffic (Clarke et al. 2011a, Fischbach et al. 2009). Use of shore-based haul outs may leave walrus, particularly calves and juveniles, vulnerable to disturbance related stampedes and trampling mortalities (Fischbach et al. 2009) and predation from similarly shore-bound polar bears.

Walrus have been displaced from pack ice and ice floes by icebreakers and other vessels used for scientific and commercial purposes. Low-flying fixed-wing and helicopter traffic over the ice and in nearshore areas has caused disturbance of walrus on the ice and on shore-based haul outs. There have been no commercial or subsistence fishing operations in the Arctic seas large enough to affect their prey base but large bottom trawl fisheries in the Bering Sea may affect the winter prey base of walrus. Like all Arctic-dwelling animals, walrus have been exposed to man-made and potentially toxic chemical compounds in the water and the food web that have been transported to the Arctic from around the world through the atmosphere, water currents, and migrating animals (AMAP 2010). Walrus are also subject to subsistence hunting in various parts of their range, primarily near coastal communities adjacent to the Bering and Chukchi seas in Alaska and Russia. The USFWS estimates that the most recent five-year average subsistence harvest in Alaska and Russia (2003 to 2007) is 4,960 to 5,457 walrus per year, including animals estimated to be struck and lost (Allen and Angliss 2011).

4.11.4.10.5.3 Reasonably Foreseeable Future Actions

All of the same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that have affected walrus in the past are likely to continue in the future. Marine vessel traffic is expected to increase as the ice pack recedes due to climate change, primarily involving large international commercial ships. Offshore oil and gas exploration and development is also likely to increase in Arctic waters of other countries (i.e. Russia and Canada) as the ice pack recedes and allows access to previously ice-covered areas. On-shore oil and gas exploration and production activities are also expected to continue on the Alaskan North Slope. Although very few walrus would likely occur east of Barrow they could be exposed to vessels and barges passing through the Chukchi and Bering seas between southern ports and the Prudhoe Bay area. Reasonably foreseeable natural gas development projects (the Point Thomson production unit and the Alaska Pipeline Project) could affect walrus during their construction phases due to their use of large sea lifts for pre-built facilities and materials. Potentially toxic compounds will continue to be produced around the world and many will find their way to the Arctic, with unknown impacts on walrus and their habitat. Subsistence hunting will likely continue to be the largest source of direct human-induced mortality on walrus. The greatest concern for walrus in the reasonably foreseeable future is the continued Arctic warming trends and the resulting deterioration of sea ice conditions that are so important to this species. Most of the other factors that could affect walrus would have more localized effects but climate change affects the entire range of this species and could adversely affect every life stage.

4.11.4.10.5.4 Contribution of Alternative 2 to Cumulative Effects

The exploration activities authorized under Alternative 2 would add to the disturbance of walrus from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to walrus, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 2 would therefore have negligible to minor contributions to the cumulative effects on Pacific walrus.

4.11.4.10.5.5 Conclusion

The direct and indirect effects of Alternative 2 on Pacific walrus would be considered minor. Alternative 2 would have negligible to minor contributions to the cumulative effects.

There would be a remote chance of a very large oil spill occurring during exploratory drilling under Alternative 2 (Section 4.10.7.11). The implications for walrus would depend on the amount and distribution of the accidental spill, especially in relation to the ice pack, and how quickly and thoroughly it could be cleaned up. Walrus are not dependent on their fur to keep them warm so they are not as susceptible to rapid lethal effects from spilled oil as are birds or polar bears. Ingestion of oil or oil contaminated prey items can cause tissue changes (Kooyman et al. 1976). It is not clear if walrus are able to metabolize small amounts of oil as has been demonstrated with ringed and bearded seals but they have a similar physiology so tissue damage may be temporary unless they are exposed to chronic contamination (Kooyman et al. 1976). Chronic exposure may result in mortality or long term sub-lethal effects that reduce fitness. A very large oil spill could contribute substantially to the cumulative effects of disturbance on walrus because of the large number of marine vessels and aircraft that would be involved in any clean-up effort, which would likely extend for more than one year and involve a large area. It could also contribute to injury and mortality of walrus if such disturbance causes stampedes of animals hauled out on land, especially young animals and those with poor health. The contribution to habitat effects could be long-term because of the potential for spilled oil to persist in benthic sediments, to be captured in the food web, and to persist on shore-based haulouts for greater than 5 years. Given the conservation concerns for the walrus population due to changing ice conditions, the additional mortality and disturbance caused by a very large oil spill that impacts the Chukchi Sea could have population-level effects. If a VLOS were to occur, there would be a moderate to major additive effect to the cumulative effects associated with Alternative 2 on Pacific walrus.

4.11.4.10.6 Polar Bears

4.11.4.10.6.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 2 on polar bears are described in Section 4.5.2.4.14 and are summarized here. Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected under the MMPA and ESA, have a unique ecological role in the Arctic, and are important to subsistence cultures and are therefore considered a unique resource. Given the mitigation measures that would be required by USFWS LOAs and NMFS as considered in this EIS, the effects of exploration activities that could be authorized under Alternative 2 on polar bears would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 2 would therefore be considered minor for polar bears.

4.11.4.10.6.2 Past and Present Actions

There are two populations of polar bears in Alaska waters, the Southern Beaufort Sea stock and the Chukchi/Bering seas stock. Abundance levels and trend information on polar bears have been difficult to obtain due to their wide but sparse distribution and the logistical difficulties in conducting research over the shifting ice pack. The current best estimate is that the Southern Beaufort Sea stock has about 1,500 animals and is declining slowly (Allen and Angliss 2010, Hunter et al. 2007). There is currently no reliable population estimate or trend information for the Chukchi/Bering seas stock. In 2008, the USFWS determined that polar bears should be listed as threatened under the ESA throughout their range (73 FR 28212, May 15, 2008). This determination was based on declining sea ice habitat throughout the species range and the anticipated continued decline in the foreseeable future. Critical habitat, which was designated in 2010, included sea-ice habitat, terrestrial denning habitat, and barrier island habitat (75 FR 76086, December 7, 2010); however, this designation has recently been overturned by the courts.

Polar bears are highly dependent on sea-ice for critical life functions and their seasonal distribution is heavily influenced by the seasonal distribution of the ice seal species, which are their main prey, and by seasonal ice movement in Arctic waters. All polar bears except denning females typically roam across the pack ice as it recedes north in summer and south in the winter, although some bears spend time on barrier islands and the coast in the fall and winter to scavenge on whale carcasses. In the past, the majority of denning females in Alaska chose den sites on the pack ice (Amstrup and Gardner 1994) but more recent data indicate that the majority now choose den sites on land (Fishbach et al. 2007), a trend that appears related to thinning of the ice cap due to climate change (Durner et al. 2006). Another result of climate change is the increasingly delayed formation of sea-ice in the fall, forcing more bears to spend more time on land where they have difficulty catching prey and subsequently increasing the chance of human-bear interactions with increased mortality of bears killed in defense of life or property (Amstrup 2000b).

Polar bears have been subject to subsistence and sport hunting in many parts of their range but several treaties and inter-government agreements have been implemented to limit hunting mortality. Only subsistence hunting by Alaska Natives is allowed in Alaska. The 2003-2007 average Alaska harvest for the Southern Beaufort Sea stock was 33 bears per year and an additional 21 bears per year were taken from this stock in Canada (Allen and Angliss 2011). Harvest levels from the Chukchi/Bering stock are not as well known. An average of 65 bears per year are known to be harvested in Alaska and Russia but illegal harvests in Russia may account for an additional 150 to 250 bears per year (Allen and Angliss 2010).

Relatively few polar bears have been exposed to the many exploration and shipping vessels traversing the Arctic seas in the past because these large ships tend to stay away from the ice edge if possible. In the Beaufort Sea, polar bear sightings from exploration vessels are uncommon and most of these have been of polar bears on or near barrier islands in the fall (Savarese et al. 2010). In the Chukchi Sea, polar bear sightings from vessels have been relatively rare, with half the bears sighted in the water, and they generally do not react strongly to the presence of vessels (Haley et al. 2010b). Other temporary sources of disturbance in the past include icebreakers and low-flying fixed-wing and helicopter traffic.

Like all Arctic-dwelling animals, polar bears have been exposed to man-made and potentially toxic chemical compounds in the water and the food web that have been transported to the Arctic from around the world through the atmosphere, water currents, and migrating animals (AMAP 2010). As a top predator, polar bears could have high levels of potentially toxic compounds that bioaccumulate in the food chain, such as organochlorines and mercury (Braune et al. 2005, AMAP 2005).

4.11.4.10.6.3 Reasonably Foreseeable Future Actions

All of the same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that have affected polar bears in the past are likely to continue in the future. The greatest concern for polar bears in the reasonably foreseeable future is the continued Arctic warming trends and the resulting deterioration of sea ice conditions that are necessary for this species and its prey. Most of the other factors that could affect polar bears would have more localized effects but climate change affects the entire range of this species and could adversely affect every life stage.

Marine vessel traffic is expected to increase as the ice pack recedes due to climate change, primarily involving large international commercial ships, which contributes to the risks of accidental fuel spills and other contamination. Offshore oil and gas exploration and development is also likely to increase in Arctic waters of other countries (i.e. Russia and Canada) as the ice pack recedes and allows access to previously ice-covered areas. These developments outside of Alaska could affect polar bears through oil spills transported in the ice pack or ocean currents. On-shore oil and gas exploration and production activities are also expected to continue on the Alaskan North Slope, although the impacts should be mitigated through LOAs issued by the USFWS. Reasonably foreseeable natural gas development projects (the Point Thomson production unit and the Alaska Pipeline Project) could affect polar bears through disturbance in denning and barrier island habitats, especially during construction, although these activities would also be mitigated through USFWS LOAs. Potentially toxic compounds will continue to be produced around the world and many will find their way to the Arctic, with unknown impacts on polar bears and their habitat. Hunting will likely continue to be the largest source of direct human-induced mortality on polar bears.

4.11.4.10.6.4 Contribution of Alternative 2 to Cumulative Effects

The exploration activities authorized under Alternative 2 would add to the disturbance of polar bears from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of injury or additional mortality to polar bears, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 2 would therefore have a negligible to minor contribution to the cumulative effects on polar bears.

4.11.4.10.6.5 Conclusion

The direct and indirect effects of Alternative 2 on polar bears would be considered minor. Alternative 2 would have negligible to minor contributions to the cumulative effects.

There would be a remote chance of a VLOS occurring during exploratory drilling under Alternative 2 (Section 4.10.7.11). The implications for polar bears would depend on the amount and distribution of the accidental spill, especially in relation to the ice pack and to denning areas, and how quickly and thoroughly it could be cleaned up. Polar bears are susceptible to oil spill-induced injury and death through lost insulation value of their fur and ingestion of oil by grooming or contaminated prey (Hurst and Oritsland 1982, Neff 1990). Polar bears are curious about new things in their environment and may not avoid oil spill areas or contaminated prey or carcasses (St. Aubin 1990, Derocher and Stirling 1991). Marine mammal observers on clean-up crews may be effective at diverting curious bears from small spill areas but would likely be ineffective if the spill covers a large area or occurs during periods of darkness. A VLOS could contribute substantially to the cumulative effects of disturbance on polar bears because of the large number of marine vessels and aircraft that would be involved in any clean-up effort, which would likely extend for more than one year and involve a large area. The contribution to habitat effects could be long-term because of the potential for spilled oil to persist on coast lines and barrier islands for greater than five years.

Given the conservation concerns for polar bears due to changing ice conditions, the additional mortality and disturbance caused by a VLOS in either the Beaufort or Chukchi seas could have population-level effects. If such a spill were to occur, there would be a moderate to major additive effect to the cumulative effects associated with Alternative 2 on polar bears.

4.11.4.11 Terrestrial Mammals

4.11.4.11.1 Summary of Direct and Indirect Effects

The oil and gas exploration activities proposed in Alternative 2 could have direct and indirect effects on caribou, and possibly other terrestrial mammals from disturbances created by helicopters and fixed wing aircraft fly overs used for crew changes and other support of exploratory drilling programs in the Beaufort and Chukchi seas. Disturbances to caribou may also result from a general increase in human activities (air or ground) in the EIS project area, due to an overall increase in human population from support crews living in the North Slope area.

Disturbance to caribou may result in movements away from preferred habitats or away from preferred migration routes. Caribou respond to flyovers and nearby landings in a variety of ways depending on the degree of their habituation, weather conditions, sex and age composition of the herd, and the aircraft itself (Calef et al. 1976, Horejsi 1981). The type of aircraft, altitude, airspeed and frequency of flyovers all play a role on the caribou's reaction. Disturbance of caribou could also cause immediate physical injury or death to animals fleeing the disturbance, or could result in increased expenditures of energy or changes in the physiological condition of the animals, which reduces their rates of survival and reproduction. These reactions can result in long-term changes in behavior, especially the traditional use of calving areas and insect relief areas (Calef et al. 1976). An increase in human population within the EIS project area and the associated vehicle traffic from support crews or the population in general may result in an increase in the number of vehicle strikes causing injury or mortality to caribou. Increased hunting pressure from increased human populations in the EIS project area may also have short term effects on the caribou populations and an increase in the number of local sport hunters may compete with subsistence users.

4.11.4.11.2 Past and Present Actions

Numerous past and present actions have caused disturbances to the four caribou herds that may be affected by the implementation of Alternative 2. Although most of these probable disturbances may not be occurring within the EIS project area they have occurred in the past and continue to occur at several other locations within the migratory ranges of these North Slope caribou herds. Activities causing disturbance to caribou throughout their range contribute to the overall disturbance levels of these animals.

Past and present actions include North Slope oil and gas exploration, development, and production activities including the construction and operation of the Trans-Alaska Pipeline System, permanent roads and winter ice roads; construction of support facilities; and transportation activities involving surface vehicles, aircraft or marine traffic along the coast or within the barrier islands. The Central Arctic Herd's use of calving and midsummer habitats declined from the mid 1970's through the mid 1980's near oil field infrastructure on Alaska's Arctic Coastal Plain (Dau and Cameron 1986).

Caribou habitat has also experienced direct and indirect effects. Road construction, as well as pipeline construction, has not only destroyed some caribou habitat within the footprint of the road, but has also resulted in a reduction of habitat use within the adjacent areas. Cameron et al. (1992) found that calving caribou were displaced outward after construction of the Milne Point road system, resulting in underutilization of habitats adjacent to roads and overutilization elsewhere, effectively diminishing the capacity of the area to support caribou. Cameron et al. (2005) also reported that in the Kuparuk Development Area, west of Prudhoe Bay, abundance of calving caribou was less than expected within 4 km (2.5 mi) of roads and declined exponentially with road density. Currently there are thirty-five Alaska oil fields and satellite oil fields producing oil within the migratory ranges of the North Slope caribou herds, and additional discoveries are under development. There are also numerous oil and gas development activities occurring in Canada within the migratory range of the Porcupine Caribou Herd.

Mining is another example of past and present activities with direct and indirect effects on caribou, such as the development and operation of Red Dog Mine within the Northwest Arctic Caribou Herd range, which is the world's largest known zinc resource. As much as 25 million tons of high-grade zinc was estimated to be present near Red Dog Mine. Mining activities relative to caribou include the loss of habitat within the foot print of the mine and its support facilities and vehicle traffic between the mine and the coast.

Scientific research such as the continuation of ongoing and special biological surveys, and geophysical studies using both surface and aircraft transportation throughout the North Slope and Brooks Range can effect caribou. BOEM Alaska OCS region Oceanographic research in 2011 included physical oceanography studies, habitat and ecology studies including mapping the distribution of shorebirds. Many of these activities involve aircraft support with potential for caribou disturbances along the coast.

Military activity in the Arctic is thought to have increased in recent years. The Distant Early Warning Line, also known as the DEW-Line, was a system of 63 radar stations located across the northern edge of the North American Continent, roughly along the 69th parallel. Many of these coastal sites are associated with insect relief areas used by caribou. The radar stations were constructed between 1954 and 1957, and decommissioned during the 1990s. The Bullen Point site is currently managed by the U.S. Air Force and has a gravel airstrip and a small radar system.

Subsistence activities, such as routine travel to subsistence camps using aircraft, snow machines and boats along the coast or within the barrier islands cause some disturbance to caribou utilizing those areas. Sport hunting, as well as other recreational activities utilizing aircraft support also cause some level of disturbances to caribou throughout the seasonal ranges of these four caribou herds.

4.11.4.11.3 Reasonably Foreseeable Future Actions

There are numerous reasonably foreseeable future actions that may result in direct or indirect effects to caribou, through construction and operation of many projects, as well as the related activities of the associated human population expected to increase as a result. Oil and gas development in NPR-A will include the development of exploration and production facilities, road networks and support facilities. The Alaska Pipeline Project near Prudhoe Bay will include facilities to treat, transport and deliver gas from the North Slope of Alaska to markets in North America, which will include the installation and operation of a gas treatment plant at Prudhoe Bay with construction targeted for 2014. The Point Thompson project, located about 60 miles east of Prudhoe Bay will include the construction of three production pads, process facilities, an infield road system, an export pipeline, infield gathering lines and an airstrip.

Mining exploration, development, and production are expected in increase, which includes operations at the Red Dog Mine and the Red Dog Port within the migratory range of the Western Arctic Caribou Herd. The Red Dog Mine port site may also become the port facility for a very large proposed coal mining operation adjacent to the Chukchi Sea. In addition, coal mine prospecting proposals for the Brooks Range have been submitted to ADNR, Division of Mining, Land and Water (DMLW) for approval.

Military activity in the Arctic are expect to continue to increase in the foreseeable future. Activities may include training exercises and dismantling of DEW-Line sites (which may include demolition projects).

Routine travel and growth of transportation facilities is expected to continue within the North Slope. Industry uses helicopters and fixed wing aircraft to support routine activities. In addition, at least four companies operate air cargo services between North Slope communities and population centers. The majority of air travel and freight hauling between Arctic coastal communities involves small commuter-type aircraft, and government agencies and researchers often charter aircraft for travel and research purposes. These activities are expected to continue, and the level of aircraft traffic within the EIS project area may increase as a result of increased industrial activity. Activities associated with planned community development projects also have potential for direct and indirect effects on caribou. These include the Kaktovik airport project and ongoing water and sewage projects facilitated by the North Slope and Northwest Arctic boroughs.

Recreation and tourism will continue to increase, such as sport hunting, hiking, floating rivers, etc., particularly in the Arctic National Wildlife Refuge, as a result of elevated media exposure of the Refuge. Finally, subsistence hunting is a major source of mortality to caribou, and will continue in the future.

4.11.4.11.4 Contribution of Alternative to Cumulative Effects

The direct and indirect effects from Alternative 2 on caribou may be additive with some countervailing beneficial impacts, when considered in addition to the cumulative effects from other past, present and future activities identified above. Kutz et al. (2004) and Urban (2006) found that the construction of roads and gravel pads may provide caribou with additional insect-relief habitat, particularly when there is little or no road traffic present. However they also recognized that the construction of roads and pipelines could provide vectors by which invasive species, parasites, and new diseases could be introduced into the Arctic environment resulting in negative effects for caribou. Some studies of caribou responses to disturbances indicate that avoidance is not absolute and caribou may habituate to infrastructure and human activity (Haskell et al. 2006). Several studies have reported that ungulate populations in North America, including caribou have developed tolerance to aircraft, ground-vehicle traffic, and other human activities (Johnson and Todd 1977). Cronin et al. (2000) maintain that effects from onshore development and production have not resulted in negative population-level effects, and that the Central Arctic Herd has grown throughout the period of oil field development at a rate comparable to other herds in undeveloped areas (Lenart 2007).

Cow and calf groups appear to be the most sensitive to vehicle traffic, especially during the early summer months immediately after calving, and bulls appear to be least sensitive during that season. Minimizing traffic, especially within calving areas during the calving period, would reduce the potential for negative impacts on caribou (BOEM 2011b).

These findings suggest that caribou are able to habituate and adapt to some human activities, including vehicle traffic, aircraft operations and the construction and operation of oil and gas production facilities, but cow and calf groups are sensitive to these disturbances.

4.11.4.11.5 Conclusion

The incremental contribution of activities associated with Alternative 2 to cumulative effects on caribou would be negligible.

In the event of a VLOS, there would be a minor to moderate additive effect to the cumulative effects associated with Alternative 2 on caribou, depending on the magnitude and duration of the spill.

4.11.4.12 Time/Area Closures

The analysis of the cumulative effects associated with time/area closures can be found in Sections 4.11.4.10 (Marine Mammals), 4.11.4.9 (Marine and Coastal Birds) and 4.11.4.14 (Subsistence).

4.11.4.13 Socioeconomics

4.11.4.13.1 Summary of Direct and Indirect Effects

There would be no new Federal or State revenues generated under the implementation of Alternative 2 during the time period covered by this EIS because lease sales in federal and state waters have already been conducted and are the subject of proposed exploration activities. Some local revenues would be generated in communities that would stage crew or support services and that have a sales tax.

There would be a limited number of direct local North Slope employment opportunities associated with the standard mitigation measures for PSOs, Subsistence Advisors, Com Centers, and oil spill responders. There would be direct and indirect employment opportunities for Regional and Village Corporations that procure service contracts related to the above activities or support of crews and staging. In the communities of Barrow, Wainwright, Nome and Unalaska/Dutch Harbor (where crew changes occur or vessels are based), there could be short-term, seasonal demand on institutions and social services.

If a deflection or disturbance of subsistence resources occurs as a result of Alternative 2 (see the Subsistence Section), the activities of non-profit organizations could be impacted in order to coordinate adaptive strategies regarding potential economic and social implications of reduced harvest of subsistence resources. The Conflict Avoidance Agreement (CAA), Com Centers, and Plans of Cooperation (POC) are mechanisms currently used for communication, cooperation, and conflict avoidance between industry and local groups like the AEWC.

The magnitude of the socioeconomic impact is positive but low because total personal income and local employment rates are not increased by more than five percent. Revenues to the North Slope Borough would also not exceed five percent of their annual operating budgets. The duration of the socioeconomic impacts is temporary because it is not year-round. However, the activity is scheduled to occur over a fixed number of years. The positive economic impacts of the activity are statewide and even national in extent. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat communities. The summary impact level for Socioeconomics under Alternative 2 is minor, not exceeding the significance threshold.

4.11.4.13.2 Past and Present Actions

The ongoing activities of the oil and gas industry are generally contained within the Prudhoe Bay industrial complex, between the Alpine Project to the west and Point Thomson Project to the east. The past and present actions that would contribute to the cumulative effects to socioeconomics under Alternative 2 are the same as those described for Alternative 1.

4.11.4.13.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions for Alternative 2 would be the same as those described for Alternative 1. This analysis assumes current levels of oil and gas production and on-shore exploration would continue, but does not assume that offshore exploration associated with Alternative 2 would result in future oil and gas production.

4.11.4.13.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 2 to socioeconomic cumulative effects would be minor to negligible at a statewide and national level because the magnitude is low, the duration is temporary and the context is common. However, at a local level, the new direct employment, public revenue generation, and impact to social institutions would be greater and the Iñupiat community is a unique context, therefore the contribution would be minor.

4.11.4.13.5 Conclusion

The direct and indirect effects of Alternative 2 would be minor. The contribution to the cumulative effects of socioeconomics would be negligible to minor.

A VLOS in the Beaufort Sea or Chukchi Sea could result in short to long-term employment, potential new NSB revenues (property taxes for the construction of worker infrastructure) as well as potential lost revenue for NSB, state and federal revenues due to permitting delays, and exploration moratoria. Local and state agencies may also increase expenditures associated with the administration of oil spill response and social services related to the influx of new workers. The influx of workers would create a short to long-term demand on institutions and social services in NSB communities. Employment and local revenues associated with clean-up of a VLOS in the either the Beaufort or Chukchi Sea would be high intensity, long-term in duration, statewide to national in extent, and unique in context. The impact to the non-monetary economy is discussed in detail in Subsistence Section 4.10.6.15, but would be high intensity, long-term in duration, regional in extent, and important to unique in context. If a VLOS were to occur, there would be a major additive effect to the cumulative effects associated with Alternative 2 to socioeconomics.

4.11.4.14 Subsistence

4.11.4.14.1 Summary of Direct and Indirect Effects

Using the impact criteria identified in Table 4.2-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources and harvests resulting from implementation of Alternative 2 would be of low intensity, temporary in duration, local to regional in extent, and the context would be common to unique. Protected resources (bowhead whales and polar bears are considered unique in context as these resources are protected by legislation (e.g. MMPA, ESA) or are considered an important subsistence resource (beluga whales). Therefore the summary impact level of Alternative 2 on subsistence resources and harvests would be considered to range from negligible to moderate depending upon the specific subsistence resource affected and source of disturbance (Section 4.5.3.2).

4.11.4.14.2 Past and Present Actions

Numerous past and present actions (Section 4.11.2) have likely caused disturbances to subsistence resources and hunting/harvest activities that may be affected by the implementation of Alternative 2. Although most of these probable disturbances may not be occurring within the EIS project area they have occurred in the past and would likely continue to occur at several other locations within mapped subsistence harvest areas (Figure 3.3-13). Past and present actions that cause disturbance to subsistence activities throughout the ranges of harvested resources contribute to the overall disturbance levels on resources and affect the success of subsistence hunting, harvests and rates of sharing between communities.

Past and present actions include North Slope oil and gas exploration, development, and production activities including the construction and operation of the Trans-Alaska Pipeline System, permanent roads and winter ice roads; construction of support facilities; and transportation activities involving surface vehicles, aircraft or marine traffic along the coast or within the barrier islands. Issues with user access and disturbance associated with these activities have caused real and perceived impacts to subsistence activities and harvest success. The habitat of subsistence resources has previously experienced direct and indirect effects which in turn have affected subsistence harvest. For instance road construction, as well as pipeline construction, has destroyed some caribou habitat within the footprint of the road, and has also resulted in a reduction of habitat use by this subsistence resource and limited harvest areas available within the adjacent areas (Section 4.11.4.11).

Mining is an example of past and present activities with direct and indirect effects on marine mammals and caribou, such as the development and operation of Red Dog Mine. This mine is located within the Northwest Arctic Caribou Herd range and barge traffic occurs through marine mammals harvest areas of Kivalina hunters. Subsistence users from Kivalina have noted a change in the seasonal pattern of harvest of beluga whales since the mine has been operational (Section 4.5.3.2). Mining activities relative to subsistence resources include the loss of habitat within the foot print of the mine and its support facilities and vehicle traffic between the mine and the coast and maritime shipping traffic.

Scientific research such as the continuation of ongoing and special biological surveys, and geophysical studies using both surface and aircraft transportation along the coast lines and throughout the North Slope can affect subsistence hunting and harvest activities. Past and present scientific research activities are described in Table 4.10-3. Many of these activities have included vessel, aircraft and over ice-support that potentially disturbs marine mammals and terrestrial resource subsistence hunting and harvest activities along the coast.

Military activity in the Arctic is thought to have increased in recent years. Vessel traffic through open water, aircraft overflights and related maneuvers have likely and will continue to contribute to cumulative effects on subsistence resources and their harvest by hunters.

Past and present subsistence activities, such as routine travel to subsistence camps using aircraft, snow machines and boats along the coast and small boat traffic within the barrier islands causes some disturbance to the subsistence resources and rates of harvest of the resources that are utilizing those areas. It is unlikely that past subsistence bowhead whaling led to adverse effects on a population level. Subsistence harvests are currently the primary source of mortality for bowhead whales, with an average of about 40 takes per year (Suydam et al. 2011). The subsistence harvest is well-managed and regulated through a quota system by the IWC (Section 3.3.2). There is no indication of long-term adverse effects on the population from the level of take through the subsistence harvest (approximately 0.1 to 0.5 percent of the population per year [Philo et al. 1993b]) appears to be sustainable.

Recreation, tourism and sport hunting, as well as other recreational activities utilizing aircraft support also cause some level of disturbances to subsistence activities such as caribou hunting, fishing, and migratory bird hunting throughout the project area.

Subsistence hunters have noted that climate change has affected the trends and methods of subsistence harvest of marine mammals (Section 3.3.2.6). Changes in ice conditions have influenced the spring bowhead whale hunt in the Beaufort and Chukchi seas communities. Wainwright, Point Hope and Point Lay have recently been conducting fall bowhead whale hunts to provide for their communities and meet allotted quotas when ice conditions have been considered less dangerous than in recent spring seasons when it has been considered too dangerous for crews to hunt (Comstock 2011).

4.11.4.14.3 Reasonably Foreseeable Future Actions

The same factors external to offshore oil and gas exploration in the Beaufort and Chukchi seas that have affected subsistence harvests in the past and present (Table 4.10-1) are likely to continue in the future. Subsistence hunting will likely continue to be the largest source of direct human-induced mortality on marine mammals. Marine vessel traffic is anticipated to increase and vessels would include those used for used for fishing and hunting, cruise ships, icebreakers, Coast Guard vessels, supply ships, tugs, and barges. The retreat of sea ice will make navigation easier during the longer open ice periods and increases in the levels of commercial shipping and tourism are expected to occur (Arctic Council 2009). The reduced sea ice extent will likely open up the Northwest and Northeast Passages for maritime shipping. Offshore oil and gas exploration, mineral exploration and development are also likely to increase in Arctic waters of other countries (i.e. Canada, Russia and Norway) as the ice pack recedes and allows access to previously ice-covered areas. Icebreakers from other nations are expected to become increasingly more present in the Arctic seas contributing the levels of noise introduced into the marine environment which in turn could impact subsistence resources and rates of harvest. The distribution of subsistence resources could change if the disturbance or alters resource distribution and/or migratory patterns.

Onshore oil and gas exploration and production activities are expected to continue on the Alaskan North Slope. Reasonably foreseeable natural gas development projects (the Point Thomson production unit and a large diameter natural gas pipeline) could affect subsistence resources and harvests during their construction phases which involve sea lifts of processing facilities infrastructure and materials during the open water season and development of nearshore structures. Access to subsistence resources and subsistence-hunting areas could change if the disturbance reduces the availability of subsistence resources for harvest or alters species distribution and or migratory patterns.

Potentially toxic compounds will continue to be produced around the world and many could find their way to the Arctic. There is the potential that some contaminants may accumulate in marine and terrestrial subsistence resources and in turn may have human health implications.

The greatest concern for subsistence resources in the reasonably foreseeable future is the continued trends of Arctic warming and the resulting deterioration of sea ice conditions that are important to subsistence resources and users. Climate change affects the entire range of subsistence resources and eventually could adversely affect harvest rates and success. Climate change could lead to changes in diversity, abundance, and distribution of traditional subsistence resources and harvest patterns and in turn lead to rapid and long-term impacts on the availability of some subsistence resources. Changing ice conditions are noted as a threat to indigenous lifestyles and subsistence practices. As ice conditions deteriorate, travel to hunting areas, and hunting itself become more hazardous due to more hunting in open water. Larger and more expensive vessels and motors may be required (Forbes 2011).

4.10.4.14.4 Contribution of Alternatives to Cumulative Effects

The activities authorized under Alternative 2 would add to the disturbance of subsistence resources from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary and local. Of greatest concern would be potential effects on fall bowhead whale and other subsistence hunting activities associated with disturbance and behavioral responses. A low number of seals and polar bears could be disturbed during on-ice seismic surveys. Exploration activities would constitute a minor contribution to the disturbance of subsistence resources. Exploration activities could contribute to habitat change of subsistence resources through aircraft and vessel traffic, icebreaking efforts, on-ice surveys and discharge of drilling muds but these effects would be of low intensity, localized and temporary or short-term in duration, and affecting common to unique resources in context. This contribution to habitat change would be negligible when compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems and resource abundance due to ocean acidification. The exploration activities authorized under Alternative 2 would therefore have a negligible to moderate contribution to the cumulative effects on subsistence resources. Implementation of Alternative 2 would be considered additive to cumulative effects on subsistence resources.

4.11.4.14.5 Conclusion

Under Alternative 2, the direct and indirect effects to subsistence resources are considered low in intensity, temporary in duration, local to regional in extent and affect subsistence resources that range from common to unique in context. Implementation of Alternative 2 would be considered additive to cumulative effects on subsistence resources. The contribution of the direct and indirect impacts in consideration of the past, present, and reasonably foreseeable future actions would be negligible to moderate on subsistence, depending on the subsistence resources affected.

There would be a low probability of a VLOS occurring during exploratory drilling under Alternative 2. The implications for subsistence resources and harvests would depend on the amount and distribution of the accidental spill, especially in relation to the ice pack, and how quickly and thoroughly it could be cleaned up. A VLOS could contribute substantially to the cumulative effects of disturbance on marine mammals. This would be due to the large number of marine vessels and aircraft that would be involved in any clean-up effort, which would likely extend for more than one year and involve a large area. It could also contribute to injury and mortality of fish, marine and coastal birds and terrestrial resources which are important subsistence resources. If a VLOS were to occur, there would be a major additive effect to the cumulative effects associated with Alternative 2 to subsistence resources and harvests.

4.11.4.15 Public Health

4.11.4.15.1 Summary of Direct and Indirect Effects

As described in Section 4.5.3.3, both beneficial and adverse impacts on public health and safety could result from Alternative 2. Possible changes could occur to the numbers of people experiencing chronic disease and injury/trauma, primarily as a result of effects on traditional practices and subsistence activities. However, there is a very low likelihood of these health outcomes occurring, and effects are unlikely to be large enough cause a measurable change in health outcomes at a population level. The magnitude or intensity of effects is estimated to be low: above background conditions, but small and within both the natural variation and adaptive ability of the local population. If health changes do occur, the duration of changes may be permanent, and multiple communities could be affected.

4.11.4.15.2 Past and Present Actions

Over the last 50 to 100 years, as development and industrialization have increased, the population living in the EIS project area has experienced rapid modernization and acculturation, with significant changes in diet, housing, employment, and traditional culture. These changes have been accompanied by a shift in the burden of disease experienced by the population, as infectious disease and infant mortality have abated and chronic disease and cancer have become leading causes of death. This phenomenon, often known as the epidemiologic transition, is typical in any population as it develops, but is particularly acute in populations experiencing rapid modernization. Indigenous populations worldwide have seen particularly dramatic health changes over the last several decades as modernization has brought with it significant changes in diet, sociocultural systems and economic conditions. Circumpolar regions such as the EIS project area are particularly impacted.

Much of the change associated with this transition is for the better. For example, life expectancy increases, infant mortality decreases and age-specific mortality decreases. Rates of infectious diseases such as tuberculosis and vaccine-preventable illnesses also decline. Health care services, public health programs and municipal health infrastructure such as sanitation and water treatment also improve with development. Most population health indicators show that health in the EIS project area has significantly and steadily improved since the 1950s.

However, the epidemiologic transition also comes with some adverse health outcomes. The rates of chronic diseases such as cancer, cardiovascular disease and metabolic disorders rise. Health outcomes related to social conflict and stress also increase. In the EIS project area, as in most other circumpolar and indigenous populations, development has been commensurate with increases in alcohol and substance misuse, suicide, violence and other social dysfunction.

Much of this change in the burden of disease among the Iñupiat is a result of general development, economic growth and cultural change. The extent to which oil and gas development has contributed to it is unknown; however, there are well-documented causal pathways between oil and gas development activities and changes in both health determinants and outcomes, and local testimony supports the association of oil and gas with both positive and adverse health outcomes. Although the exact contribution of oil and gas development is unknown, its role as the primary driver of economic and industrial development in the region does support at least an indirect causal association.

However, the pattern of development and modernization that has taken place in the EIS project area has led to the creation of certain health areas that are of particular importance when considering cumulative effects. These include:

- **Injury and trauma.** The population living in the EIS project area experience high levels of injury and trauma, with high morbidity and mortality rates across most age groups. This is common in any rural or remote region and is particularly high in populations that engage in subsistence activities. These high rates of injury may be exacerbated by the way in which traditional subsistence activities have adapted to the presence of development – for example, hunters report that they need to travel farther to reach subsistence resources due to both a displacement of animals and to avoidance of industrialized areas.
- **Social pathologies such as alcohol and drug misuse, social dysfunction and violence.** Oil and gas development, with its large in-migrations of outside workers and influxes of money into the local economies, is associated with increased social pathology. In addition, the development of roads and seasonal access to the region increase opportunities to import alcohol.
- **Health disparities.** There already exist patterns of economic and health disparity within the EIS project area, with health outcomes and health determinants unevenly distributed within and across the population. Recent/present development, as well as future development has the potential to exacerbate these disparities both because of the uneven distribution of the "rewards" of development and because of uneven distribution of the risks.

4.11.4.15.3 Reasonably Foreseeable Future Actions

As described in Tables 4.10-1 through 4.10-7 and 4.10-9, there are a significant number of activities planned and/or approved in the EIS project area, including oil /gas exploration, development and production; scientific research activities; mining projects; military developments and activities; transportation plans; community development projects; and recreation and tourism activities. These future actions will continue to influence public health and safety. The common components of these future actions that are most likely to drive public health and safety outcomes are:

- A potential growth in population in the communities of the EIS project area;

- In-migration of workers not originally from the EIS project area;
- Economic changes at the level of both individual residents and the Native Corporations;
- Changes in the level or success of subsistence activities;
- Regional industrialization;
- Changes in/improvements to public infrastructure;
- Potential exposure to environmental contaminants;
- Changes in access to or use of the land; and
- Continued acculturation of the Iñupiat people and deterioration of sociocultural traditions.

As the reasonably foreseeable future actions continue the path and progress of development seen in past actions, it can be expected that the changes in public health and safety outcomes will follow the same trends that have been observed in recent years. These include:

- Improvements in general health indicators such as mortality and life expectancy;
- A shift in the burden of illness away from infectious disease and towards higher rates of chronic conditions;
- Changes in diet towards increased use of store-bought foods and associated changes in nutritional outcomes;
- Increasing disparities in health outcomes between the more-wealthy and the less-wealthy; and
- Increased rates of social ills including crime, violence, and alcohol and drug misuse.

Of particular significance for public health and safety is further increases in offshore oil and gas exploration, development and production following the demonstration of economically feasible opportunities. A ramp-up of offshore development has been posited by key informants to lead to potentially substantive changes in public health outcomes via three pathways: a) via displacement of marine mammals and the subsequent reduction of success and safety of subsistence hunting; b) via the potential for contamination and the fear of contamination through oil spills or routine discharge; and c) via substantially increased economic returns to the NSB, village corporations and individuals with resulting positive and negative health effects and disparities as outlined in Section 4.5.3.3.

4.11.4.15.4 Contribution of Alternative to Cumulative Effects

The effects on public health and safety resulting from Alternative 2 are likely to be low; and the direct contribution of the actions specified in Alternative 2 to cumulative effects on public health and safety should best be characterized as negligible. The pathways through which health effects would occur include diet and nutrition, contamination, safety, acculturative stress and economic impacts, as described in Section 4.5.3.3.

However, the health impacts of oil and gas development in the North Slope have been well documented in the past and insomuch as the activity in Alternative 2 will lead to further offshore oil and gas activity, there could be significant cumulative impacts in the future. These may also include health effects in other areas not anticipated through the direct and indirect effects of Alternative 2, such as increases in infectious disease and health outcomes related to air quality.

4.11.4.15.5 Conclusion

As described above, the contribution of the actions of Alternative 2 on public health and safety are likely to be negligible; however, the possibility of the exploration activity leading to further development raises the possibility of health consequences subsequent to this further activity.

As described in Sections 4.10.6.16 and 4.10.7.16, the magnitude of impacts from a VLOS would be medium to high, as some public health outcomes would be treatable and/or transient, but some may be irreversible. Some predicted public health effects would last for only a brief period and would be associated with the influx of workers during the Phase 4 clean-up period. However, health effects of a

VLOS resulting from changes in subsistence patterns would be likely to persist for many years. The geographic extent of the impact would vary depending on the size and location of the spill, but all EIS project area communities would be affected to some degree.

Alternative 2 therefore contributes to cumulative impacts on public health and safety via three mechanisms: a) the relatively small contribution of the direct and indirect impacts; b) acting as the gateway for additional future offshore oil and gas development; and c) and an unlikely but potentially large contribution from a VLOS. If a VLOS were to occur, there would be moderate to major additive effects to the cumulative effects associated with Alternative 2 to public health, depending on the size, nature, and location of the spill.

4.11.4.16 Cultural Resources

4.11.4.16.1 Summary of Direct and Indirect Effects

Direct and indirect impacts to cultural resources resulting from the implementation of Alternative 2 would be low-intensity and long-term in duration, but in a very localized area. Therefore, the summary impact level of direct and indirect effect from Alternative 2 for cultural resources is minor, not exceeding the significance threshold.

Direct effects to cultural resources include those activities that physically impact the condition or integrity of the resource. Specifically, construction of on-shore pipelines or staging areas could result in direct effects to surface or subsurface prehistoric or historic archaeological sites. Likewise, sea-floor based seismic activities and exploratory drilling could directly affect submerged prehistoric sites or historic vessels on the seafloor.

Indirect effects to offshore resources are unlikely, given that impacts would likely result during the exploratory phase of the project. Previously undiscovered resources, however, could be inadvertently damaged during this phase of the project. On-shore resources are more susceptible to indirect effects and can include inadvertent damage, looting caused by the introduction of increased access and local activity; and visual impacts to historic or traditional cultural properties.

4.11.4.16.2 Past and Present Actions

Past and present actions related to oil and gas exploration, development, production, and transportation are the main activities that have the potential to affect cultural resources in the EIS area. Currently there are 35 fields and satellites producing oil on the North Slope and in nearshore areas of the Beaufort Sea, and additional discoveries are under development. Specifically, these actions include North Slope oil and gas exploration, development, and production activities including the construction and operation of the Trans-Alaska Pipeline System, permanent roads and winter ice roads; construction of support facilities; and transportation activities involving surface vehicles, aircraft or marine traffic along the coast or within the barrier islands.

Mining is another example of past and present activities with direct and indirect effects on cultural resources, such as the development and operation of Red Dog Mine which is the world’s largest known zinc resource. As much as 25 million tons of high-grade zinc was estimated to be present near Red Dog Mine. Mining activities relative to cultural resources include ground-disturbing activities within the foot print of the mine and its support facilities and vehicle traffic between the mine and the coast.

Scientific research such as the continuation of ongoing and special biological surveys, and geophysical studies using both surface and aircraft transportation throughout the North Slope and Brooks Range can effect cultural resources with potential for ground disturbances along the coast.

Military activity in the Arctic, such as the development of the Distant Early Warning Line, also known as the DEW-Line, was a system of 63 radar stations located across the northern edge of the North American Continent, roughly along the 69th parallel. The radar stations were constructed between 1954 and 1957, and decommissioned during the 1990s. The Bullen Point site is currently managed by the U.S. Air Force and has a gravel airstrip and a small radar system.

Additionally, subsistence activities, such as routine travel to subsistence camps using aircraft, snow machines and boats along the coast or within the barrier islands cause some ground disturbance.

4.11.4.16.3 Reasonably Foreseeable Future Actions

There are numerous reasonably foreseeable future actions that may result in direct or indirect effects to cultural resources, through construction and operation of many projects, as well as the related activities of the associated human population expected to increase as a result. Oil and gas development will include the development of exploration and production facilities, road networks and support facilities.

The Alaska Pipeline Project near Prudhoe Bay will include facilities to treat, transport and deliver gas from the North Slope of Alaska to markets in North America, which will include the installation and operation of a gas treatment plant at Prudhoe Bay with construction targeted for 2014. The Point Thompson project, located about 60 miles east of Prudhoe Bay will include the construction of three production pads, process facilities, an infield road system, an export pipeline, infield gathering lines and an airstrip.

Mining exploration, development, and production are expected in increase, which includes operations at the Red Dog Mine and the Red Dog Port. The Red Dog Mine port site may also become the port facility for a very large proposed coal mining operation adjacent to the Chukchi Sea. In addition, coal mine prospecting proposals for the Brooks Range have been submitted to ADNR, Division of Mining, Land and Water (DMLW) for approval.

Military activity in the Arctic are expect to continue to increase in the foreseeable future. Activities may include training exercises and dismantling of DEW-Line sites (which may include demolition projects).

Routine travel and growth of transportation facilities is expected to continue within the North Slope. Activities associated with planned community development projects also have potential for direct and indirect effects on cultural resources. These include the Kaktovik airport project and ongoing water and sewage projects facilitated by the North Slope and Northwest Arctic boroughs.

Recreation and tourism will continue to increase, such as sport hunting, hiking, floating rivers, etc., particularly in the Arctic National Wildlife Refuge, as a result of elevated media exposure of the Refuge.

4.11.4.16.4 Contribution of Alternative to Cumulative Effects

The incremental contribution of activities associated with Alternative 2 to cumulative effects on cultural resources would be negligible.

4.11.4.16.5 Conclusion

Direct and indirect effects associated with Alternative 2 are considered to be minor. The incremental contribution of activities associated with Alternative 2 to cumulative effects on cultural resources would be negligible.

If a VLOS were to occur, there would be minor to moderate additive effects to the cumulative effects associated with Alternative 2 to cultural resources.

4.11.4.17 Land and Water Ownership, Use, Management

4.11.4.17.1 Summary of Direct and Indirect Effects

Land and Water Ownership

Based on Table 4.4-2, and the analysis provided in Section 4.5.3.5, the impacts on land and water ownership under Alternative 2 would be low in magnitude, temporary in duration, local in extent, and common in context. In total, the direct and indirect impacts on land ownership are considered to be negligible; they would result in no change of ownership or development rights.

Land and Water Use

Based on Table 4.4-2 and the analysis provided in Section 4.5.3.5, the impacts of land and water use caused by Alternative 2 would be high in magnitude where activity occurs in areas of little to no previous activity (such as Wainwright), and low in magnitude where activity occurs in areas where previous activity is common (Prudhoe Bay, Barrow, Nome, Dutch Harbor). Impacts would be temporary in duration, although the impact could be permanent if construction of a new facility or infrastructure to accommodate shipping traffic were built in Wainwright. The extent of impacts would be local and the context would be common. In summary, the direct and indirect effects of Alternative 2 on land and water use would be moderate.

Land and Water Management

Based on Table 4.4-2 and the analysis provided in Section 4.5.3.5, the impacts on land and water management caused by Alternative 2 would be low in magnitude temporary in duration, local in extent, and common in context. In total, the direct and indirect impacts of Alternative 2 on land and water management would be minor.

4.11.4.17.2 Past and Present Actions

Past and present actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 1, Section 4.4.1.2.

4.11.4.17.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 1, Section 4.4.1.2.

4.11.4.17.4 Contribution of Alternative to Cumulative Effects

The level of impact for land and water ownership under Alternative 2 would be negligible, and past, present, and reasonably foreseeable future actions are not expected to result in any changes in ownership. The level of impact on land and water use under Alternative 2 would be moderate, and duration would be short-term and seasonal in nature. With the possibility of some small changes in land use in the foreseeable future, the cumulative impact would remain moderate, as any additional changes in land use and water use would be incrementally small, short-term in duration and geographically dispersed. The level of impact on land management under Alternative 2 would be minor, and effects from past, present, and reasonably foreseeable future actions are negligible. Under Alternative 2, all changes would be incrementally small and geographically dispersed, and thus would not have combined effects creating cumulative impacts on land ownership, use, or management.

4.11.4.17.5 Conclusion

Under Alternative 2, the levels of direct, indirect and cumulative impacts for land and water ownership, use, and management would be negligible, moderate, and minor, respectively. Based on this, the overall level of impact is considered minor. The contribution of Alternative 2 to cumulative effects would be considered negligible.

If a VLOS were to occur, there would be major additive effects to the cumulative effects associated with Alternative 2 on land and water ownership, use, and management.

4.11.4.18 Transportation

4.11.4.18.1 Summary of Direct and Indirect Effects

Alternative 2 would increase the levels of air, roadway, and vessel traffic in the EIS project area. However, the increased traffic levels would be of low intensity, temporary, local in extent, and affecting resources considered common in context. As a result, the overall direct and indirect effects would be considered minor.

4.11.4.18.2 Past and Present Actions

Past and present actions such as: transportation of freight and local residents to, from, and between communities in the EIS project area; oil and gas exploration, drilling, and development; military development; mining; and tourism have included construction and expansion of local roads, airstrips, docks, seasonal ice roads, and the presence of vessels in the EIS project area. Coastal and marine vessel/barge traffic, fixed-wing and helicopter traffic, low-pressure tundra-travel, off road vehicles (four wheelers), snowmobile traffic, and vehicle traffic on local roadways have been generated as a result of these actions.

4.11.4.18.3 Reasonably Foreseeable Future Actions

It is reasonable to assume that trends associated with transportation to facilitate the maintenance and development of coastal communities, Red Dog Mine, and Prudhoe Bay area oil and gas facilities will continue. In some specific cases, described below, transportation and associated infrastructure in the proposed activity area may increase as a result of increased commercial activity in the area.

Aircraft Traffic: Existing air travel and freight hauling for local residents is likely to continue at approximately the same levels. Air traffic to support mining is expected to continue to be related to exploration because there are no new large mining projects in the EIS project area in the permitting process. Tourism air traffic will not likely change much because there are no reasonably foreseeable events that would draw large numbers of visitors to travel to or from the area using aircraft. Sport hunting and fishing demand for air travel will likely continue at approximately the same levels. Use of aircraft for scientific and search and rescue operations is likely to continue a present levels.

Oil and gas industry use of helicopters and fixed wing aircraft to support routine activities and exploration within the EIS project area is likely to increase as a result of increased interest in North Slope exploration. Air traffic would also increase if the Point Thomson Project or the Alaska Pipeline Project were constructed. These increases could cause congestion at the Deadhorse Airport during construction seasons.

Vehicle Traffic: None of the RFFAs propose to construct permanent roads to the communities in the EIS project area. Construction of ice roads could allow industry vehicles access to community roads, and likewise allow residents vehicular access to the highway system.

Vessel Traffic: Vessel traffic through the Bering Strait has risen steadily over recent years according to USCG estimates, and Russian efforts to promote a Northern Seas Route for shipping may lead to continued increases in vessel traffic adjacent to the western portion of the EIS project area.

In addition, research vessels, including NSF and USCG icebreakers, also operate in the EIS project area. USCG anticipates a continued increase in vessel traffic in the Arctic. Cruise ships and private sailboats sometimes transit through the proposed action area. Changes in the distribution of sea ice, longer open-water periods, and increasing interest in studying and viewing Arctic wildlife and habitats may support an increase in research and recreational vessel traffic in the proposed action area regardless of oil and gas activity.

Increased barge traffic would occur if the Point Thomson Project or the Alaska Pipeline Project were constructed during the time period covered under this EIS. Coastal barges would support these projects by delivering fuel, construction equipment, and materials and sea lift barges would deliver modules for processing and camp facilities. If realized, this would result in additional barge traffic transiting through the EIS project area but potential for congestion would only be expected near Prudhoe Bay docks and only during construction. Offshore oil and gas exploration drilling would also result in some additional tug and barge, support, icebreaker, and other vessel traffic (Petroleum News 2011a) that could contribute to congestion if they used Prudhoe Bay area docks.

4.11.4.18.4 Contribution of Alternative to Cumulative Effects

Alternative 2 would be expected to have minor direct and indirect impacts on transportation infrastructure. Alternative 2 could cause a minor increase in vessel activity in the area, potentially adding to the congestion that would be expected at Prudhoe Bay docks if large projects such as Point Thomson or the Alaska Pipeline Project were being constructed simultaneously. It is likely however that dock operators would schedule vessel callings to reduce potential for congestion and operate continuously to speed the servicing of vessels and barges. Barge traffic would cease in the winter and continue at a reduced frequency during the open water season when the proposed projects are in operation.

Likewise, Alternative 2 could result in increased air travel through the EIS project area. This could contribute to congestion at the Deadhorse Airport if major projects were also being constructed. Airlines would probably increase the number of flights during the busiest seasons and the flight volume would be within the overall capacity of the system. Following construction, there would be a modest long-term increase in flights to support operation of newly constructed projects.

Alternative 2 could cause minor temporary increases in local road traffic when aircraft or vessels use local community airstrips or docks. RFFAs are unlikely to increase local traffic to levels approaching a use that could interrupt service or cause congestion and the combined total local road traffic would not be expected to result in congestion.

4.11.4.18.5 Conclusion

In summary, no concerns related to adverse cumulative impacts have been identified. Some cumulative impacts may exist if Alternative 2 overlaps with large-scale development projects but those impacts would be of low intensity, temporary in duration affecting local areas of common resources, and are considered unlikely to have long-term impacts on regional transportation infrastructure.

A VLOS would be considered an additive adverse long term impact to cumulative impacts of transportation. Following a VLOS cumulative impacts to transportation in the Beaufort and Chukchi seas could be of high intensity (potentially year round), and long-term in duration lasting one to two years or more during response and surveillance monitoring during recovery. The extent would be regional to statewide extent, and important in context. If a VLOS were to occur, there would be moderate additive effect to the cumulative effects associated with Alternative 2 on transportation.

4.11.4.19 Recreation and Tourism

4.11.4.19.1 Summary of Direct and Indirect Effects

As discussed in Section 4.5.3.7, the direct impacts on recreation and tourism would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the direct and indirect impacts associated with Alternative 2 on recreation and tourism would be minor.

4.11.4.19.2 Past and Present Actions

Recreation and tourism occur at generally low levels of use in the EIS project area and are more common onshore (hiking, river float trips) than offshore (small cruise ships, kayaking). It is important to distinguish between recreation and subsistence uses. The vast majority of fishing, hunting, and boating that occurs in the EIS project area are *subsistence*-based, managed completely apart from *recreation*-based activities, with separate rights and privileges (see Section 4.5.3.2, Subsistence for further discussion). Past activities that have affected recreation include the discovery of oil and natural gas, and the resulting development of Deadhorse, industrial support facilities in the vicinity of Barrow, and the construction and operation of the Dalton Highway. The EIS project area became more accessible to recreationists, including minimal accommodations. Another past action that affected recreation and tourism use was the designation of the Arctic National Wildlife Refuge (ANWR). The designation brought attention to the area; it became a destination for recreation and tourism. All of these factors may have increased levels of recreation and tourism in the EIS project area. However, total recreation and tourism use in the EIS project area remains low, and impact would be minor.

4.11.4.19.3 Reasonably Foreseeable Future Actions

Most of the North Slope areas are underused for recreation and have the potential to support increased levels of recreation use in the future. The continuation of development for oil and natural gas drilling is highly likely. As development increases, the increase in noise and visibility, and simply the knowledge of the existence of industrial development is expected to impact the setting for recreation. Despite this, continued development may make the North Slope more accessible, and as a result bring more recreationists and tourists. As infrastructure improves and accommodations are increased in places like Deadhorse and Wainwright, there is a higher possibility that people would go to those places to recreate, or use those areas as a base to access recreation opportunities. Overall impact would be minor; recreation and tourism levels will not increase or decrease substantially in the foreseeable future.

4.11.4.19.4 Contribution of Alternative to Cumulative Effects

Under Alternative 2, the direct and indirect effects to recreation and tourism would be minor. The contribution of the direct and indirect impacts to the past, present, and reasonably foreseeable future actions would be minor; the additional demands on the recreation setting would be low, and the levels of activities are expected to remain low. Recreation and tourism would not be stressed to a point that would cause an irreversible impact. Therefore, the contribution of Alternative 2 to cumulative effects to recreation and tourism would be minor.

4.11.4.19.5 Conclusion

The direct and indirect impacts associated with Alternative 2 on recreation and tourism would be minor. Alternative 2 would have a minor contribution to cumulative effects on recreation and tourism.

In the event of a VLOS, offshore and coastal settings would be altered by the amount of vessels, aircraft, and support for response. The recreation setting in the EIS project that would be most affected would be near the water, and activities would be affected by the presence of the response teams and the oil; particularly wildlife viewing, fishing and yachting. If a VLOS were to occur, there would be major additive effect to the cumulative effects associated with Alternative 2 on recreation and tourism.

4.11.4.20 Visual Resources

4.11.4.20.1 Summary of Direct and Indirect Effects

Alternative 2 would include vessel-based surveys implemented in the Beaufort and Chukchi seas, and a single exploratory drilling program in both the Beaufort and Chukchi seas. Although the actions associated with this alternative could occur across the EIS project area, actions would primarily be seen from population centers located east of Barrow, extending to the Canadian border (including the ANWR). Due to the distances offshore, views of the proposed project in the Chukchi Sea would be restricted to those of industrial workers or commercial marine traffic occurring in offshore locations in the Chukchi and would not be detected by any sensitive viewer groups located in on-land or near-shore locations (see Section 3.3.9.7 for a description of viewer groups).

Seismic and hazard survey operations would not require a construction phase. Implementation of seismic and hazard surveys is expected to result in weak visual contrast where actions occur at close proximity (within 3 to 5 miles) to on-land and near-shore locations state waters of the Beaufort Sea. Visual contrast is expected to attenuate beyond 5 miles due to the scale of the vessels relative to the landscape and the transient nature of the proposed action.

The exploratory drilling program would include construction, operation, and decommissioning phases. Construction-related impacts may occur as part of exploratory drilling programs situated in state waters (located within 3 miles) of the Beaufort Sea. Construction-related actions would result in a temporary increase in marine barge, vehicle, and potentially air traffic around localized drill site(s). Such actions would contribute color, angular lines, and movement to the landscape; however, because oil and gas activity is underway in this area, change in visual resources and scenic quality as a result of construction of drill site(s) is not expected to create visual contrast or attract attention of the casual observer.

During the operational phase, the moderate to strong visual contrast may result from operation of drill sites, particularly where situated within five miles of viewers. Like vessel traffic, visual contrast of drilling facilities (i.e. ice islands) and lighting would be maximized where viewed from proximate locations and would attenuate with distance from the viewer. Project-related actions in the nearshore Beaufort Sea would be viewed by both highly sensitive viewers from the Alaska Native community of Nuiqsut and viewers located in the industrial centers of Deadhorse and Prudhoe Bay characterized as having low visual sensitivity.

Standard mitigation measures implemented as part of the proposed action would not alter the level of anticipated impacts to visual resources or scenic quality. Although Category D Mitigation Measures would limit exposure of sensitive viewers (individuals engaged in the culturally important activity of bowhead whaling) to vessel-based surveys during certain periods. However it would not change exposure to drill sites, as these structures would remain in place during shutdown periods unless the operator agrees to move off location during such shutdown periods.

In conclusion, implementation of Alternative 2 is expected to result in *short-term moderate effects* to scenic quality and visual resources. Potential impacts could be of low to medium intensity depending on specific location of drill sites. The geographic extent of potential impacts would be localized; however they would occur in an important ecosystem.

4.11.4.20.2 Past and Present Actions

Large scale oil and gas exploration is a major component of the landscape character of the West Beaufort Sea analysis unit, located on the North Slope. Oil and gas-related development has occurred in this area since the 1940's, with major onshore development in Prudhoe Bay and offshore exploration in the Beaufort and Chukchi seas underway by the 1970s. Development and production in the near shore Beaufort Sea began in the early 1980s. The TAPS was completed in 1977, providing a transport mechanism to move oil from the North Slope to Valdez, AK. Industrial development is primarily situated on the Beaufort Sea. Onshore and near-shore (within three miles) activity extends from the Colville River Unit west of Wainwright, east to the Badami Unit, and includes discrete industrial facilities connected by a network of roads, pipelines. Recent discoveries have led to at least six additional offshore operations in the Beaufort Sea; three of which are supported by on on-shore production facilities (MMS 2008). Currently, 35 fields and satellites producing oil are in operation on the North Slope and in near-shore areas of the Beaufort Sea.

Cultural modification is the most defining landscape characteristic separating the West Beaufort Sea analysis unit from other analysis units. This unit is characterized by ongoing oil and gas activity. Views of the EIS project area from native communities and industrial nodes along the shoreline of this unit would experience views of existing on- and offshore oil and gas activity. Viewers situated along the shoreline of the adjacent East Beaufort analysis unit may also experience views of on- and offshore oils and gas development. Developments may be long-term or temporary. Developments appear as compact areas of dense development with distinct vertical lines that contrast color, texture and reflexivity to varying extents with the surrounding landscape. When viewed from the EIS project area, the low-lying, horizontal lines of onland roads and pipelines blend with predominant horizontal lines of the landscape; however, when viewed from the air, the broad network of linear roads and pipelines are apparent. In contrast, because much of the oil and gas activity occurs approximately 75 miles offshore in the Chukchi Sea, these areas are not seen by viewer group's located on-land, and are rarely observed by non-industrial marine travelers.

4.11.4.20.3 Reasonably Foreseeable Future Actions

Several reasonably foreseeable future actions are planned for the EIS project area that may affect visual resources. Actions include:

- Natural gas-related development, including a pipeline, and expansion of near shore and shore-based natural gas production facilities.
- State of Alaska lease sales in the near-shore portions of the Beaufort Sea.
-
- Construction and operation of the Point Thompson Project located 60 miles east of Prudhoe Bay.

The reasonably foreseeable future actions listed above are expected to affect visual resources during both construction and operation phases. Actions would be seen from population centers located east of Barrow, extending to the Kaktovok, nearshore areas, and from the air. Construction-related impacts are expected to result from heightened activity due to increase in personnel, air and marine traffic, including sealifts, channel dredging, and modifications of an existing structure (i.e. Dock Head, airstrips). All projects would require installation of temporary work camps and access roads to support construction activities. Operations-related impacts are expected to result from the expanded footprint of industrial nodes – including associated light and movement -- particularly due to the operation of the Point Thomson Project in a geographically distinct area located 60 miles to the east. Reasonably foreseeable future actions are expected to have a major effect on visual resources as the cumulative actions would be high intensity, long-term, local in geographic extent, and affecting an important resource.

4.11.4.20.4 Contribution of Alternative to Cumulative Effects

Implementation of Alternative 2 would contribute to cumulative effects by increasing the industrial character of the area through introduction of an exploratory drilling structure and associated support vessels. Impacts are expected to be greatest if exploratory drilling is implemented in near-shore areas of the Beaufort Sea, between Harrison Bay and Kaktovik, where the majority of past, present, and reasonably foreseeable future actions are located. This area coincides with locations of sensitive viewers, including native communities or recreators using the ANWR. Transient views of seismic and shallow hazard survey vessels are not expected to contribute to the industrial character of the area, as views of vessels would be episodic. Proposed actions on the Chukchi Sea are, likewise, not expected to contribute to cumulative effects, as actions are separated geographically from reasonably foreseeable future actions.

4.11.4.20.5 Conclusion

Under Alternative 2, anticipated cumulative effects to visual resources are expected to be major. Impacts would be of high intensity, long-term in duration, regional in geographic extent and occurring in an important context.

If a VLOS were to occur, there would be major additive effect to the cumulative effects associated with Alternative 2 on visual resources, as the event would be high intensity, long-term or permanent, extended in scope, and would affect an important resource.

4.11.4.21 Environmental Justice

4.11.4.21.1 Summary of Direct and Indirect Effects

Impacts to Subsistence Foods and Human Health

Activities related to implementation of Alternative 2 would have a low intensity impact to the number of marine mammals harvested for subsistence use and access to marine mammals. Impacts would be of a temporary duration and would occur over a regional extent to unique Iñupiat communities.

Activities associated with Alternative 2 are expected to cause low intensity health outcomes (within normal human variation) due to potential exposure to contamination from subsistence foods. The changes in health would be long-term, persisting after the actions cease, and would be regional in extent. Alternative 2 may have an indirect effect of adding to the perception that subsistence foods are contaminated and alter confidence in their consumption. Subsistence foods and human health are unique resources, protected under the MMPA and Executive Order 12898. Thus, the direct and indirect effects of Alternative 2 to subsistence would be minor. Thus, the direct and indirect effects of Alternative 2 to public health would be minor.

4.11.4.21.2 Past and Present Actions

Impacts to the abundance and distribution or access to subsistence resources associated with past and present actions are described in Subsistence Section 4.11.4.14.

Impacts to subsistence foods and impacts to health indicators from past and present actions are described in the Public Health Section 4.11.4.15.

4.11.4.21.3 Reasonably Foreseeable Future Actions

Future industrial activities in the Arctic (including oil and gas exploration and production, mining, military activity, shipping) have the potential to impact the environmental justice indicators of subsistence and public health. Climate change can affect temperature, ice conditions and ocean circulation which can adversely impact abundance and distribution of subsistence resources. Therefore, climate change can have an indirect adverse impact on subsistence access and public health.

4.11.4.21.4 Contribution of Alternative to Cumulative Effects

The incremental contribution of Alternative 2 to the overall industrial activity in the area includes a potential: increase in contamination of subsistence foods; increased perception of contamination of subsistence foods; overall decrease in access or availability of subsistence resources; and decline in public health indicators. The contribution of Alternative 2 to subsistence cumulative effects would be minor because the impacts to subsistence resources and uses would be low intensity, temporary duration, regional in extent, and unique in context. The contribution of Alternative 2 to public health cumulative effects would be similar to subsistence except the duration would be long-term. Therefore, the contribution to cumulative effects of these environmental justice indicators would be minor.

4.11.4.21.5 Conclusion

The direct and indirect effects of Alternative 2 would be minor. The contribution to the cumulative effects of environmental justice indicators would be minor. Therefore, there would be a disproportionate impact to Alaska Natives in the EIS project area.

In the event of a VLOS in the Beaufort or Chukchi Sea, an indirect impact of the proposed action to issue G&G permits and ITAs for an exploratory drilling program, the allocation quota for bowhead whales would be reduced. The intensity of the VLOS on subsistence resources and subsistence harvest would be of high intensity and cause a year round change in subsistence use patterns. Subsistence harvests of marine mammals, fish, migratory birds and caribou would be affected by direct contact with oil and the presence of the response equipment and personnel. Subsistence harvests could be altered long-term to permanent in duration. The impacts of a VLOS in the Beaufort Sea would be high intensity, long-term to permanent in duration, regional to statewide in extent, and affecting resources that are unique and important in context. In summary, the impact of a VLOS on subsistence harvest would be major.

In addition to the long-term impacts on sociocultural systems, a VLOS could cause a large influx of outside workers that could spread infectious disease and strain the health care system in villages used as staging areas, and respiratory irritation or illness related to air quality. The greatest and most persistent impacts to public health would result from the stress, anxiety and changes to subsistence harvest patterns. Adverse public health effects would be medium to high in intensity because some are treatable and/or transient, but some effects may be irreversible. These health effects may be temporary to permanent lasting for a brief period or persisting for many years in two more communities in the EIS project area. In summary, the impact of a VLOS on public health would be moderate to major depending on the nature and location of the spill.

Therefore a VLOS would have disproportionate adverse additive impacts to Alaska Natives living in communities near the EIS project area.

4.11.5 Alternative 3 – Authorization for Level 2 Exploration Activity

4.11.5.1 Physical Oceanography

4.11.5.1.1 Summary of Direct and Indirect Effects

The effects of Alternative 3 on physical ocean resources would be medium-intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. Under Alternative 3, changes in water depth resulting from exploratory drilling programs would be the same in nature as those described for Alternative 2. Alternative 3 would allow additional drilling programs in the EIS project area, and as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact could effectively be doubled. Relative to Alternative 2, water depth would be affected over a larger area. Construction of artificial islands, which could occur in nearshore state waters of the Beaufort Sea at a rate of two islands per year under Alternative 3, would result in medium-intensity, permanent/temporary (permanent if gravel, temporary if ice), localized effects on nearshore currents in the waters adjacent to the artificial islands. Relative to Alternative 2, sea ice would be affected over a larger area due to more extensive icebreaking activity and thermal inputs associated with exploratory drilling activities. Although common resources would be affected across increased spatial and temporal scales relative to Alternative 2, the overall effects of Alternative 3 on physical ocean resources in the EIS project area would be minor, particularly with the implementation of additional mitigation measures related to reducing or eliminating certain discharge streams.

4.11.5.1.2 Past and Present Actions

Past and present actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.5.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.5.1.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 3 would cause localized minor impacts to physical ocean resources in the EIS project area. While some actions associated with Alternative 3, such as the construction of man-made gravel islands, would interact in a synergistic fashion with past, present, and reasonably foreseeable future actions to influence physical ocean resources in the EIS project area, the impacts resulting from such synergies would represent only a small fraction of foreseeable cumulative impact.

4.11.5.1.5 Conclusion

The incremental contribution of activities associated with Alternative 3 to cumulative effects on physical ocean resources in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with physical ocean resources were discussed under Alternative 2 (Section 4.11.4.1).

4.11.5.2 Climate & Meteorology

4.11.5.2.1 Summary of Direct and Indirect Effects

Alternative 3 would directly emit more GHGs than Alternative 2; however direct impacts to climate change are estimated to have the same level of impact (minor) due to their low magnitude and low contribution to GHG emissions on a state level. Due to uncertainties in the outcome of exploration activities, indirect effects associated with Alternative 3 are assumed to be the same as those for Alternative 2: minor to moderate.

4.11.5.2.2 Past and Present Actions

Past and present actions affecting climate change are discussed under Alternative 2, Section 4.11.4.2.

4.11.5.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting climate change are discussed under Alternative 2, Section 4.11.4.2.

4.11.5.2.4 Contribution of Alternative to Cumulative Effects

Alternative 3 would directly emit more GHGs than Alternative 2; therefore it would directly contribute more to cumulative climate change impacts than Alternative 2. Alternative 3 would result in approximately 82,308 tpy more CO_2e emissions than Alternative 2 (See Sections 4.5.1.2 and 4.6.1.2). Alone, this difference would not result in a noticeably larger cumulative effect than Alternative 2. However, when accounting for all past, present, and future projects with GHG emissions, even a minor contribution such as 82,308 tpy of CO_2e per project, can cumulatively result in a perceptible impact. Therefore, Alternative 3 could have a larger impact on cumulative impacts to climate change than Alternative 2. Indirect effects from Alternative 3 are expected to have the same contribution to cumulative effects as Alternative 2, resulting in observable, global changes that could be long-term and could affect unique resources.

4.11.5.2.5 Conclusion

Due to the additive and synergistic nature of GHG emissions on climate change impacts, Alternative 3 could contribute to a moderate to major cumulative impact to climate change.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with climate change were discussed under Alternative 2 (Section 4.11.4.2).

4.11.5.3 Air Quality

4.11.5.3.1 Summary of Direct and Indirect Effects

The air quality effects due to the worst-case activity under Alternative 3, Level 2 Exploration Activity, are expected to be the same as those predicted for Alternative 2. The emissions would be moderate in magnitude, and minor in duration, extent, and content. The total emissions from the Level 2 Exploration

Activity is greater than that for Level 1 Exploration Activity, however the overall direct effect on air quality is expected to be moderate. Indirect effects on air quality would remain at negligible to minor.

4.11.5.3.2 Past and Present Actions

Past and present actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.5.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.5.3.4 Contribution of Alternative to Cumulative Effects

As with Alternative 2, Alternative 3 has the potential to contribute to future cumulative effects on air quality if activities occur during the same time period(s) and vicinity of any of the actions identified above that have the potential to affect air quality. Because of the short time duration for activities, cumulative effects would be highly dependent on actual meteorological conditions at the time, and the relative location of sources. The cumulative effects would be negligible (lower than the sum of the total maximum effects). There are no accumulative or synergistic effects associated with air quality.

4.11.5.3.5 Conclusion

Alternative 3 has the potential to contribute to cumulative effects on air quality when activities occur in the vicinity of other sources of air pollution. Due to distance between activities, and the mobile and intermittent source activities, the cumulative effects are expected to be less than the sum of each, likely remaining moderate in magnitude.

The additive effects resulting from a VLOS within the seas Arctic OCS associated with air quality were discussed under Alternative 2 (Section 4.11.4.3).

4.11.5.4 Acoustics

4.11.5.4.1 Summary of Direct and Indirect Effects

The summary of direct and indirect effects provided in Section 4.11.4 (Alternative 2) is relevant also for Alternative 3. The overall impact rating for direct and indirect effects to the acoustic environment under Alternative 3 would be moderate.

4.11.5.4.2 Past and Present Actions

The past actions for Alternative 3 are the same as listed for Alternative 2 (Section 4.11.4.4). The present actions will consist of up to six deep penetration seismic surveys in the Beaufort Sea and up to five seismic surveys in the Chukchi Sea. This alternative also allows for up to five site clearance and high resolution shallow hazards surveys in Beaufort and five of these surveys in the Chukchi. Up to two drilling programs in each of the Beaufort and Chukchi seas and one on-ice seismic survey would be permitted.

4.11.5.4.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting acoustics within the EIS project area are discussed under Alternative 2, Section 4.11.4.4.

4.11.5.4.4 Contribution of Alternative to Cumulative Effects

This alternative permits the highest level of activity of all alternatives. The possibility of up to six deep-penetration seismic surveys and five site clearance and high resolution shallow hazards surveys with inclusion of two potential drilling operations in the Beaufort Sea open water season produces substantial total disturbance zone areas. Marine mammals could have difficulty navigating between the disturbance zones surrounding each of the surveys and drill operations if these activities were performed concurrently. The concurrent operation of multiple noise sources could lead to confusion by marine mammals at choosing a path to avoid regions of high noise. If cumulative SEL criteria for auditory system injury were considered, the total effects of exposures to multiple operations could be substantially greater than from individual activities. The large number of deep penetration seismic surveys would be the primary source of higher cumulative exposures.

Cumulative effects in the Chukchi Sea would be fewer than in the Beaufort Sea because the marine mammal migration corridors there are less concentrated. There would consequently be more opportunity for migrating marine mammals to choose paths between the surveys and drilling locations to avoid passing close to individual operations where noise levels are highest.

4.11.5.4.5 Conclusion

Cumulative effects from noise exposures to marine mammals under Alternative 3 are similar but larger than the effects described for Alternative 2 due to the greater number of noise-generating activities that would be permitted. The ability of marine mammals to avoid close approaches to seismic survey sources would be reduced when many sources were concurrently in operation with limited spatial separation. These animals would therefore be exposed to higher sound levels and higher cumulative sound levels than if fewer concurrent operations were present.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with acoustics were discussed under Alternative 2 (Section 4.11.4.4).

4.11.5.5 Water Quality

4.11.5.5.1 Summary of Direct and Indirect Effects

Impacts to water quality from Alternative 3 would be the same in nature as those described for Alternative 2 in Section 4.11.4.5. The only difference between the two alternatives is the level of activity. Alternative 3 would allow additional surveys and exploratory drilling programs in the EIS project area, and as a result of the additional drilling programs, the intensity as well as the spatial extent of the impacts may effectively be doubled. Relative to Alternative 2, water quality parameters may be affected over larger areas and over longer periods of time. However, the effects of Alternative 3 on water quality would be low intensity, temporary, and localized to areas in the immediate vicinity of the activities. Although common resources may be affected across increased spatial scales relative to Alternative 2, the overall effects of Alternative 3 on water quality are expected to be minor.

4.11.5.5.2 Past and Present Actions

Past and present actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.5.5.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.5.5.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 3 would cause temporary local impacts to water quality such as increases in temperature, turbidity, and concentrations of pollutants. Some actions associated with Alternative 3, such as discharges of cooling water and waste material, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to water quality. These interactions would be local and temporary and would represent only a small fraction of foreseeable cumulative impact.

4.11.5.5.5 Conclusion

The incremental contribution of activities associated with Alternative 3 to cumulative effects on water quality in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with water quality were discussed under Alternative 2 (Section 4.11.4.5).

4.11.5.6 Environmental Contaminants and Ecosystem Functions

4.11.5.6.1 Summary of Direct and Indirect Effects

Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 3 would be medium-intensity, temporary, and local. Regulation functions such as nutrient cycling and waste assimilation, which depend on biota and physical processes to facilitate storage and recycling of nutrients and breakdown or assimilation of contaminants, would be affected within the EIS project area. While the geographic extent of such impacts would potentially be greater than that resulting from Alternative 2, the overall geographic extent of impacts to regulation functions would be limited. Habitat functions, particularly those related to benthic habitats, would be impacted as a result of discharges and other activities associated with exploratory drilling. Production functions including primary productivity and subsequent transfers to higher trophic levels could potentially be impacted as a result of activities associated with Alternative 3, while the effects of Alternative 3 on information ecosystem functions would depend upon interrelationships between impacts to cultural resources, social resources, and aesthetic resources, which are addressed in other sections of this EIS. Overall effects of Alternative 3 on ecosystem functions would be minor.

4.11.5.6.2 Past and Present Actions

Past and present actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.5.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.5.6.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 3 would cause localized minor impacts to environmental contaminants and ecosystem functions within the EIS project area. Some actions associated with Alternative 3, such as discharges from exploratory drilling operations, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to ecosystem functions. Relative to Alternative 2, these interactions would potentially be distributed over a greater geographic area. The impacts resulting from such interactions would represent a relatively small fraction of foreseeable cumulative impact, and the accumulation of impacts is unlikely to be substantial over the lifespan of this EIS.

4.11.5.6.5 Conclusion

The incremental contribution of activities associated with Alternative 3 to cumulative effects on environmental contaminants and ecosystem functions in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with environmental contaminants and ecosystem functions were discussed under Alternative 2 (Section 4.11.4.6).

4.11.5.7 Lower Trophic Levels

4.11.5.7.1 Summary of Direct and Indirect Effects

Alternative 3 is the same as Alternative 2 except with increased levels of activity. The impacts discussed in Section 4.11.4.7 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to lower trophic levels. The conclusions for Alternative 2 are applicable to Alternative 3; therefore, the overall impact to lower trophic levels would be minor.

4.11.5.7.2 Past and Present Actions

Past and present actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.5.7.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.5.7.4 Contribution of Alternative to Cumulative Effects

Alternative 3 would have the same types of effects as Alternative 2 but the increased level of exploration activities under Alternative 3 would add incrementally to its contribution to cumulative effects on lower trophic levels. However, the conclusions about Alternative 3 would be similar to Alternative 2 discussed in Section 4.11.4.7 and the overall impact would be moderate. In the absence of a very large oil spill, the exploration activities authorized under Alternative 3 would have moderate contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on lower trophic levels.

4.11.5.7.5 Conclusion

Alternative 3 could have a moderate contribution to cumulative effects on lower trophic organisms.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with lower trophic levels were discussed under Alternative 2 (Section 4.11.4.7).

4.11.5.8 Fish and Essential Fish Habitat

4.11.5.8.1 Summary of Direct and Indirect Effects

The overall impact of Alternative 3 on Fish Resources and EFH is minor. Despite a substantial increase in level of activity over Alternative 2, there would be no corresponding increase in the overall impact level. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 3, there would be no measurable effect on the resource.

The direct and indirect effects on marine fish resulting from Alternative 3 would be very similar to those described under Alternative 2. Due to the uneven nature of the increases in activity levels by activity type, the increase in impacts to different fish assemblages would vary. The cryopelagic assemblage would have essentially no additional impacts, as the level for activities likely to affect that group (icebreaking and on-ice seismic surveys) would not change from Alternative 2. Demersal assemblages, on the other hand, would feel the additional effects from the increase in seismic survey levels and exploratory drilling, both in terms of habitat loss and the effects from noise. Pelagic assemblages would be impacted by the increase in surveys but less so by the increased drilling programs. However, in spite of the potential for different resource groups to experience uneven increases in level of effect, the overall impact would remain the same given the limited area affected compared to the distribution of fish populations. The impacts to marine fish would be considered minor.

The direct and indirect effects on migratory fish resulting from Alternative 3 would be very similar to those described under Alternative 2. Because anadromous fish are more likely to be impacted by the activity types than amphidromous fish, as discussed under Alternative 2, they are likely to experience a disproportionate increase in adverse impacts when the two groups are compared. However, as described in Alternative 2, those anadromous species known to inhabit the area where project activities would occur are not very abundant, and they are unlikely to be impacted. Therefore, the overall impact to the resource group would remain the same. The impacts to migratory fish would be considered negligible.

The direct and indirect effects on essential fish habitat resulting from Alternative 3 would be very similar to those described under Alternative 2, with an increase in effects due to the increase in oil and gas exploration activities. In particular, the increase in exploratory drilling programs would result in increased habitat loss and alteration, potentially to EFH for saffron cod and salmon. Since there would be no increase in icebreaking activities, EFH for Arctic cod would be impacted the least. The opportunity for habitat loss or alteration resulting from Alternative 3 is very small and only incrementally larger than for Alternative 2. Most impacts would be of such low intensity and of such small geographic extent that the effects would be considered minor.

4.11.5.8.2 Past and Present Actions

Past and present actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.5.8.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.5.8.4 Contribution of Alternative to Cumulative Effects

Climate change is the only past, present, or reasonably foreseeable future action that is anticipated to have any measurable effect on fish and EFH within the EIS project area, and those effects are likely to be beneficial. As Arctic waters warm, productivity is likely to increase, thereby creating more favorable fish habitat throughout the region. The lack of measurable effect on fish and EFH resulting from the implementation of Alternative 3 would not add to any cumulative effects.

4.11.5.8.5 Conclusion

Direct and indirect impacts resulting from Alternative 3 on fish and EFH would be of such low intensity and of such small geographic extent that the effects would be considered minor. The incremental contribution of activities associated with Alternative 3 to cumulative effects on fish would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with fish and EFH were discussed under Alternative 2 (Section 4.11.4.8).

4.11.5.9 Marine and Coastal Birds

4.11.5.9.1 Summary of Direct and Indirect Effects

As discussed in Section 4.6.2.3, the effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. In summary, the impact of Alternative 3 on marine and coastal birds would be considered negligible to minor.

4.11.5.9.2 Past and Present Actions

Past and present actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.5.9.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.5.9.4 Contribution of Alternative 3 to Cumulative Effects

Alternative 3 would have the same types of effects as Alternative 2 but the increased level of exploration activities under Alternative 3 would add incrementally to its contribution to cumulative effects on marine and coastal birds. However, the conclusions about Alternative 3 would be similar to Alternative 2 (4.11.4.9). The exploration activities authorized under Alternative 3 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds.

4.11.5.9.5 Conclusion

The direct and indirect effects of Alternative 3 on marine and coastal birds would be considered negligible to minor. Alternative 3 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds, as discussed under Alternative 2 (Section 4.11.4.9).

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with marine and coastal birds were discussed under Alternative 2 (Section 4.11.4.9).

4.11.5.10 Marine Mammals

4.11.5.10.1 Bowhead Whales

4.11.5.10.1.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 3 on bowhead whales are described in Section 4.6.2.4.1 and are summarized here. Impacts of individual activities associated with oil and gas exploration in the EIS project area under Alternative 3 are similar to Alternative 2. Despite a substantial increase in level of activity over Alternative 2, the overall impact level would be the same (See Section 4.11.4.10.1).

In terms of the impact criteria identified in Table 4.5-17, most effects of individual exploratory activities authorized under Alternative 3 are of medium intensity and temporary in duration. Potential long-term effects from repeated disturbance over time or over a broad geographic range are unknown. Individually, the various activities may elicit localized effects on bowhead whales, yet the area and extent of the population over which effects would be felt would increase with multiple activities occurring simultaneously or consecutively throughout much of the summer-fall range of this population. Since the EIS project area extends across most of the migratory path of bowhead whales in U.S. waters, the combined oil and gas exploration activities could result in regional level effects on bowhead whales. Bowhead whales are listed as endangered and are an essential subsistence resource for Iñupiat and Yupik Eskimos of the Arctic coast, which places them in the context of being a unique resource. Evaluated collectively, and with consideration given to reduced adverse impacts through the imposition of the required standard mitigation measures, the overall effect of activities authorized under Alternative 3 on bowhead whales is likely to be moderate.

4.11.5.10.1.2 Past and Present Actions

Past and present actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.1.

4.11.5.10.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.1.

4.11.5.10.1.4 Contribution of Alternative to Cumulative Effects

The contribution of the direct and indirect impacts resulting from Alternative 3, when combined with the past, present, and reasonably foreseeable future actions would be minor to moderate, the same as under Alternative 2 (Section 4.11.4.10.1), with most potential impacts due to acoustic disturbance that could, at least temporarily, disrupt or displace bowhead whales.

4.11.5.10.1.5 Conclusion

Under Alternative 3, the direct and indirect effects to bowhead whales would be moderate. Overall, Alternative 3 would have a minor to moderate contribution to cumulative effects on bowhead whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with bowhead whales were discussed under Alternative 2 (Section 4.11.4.10.1).

4.11.5.10.2 Beluga Whales

4.11.5.10.2.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 3 on beluga whales are described in Section 4.6.2.4.2 and are summarized here. The additional oil and gas exploration activities proposed in Alternative 3 could directly and indirectly affect beluga whales by causing noise disturbance, habitat degradation, and potential ship strikes. Beluga whales disturbed by oil and gas exploration activities may move away from important habitats. The scale of the avoidance depends on the number and relative proximity of the surveys. Numerous simultaneous seismic activities could cause avoidance over large distances. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

The direct and indirect effects on beluga whales from the exploration activities under Alternative 3 would be low to medium intensity, short-term duration, local to regional extent, and would affect a unique resource. The summary impact level of Alternative 3 on beluga whales would be considered moderate.

4.11.5.10.2.2 Past and Present Actions

Past and present actions affecting beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.5.10.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions that would affect beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.5.10.2.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 3 would add to the acoustic disturbance of beluga whales from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible since it would affect an extremely small proportion of habitat or prey base available to beluga whales. The exploration activities authorized under Alternative 3 would therefore have minor to moderate additive contributions to the cumulative effects on beluga whales.

4.11.5.10.2.5 Conclusion

As stated above, most exploration activities authorized under Alternative 3 would result in minor to moderate contributions to cumulative effects on beluga whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with beluga whales were discussed under Alternative 2 (Section 4.11.4.10.2).

4.11.5.10.3 Other Cetaceans

4.11.5.10.3.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 3 on cetaceans are described in Section 4.6.2.4.3 and are summarized here. Evaluated collectively, the overall impact of Alternative 3 on other cetaceans is minor. Despite a substantial increase in level of activity over Alternative 2, there would be no corresponding increase in impact level. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 3, impacts on the resource would be low in intensity, of short duration, and limited extent. Long term impacts are unknown, but anticipated to be minor.

The primary direct and indirect effects on other cetaceans would result from noise exposure. Potential noise sources include 2D/3D seismic survey equipment (airgun arrays), CSEM electromagnetic signals, echosounder and sonar devices associated with site clearance and shallow hazards surveys, support, monitoring and receiving vessels associated with these surveys, icebreaking activities, on-ice vibroseis seismic surveys (Beaufort Sea only), exploratory drilling, and helicopter and fixed wing aircraft associated with the different programs.

Direct and indirect effects arising from ship strikes and habitat degradation are also possible. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

4.11.5.10.3.2 Past and Present Actions

Past and present actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.5.10.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.5.10.3.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 3 would add to the acoustic disturbance of other cetaceans from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible. Despite a substantial increase in level of activity over Alternative 2, there would be no corresponding increase in impact level.

None of the past, present, or reasonably foreseeable future actions described above are expected to have any substantial impact on cetacean populations within the EIS project area. Populations for most species are stable or increasing, and climate change is likely to add nominal beneficial impacts in the future. The exploration activities authorized under Alternative 3 would therefore have minor additive contributions to the cumulative effects on other cetaceans.

4.11.5.10.3.5 Conclusion

As stated above, most exploration activities authorized under Alternative 3 would result in minor contributions to cumulative effects on other cetaceans.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with other cetaceans were discussed under Alternative 2 (Section 4.11.4.10.3).

4.11.5.10.4 Ice Seals

4.11.5.10.4.1 Summary of Direct and Indirect Effects

There are four species of seals considered in this section that are often collectively called “ice seals”; ringed seal, spotted seal, ribbon seal, and bearded seal. The direct and indirect effects of Alternative 3 on ice seals are described in Section 4.6.2.4.4 and are summarized here. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past offshore oil and gas exploration activities in the Alaskan Beaufort and Chukchi seas and would likely be affected more frequently by exploration activities authorized under Alternative 3 than either ribbon or spotted seals. Data from observers on board seismic source vessels and monitoring vessels indicate that seals tend to avoid on-coming vessels and active seismic arrays but they do not appear to react strongly even as ships pass fairly close with active arrays. They also do not appear to react strongly to icebreaking or on-ice surveys, keeping their distance or moving away at some point to an alternate breathing hole or haulout, but the scope of these behavioral responses appears to be within their natural abilities and responses to their naturally dynamic environment. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and they would be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are legally protected, have unique ecological roles in the Arctic, and are important subsistence resources and are therefore considered to be unique resources. Given the standard mitigation measures that have been required in the past, the effects of exploration activities that could be authorized under Alternative 3 on ice seals would likely be low in magnitude, distributed over a wide geographic area, and temporary to short-term in duration. The effects of Alternative 3 would therefore be considered minor for all ice seal species according to the criteria established in Section 4.1.3.

4.11.5.10.4.2 Past and Present Actions

Past and present actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.5.10.4.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.5.10.4.4 Contribution of Alternative 3 to Cumulative Effects

The exploration activities authorized under Alternative 3 would add to the disturbance of ice seals from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Very small numbers of ringed seals could be exposed to exploration activities during the denning season (winter-spring) when females with young are more susceptible to disturbance. Exploration activities would contribute negligible risk of additional mortality to any species, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 3 would therefore have negligible to minor contributions to the cumulative effects on the four species of ice seals considered.

4.11.5.10.4.5 Conclusion

The direct and indirect effects of Alternative 3 on pinnipeds would be considered minor. Alternative 3 would have negligible to minor contributions to the cumulative effects on the four species of ice seals.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with pinnipeds were discussed under Alternative 2 (Section 4.11.4.10.4).

4.11.5.10.5 Walrus

4.11.5.10.5.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 3 on walrus are described in Section 4.6.2.4.5 and are summarized here. Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. These data indicate that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest sounds generated by the ships. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of calf and juvenile mortality from stampedes. Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for NEPA purposes. Given the level and type of exploration activities that would be authorized under Alternative 3, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on walrus would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 3 on Pacific walrus would therefore be considered minor.

4.11.5.10.5.2 Past and Present Actions

Past and present actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.5.10.5.3 Reasonably Foreseeable Future Actions

Past and present actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.5.10.5.4 Contribution of Alternative 3 to Cumulative Effects

The exploration activities authorized under Alternative 3 would add to the disturbance of walrus from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to walrus, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 3 would therefore have negligible to minor contributions to the cumulative effects on Pacific walrus.

4.11.5.10.5.5 Conclusion

The direct and indirect effects of Alternative 3 on Pacific walrus would be considered minor. Alternative 3 would have negligible to minor contributions to the cumulative effects.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with Pacific walrus were discussed under Alternative 2 (Section 4.11.4.10.5).

4.11.5.10.6 Polar Bears

4.11.5.10.6.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 3 on polar bears are described in Section 4.6.2.4.6 and are summarized here. The types and levels of effects on polar bears are essentially the same under Alternative 3 as for Alternative 2**.** The primary difference for polar bears would be an incremental increase in disturbance from vessel and air traffic and an incremental increase in risk of habitat contamination**.** Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. The gradual introduction of alternative technologies for seismic surveys would make very little difference to polar bears because they are unlikely to be affected in any biologically meaningful way by seismic noise. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important to subsistence cultures and are therefore considered a unique resource. Given the level and type of exploration activities that would be authorized under Alternative 3, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on polar bears would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 3 on polar bears would therefore be considered minor.

4.11.5.10.6.2 Past and Present Actions

Past and present actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.5.10.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.5.10.6.4 Contribution of Alternative 3 to Cumulative Effects

The exploration activities authorized under Alternative 3 would add to the disturbance of polar bears from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to polar bears, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 3 would therefore have negligible to minor contributions to the cumulative effects on polar bears.

4.11.5.10.6.5 Conclusion

The direct and indirect effects of Alternative 3 on polar bears would be considered minor. Alternative 3 would have negligible to minor contributions to the cumulative effects.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with polar bears were discussed under Alternative 2 (Section 4.11.4.10.6).

4.11.5.11 Terrestrial Mammals

4.11.5.11.1 Summary of Direct and Indirect Effects

Alternative 3 is the same as Alternative 2 except with increased levels of activity, with two exploratory drilling programs. The impacts discussed for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to terrestrial mammals. The conclusions for Alternative 2 are applicable to Alternative 3; and while the level of activity would increase, due to the relatively small area affected and short term, infrequent nature of crew changes, the overall impact to terrestrial mammals from aircraft activity would be minor.

4.11.5.11.2 Past and Present Actions

Past and present actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.5.11.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.5.11.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.5.11.5 Conclusion

The incremental contribution of activities associated with Alternative 3 to cumulative effects on caribou would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with caribou were discussed under Alternative 2 (Section 4.11.4.11).

4.11.5.12 Time/Area Closures

The analysis of the cumulative effects associated with the time/area closures can be found in Sections 4.11.5.10 (Marine Mammals), 4.11.5.9 (Marine and Coastal Birds) and 4.11.5.14 (Subsistence).

4.11.5.13 Socioeconomics

4.11.5.13.1 Summary of Direct and Indirect Effects

Direct and indirect effects associated with Alternative 3 are similar to those described in Alternative 2. Alternative 3 represents an increased level of oil and gas exploration therefore there would be an increased level of local revenue generated in staging communities; direct and indirect employment opportunities for Regional and Village Corporations that procure service contracts; and countervailing negative impacts to institutions and social services in the staging communities. The magnitude of the socioeconomic impact is positive but still low because total personal income, local employment rates, and borough revenues would also not increased by more than five percent.

Direct employment opportunities associated with the standard mitigation measures could increase or stay the same due as Alternative 2 to their duplicative nature. Also similar to Alternative 2, the duration of the socioeconomic impacts is temporary (not year-round) and scheduled to occur over a fixed number of years. The geographic extent of socioeconomic impacts is local, statewide, and even national. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat communities. The summary impact level for Socioeconomics under Alternative 3 is minor, not exceeding the significance threshold.

4.11.5.13.2 Past and Present Actions

Past and present actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13.

4.11.5.13.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13. This analysis assumes current levels of oil and gas production and on-shore exploration would continue, but does not assume that offshore exploration associated with Alternative 3 would result in future oil and gas production.

4.11.5.13.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 3 would cause minor (positive) direct and indirect impacts to socioeconomics. They differ from Alternative 2 by a higher magnitude of direct employment and generation of local revenue, but with a potential increase in negative impacts on local institutions. The summary contribution of these impacts to the cumulative effectives of socioeconomics is negligible to minor at a statewide and national level and minor at the local level.

4.11.5.13.5 Conclusion

The direct and indirect effects of Alternative 3 would be minor. The contribution to cumulative effects of socioeconomics would be negligible to minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with socioeconomics were discussed under Alternative 2 (Section 4.11.4.13).

4.11.5.14 Subsistence

4.11.5.14.1 Summary of Direct and Indirect Effects

Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources and harvests resulting from implementation of Alternative 3 would be of low intensity, temporary in duration, local to regional in extent, and the context would be common to unique. Protected resources (bowhead whales and polar bears are considered unique in context as these resources are protected by legislation (e.g. MMPA, ESA) or are considered an important subsistence resource (beluga whales). Even with the increase in the number of activities/programs that could potentially occur under Alternative 3, the impacts to subsistence resources and harvest are anticipated to be similar in type, generally of similar intensity, and comparable duration, but occurring in more locations. Therefore the summary impact level of Alternative 3 on subsistence resources and harvests would be considered to range from negligible to moderate depending upon the specific subsistence resource affected and source of disturbance (Section 4.6.3.2).

4.11.5.14.2 Past and Present Actions

Past and present actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.5.14.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.5.14.4 Contribution of Alternatives to Cumulative Effects

The activities authorized under Alternative 3 would add to the disturbance of subsistence resources from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary and local. A low number of seals and polar bears could be disturbed during on-ice seismic surveys. Exploration activities would constitute a minor contribution to the disturbance of subsistence resources. Exploration activities could contribute to habitat change of subsistence resources through aircraft and vessel traffic, icebreaking efforts, on-ice surveys and discharge of drilling muds but these effects would be of low intensity, localized to regional in extent, temporary in duration, and affect subsistence resources that are common to unique in context. This contribution to habitat change would be negligible when compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems and resource abundance due to ocean acidification. The exploration activities authorized under Alternative 3 would occur at a higher level of activity in comparison to those proposed under Alternative 2. The contribution of Alternative 3 would have a negligible to moderate contribution to the cumulative effects on subsistence resources.

4.11.5.14.5 Conclusion

Under Alternative 3, the direct and indirect effects to subsistence resources as a result of the increased levels of activity associated with this alternative are considered low in intensity, temporary in duration, local to regional in extent and affect subsistence resources that range from common to unique in context. The contribution of the direct and indirect impacts in consideration of the past, present, and reasonably foreseeable future actions would be negligible to moderate on subsistence.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with subsistence resources were discussed under Alternative 2 (Section 4.11.4.14).

4.11.5.15 Public Health

4.11.5.15.1 Summary of Direct and Indirect Effects

As described in Section 4.6.3.3, anticipated direct and indirect effects on public health and safety as a result of Alternative 3 are expected to be similar to those expected under Alternative 2.

4.11.5.15.2 Past and Present Actions

The effects of past and present actions on public health and safety are the same as those described in Section 4.11.3.15.

4.11.5.15.3 Reasonably Foreseeable Future Actions

The effects of reasonably foreseeable future actions on public health and safety are the same as those described in Section 4.11.3.15.

4.11.5.15.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 3 to cumulative effects on public health and safety are the same as those for Alternative 2, described in Section 4.11.4.15.

4.11.5.15.5 Conclusion

Similar to the contribution of Alternative 2 described in Section 4.11.4.15, Alternative 3 contributes to cumulative impacts on public health and safety via the relatively small contribution of the direct and indirect impacts.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with public health and safety were discussed under Alternative 2 (Section 4.11.4.15).

4.11.5.16 Cultural Resources

4.11.5.16.1 Summary of Direct and Indirect Effects

Alternative 3 is the same as Alternative 2 except with increased levels of activity, with two exploratory drilling programs. The impacts discussed for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to cultural resources. The conclusions for Alternative 2 are applicable to Alternative 3; and while the level of activity would increase, due to the relatively small area affected and short term, infrequent nature of crew changes, the overall impact to cultural resources from increased levels of \activity would be minor.

4.11.5.16.2 Past and Present Actions

Past and present actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.5.16.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.5.16.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.5.16.5 Conclusion

The incremental contribution of activities associated with Alternative 3 to cumulative effects on cultural resources would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with cultural resources were discussed under Alternative 2 (Section 4.11.4.16).

4.11.5.17 Land and Water Ownership, Use, Management

4.11.5.17.1 Summary of Direct and Indirect Effects

As discussed in Section 4.11.4.17, the direct and indirect impacts on land and water ownership would be low magnitude, temporary duration, local extent, and common in context. The direct and indirect impacts on land and water use would have a high magnitude, be temporary in duration, local and common. The direct and indirect impacts to land and water management would be low intensity, temporary in nature, local, and common. In summary, the impacts of Alternative 3 on land and water ownership, use, and management would be negligible, moderate, and minor, respectively.

4.11.5.17.2 Past and Present Actions

Past and present actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.5.17.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.5.17.4 Contribution of Alternative to Cumulative Effects

Alternative 3 is the same as Alternative 2 except with increased levels of activity. The cumulative effects discussed in Section 4.11.4.17 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to land or water ownership, use, and management. The conclusions for Alternative 2 are applicable to Alternative 3; all changes would be incrementally small, short-term in duration, and geographically dispersed, and thus would not have combined effects creating cumulative impacts on land ownership, use, or management and would be considered minor.

4.11.5.17.5 Conclusion

Under Alternative 3, the levels of direct, indirect and cumulative impacts for land and water ownership, use, and management are negligible, moderate, and minor, respectively. Based on this, the overall level of impact of Alternative 3 is considered minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with land and water ownership, use, and management were discussed under Alternative 2 (Section 4.11.4.17).

4.11.5.18 Transportation

4.11.5.18.1 Summary of Direct and Indirect Effects

Increased levels of marine vessel traffic in Alternative 3 associated with the seismic survey and exploratory drilling programs would be expected to primarily occur in offshore areas where local marine transportation does not occur. Industry vessels would likely encounter local marine traffic when littering to designated nearshore marine facilities (which are limited). The impact of increased vessel presence would be low in intensity, temporary in duration, limited in geographic extent to a local area, and common to potentially unique context (in respect to protected marine mammal resources). The summary impact from increases in vessel traffic would be considered minor.

4.11.5.18.2 Past and Present Actions

Past and present actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.5.18.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.5.18.4 Contribution of Alternative to Cumulative Effects

The contribution of impacts from Alternative 3 would be similar but of slightly higher intensity than described for Alternative 2 in Section 4.11.4.18.

4.11.5.18.5 Conclusion

In summary, no concerns related to adverse cumulative impacts have been identified. Some cumulative impacts may exist if Alternative 3 overlaps with another large-scale development project but those impacts would be of low intensity, temporary in duration affecting local areas of common resources, and are considered unlikely to have long-term impacts on regional transportation infrastructure.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with transportation were discussed under Alternative 2 (Section 4.11.4.18).

4.11.5.19 Recreation and Tourism

4.11.5.19.1 Summary of Direct and Indirect Effects

As discussed in Section 4.6.3.7, the direct impacts on recreation and tourism would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 3 on recreation and tourism would be minor.

4.11.5.19.2 Past and Present Actions

Past and present actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.5.19.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.5.19.4 Contribution of Alternative to Cumulative Effects

Alternative 3 is the same as Alternative 2 except with increased levels of activity. The cumulative effects discussed in Section 4.10.4.19 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to recreation and tourism. The conclusions for Alternative 2 are applicable to Alternative 3; the contribution of Alternative 3 to cumulative effects to recreation and tourism would be minor.

4.11.5.19.5 Conclusion

Alternative 3 would have a minor contribution to cumulative effects on recreation and tourism.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with recreation and tourism were discussed under Alternative 2 (Section 4.11.4.19).

4.11.5.20 Visual Resources

4.11.5.20.1 Summary of Direct and Indirect Effects

Implementation of Alternative 3 would be similar to that describe in Section 4.11.4.20, however there would be an increase in the level of permitted activity and a consequent potential increase in impacts to visual resources. The proposed action is expected to result in short-term moderate effects to scenic quality and visual resources similar to that described in Alternative 2. Because of the greater number of support vessels used in the two exploratory drilling programs proposed under Alternative 3, this action could be high intensity if both programs are implemented in close proximity to each other. Potential impacts could be of low to medium intensity depending if programs are geographically separated. In either case, actions would be temporary, localized and occur in an important context.

Standard mitigation measures implemented as part of the proposed action would not alter the level of anticipated impacts to visual resources or scenic quality. Although Category D Mitigation Measures would limit exposure of sensitive viewers (individuals engaged in the culturally important activity of bowhead whaling) to vessel-based surveys during certain periods. However it would not change exposure to drill sites, as these structures would remain in place during shutdown periods unless the operator agrees to move off location during such shutdown periods.

4.11.5.20.2 Past and Present Actions

Past and present actions associated with visual resources are presented under Alternative 2 (Section 4.11.4.20).

4.11.5.20.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions associated with visual resources are presented under Alternative 2 (Section 4.11.4.20).

4.11.5.20.4 Contribution of Alternative to Cumulative Effects

Implementation of Alternative 3 would increase the level of permitted activity (i.e. three versus two 2D/3D seismic surveys; two versus one exploratory drilling program). Actions could occur at any location within the EIS project area; however, like Alternative 2, actions associated with implementation of Alternative 3 would result in the greatest impact to visual resources if sited in near-shore areas between Harrison Bay and Kaktovik, where the majority of past, present, and reasonably foreseeable future actions are located. The location would also coincide with locations of sensitive viewers, such as residents of native communities or recreators using the ANWR. If actions associated with Alternative 3 are concentrated in areas where the majority of past, present, and reasonably foreseeable future actions are located, Alternative 3 would contribute to the industrialized landscape character of the area. Transient views of seismic and shallow hazard survey vessels are not expected to contribute to the industrial character of the area, as views of vessels would be episodic.

4.11.5.20.5 Conclusion

Under Alternative 3, anticipated cumulative effects to visual resources are expected to be major. Impacts would be of high intensity, long-term in duration, regional in geographic extent and occurring in an important context.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with visual resources were discussed under Alternative 2 (Section 4.11.4.20).

4.11.5.21 Environmental Justice

4.11.5.21.1 Summary of Direct and Indirect Effects

Direct and indirect effects to subsistence and public health associated with Alternative 3 would be minor, similar to those described in Alternative 2. The level of activity associated with Alternative 3 is greater than Alternative 2, but the effects do not change the summary impact level for these environmental justice indicators.

4.11.5.21.2 Past and Present Actions

Past and present actions associated with environmental justice are presented under Alternative 2 (Section 4.11.4.21).

4.11.5.21.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions associated with environmental justice are presented under Alternative 2 (Section 4.11.4.21).Future industrial activities and climate change would have an adverse impact on subsistence resources and uses and public health.

4.11.5.21.4 Contribution of Alternative to Cumulative Effects

The incremental contribution of Alternative 3 to the overall industrial activity in the area would be similar that that described for Alternative 2. Therefore, the contribution of Alternative 3 to environmental justice indicator cumulative effects would be minor.

4.11.5.21.5 Conclusion

The direct and indirect effects of Alternative 3 would be minor. The contribution to the cumulative effect of environmental justice indicators would be minor. Therefore, there would be a disproportionate impact to Alaska Native communities in the EIS project area.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with environmental justice were discussed under Alternative 2 (Section 4.11.4.21). A VLOS would have disproportionate adverse impacts to Alaska Native communities in the EIS project area.

4.11.6 Alternative 4 – Authorization for Level 3 Exploration Activity

4.11.6.1 Physical Oceanography

4.11.6.1.1 Summary of Direct and Indirect Effects

The effects of Alternative 4 on physical ocean resources would be medium-intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. Under Alternative 4, changes in water depth resulting from exploratory drilling programs would be the same in nature as those described for Alternative 3. Alternative 4 would allow additional drilling programs in the EIS project area, and as a result of the additional drilling programs, the intensity as well as the spatial extent of the impact could effectively be doubled. Relative to Alternative 3, water depth would be affected over a larger area. Construction of artificial islands, which could occur in nearshore state waters of the Beaufort Sea at a rate of two islands per year under Alternative 3, would result in medium-intensity, permanent/temporary (permanent if gravel, temporary if ice), localized effects on nearshore currents in the waters adjacent to the artificial islands. Relative to Alternative 3, sea ice would be affected over a larger area due to more extensive icebreaking activity and thermal inputs associated with exploratory drilling activities. Although common resources would be affected across increased spatial and temporal scales relative to Alternative 3, the overall effects of Alternative 4 on physical ocean resources in the EIS project area would be minor, particularly with the implementation of additional mitigation measures related to reducing or eliminating certain discharge streams.

4.11.6.1.2 Past and Present Actions

Past and present actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.6.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.6.1.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 4 would cause localized minor impacts to physical ocean resources in the EIS project area. While some actions associated with Alternative 4, such as the construction of man-made gravel islands, would interact in a synergistic fashion with past, present, and reasonably foreseeable future actions to influence physical ocean resources in the EIS project area, the impacts resulting from such synergies would represent only a small fraction of foreseeable cumulative impact.

4.11.6.1.5 Conclusion

The incremental contribution of activities associated with Alternative 4 to cumulative effects on physical ocean resources in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with physical ocean resources were discussed under Alternative 2 (Section 4.11.4.1).

4.11.6.2 Climate & Meteorology

4.10.5.2.1 Summary of Direct and Indirect Effects

Alternative 4 would directly emit more GHGs than Alternative 3; however direct impacts to climate change are estimated to have the same level of impact (minor) due to their low magnitude and low contribution to GHG emissions on a state level. Due to uncertainties in the outcome of exploration activities, indirect effects associated with Alternative 4 are assumed to be the same as those for Alternative 3, which would be minor to moderate.

4.11.6.2.2 Past and Present Actions

Past and present actions affecting climate change are discussed under Alternative 2, Section 4.11.4.2.

4.11.6.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting climate change are discussed under Alternative 2, Section 4.11.4.2.

4.11.6.2.4 Contribution of Alternative to Cumulative Effects

Alternative 4 would directly emit more GHGs than Alternative 3; therefore it would directly contribute more to cumulative climate change impacts than Alternative 3. Alternative 4 would result in approximately 82,308 tpy more CO_2e emissions than Alternative 3 (See Sections 4.5.1.2 and 4.6.1.2). Alone, this difference would not result in a noticeably larger cumulative effect than Alternative 3. However, when accounting for all past, present, and future projects with GHG emissions, even a minor contribution such as 82,308 tpy of CO_2e per project, can cumulatively result in a perceptible impact. Therefore, Alternative 4 could have a larger impact on cumulative impacts to climate change than Alternative 3. Indirect effects from Alternative 4 are expected to have the same contribution to cumulative effects as Alternative 3, resulting in observable, global changes that could be long-term and could affect unique resources.

4.11.6.2.5 Conclusion

Due to the additive and synergistic nature of GHG emissions on climate change impacts, Alternative 4 could contribute to a moderate to major cumulative impact to climate change.

The additive effects resulting from a VLOS within the seas Arctic OCS associated with climate change were discussed under Alternative 2 (Section 4.11.4.2).

4.11.6.3 Air Quality

4.11.6.3.1 Summary of Direct and Indirect Effects

The air quality effects due to the worst-case activity under Alternative 4, Level 3 Exploration Activity, are expected to be the same as those predicted for Alternative 3. The emissions would be moderate in magnitude, and minor in duration, extent, and content. The total emissions from the Level 3 Exploration Activity is greater than that for Level 2 Exploration Activity, however the overall direct effect on air quality is expected to be moderate. Indirect effects on air quality would remain at negligible to minor.

4.11.6.3.2 Past and Present Actions

Past and present actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.6.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.6.3.4 Contribution of Alternative to Cumulative Effects

As with Alternative 3, Alternative 4 has the potential to contribute to future cumulative effects on air quality if activities occur during the same time period(s) and vicinity of any of the actions identified above that have the potential to affect air quality. Because of the short time duration for activities, cumulative effects would be highly dependent on actual meteorological conditions at the time, and the relative location of sources. The cumulative effects would be negligible (lower than the sum of the total maximum effects). There are no accumulative or synergistic effects associated with air quality.

4.11.6.3.5 Conclusion

Alternative 4 has the potential to contribute to cumulative effects on air quality when activities occur in the vicinity of other sources of air pollution. Due to distance between activities, and the mobile and intermittent source activities, the cumulative effects are expected to be less than the sum of each, likely remaining moderate in magnitude.

The additive effects resulting from a VLOS within the seas Arctic OCS associated with air quality were discussed under Alternative 2 (Section 4.11.4.3).

4.11.6.4 Acoustics

4.11.6.4.1 Summary of Direct and Indirect Effects

The summary of direct and indirect effects provided in Section 4.11.4 (Alternative 2) is relevant also for Alternative 4. The overall impact rating for direct and indirect effects to the acoustic environment under Alternative 4 would be moderate.

4.11.6.4.2 Past and Present Actions

The past actions for Alternative 4 are the same as listed for Alternative 2 (Section 4.11.4.4). The present actions will consist of up to six deep penetration seismic surveys in the Beaufort Sea and up to five seismic surveys in the Chukchi Sea. This alternative also allows for up to five site clearance and high resolution shallow hazards surveys in Beaufort and five of these surveys in the Chukchi. Up to four drilling programs in each of the Beaufort and Chukchi seas and one on-ice seismic survey would be permitted in the Beaufort Sea only.

4.11.6.4.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting acoustics within the EIS project area are discussed under Alternative 2, Section 4.11.4.4.

4.11.6.4.4 Contribution of Alternative to Cumulative Effects

This alternative permits the highest level of activity of all alternatives. The possibility of up to six deep-penetration seismic surveys and five site clearance and high resolution shallow hazards surveys with inclusion of two potential drilling operations in the Beaufort Sea open water season produces substantial total disturbance zone areas. Marine mammals could have difficulty navigating between the disturbance zones surrounding each of the surveys and drill operations if these activities were performed concurrently. The concurrent operation of multiple noise sources could lead to confusion by marine mammals at choosing a path to avoid regions of high noise. If cumulative SEL criteria for auditory system injury were considered, the total effects of exposures to multiple operations could be substantially greater than from individual activities. The large number of deep penetration seismic surveys would be the primary source of higher cumulative exposures.

Cumulative effects in the Chukchi Sea would be fewer than in the Beaufort Sea because the surveys will have greater spatial separation and marine mammal migration corridors there are less concentrated. There would consequently be more opportunity for migrating marine mammals to choose paths between the surveys and drilling locations to avoid passing close to individual operations where noise levels are highest.

4.11.6.4.5 Conclusion

Cumulative effects from noise exposures to marine mammals under Alternative 4 are similar but slightly larger than the effects described for Alternative 3 due to the greater number of noise-generating activities that would be permitted. The ability of marine mammals to avoid close approaches to seismic survey sources would be reduced when many sources were concurrently in operation with limited spatial separation. These animals would therefore be exposed to higher sound levels and higher cumulative sound levels than if fewer concurrent operations were present.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with acoustics were discussed under Alternative 2 (Section 4.11.4.4).

4.11.6.5 Water Quality

4.11.6.5.1 Summary of Direct and Indirect Effects

Impacts to water quality from Alternative 4 would be the same in nature as those described for Alternative 2 in Section 4.11.4.5. The only difference between the two alternatives is the level of activity. Alternative 4 would allow additional surveys and exploratory drilling programs in the EIS project area, and as a result of the additional drilling programs, the intensity as well as the spatial extent of the impacts may effectively be doubled. Relative to Alternative 2, water quality parameters may be affected over larger areas and over longer periods of time. However, the effects of Alternative 4 on water quality would be low intensity, temporary, and localized to areas in the immediate vicinity of the activities. Although common resources may be affected across increased spatial scales relative to Alternative 2, the overall effects of Alternative 4 on water quality are expected to be minor.

4.11.6.5.2 Past and Present Actions

Past and present actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.6.5.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.6.5.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 4 would cause temporary local impacts to water quality such as increases in temperature, turbidity, and concentrations of pollutants. Some actions associated with Alternative 4, such as discharges of cooling water and waste material, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to water quality. These interactions would be local and temporary and would represent only a small fraction of foreseeable cumulative impact.

4.11.6.5.5 Conclusion

The incremental contribution of activities associated with Alternative 4 to cumulative effects on water quality in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with water quality were discussed under Alternative 2 (Section 4.11.4.5).

4.11.6.6 Environmental Contaminants and Ecosystem Functions

4.11.6.6.1 Summary of Direct and Indirect Effects

Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 4 would be medium-intensity, temporary, and local. Regulation functions such as nutrient cycling and waste assimilation, which depend on biota and physical processes to facilitate storage and recycling of nutrients and breakdown or assimilation of contaminants, would be affected within the EIS project area. While the geographic extent of such impacts would potentially be greater than that resulting from Alternative 3, the overall geographic extent of impacts to regulation functions would be limited. Habitat functions, particularly those related to benthic habitats, would be impacted as a result of discharges and other activities associated with exploratory drilling. Production functions including primary productivity and subsequent transfers to higher trophic levels could potentially be impacted as a result of activities associated with Alternative 4, while the effects of Alternative 4 on information ecosystem functions would depend upon interrelationships between impacts to cultural resources, social resources, and aesthetic resources, which are addressed in other sections of this EIS. Overall effects of Alternative 4 on ecosystem functions would be minor.

4.11.6.6.2 Past and Present Actions

Past and present actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.6.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.6.6.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 4 would cause localized minor impacts to environmental contaminants and ecosystem functions within the EIS project area. Some actions associated with Alternative 4, such as discharges from exploratory drilling operations, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to ecosystem functions. Relative to Alternative 3, these interactions would potentially be distributed over a greater geographic area. The impacts resulting from such interactions would represent a relatively small fraction of foreseeable cumulative impact, and the accumulation of impacts is unlikely to be substantial over the lifespan of this EIS.

4.11.6.6.5 Conclusion

The incremental contribution of activities associated with Alternative 4 to cumulative effects on environmental contaminants and ecosystem functions in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with environmental contaminants and ecosystem functions were discussed under Alternative 2 (Section 4.11.4.6).

4.11.6.7 Lower Trophic Levels

4.11.6.7.1 Summary of Direct and Indirect Effects

Alternative 4 is the same as Alternative 3 except with increased levels of activity. The impacts discussed in Section 4.11.4.7 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to lower trophic levels. The conclusions for Alternative 2 are applicable to Alternative 4; therefore, the overall impact to lower trophic levels would be minor.

4.11.6.7.2 Past and Present Actions

Past and present actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.6.7.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.6.7.4 Contribution of Alternative to Cumulative Effects

Alternative 4 would have the same types of effects as Alternative 3 but the increased level of exploration drilling activities under Alternative 4 would add incrementally to its contribution to cumulative effects on lower trophic levels. However, the conclusions about Alternative 4 would be similar to Alternative 3 discussed in Section 4.11.5.7 and the overall impact would be moderate. In the absence of a very large oil spill, the exploration activities authorized under Alternative 4 would have moderate contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on lower trophic levels.

4.11.6.7.5 Conclusion

Alternative 4 could have a moderate contribution to cumulative effects on lower trophic organisms.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with lower trophic levels were discussed under Alternative 2 (Section 4.11.4.7).

4.11.6.8 Fish and Essential Fish Habitat

4.11.6.8.1 Summary of Direct and Indirect Effects

The overall impact of Alternative 4 on Fish Resources and EFH is minor. Despite a substantial increase in level of activity over Alternative 2, there would be no corresponding increase in the overall impact level. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 4, there would be no measurable effect on the resource.

The direct and indirect effects on marine fish resulting from Alternative 4 would be very similar to those described under Alternative 2. Due to the uneven nature of the increases in activity levels by activity type, the increase in impacts to different fish assemblages would vary. The cryopelagic assemblage would have essentially no additional impacts, as the level for activities likely to affect that group (icebreaking and on-ice seismic surveys) would not change from Alternative 2. Demersal assemblages, on the other hand, would feel the additional effects from the increase in seismic survey levels and exploratory drilling, both in terms of habitat loss and the effects from noise. Pelagic assemblages would be impacted by the increase in surveys but less so by the increased drilling programs. However, in spite of the potential for different resource groups to experience uneven increases in level of effect, the overall impact would remain the same given the limited area affected compared to the distribution of fish populations. The impacts to marine fish would be considered minor.

The direct and indirect effects on migratory fish resulting from Alternative 4 would be very similar to those described under Alternative 2. Because anadromous fish are more likely to be impacted by the activity types than amphidromous fish, as discussed under Alternative 2, they are likely to experience a disproportionate increase in adverse impacts when the two groups are compared. However, as described in Alternative 2, those anadromous species known to inhabit the area where project activities would occur are not very abundant, and they are unlikely to be impacted. Therefore, the overall impact to the resource group would remain the same. The impacts to migratory fish would be considered negligible.

The direct and indirect effects on essential fish habitat resulting from Alternative 4 would be very similar to those described under Alternative 2, with an increase in effects due to the increase in oil and gas exploration activities. In particular, the increase in exploratory drilling programs would result in increased habitat loss and alteration, potentially to EFH for saffron cod and salmon. Since there would be no increase in icebreaking activities, EFH for Arctic cod would be impacted the least. The opportunity for habitat loss or alteration resulting from Alternative 4 is small and only incrementally larger than for Alternative 3. Most impacts would be of such low intensity and of such small geographic extent that the effects would be considered minor.

4.11.6.8.2 Past and Present Actions

Past and present actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.6.8.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.6.8.4 Contribution of Alternative to Cumulative Effects

Climate change is the only past, present, or reasonably foreseeable future action that is anticipated to have any measurable effect on fish and EFH within the EIS project area, and those effects are likely to be beneficial. As Arctic waters warm, productivity is likely to increase, thereby creating more favorable fish habitat throughout the region. The lack of measurable effect on fish and EFH resulting from the implementation of Alternative 4 would not add to any cumulative effects.

4.11.6.8.5 Conclusion

Direct and indirect impacts resulting from Alternative 4 on fish and EFH would be of such low intensity and of such small geographic extent that the effects would be considered minor. The incremental contribution of activities associated with Alternative 4 to cumulative effects on fish would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with fish and EFH were discussed under Alternative 2 (Section 4.11.4.8).

4.11.6.9 Marine and Coastal Birds

4.11.6.9.1 Summary of Direct and Indirect Effects

As discussed in Section 4.6.2.3, the effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. In summary, the impact of Alternative 4 on marine and coastal birds would be considered negligible to minor.

4.11.6.9.2 Past and Present Actions

Past and present actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.6.9.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.6.9.4 Contribution of Alternative 4 to Cumulative Effects

Alternative 4 would have the same types of effects as Alternative 2 but the increased level of exploration activities under Alternative 4 would add incrementally to its contribution to cumulative effects on marine and coastal birds. However, the conclusions about Alternative 4 would be similar to Alternative 3 (4.11.5.9). The exploration activities authorized under Alternative 4 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds.

4.11.6.9.5 Conclusion

The direct and indirect effects of Alternative 4 on marine and coastal birds would be considered negligible to minor. Alternative 4 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds, as discussed under Alternative 2 (Section 4.11.4.9).

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with marine and coastal birds were discussed under Alternative 2 (Section 4.11.4.9).

4.11.6.10 Marine Mammals

4.11.6.10.1 Bowhead Whales

4.11.6.10.1.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 4 on bowhead whales are described in Section 4.7.2.4.1 and are summarized here. Impacts of individual activities associated with oil and gas exploration in the EIS project area under Alternative 4 are similar to Alternative 3. Despite a substantial increase in level of activity over Alternative 2, the overall impact level would be the same (See Section 4.11.4.10.1).

In terms of the impact criteria identified in Table 4.5-17, most effects of individual exploratory activities authorized under Alternative 4 are of medium intensity and temporary in duration. Potential long-term effects from repeated disturbance over time or over a broad geographic range are unknown. Individually, the various activities may elicit localized effects on bowhead whales, yet the area and extent of the population over which effects would be felt would increase with multiple activities occurring simultaneously or consecutively throughout much of the summer-fall range of this population. Since the EIS project area extends across most of the migratory path of bowhead whales in U.S. waters, the combined oil and gas exploration activities could result in regional level effects on bowhead whales.

Bowhead whales are listed as endangered and are an essential subsistence resource for Iñupiat and Yupik Eskimos of the Arctic coast, which places them in the context of being a unique resource. Evaluated collectively, and with consideration given to reduced adverse impacts through the imposition of the required standard mitigation measures, the overall effect of activities authorized under Alternative 4 on bowhead whales is likely to be moderate to major.

4.11.6.10.1.2 Past and Present Actions

Past and present actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.1.

4.11.6.10.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.1.

4.11.6.10.1.4 Contribution of Alternative to Cumulative Effects

The contribution of the direct and indirect impacts resulting from Alternative 4, when combined with the past, present, and reasonably foreseeable future actions would be moderate, with most potential impacts due to acoustic disturbance that could, at least temporarily, disrupt or displace bowhead whales.

4.11.6.10.1.5 Conclusion

Under Alternative 4, the direct and indirect effects to bowhead whales would be moderate to major. Overall, Alternative 4 would have a moderate contribution to cumulative effects on bowhead whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with bowhead whales were discussed under Alternative 2 (Section 4.11.4.10.1).

4.11.6.10.2 Beluga Whales

4.11.6.10.2.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 4 on beluga whales are described in Section 4.7.2.4.2 and are summarized here. The additional oil and gas exploration activities proposed in Alternative 4 could directly and indirectly affect beluga whales by causing noise disturbance, habitat degradation, and potential ship strikes. Beluga whales disturbed by oil and gas exploration activities may move away from important habitats. The scale of the avoidance depends on the number and relative proximity of the surveys. Numerous simultaneous seismic activities could cause avoidance over large distances. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

The direct and indirect effects on beluga whales from the exploration activities under Alternative 4 would be low to medium intensity, short-term duration, local to regional extent, and would affect a unique resource. The summary impact level of Alternative 4 on beluga whales would be considered moderate.

4.11.6.10.2.2 Past and Present Actions

Past and present actions affecting beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.6.10.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions that would affect beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.6.10.2.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 4 would add to the acoustic disturbance of beluga whales from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible since it would affect an extremely small proportion of habitat or prey base available to beluga whales. The exploration activities authorized under Alternative 4 would therefore have minor to moderate additive contributions to the cumulative effects on beluga whales.

4.11.6.10.2.5 Conclusion

As stated above, most exploration activities authorized under Alternative 4 would result in minor to moderate contributions to cumulative effects on beluga whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with beluga whales were discussed under Alternative 2 (Section 4.11.4.10.2).

4.11.6.10.3 Other Cetaceans

4.11.6.10.3.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 4 on cetaceans are described in Section 4.7.2.4.3 and are summarized here. Evaluated collectively, the overall impact of Alternative 4 on other cetaceans is minor to moderate. Despite a doubling in the level of exploratory drilling activity over Alternative 3, there would be no corresponding increase in impact level. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 4, impacts on the resource would be low in intensity, of short duration, and limited extent. Long term impacts are unknown, but anticipated to be minor.

The primary direct and indirect effects on other cetaceans would result from noise exposure. Potential noise sources include 2D/3D seismic survey equipment (airgun arrays), CSEM electromagnetic signals, echosounder and sonar devices associated with site clearance and shallow hazards surveys, support, monitoring and receiving vessels associated with these surveys, icebreaking activities, on-ice vibroseis seismic surveys (Beaufort Sea only), exploratory drilling, and helicopter and fixed wing aircraft associated with the different programs.

Direct and indirect effects arising from ship strikes and habitat degradation are also possible. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

4.11.6510.3.2 Past and Present Actions

Past and present actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.6.10.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.6.10.3.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 4 would add to the acoustic disturbance of other cetaceans from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible. Despite a doubling in the level of exploratory drilling activity over Alternative 3, there would be no corresponding increase in impact level.

None of the past, present, or reasonably foreseeable future actions described above are expected to have any substantial impact on cetacean populations within the EIS project area. Populations for most species are stable or increasing, and climate change is likely to add nominal beneficial impacts in the future. The exploration activities authorized under Alternative 4 would therefore have minor additive contributions to the cumulative effects on other cetaceans.

4.11.6.10.3.5 Conclusion

As stated above, most exploration activities authorized under Alternative 4 would result in minor contributions to cumulative effects on other cetaceans.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with other cetaceans were discussed under Alternative 2 (Section 4.11.4.10.3).

4.11.6.10.4 Ice Seals

4.11.6.10.4.1 Summary of Direct and Indirect Effects

There are four species of seals considered in this section that are often collectively called “ice seals”; ringed seal, spotted seal, ribbon seal, and bearded seal. The direct and indirect effects of Alternative 4 on ice seals are described in Section 4.7.2.4.4 and are summarized here. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past offshore oil and gas exploration activities in the Alaskan Beaufort and Chukchi seas and would likely be affected more frequently by exploration activities authorized under Alternative 4 than either ribbon or spotted seals. Data from observers on board seismic source vessels and monitoring vessels indicate that seals tend to avoid on-coming vessels and active seismic arrays but they do not appear to react strongly even as ships pass fairly close with active arrays. They also do not appear to react strongly to icebreaking or on-ice surveys, keeping their distance or moving away at some point to an alternate breathing hole or haulout, but the scope of these behavioral responses appears to be within their natural abilities and responses to their naturally dynamic environment. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and they would be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are legally protected, have unique ecological roles in the Arctic, and are important subsistence resources and are therefore considered to be unique resources. Given the standard mitigation measures that have been required in the past, the effects of exploration activities that could be authorized under Alternative 4 on ice seals would likely be low in magnitude, distributed over a wide geographic area, and temporary to short-term in duration. The effects of Alternative 3 would therefore be considered minor to moderate for all ice seal species according to the criteria established in Section 4.1.3.

4.11.6.10.4.2 Past and Present Actions

Past and present actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.6.10.4.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.6.10.4.4 Contribution of Alternative 4 to Cumulative Effects

The exploration activities authorized under Alternative 4 would add to the disturbance of ice seals from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Very small numbers of ringed seals could be exposed to exploration activities during the denning season (winter-spring) when females with young are more susceptible to disturbance. Exploration activities would contribute negligible risk of additional mortality to any species, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 4 would therefore have minor contributions to the cumulative effects on the four species of ice seals considered.

4.11.6.10.4.5 Conclusion

The direct and indirect effects of Alternative 4 on pinnipeds would be considered minor to moderate. Alternative 4 would have minor contributions to the cumulative effects on the four species of ice seals.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with pinnipeds were discussed under Alternative 2 (Section 4.11.4.10.4).

4.11.6.10.5 Walrus

4.11.6.10.5.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 4 on walrus are described in Section 4.7.2.4.5 and are summarized here. Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. These data indicate that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest sounds generated by the ships. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of calf and juvenile mortality from stampedes. Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for NEPA purposes. Given the level and type of exploration activities that would be authorized under Alternative **4**, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on walrus would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative **4** on Pacific walrus would therefore be considered minor.

4.11.6.10.5.2 Past and Present Actions

Past and present actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.6.10.5.3 Reasonably Foreseeable Future Actions

Past and present actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.6.10.5.4 Contribution of Alternative 4 to Cumulative Effects

The exploration activities authorized under Alternative 4 would add to the disturbance of walrus from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to walrus, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 4 would therefore have negligible to minor contributions to the cumulative effects on Pacific walrus.

4.11.6.10.5.5 Conclusion

The direct and indirect effects of Alternative 4 on Pacific walrus would be considered minor. Alternative 4 would have negligible to minor contributions to the cumulative effects.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with Pacific walrus were discussed under Alternative 2 (Section 4.11.4.10.5).

4.11.6.10.6 Polar Bears

4.11.6.10.6.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 4 on polar bears are described in Section 4.7.2.4.6 and are summarized here. The types and levels of effects on polar bears are essentially the same under Alternative **4** as for Alternative **3.** The primary difference for polar bears would be an incremental increase in disturbance from vessel and air traffic and an incremental increase in risk of habitat contamination**.** Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. The gradual introduction of alternative technologies for seismic surveys would make very little difference to polar bears because they are unlikely to be affected in any biologically meaningful way by seismic noise. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important to subsistence cultures and are therefore considered a unique resource. Given the level and type of exploration activities that would be authorized under Alternative **4**, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on polar bears would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 3 on polar bears would therefore be considered minor.

4.11.6.10.6.2 Past and Present Actions

Past and present actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.6.10.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.6.10.6.4 Contribution of Alternative 3 to Cumulative Effects

The exploration activities authorized under Alternative 4 would add to the disturbance of polar bears from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to polar bears, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 4 would therefore have negligible to minor contributions to the cumulative effects on polar bears.

4.11.6.10.6.5 Conclusion

The direct and indirect effects of Alternative 4 on polar bears would be considered minor. Alternative 4 would have negligible to minor contributions to the cumulative effects.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with polar bears were discussed under Alternative 2 (Section 4.11.4.10.6).

4.11.6.11 Terrestrial Mammals

4.11.6.11.1 Summary of Direct and Indirect Effects

Alternative 4 is the same as Alternative 3 except with increased level of exploratory drilling activity (a total of four programs in each sea instead of two programs in each sea). The impacts discussed for Alternative 3 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to terrestrial mammals. The conclusions for Alternative 3 are applicable to Alternative 4; and while the level of activity would increase, due to the relatively small area affected and short term, infrequent nature of crew changes, the overall impact to terrestrial mammals from aircraft activity would be minor.

4.11.6.11.2 Past and Present Actions

Past and present actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.6.11.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.6.11.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.6.11.5 Conclusion

The incremental contribution of activities associated with Alternative 4 to cumulative effects on caribou would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with caribou were discussed under Alternative 2 (Section 4.11.4.11).

4.11.6.12 Time/Area Closure Locations

The analysis of the cumulative effects associated with time/area closures can be found in Sections 4.11.5.10 (Marine Mammals), 4.11.5.9 (Marine and Coastal Birds) and 4.11.5.14 (Subsistence).

4.11.6.13 Socioeconomics

4.11.6.13.1 Summary of Direct and Indirect Effects

Direct and indirect effects associated with Alternative 4 are similar to those described in Alternative 3. Alternative 4 represents an increased level of oil and gas exploration therefore there would be an increased level of local revenue generated in staging communities; direct and indirect employment opportunities for Regional and Village Corporations that procure service contracts; and countervailing negative impacts to institutions and social services in the staging communities. The magnitude of the socioeconomic impact is positive but still low because total personal income, local employment rates, and borough revenues would also not increased by more than five percent.

Direct employment opportunities associated with the standard mitigation measures could increase or stay the same as Alternative 3 due to their duplicative nature. Also similar to Alternative 3, the duration of the socioeconomic impacts is temporary (not year-round) and scheduled to occur over a fixed number of years. The geographic extent of socioeconomic impacts is local, statewide, and even national. The context of the socioeconomic impacts is unique because the people that would experience the flow of workers and research vessels are predominantly Iñupiat communities. The summary impact level for Socioeconomics under Alternative 4 is minor, not exceeding the significance threshold.

4.11.6.13.2 Past and Present Actions

Past and present actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13.

4.11.6.13.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13. This analysis assumes current levels of oil and gas production and on-shore exploration would continue, but does not assume that offshore exploration associated with Alternative 3 would result in future oil and gas production.

4.11.6.13.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 4 would cause minor (positive) direct and indirect impacts to socioeconomics. They differ from Alternative 3 by a higher magnitude of direct employment and generation of local revenue, but with a potential increase in negative impacts on local institutions. The summary contribution of these impacts to the cumulative effectives of socioeconomics is negligible to minor at a statewide and national level and minor at the local level.

4.11.6.13.5 Conclusion

The direct and indirect effects of Alternative 4 would be minor. The contribution to cumulative effects of socioeconomics would be negligible to minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with socioeconomics were discussed under Alternative 2 (Section 4.11.4.13).

4.11.6.14 Subsistence

4.11.6.14.1 Summary of Direct and Indirect Effects

Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources and harvests resulting from implementation of Alternative 4 would be of low intensity, temporary in duration, local to regional in extent, and the context would be common to unique. Protected resources (bowhead whales and polar bears are considered unique in context as these resources are protected by legislation (e.g. MMPA, ESA) or are considered an important subsistence resource (beluga whales). Even with the increase in the number of activities/programs that could potentially occur under Alternative 4, the impacts to subsistence resources and harvest are anticipated to be similar in type, generally of similar intensity, and comparable duration, but occurring in more locations. Therefore the summary impact level of Alternative 4 on subsistence resources and harvests would be considered to range from negligible to moderate depending upon the specific subsistence resource affected and source of disturbance (Section 4.7.3.2).

4.11.6.14.2 Past and Present Actions

Past and present actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.6.14.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.6.14.4 Contribution of Alternatives to Cumulative Effects

The activities authorized under Alternative 4 would add to the disturbance of subsistence resources from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary and local. A low number of seals and polar bears could be disturbed during on-ice seismic surveys. Exploration activities would constitute a minor contribution to the disturbance of subsistence resources. Exploration activities could contribute to habitat change of subsistence resources through aircraft and vessel traffic, icebreaking efforts, on-ice surveys and discharge of drilling muds but these effects would be of low intensity, localized to regional in extent, temporary in duration, and affect subsistence resources that are common to unique in context. This contribution to habitat change would be negligible when compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems and resource abundance due to ocean acidification. The exploration activities authorized under Alternative 4 would occur at a higher level of activity in comparison to those proposed under Alternative 3. The contribution of Alternative 4 would have a negligible to moderate contribution to the cumulative effects on subsistence resources.

4.11.6.14.5 Conclusion

Under Alternative 4, the direct and indirect effects to subsistence resources as a result of the increased levels of activity associated with this alternative are considered low in intensity, temporary in duration, local to regional in extent and affect subsistence resources that range from common to unique in context.

The contribution of the direct and indirect impacts in consideration of the past, present, and reasonably foreseeable future actions would be negligible to moderate on subsistence.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with subsistence resources were discussed under Alternative 2 (Section 4.11.4.14).

4.11.6.15 Public Health

4.11.6.15.1 Summary of Direct and Indirect Effects

As described in Section 4.7.3.3, anticipated direct and indirect effects on public health and safety as a result of Alternative 4 are expected to be similar to those expected under Alternative 3.

4.11.6.15.2 Past and Present Actions

The effects of past and present actions on public health and safety are the same as those described in Section 4.11.4.15.

4.11.6.15.3 Reasonably Foreseeable Future Actions

The effects of reasonably foreseeable future actions on public health and safety are the same as those described in Section 4.11.4.15.

4.11.6.15.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 4 to cumulative effects on public health and safety are the same as those for Alternative 2, described in Section 4.11.4.15.

4.11.6.15.5 Conclusion

Similar to the contribution of Alternative 2 described in Section 4.11.4.15, Alternative 4 contributes to cumulative impacts on public health and safety via the relatively small contribution of the direct and indirect impacts.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with public health and safety were discussed under Alternative 2 (Section 4.11.4.15).

4.11.6.16 Cultural Resources

4.11.6.16.1 Summary of Direct and Indirect Effects

Alternative 4 is the same as Alternative 3 except with increased level of exploratory drilling activity, with two additional programs in each sea per season. The impacts discussed for Alternative 3 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to cultural resources. The conclusions for Alternative 3 are applicable to Alternative 4; and while the level of activity would increase, due to the relatively small area affected and short term, infrequent nature of crew changes, the overall impact to cultural resources from increased levels of activity would be minor.

4.11.6.16.2 Past and Present Actions

Past and present actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.6.16.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.6.16.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.6.16.5 Conclusion

The incremental contribution of activities associated with Alternative 4 to cumulative effects on cultural resources would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with cultural resources were discussed under Alternative 2 (Section 4.11.4.16).

4.11.6.17 Land and Water Ownership, Use, Management

4.11.6.17.1 Summary of Direct and Indirect Effects

As discussed in Section 4.11.4.17, the direct and indirect impacts on land and water ownership would be low magnitude, temporary duration, local extent, and common in context. The direct and indirect impacts on land and water use would have a high magnitude, be temporary in duration, local and common. The direct and indirect impacts to land and water management would be low intensity, temporary in nature, local, and common. In summary, the impacts of Alternative 4 on land and water ownership, use, and management would be negligible, moderate, and minor, respectively.

4.11.6.17.2 Past and Present Actions

Past and present actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.6.17.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.6.17.4 Contribution of Alternative to Cumulative Effects

Alternative 4 is the same as Alternative 3 except with increased levels of activity. The cumulative effects discussed in Section 4.11.4.17 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to land or water ownership, use, and management. The conclusions for Alternative 2 are applicable to Alternative 4; all changes would be incrementally small, short-term in duration, and geographically dispersed, and thus would not have combined effects creating cumulative impacts on land ownership, use, or management and would be considered minor.

4.11.5.17.5 Conclusion

Under Alternative 4, the levels of direct, indirect and cumulative impacts for land and water ownership, use, and management are negligible, moderate, and minor, respectively. Based on this, the overall level of impact of Alternative 4 is considered minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with land and water ownership, use, and management were discussed under Alternative 2 (Section 4.11.4.17).

4.11.6.18 Transportation

4.11.6.18.1 Summary of Direct and Indirect Effects

Increased levels of marine vessel traffic in Alternative 4 associated with the seismic survey and exploratory drilling programs would be expected to primarily occur in offshore areas where local marine transportation does not occur. Industry vessels would likely encounter local marine traffic when littering to designated nearshore marine facilities (which are limited). The impact of increased vessel presence would be low in intensity, temporary in duration, limited in geographic extent to a local area, and common to potentially unique context (in respect to protected marine mammal resources). The summary impact from increases in vessel traffic would be considered minor.

4.11.6.18.2 Past and Present Actions

Past and present actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.6.18.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.6.18.4 Contribution of Alternative to Cumulative Effects

The contribution of impacts from Alternative 4 would be similar but of slightly higher intensity than described for Alternative 2 in Section 4.11.4.18.

4.11.6.18.5 Conclusion

In summary, no concerns related to adverse cumulative impacts have been identified. Some cumulative impacts may exist if Alternative 4 overlaps with another large-scale development project but those impacts would be of low intensity, temporary in duration affecting local areas of common resources, and are considered unlikely to have long-term impacts on regional transportation infrastructure.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with transportation were discussed under Alternative 2 (Section 4.11.4.18).

4.11.6.19 Recreation and Tourism

4.11.6.19.1 Summary of Direct and Indirect Effects

As discussed in Section 4.6.3.7, the direct impacts on recreation and tourism would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 4 on recreation and tourism would be minor.

4.11.6.19.2 Past and Present Actions

Past and present actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.6.19.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.6.19.4 Contribution of Alternative to Cumulative Effects

Alternative 4 is the same as Alternative 3 except with increased levels of exploratory drilling activity. The cumulative effects discussed in Section 4.11.4.19 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to recreation and tourism. The conclusions for Alternative 2 are applicable to Alternative 4; the contribution of Alternative 4 to cumulative effects to recreation and tourism would be minor.

4.11.6.19.5 Conclusion

Alternative 4 would have a minor contribution to cumulative effects on recreation and tourism.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with recreation and tourism were discussed under Alternative 2 (Section 4.11.4.19).

4.11.6.20 Visual Resources

4.11.6.20.1 Summary of Direct and Indirect Effects

Implementation of Alternative 4 would be similar to that describe in Section 4.10.4.20, however there would be an increase in the level of permitted activity and a consequent potential increase in impacts to visual resources. The proposed action is expected to result in short-term moderate effects to scenic quality and visual resources similar to that described in Alternative 2. Because of the greater number of support vessels used in the two exploratory drilling programs proposed under Alternative 4, this action could be high intensity if both programs are implemented in close proximity to each other. Potential impacts could be of low to medium intensity depending if programs are geographically separated. In either case, actions would be temporary, localized and occur in an important context.

Standard mitigation measures implemented as part of the proposed action would not alter the level of anticipated impacts to visual resources or scenic quality. Although Category D Mitigation Measures would limit exposure of sensitive viewers (individuals engaged in the culturally important activity of bowhead whaling) to vessel-based surveys during certain periods. However it would not change exposure to drill sites, as these structures would remain in place during shutdown periods unless the operator agrees to move off location during such shutdown periods.

4.11.6.20.2 Past and Present Actions

Past and present actions associated with visual resources are presented under Alternative 2 (Section 4.11.4.20).

4.11.6.20.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions associated with visual resources are presented under Alternative 2 (Section 4.11.4.20).

4.11.6.20.4 Contribution of Alternative to Cumulative Effects

Implementation of Alternative 4 would increase the level of permitted activity (i.e. four versus two exploratory drilling programs per sea each year). Actions could occur at any location within the EIS project area; however, like Alternative 3, actions associated with implementation of Alternative 4 would result in the greatest impact to visual resources if sited in near-shore areas between Harrison Bay and Kaktovik, where the majority of past, present, and reasonably foreseeable future actions are located. The location would also coincide with locations of sensitive viewers, such as residents of native communities or recreators using the ANWR. If actions associated with Alternative 4 are concentrated in areas where the majority of past, present, and reasonably foreseeable future actions are located, Alternative 4 would contribute to the industrialized landscape character of the area. Transient views of seismic and shallow hazard survey vessels are not expected to contribute to the industrial character of the area, as views of vessels would be episodic.

4.11.6.20.5 Conclusion

Under Alternative 3, anticipated cumulative effects to visual resources are expected to be major. Impacts would be of high intensity, long-term in duration, regional in geographic extent and occurring in an important context.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with visual resources were discussed under Alternative 2 (Section 4.11.4.20).

4.11.6.21 Environmental Justice

4.11.6.21.1 Summary of Direct and Indirect Effects

Direct and indirect effects to subsistence and public health associated with Alternative 4 would be minor, similar to those described in Alternative 2. The level of activity associated with Alternative 4 is greater than Alternative 2, but the effects do not change the summary impact level for these environmental justice indicators.

4.11.6.21.2 Past and Present Actions

Past and present actions associated with environmental justice are presented under Alternative 2 (Section 4.11.4.21).

4.11.6.21.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions associated with environmental justice are presented under Alternative 2 (Section 4.11.4.21).Future industrial activities and climate change would have an adverse impact on subsistence resources and uses and public health.

4.11.6.21.4 Contribution of Alternative to Cumulative Effects

The incremental contribution of Alternative 4 to the overall industrial activity in the area would be similar that that described for Alternative 2. Therefore, the contribution of Alternative 4 to environmental justice indicator cumulative effects would be minor.

4.11.6.21.5 Conclusion

The direct and indirect effects of Alternative 4 would be minor. The contribution to the cumulative effect of environmental justice indicators would be minor. Therefore, there would be a disproportionate impact to Alaska Native communities in the EIS project area.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with visual resources were discussed under Alternative 2 (Section 4.11.4.20). A VLOS would have disproportionate adverse impacts to Alaska Native communities in the EIS project area.

4.11.7 Alternative 5 – Authorization for Level 3 Exploration Activity with Additional Required Time/Area Closures

4.11.7.1 Physical Oceanography

4.11.7.1.1 Summary of Direct and Indirect Effects

The effects of Alternative 5 on physical ocean resources would be substantially the same as those described for Alternative 4. The required time/area closures in Alternative 5 would not substantially change the effects of the alternative on physical ocean resources in the EIS project area. The effects of Alternative 5 on physical ocean resources would be medium-intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. The direct and indirect effects of Alternative 5 on physical ocean resources in the proposed action area would be minor.

4.11.7.1.2 Past and Present Actions

Past and present actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.7.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.7.1.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 5 would cause localized minor impacts to physical ocean resources in the EIS project area. While some actions associated with Alternative 5, such as the construction of man-made gravel islands, would interact with past, present, and reasonably foreseeable future actions to influence physical ocean resources in the EIS project area, resulting in a minor contribution to cumulative impacts.

4.11.7.1.5 Conclusion

The direct and indirect effects of Alternative 5 on physical ocean resources in the EIS project area would be minor. The incremental contribution of activities associated with Alternative 5 to cumulative effects on physical ocean resources in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with physical ocean resources were discussed under Alternative 2 (Section 4.11.4.1).

4.11.7.2 Climate & Meteorology

4.11.7.2.1 Summary of Direct and Indirect Effects

Alternative 5 involves the same exploration activities as proposed in Alternative 4, except with the inclusion of time/area closures. Assuming that the same level of activity would occur and work around time/area closures, the estimated amount of GHG emissions associated with Alternative 5 are the same as those for Alternative 4. Therefore the impact levels are expected to be the same as Alternative 4, which are minor direct impacts and minor to moderate indirect impacts.

4.11.7.2.2 Past and Present Actions

Past and present actions affecting climate change within the EIS project area are discussed under Alternative 2, Section 4.11.4.2.

4.11.7.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting climate change within the EIS project area are discussed under Alternative 2, Section 4.11.4.2.

4.11.7.2.4 Contribution of Alternative to Cumulative Effects

Alternative 5 would emit approximately the same amount of GHGs as Alternative 4; therefore its direct impacts would contribute more to cumulative climate change impacts than Alternative 2. As with Alternatives 2 and 3, the indirect effects from Alternative 5 would contribute more to cumulative impacts than the direct effects. The magnitude of indirect effects cannot be quantified and is considered to be the same as for Alternatives 2 and 3. Indirect effects from Alternative 5 are expected to result in changes that could be long-term and could affect unique resources.

4.11.7.2.5 Conclusion

Alternative 5 could contribute to a moderate to major cumulative impact to climate change, to the same as Alternative 4.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with climate change were discussed under Alternative 2 (Section 4.11.4.2).

4.11.7.3 Air Quality

4.11.7.3.1 Summary of Direct and Indirect Effects

The air quality effects due to the worst-case activity under Alternative 5, Level 3 Exploration Activity, are expected to be the same as those for Alternative 4. The overall direct effect on air quality is expected to be moderate, and indirect effects would be moderate.

4.11.7.3.2 Past and Present Actions

Past and present actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.7.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.7.3.4 Contribution of Alternative to Cumulative Effects

The potential cumulative effects on air quality for Alternative 5 are the same as those for Alternative 4. These are expected to be moderate, with worst-case effect being less than additive.

4.11.7.3.5 Conclusion

Alternative 5 has the potential to contribute to cumulative effects on air quality when activities occur in the vicinity of other sources of air pollution. Due to distance between activities, and the mobile and intermittent source activities, the cumulative effects are expected to be less than the sum of each, likely remaining moderate in magnitude.

The additive effects resulting from a VLOS within the seas Arctic OCS associated with air quality were discussed under Alternative 2 (Section 4.11.4.3).

4.11.7.4 Acoustics

4.11.7.4.1 Summary of Direct and Indirect Effects

The summary of direct and indirect effects provided in Section 4.11.4 (Alternative 2) is relevant also for Alternative 5.

4.11.7.4.2 Past and Present Actions

Past and present actions affecting acoustics within the EIS project area are discussed under Alternative 2, Section 4.11.4.4.

4.11.7.4.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting acoustics within the EIS project area are discussed under Alternative 2, Section 4.11.4.4. The inclusion of time/area closures may cause greater seismic survey activity levels during non-closure times unless scheduling of individual activities can be performed as part of the closure decisions.

4.11.7.4.4 Contribution of Alternative to Cumulative Effects

The contributions to cumulative effects for Alternative 5 should be substantially less than from Alternative 4 if the closures were scheduled to avoid peak marine mammal migration times. This approach should work relatively well to avoid bowhead migrations that are low in the Beaufort Sea EIS project area prior to mid-September. The number of individual exposures, and hence the total exposures will be reduced. However, the shorter available working season is likely to lead to increased activity during the open periods. Animals that are present during those open periods may have higher activity levels to contend with than if closures were not implemented. Those animals may therefore be exposed to higher sound levels and possibly injurious levels. While the total number of disturbance exposures should decrease, there could be higher chance of injurious exposures for marine mammals present during non-closed periods due to reduced ability to avoid close approaches with seismic survey sources.

4.11.7.4.5 Conclusion

Use of closures as proposed in Alternative 4 should be effective for reducing total exposures to sound levels that could disturb marine mammals. Implementing closures may however lead to compressed periods of higher activity during the reduced open periods. Animals present during those open periods could be exposed to high noise levels that could lead to injuries. Scheduling of individual activities might be considered as part of the closure scheduling to mitigate this possible outcome.

The additive effects resulting from a VLOS within the seas Arctic OCS associated with acoustics were discussed under Alternative 2 (Section 4.11.4.4).

4.11.7.5 Water Quality

4.11.7.5.1 Summary of Direct and Indirect Effects

Impacts to water quality from Alternative 5 are expected to be very similar to those described above for Alternative 4. The only difference between Alternative 4 and Alternative 5 is the addition of required time/area closures. The level of activity would be the same for Alternatives 4 and 5, but the times and locations of the activity could be different. Time/area closures established under Alternative 5 as additional mitigation measures could reduce the likelihood of adverse impacts to water quality in sensitive areas during certain times. The effects of Alternative 5 on water quality are expected to be low intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1. The overall effects of Alternative 5 on water quality are expected to be minor.

4.11.7.5.2 Past and Present Actions

Past and present actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.7.5.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.7.5.4 Contribution of Alternative to Cumulative Effects

Additional time/area closures would reduce the potential for incremental degradation of water quality in sensitive areas. Actions associated with Alternative 5 would cause temporary local impacts to water quality such as increases in temperature, turbidity, and concentrations of pollutants. Some actions associated with Alternative 5, such as discharges of cooling water and waste material, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to water quality. These interactions would be local and temporary and would represent only a small fraction of foreseeable cumulative impact.

4.11.7.5.5 Conclusion

The incremental contribution of activities associated with Alternative 5 to cumulative effects on water quality in the EIS project area would be minor. The additional time/area closures required under Alternative 5 would reduce the potential for cumulative adverse water quality impacts to occur in sensitive areas.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with water quality were discussed under Alternative 2 (Section 4.11.4.5).

4.11.7.6 Environmental Contaminants and Ecosystem Functions

4.11.7.6.1 Summary of Direct and Indirect Effects

Additional mitigation measures related to time/area closures under Alternative 5 would potentially result in decreased impacts to environmental contaminants and ecosystem functions relative to Alternative43. The time area closures proposed under Alternative 4 would limit impacts to certain coastal areas and convergence zones during particular times and therefore have the potential to reduce adverse impacts to all categories of ecosystem functions.

Regulation functions such as nutrient cycling and waste assimilation, which depend on biota and physical processes to facilitate storage and recycling of nutrients and breakdown or assimilation of contaminants, would be affected over a limited geographic extent within the EIS project area. Habitat functions, particularly those related to benthic habitats, would be impacted as a result of discharges and other activities associated with exploratory drilling. However, time/area closures associated with Alternative 5 would limit the potential for adverse impacts to certain important habitats. Production functions including primary productivity and subsequent transfers to higher trophic levels could potentially be impacted as a result of activities associated with Alternative 5, while the effects of Alternative 4 on information ecosystem functions would depend upon interrelationships between impacts to cultural resources, social resources, and aesthetic resources, which are addressed in other sections of this EIS. Direct and indirect impacts to ecosystem functions resulting from the implementation of Alternative 5 would be medium-intensity, temporary, and local. Overall effects of Alternative 5 on environmental contaminants and ecosystem functions would be minor.

4.11.7.6.2 Past and Present Actions

Past and present actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.7.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.7.6.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 5 would cause localized minor impacts to environmental contaminants and ecosystem functions within the EIS project area. Some actions associated with Alternative 5, such as discharges from exploratory drilling operations, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to ecosystem functions. The impacts resulting from such interactions would represent a relatively small fraction of foreseeable cumulative impact, and the accumulation of impacts is unlikely to be substantial. Time/area closures associated with Alternative 5 would limit the potential for aggregation of adverse impacts to occur in sensitive areas.

4.11.7.6.5 Conclusion

The incremental contribution of activities associated with Alternative 5 to cumulative effects on environmental contaminants and ecosystem functions in the EIS project area would be minor. The additional time/area closures required under Alternative 5 would reduce the potential for cumulative adverse impacts to all categories of environmental contaminants and ecosystem functions in sensitive areas.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with environmental contaminants and ecosystem functions were discussed under Alternative 2 (Section 4.11.4.6).

4.11.7.7 Lower Trophic Levels

4.11.7.7.1 Summary of Direct and Indirect Effects

Activity levels in Alternative 5 are the same as in Alternative 4, and there are additional mitigation measures for seasonal closures for certain areas. These mitigated closures do not affect lower trophic levels in the EIS project area, so the impacts discussed for Alternative 4 are the same for Alternative 5, therefore, the overall impact to lower trophic levels would be minor.

4.11.7.7.2 Past and Present Actions

Past and present actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.7.7.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.7.7.4 Contribution of Alternative to Cumulative Effects

Alternative 5 would have the same types of effects as Alternative 2 with the addition of certain time/area closures. Therefore, the conclusions about Alternative 5 would be similar to Alternative 2 discussed in Section 4.11.4.7 and the overall impact would be moderate. In the absence of a very large oil spill, the exploration activities authorized under Alternative 4 would have moderate contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on lower trophic levels.

4.11.6.7.5 Conclusion

Alternative 5 could have a moderate contribution to cumulative effects on lower trophic organisms.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with lower trophic levels were discussed under Alternative 2 (Section 4.11.4.7).

4.11.7.8 Fish and Essential Fish Habitat

4.11.7.8.1 Summary of Direct and Indirect Effects

The effect of the time/area closures outlined in Alternative 5 on Fish Resources and EFH would be a reduction in the overall impact. Although the overall impact is considered to be negligible based on Alternative 4 alone, any further reduction in impacts resulting from the time/area closures would be beneficial. The already low impact levels would be decreased by each of the individual closures, and any combination would reduce the impacts further. Implementing all of the time/area closures would substantially decrease all effects on fish resources by protecting the most important fish habitats where the highest fish densities are found. Due to the substantial decrease to the already very small scale of any potential effects relative to overall population levels and available habitat, there would be no measurable effect on the resource.

4.11.7.8.2 Past and Present Actions

Past and present actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.7.8.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.7.8.4 Contribution of Alternative to Cumulative Effects

Climate change is the only past, present, or reasonably foreseeable future action that is anticipated to have any measurable effect on fish and EFH within the EIS project area, and those effects are likely to be beneficial. As Arctic waters warm, productivity is likely to increase, thereby creating more favorable fish habitat throughout the region. The lack of measurable effect on fish and EFH resulting from the implementation of Alternative 5 would not add to any cumulative effects.

4.11.7.8.5 Conclusion

Direct and indirect effects associated with Alternative 5 on fish and EFH would be minor. The overall contribution of Alternative 5 to cumulative effects on fish and EFH would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with fish and EFH were discussed under Alternative 2 (Section 4.11.4.8).

4.11.7.9 Marine and Coastal Birds

4.11.7.9.1 Summary of Direct and Indirect Effects

As discussed in Section 4.7.2.3, the effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. In summary, the impact of Alternative 5 on marine and coastal birds would be considered negligible.

4.11.7.9.2 Past and Present Actions

Past and present actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.7.9.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.7.9.4 Contribution of Alternative 4 to Cumulative Effects

Alternative 5 would have the same types and level of exploration activities as Alternative 4 with the addition of certain time/area closures. The most important of these closure areas for birds, Ledyard Bay, would be the same as exists under Alternative 4 due to USFWS requirements to protect spectacled eiders. The other closure areas would be important to certain species, such as Barrow Canyon for Ross's gull in the fall, but these closures would generally be less effective at reducing adverse effects on birds as they would be to protect marine mammals or subsistence hunting. The effects of Alternative 5 would therefore be essentially the same as for Alternative 4. The exploration activities authorized under Alternative 5 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds.

4.11.7.9.5 Conclusion

Direct and indirect effects associated with Alternative 5 on marine and coastal birds would be negligible. The overall contribution of Alternative 5 to cumulative effects on marine and coastal birds would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with marine and coastal birds were discussed under Alternative 2 (Section 4.11.4.9).

4.11.7.10 Marine Mammals

4.11.7.10.1 Bowhead Whales

4.11.7.10.1.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 5 on bowhead whales are described in Section 4.8.2.4.1. Impacts of activities associated with oil and gas exploration in the EIS project area under Alternative 5 are similar to Alternative 4 (See Section 4.11.6.10.1).

Effects of disturbance on bowhead whales would be reduced in the closure areas during time periods specified in Alternative 5. Overall exploration effort may not be reduced, but, rather, redistributed and possibly concentrated in other areas. Time/Area closures that mitigate adverse impacts on concentrations of bowhead whales, mothers and calves, and important life history functions, such as feeding, could reduce impacts to a lower intensity, shorter duration and more localized areas than would result in the absence of closures. However, bowhead whale habitat use in the EIS project area is dynamic and includes large portions of the Beaufort and Chukchi seas not included in the Time/Area closures. Although the Time/Area closures specified in Alternative 5 could mitigate adverse impacts in particular times and locations, the overall impact on bowhead whales of oil and gas exploration activities allowed under this alternative would be considered moderate.

4.11.7.10.1.2 Past and Present Actions

Past and present actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.1.

4.11.7.10.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.10.4.11.1.

4.11.7.10.1.4 Contribution of Alternative to Cumulative Effects

The contribution of the direct and indirect impacts resulting from Alternative 5, when combined with the past, present, and reasonably foreseeable future actions would be similar to Alternative 4 (Section 4.11.6.10.1), with most potential impacts due to acoustic disturbance that could, at least temporarily, disrupt or displace bowhead whales. The time/area closures required under this alternative would mitigate potential adverse impacts during the specified times and within the specified locations. However, bowhead whales are not restricted to these specified areas and may be exposed to impacts by exploration activities operating outside of these closure areas. Because the closures would alleviate, but not eliminate, impacts, the contribution of activities authorized under Alternative 5 to cumulative effects on bowhead whales would be minor.

4.11.7.10.1.5 Conclusion

Under Alternative 5, the direct and indirect effects to bowhead whales would be moderate. Overall, Alternative 5 would have a minor contribution to cumulative effects on bowhead whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with bowhead whales were discussed under Alternative 2 (Section 4.11.4.10.1).

4.11.7.10.2 Beluga Whales

4.11.7.10.2.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 5 on beluga whales are described in Section 4.8.2.4.2 and are summarized here. The additional oil and gas exploration activities proposed in Alternative 5 could directly and indirectly affect beluga whales by causing noise disturbance, habitat degradation, and potential ship strikes. Beluga whales disturbed by oil and gas exploration activities may move away from important habitats. The scale of the avoidance depends on the number and relative proximity of the surveys. Numerous simultaneous seismic activities could cause avoidance over large distances. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

The time/area closures would reduce the effects of disturbance on beluga whales in the closed areas during the time periods specified. The closures of Kasegaluk Lagoon, Ledyard Bay, and the Shelf Break of the Beaufort Sea would be especially beneficial to beluga whales. Exploration activities could, however, occur during different time periods within these areas. In addition, industry may relocate exploration activities to other, possibly adjacent, areas until the closure areas are available. Overall, exploration effort may not be reduced, but, rather, redistributed and possibly concentrated in other areas. Time/area closures that mitigate adverse impacts on concentrations of beluga whales could reduce impacts to a lower intensity, shorter duration and more localized areas than would result in the absence of closures. However, beluga whale habitat use in the EIS project area is dynamic and widespread. Considering the migration corridors, it includes large portions of the Beaufort and Chukchi seas not included in the time/area closures that could coincide with oil and gas exploration activities throughout the region. Although the time/area closures specified in Alternative 5 could reduce or avoid adverse impacts in particular times and locations, the overall impact of Alternative 5 on beluga whales would be considered minor to moderate.

4.11.7.10.2.2 Past and Present Actions

Past and present actions affecting beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.7.10.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions that would affect beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.7.10.2.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 5 would add to the acoustic disturbance of beluga whales from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible since it would affect an extremely small proportion of habitat or prey base available to beluga whales. The exploration activities authorized under Alternative 5 would therefore have moderate additive contributions to the cumulative effects on beluga whales.

4.11.7.10.2.5 Conclusion

As stated above, most exploration activities authorized under Alternative 5 would result in minor to moderate contributions to cumulative effects on beluga whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with beluga whales were discussed under Alternative 2 (Section 4.11.4.10.2).

4.11.7.10.3 Other Cetaceans

4.11.7.10.3.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 5 on cetaceans are described in Section 4.8.2.4.3 and are summarized here. Evaluated collectively, the overall impact of Alternative 4 on other cetaceans is minor to moderate. Although the time/area closures specified in Alternative 5 could mitigate adverse impacts in particular times and locations, the overall impact on other cetaceans of oil and gas exploration activities allowed under this alternative would be similar to Alternative 4. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 5, impacts on the resource would be low in intensity, of short duration, and limited extent. Long term impacts are unknown, but anticipated to be minor.

Effects on other cetaceans from open-water exploration activities would be reduced in the closure areas during time periods specified in Alternative 5. Exploration activities could, however, occur during different time periods within these areas, leading to a short-term reduction of effects. In addition, industry may relocate exploration activities to other, possibly adjacent, areas until the closure areas are available. Overall exploration effort may not be reduced, but, rather, redistributed and possibly concentrated in other areas. Time/Area closures that mitigate adverse impacts on concentrations of cetaceans within the closures, mothers and calves, and important life history functions, such as feeding, could reduce impacts to a lower intensity, shorter duration and more localized areas than would result in the absence of closures. However, cetacean habitat use in the EIS project area is dynamic and, when migration corridors are considered, includes large portions of the Beaufort and Chukchi seas not included in the time/area closures that could coincide with oil and gas exploration activities throughout the region. These measures are most likely to impact gray whales and less likely to impact the remaining cetaceans in the resource group, due to species distribution.

4.11.7.10.3.2 Past and Present Actions

Past and present actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.7.10.3.2 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.7.10.3.3 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 5 would add to the acoustic disturbance of other cetaceans from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Although the time/area closures specified in Alternative 5 could mitigate adverse impacts in particular times and locations, the overall impact on other cetaceans of oil and gas exploration activities allowed under this alternative would be similar to Alternative 4. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible.

None of the past, present, or reasonably foreseeable future actions described above are expected to have any substantial impact on cetacean populations within the EIS project area. Populations for most species are stable or increasing, and climate change is likely to add nominal beneficial impacts in the future. The exploration activities authorized under Alternative 5 would therefore have minor additive contributions to the cumulative effects on other cetaceans.

4.11.7.10.3.4 Conclusion

As stated above, most exploration activities authorized under Alternative 5 would result in minor contributions to cumulative effects on other cetaceans.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with other cetaceans were discussed under Alternative 2 (Section 4.11.4.10.3).

4.11.7.10.4 Ice Seals

4.11.7.10.4.1 Summary of Direct and Indirect Effects

There are four species of seals considered in this section that are often collectively called "ice seals"; ringed seal, spotted seal, ribbon seal, and bearded seal. The direct and indirect effects of Alternative 5 on ice seals are described in Section 4.8.2.4.4 and are summarized here. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past offshore oil and gas exploration activities in the Alaskan Beaufort and Chukchi seas and would likely be affected more frequently by exploration activities authorized under Alternative 5 than either ribbon or spotted seals. Data from observers on board seismic source vessels and monitoring vessels indicate that seals tend to avoid on-coming vessels and active seismic arrays but they do not appear to react strongly even as ships pass fairly close with active arrays. They also do not appear to react strongly to icebreaking or on-ice surveys, keeping their distance or moving away at some point to an alternate breathing hole or haulout, but the scope of these behavioral responses appears to be within their natural abilities and responses to their naturally dynamic environment. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and they would be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are legally protected, have unique ecological roles in the Arctic, and are important subsistence resources and are therefore considered to be unique resources. Given the standard mitigation measures that have been required in the past, the effects of exploration activities that could be authorized under Alternative 5 on ice seals would likely be low in magnitude, distributed over a wide geographic area, and temporary to short-term in duration. The effects of Alternative 4 would therefore be considered minor for all ice seal species according to the criteria established in Section 4.1.3.

4.11.7.10.4.2 Past and Present Actions

Past and present actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.7.10.4.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.7.10.4.4 Contribution of Alternative 5 to Cumulative Effects

The exploration activities authorized under Alternative 5 would add to the disturbance of ice seals from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Very small numbers of ringed seals could be exposed to exploration activities during the denning season (winter-spring) when females with young are more susceptible to disturbance. Exploration activities would contribute negligible risk of additional mortality to any species, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 5 would therefore have negligible to minor contributions to the cumulative effects on the four species of ice seals considered.

4.11.7.10.4.5 Conclusion

The direct and indirect effects of Alternative 5 on pinnipeds would be considered minor. Alternative 5 would have negligible to minor contributions to the cumulative effects on the four species of ice seals.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with pinnipeds were discussed under Alternative 2 (Section 4.11.4.10.4).

4.11.7.10.5 Walrus

4.11.7.10.5.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 5 on walrus are described in Section 4.8.2.4.5 and are summarized here. The types and levels of effects on walrus are essentially the same under Alternative 5 as for Alternative 4 (Section 4.7.2.4.5). The primary difference for walrus would be a change in the timing of vessel traffic and impacts on benthic habitat in the Hanna Shoal area, which would be subject to a closure period in the fall. The closure period would reduce the potential for disturbance of walrus by vessels in that time period but would not change overall exploration efforts so the potential for disturbance in the Chukchi Sea would be similar to Alternative 4. Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. These data indicate that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest sounds generated by the ships. The gradual introduction of alternative technologies for seismic surveys would make very little difference to walrus because they are unlikely to be affected in any biologically meaningful way by seismic noise. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of mortality from stampedes. Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for NEPA purposes. Given the level and type of exploration activities that would be authorized under Alternative 5, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on walrus would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 5 on Pacific walrus would therefore be considered minor.

4.11.7.10.5.2 Past and Present Actions

Past and present actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.7.10.5.2 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.7.10.5.3 Contribution of Alternative 5 to Cumulative Effects

The exploration activities authorized under Alternative 5 would add to the disturbance of walrus from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to walrus, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 5 would therefore have minor to negligible contributions to the cumulative effects on Pacific walrus.

4.11.7.10.5.4 Conclusion

The direct and indirect effects of Alternative 5 on Pacific walrus would be considered minor. Alternative 5 would have negligible to minor contributions to the cumulative effects on Pacific walrus.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with Pacific walrus were discussed under Alternative 2 (Section 4.11.4.10.5).

4.11.7.10.6 Polar Bears

4.11.7.10.6.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 5 on polar bears are described in Section 4.8.2.4.6 and are summarized here. The types and levels of effects on polar bears are essentially the same under Alternative 5 as for Alternative 4 (Section 4.7.2.4.6). The time/area closure periods specified in Alternative 5 involve open-water environments where bears are rare so the potential for disturbance and other effects in the Arctic seas would be essentially the same as under Alternative 4. Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. The gradual introduction of alternative technologies for seismic surveys would make very little difference to polar bears because they are unlikely to be affected in any biologically meaningful way by seismic noise. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important to subsistence cultures and are therefore considered a unique resource. Given the level and type of exploration activities that would be authorized under Alternative 5, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on polar bears would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 5 on polar bears would therefore be considered minor.

4.11.7.10.6.2 Past and Present Actions

Past and present actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.7.10.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.7.10.6.4 Contribution of Alternative 5 to Cumulative Effects

The exploration activities authorized under Alternative 5 would add to the disturbance of polar bears from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to polar bears, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 5 would therefore have negligible to minor contributions to the cumulative effects on polar bears.

4.11.7.10.6.5 Conclusion

The direct and indirect effects of Alternative 5 on polar bears would be considered minor. Alternative 5 would have negligible to minor contributions to the cumulative effects on polar bears.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with polar bears were discussed under Alternative 2 (Section 4.11.4.10.6).

4.11.7.11 Terrestrial Mammals

4.11.7.11.1 Summary of Direct and Indirect Effects

Activity levels in Alternative 5 are the same as in Alternative 4, with the added requirement for time/area closures for certain areas. These required closures under Alternative 5 do not affect terrestrial mammals in the EIS project area, so the impacts discussed for Alternative 4 are the same for Alternative 5; the summary level direct and indirect impact to terrestrial mammals would be minor.

4.11.7.11.2 Past and Present Actions

Past and present actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.7.11.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.7.11.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.7.11.5 Conclusion

Direct and indirect impacts resulting from Alternative 5 on caribou would be minor. The incremental contribution of activities associated with Alternative 5 to cumulative effects on caribou would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with caribou were discussed under Alternative 2 (Section 4.11.4.11).

4.11.7.12 Time/Area Closures

The analysis of the cumulative effects associated with time/area closure locations can be found in Sections 4.11.7.10 (Marine Mammals), 4.11.7.9 (Marine and Coastal Birds) and 4.11.7.14 (Subsistence).

4.11.7.13 Socioeconomics

4.11.7.13.1 Summary of Direct and Indirect Effects

Direct and indirect effects associated with Alternative 5 are minor, similar to those described for Alternative 2. To the extent that time/area closures in all closure areas provide additional benefits to marine mammals and reduce net impacts on subsistence activities, there would be some potential socioeconomic benefits to the non-cash economy. Time/area closures may result in productivity costs to lease holders and reduced personal income for local hires in PSO and Com Center positions due to reductions in the duration of these positions.

4.11.7.13.2 Past and Present Actions

Past and present actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13.

4.11.7.13.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13.

4.11.7.13.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 5 to socioeconomic cumulative effects would be minor and positive. They differ from Alternative 2 by a low magnitude of lost productivity for lease holders and loss in magnitude in the new personal income sources. The mitigation measures associated with Alternative 5 would have a net benefit to subsistence resources and activities and therefore would have a countervailing positive impact to the non-cash economy. The summary contribution of these impacts to the cumulative effectives of socioeconomics is negligible to minor at a statewide and national level and minor at the local level.

4.11.7.13.5 Conclusion

The direct and indirect effects of Alternative 5 would be positive and minor. The contribution to cumulative effects of socioeconomics would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with socioeconomics were discussed under Alternative 2 (Section 4.11.4.13).

4.11.7.14 Subsistence

4.11.7.14.1 Summary of Direct and Indirect Effects

Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources and harvests resulting from implementation of Alternative 5 would be of low intensity, temporary in duration, local in extent, and the context would be common to unique. Protected resources (bowhead whales and polar bears are considered unique in context as these resources are protected by legislation (e.g. MMPA, ESA) or are considered an important subsistence resource (beluga whales). The impacts of implementing Alternative 5 could be considered beneficial to subsistence harvests and users as the time and area closures would be applied in all circumstances instead of being considered as additional mitigation measures. Direct and indirect impacts to subsistence harvest and subsistence resources are likely to be similar or less than those of Alternative 2 as discussed in Section 4.5.3.2 and Section 4.11.4.14. The summary impact to subsistence is therefore considered to range from negligible to minor depending upon the specific subsistence resource affected and source of disturbance (Section 4.5.3.2 and Section 4.8.3.2).

4.11.7.14.2 Past and Present Actions

Past and present actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.7.14.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.7.14.4 Contribution of Alternatives to Cumulative Effects

The activities authorized under Alternative 5 would add to the disturbance of subsistence resources from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary and local. A low number of seals and polar bears could be disturbed during on-ice seismic surveys. Exploration activities would constitute a minor contribution to the disturbance of subsistence resources. Exploration activities could contribute to habitat change of subsistence resources through aircraft and vessel traffic, icebreaking efforts, on-ice surveys and discharge of drilling muds but these effects would be of low intensity, localized to regional in extent, temporary in duration, and affect subsistence resources that are common to unique in context. This contribution to habitat change would be negligible when compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems and resource abundance due to ocean acidification. The exploration activities authorized under Alternative 5 would occur at a higher level of activity in comparison to those proposed under Alternative 2 but the time and area closures that would be applied under this alternative in all circumstances are considered beneficial to subsistence harvests and users. The exploration activities authorized under Alternative 5 would have a negligible to minor contribution to the cumulative effects on subsistence resources. Implementation of Alternative 5 would be considered additive to cumulative effects on subsistence resources.

4.11.7.14.5 Conclusion

Under Alternative 5, the direct and indirect effects to subsistence resources are considered low in intensity, temporary in duration, local in extent and affect subsistence resources that range from common to unique in context. Implementation of Alternative 5 while beneficial in implementing time and area closures would be additive to cumulative effects on subsistence resources. The contribution of the direct and indirect impacts in consideration of the past, present, and reasonably foreseeable future actions would be negligible to minor on subsistence.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with subsistence resources were discussed under Alternative 2 (Section 4.11.4.14).

4.11.7.15 Public Health

4.11.7.15.1 Summary of Direct and Indirect Effects

As described in Section 4.8.3.3, anticipated direct and indirect effects on public health and safety as a result of Alternative 5 are expected to be similar to those expected under Alternative 2. To the extent the time/area closures described for Alternative 4 improve the likelihood of maintaining a strong subsistence harvest, there will also be resulting benefits to public health. Similarly, insofar as time and area closures minimize dispersion of marine mammals and allow hunters to complete their hunts with less travel time, the potential impact to safety should be reduced. However, these benefits do not affect the overall impact criteria rating, as the anticipated results to public health are already negligible.

4.11.7.15.2 Past and Present Actions

The effects of past and present actions on public health and safety are the same as those described in Section 4.11.3.15.

4.11.7.15.3 Reasonably Foreseeable Future Actions

The effects of reasonably foreseeable future actions on public health and safety are the same as those described in Section 4.11.3.15.

4.11.7.15.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 5 to cumulative effects on public health and safety are the same as those for Alternative 2, described in Section 4.11.4.15.

4.11.7.15.5 Conclusion

Similar to the contribution of Alternative 2 described in Section 4.11.4.15, Alternative 5 contributes to cumulative impacts on public health and safety via the relatively small contribution of the direct and indirect impacts.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with public health and safety were discussed under Alternative 2 (Section 4.11.4.15).

4.11.7.16 Cultural Resources

4.11.7.16.1 Summary of Direct and Indirect Effects

Activity levels in Alternative 5 are the same as in Alternative 4, with the added requirement for seasonal closures for certain areas. These required closures under Alternative 5 do not affect cultural resources in the EIS project area, so the impacts discussed for Alternative 4 are the same for Alternative 5; the overall impact to cultural resources would be minor.

4.11.7.16.2 Past and Present Actions

Past and present actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.7.16.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.7.16.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.7.16.5 Conclusion

The incremental contribution of activities associated with Alternative 5 to cumulative effects on cultural resources would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with cultural resources were discussed under Alternative 2 (Section 4.11.4.16).

4.11.7.17 Land and Water Ownership, Use, Management

4.11.7.17.1 Summary of Direct and Indirect Effects

As discussed in Section 4.8.3.5, the direct and indirect impacts on land and water ownership would be low magnitude, temporary duration, local extent, and common in context. The direct and indirect impacts on land and water use would have a high magnitude, be temporary in duration, local and common. The direct and indirect impacts to land and water management would be low intensity, temporary in nature, local, and common. In summary, the impacts of Alternative 5 on land and water ownership, use, and management would be negligible, moderate, and minor, respectively.

4.11.7.17.2 Past and Present Actions

Past and present actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.7.17.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.7.17.4 Contribution of Alternative to Cumulative Effects

Alternative 5 is the same as Alternative 2 except with increased levels of activity and some specific time/area closures for exploration activities in federal marine waters. The cumulative effects discussed in Section 4.11.4.17 for Alternative 2 are applicable for this alternative. The increased levels of activity would not generate different types of impacts to land or water ownership, use, and management. The conclusions for Alternative 2 are applicable to Alternative 5; the contribution of Alternative 5 to cumulative effects to land and water ownership, use, and management would be negligible, moderate, and minor, respectively.

4.11.7.17.5 Conclusion

Under Alternative 5, the levels of direct, indirect and cumulative impact on land and water ownership, use, and management are negligible, moderate, and minor, respectively. Based on this, the overall level of impact of Alternative 5 is considered minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with land and water ownership, use, and management were discussed under Alternative 2 (Section 4.11.4.17).

4.11.7.18 Transportation

4.11.7.18.1 Summary of Direct and Indirect Effects

Impacts to transportation from Alternative 5 are expected to be very similar to those described above for Alternative 4. The only difference between Alternative 4 and Alternative 5 is the addition of required time/area closures. The level of activity would be the same for Alternatives 4 and 5, but the times and locations of the activity could be different. Any direct impact to regional marine transportation would be low in intensity, temporary in duration, and limited in geographic extent to a local area and common in context and considered minor.

4.11.7.18.2 Past and Present Actions

Past and present actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.7.18.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.7.18.4 Contribution of Alternative to Cumulative Effects

The contribution of impacts from Alternative 4 would be similar as those described for Alternative 3 in Section 4.11.5.18.

4.11.7.18.5 Conclusion

In summary, no concerns related to adverse cumulative impacts have been identified. Some cumulative impacts may exist if Alternative 5 overlaps with another large-scale development project but those impacts would be of low intensity, temporary in duration affecting local areas of common resources and are considered unlikely to have long-term impacts on regional transportation infrastructure.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with transportation were discussed under Alternative 2 (Section 4.11.4.18).

4.11.7.19 Recreation and Tourism

4.11.7.19.1 Summary of Direct and Indirect Effects

The direct impacts would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 5 on recreation and tourism would be minor.

4.11.7.19.2 Past and Present Actions

Past and present actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.7.19.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.7.19.4 Contribution of Alternative to Cumulative Effects

To the extent that the required time/area closures contemplated in Alternative 5 provide benefit to marine mammals, they would be beneficial to tourism based on wildlife viewing, and similar to the benefits of other standard and additional mitigation measures. The potential cumulative effects discussed in Sections 4.11.4.19 and 4.11.5.19 for Alternatives 2 and 3 are the same for Alternative 5; the overall impact to recreation and tourism would be minor.

4.11.7.19.5 Conclusion

Alternative 5 would have a minor contribution to cumulative effects on recreation and tourism.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with recreation and tourism were discussed under Alternative 2 (Section 4.11.4.19).

4.11.7.20 Visual Resources

4.11.7.20.1 Summary of Direct and Indirect Effects

Direct and indirect effects of past and present actions are identical to those described in Section 4.11.6.20, Alternative 4.

4.11.7.20.2 Past and Present Actions

Past and present actions affecting visual resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.20.

4.11.7.20.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting visual resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.20.

4.11.7.20.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 5 to cumulative effects would be identical to that described for Alternative 4.

4.11.7.20.5 Conclusion

Under Alternative 5, anticipated cumulative effects to visual resources are expected to be major. Impacts would be of high intensity, long-term in duration, regional in geographic extent and occurring in an important context.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with visual resources were discussed under Alternative 2 (Section 4.11.4.20).

4.11.7.21 Environmental Justice

4.11.7.21.1 Summary of Direct and Indirect Effects

Direct and indirect effects to subsistence and public health associated with Alternative 5 would be minor, similar to those described for Alternative 2. To the extent that time/area closures in all closure areas provide additional benefits to marine mammals and reduce net impacts on subsistence activities, the impacts to subsistence and public health would be lessened, however, these benefits to do not affect the summary impact level of minor.

4.11.7.21.2 Past and Present Actions

The past and present actions that would contribute to the cumulative effects of environmental justice under Alternative 5 are the same as those described for Alternative 1 in Section 4.11.3.21.

4.11.7.21.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions for Alternative 5 would be the same as those described for Alternative 2 in Section 4.11.4.21. Future industrial activities and climate change would have an adverse impact on subsistence resources and uses and public health.

4.11.7.21.4 Contribution of Alternative to Cumulative Effects

The incremental contribution of Alternative 5 to the overall industrial activity in the area would be similar that that described for Alternative 2. Therefore, the contribution of Alternative 5 to environmental justice indicator cumulative effects would be minor.

4.11.7.21.5 Conclusion

The direct and indirect effects of Alternative 5 would be minor. The contribution to the cumulative effect of environmental justice indicators would be minor. Therefore, there would be a disproportionate impact to Alaska Native communities in the EIS project area.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with environmental justice were discussed under Alternative 2 (Section 4.11.4.21). A VLOS would have disproportionate adverse impacts to Alaska Natives living in the communities near the EIS project area.

4.11.8 Alternative 6 – Authorization for Level 3 Exploration Activity with Use of Alternative Technologies

4.11.8.1 Physical Oceanography

4.11.8.1.1 Summary of Direct and Indirect Effects

The effects of Alternative 6 on physical ocean resources would be substantially the same as those described for Alternative 4. The additional mitigation measures included in Alternative 6 would not substantially change the effects of the alternative on physical ocean resources in the EIS project area. The effects of Alternative 6 on physical ocean resources would be medium-intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. The effects Alternative 6 on physical ocean resources in the EIS project area would be minor.

4.11.8.1.2 Past and Present Actions

Past and present actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.8.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting physical ocean resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.1.

4.11.8.1.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 6 would cause localized minor impacts to physical ocean resources in the EIS project area. While some actions associated with Alternative 6, such as the construction of man-made gravel islands, would interact in a synergistic fashion with past, present, and reasonably foreseeable future actions to influence physical ocean resources in the EIS project area, the impacts resulting from such synergies would represent only a small fraction of foreseeable cumulative impact.

4.11.8.1.5 Conclusion

The incremental contribution of activities associated with Alternative 6 to cumulative effects on physical ocean resources in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with physical ocean resources were discussed under Alternative 2 (Section 4.11.4.1).

4.11.8.2 Climate & Meteorology

4.11.8.2.1 Summary of Direct and Indirect Effects

Alternative 6 involves the same exploration activities as proposed in Alternatives 4 and 5, with the potential inclusion of alternative technologies. The estimated amount of GHG emissions associated with Alternative 6 is the same as those for Alternatives 4 and 5. Therefore the impact levels are expected to be the same as Alternatives 4 and 5, which are minor direct impacts and minor to moderate indirect impacts.

4.11.8.2.2 Past and Present Actions

Past and present actions affecting climate change within the EIS project area are discussed under Alternative 2, Section 4.11.4.2.

4.11.8.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting climate change within the EIS project area are discussed under Alternative 2, Section 4.11.4.2.

4.11.8.2.4 Contribution of Alternative to Cumulative Effects

Alternative 6 would emit approximately the same amount of GHGs as Alternatives 4 and 5; therefore its direct impacts would contribute more to cumulative climate change impacts than Alternative 2. As with Alternatives 2 through 5, the indirect effects would contribute more to cumulative impacts than the direct effects. The magnitude of indirect effects cannot be quantified and is considered to be the same as for Alternatives 2 through 5. Therefore indirect effects from Alternative 6 are expected to result in changes that could be long-term and could affect unique resources.

4.11.8.2.5 Conclusion

Alternative 6 could contribute to a moderate to major cumulative impact to climate change, the same as with Alternatives 2 through 5.

The additive effects resulting from a VLOS within the seas Arctic OCS associated with climate change were discussed under Alternative 2 (Section 4.11.4.2).

4.11.8.3 Air Quality

4.118.3.1 Summary of Direct and Indirect Effects

The air quality effects due to the worst-case activity under Alternative 6, Level 3 Exploration Activity, are expected to be the same as those for Alternatives 4 and 5. The overall direct effect on air quality is expected to be moderate, and indirect effects would be negligible to minor.

4.11.8.3.2 Past and Present Actions

Past and present actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.8.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting air quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.3.

4.11.8.3.4 Contribution of Alternative to Cumulative Effects

The potential cumulative effects on air quality for Alternative 6 are the same as those for Alternative 4, with a moderate contribution to cumulative effects from Alternative 6.

4.11.8.3.5 Conclusion

Alternative 6 has the potential to contribute to cumulative effects on air quality when activities occur in the vicinity of other sources of air pollution. Due to distance between activities, and the mobile and intermittent source activities, the cumulative effects are expected to be less than the sum of each, likely remaining moderate in magnitude.

The additive effects resulting from a VLOS within the seas Arctic OCS associated with air quality were discussed under Alternative 2 (Section 4.11.4.3).

4.11.8.4 Acoustics

4.11.8.4.1 Summary of Direct and Indirect Effects

The summary of direct and indirect effects provided in Section 4.11.4 (Alternative 2) is relevant also for Alternative 6. Alternative 6 suggests replacement of some impulsive airgun sources with alternate sources to reduce the emitted impulsive levels. Several alternative source types are described in Section 2.3.5.

4.11.8.4.2 Past and Present Actions

Past and present actions affecting acoustics within the EIS project area are discussed under Alternative 2, Section 4.11.4.4.

4.11.8.4.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting acoustics within the EIS project area are discussed under Alternative 2, Section 4.11.4.4.

4.11.8.4.4 Contribution of Alternative to Cumulative Effects

The contribution to cumulative effects from use of alternate technologies is difficult to assess. Simple reductions in pulse rms levels will reduce the number of auditory system injury takes and disturbance takes under the present NMFS criteria for these effects. Some of the proposed sources, such as marine vibrators, operate by extending the time period over which acoustic energy is transmitted into the water. These extended-duration sources operate at lower rms pressure levels but may produce similar SEL. These sources would not show as much improvement when evaluated against SEL-based criteria such as those proposed by Southall et al. (2007). Another important issue associated with extending the transmission time of impulsive sounds is that the source signals become less impulsive and could be reclassified as continuous noise. In that case they could be evaluated against the continuous noise disturbance threshold of 120 dB re 1 μPa instead of the impulsive threshold 160 dB re 1 μPa (rms). The above points illustrate outstanding issues with regard to developing relevant criteria upon which to base acoustic effects assessments. If this alternative is successful then further reductions of seismic survey sound levels might be achieved as improvements to the alternate technologies are made. These improvements could lead to reduced exposures and effects.

4.11.8.4.5 Conclusion

The use of alternate sources under Alternative 6 has potential to substantially reduce the size of effects zones for seismic surveys. There are potential drawbacks for modified sources that increase the duration of source signals, including the smaller reduction of SEL and the possibility the signals may be reclassified as continuous noise – thereby becoming subject to evaluation against a much lower disturbance threshold criterion. Still, these issues can be overcome if accounted for in the development of the alternate source systems.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with acoustics were discussed under Alternative 2 (Section 4.11.4.4).

4.11.8.5 Water Quality

4.11.8.5.1 Summary of Direct and Indirect Effects

Impacts to water quality resulting from Alternative 6 are expected to be very similar to those described for Alternative 4 in Section 4.11.6.5. Alternative 6 includes mitigation measures that focus on the use of alternative technologies to replace or augment traditional airgun-based seismic exploration techniques. See Chapter 2 for descriptions of the mitigation measures included under Alternative 6. These mitigation measures are not expected to affect the level of water quality impacts. The effects of Alternative 6 on water quality are expected to be low intensity, temporary, local, and would affect common resources as defined in the impact criteria in Section 4.1 of this EIS. The overall effects of Alternative 6 on water quality are expected to be minor.

4.11.8.5.2 Past and Present Actions

Past and present actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.8.5.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting water quality within the EIS project area are discussed under Alternative 2, Section 4.11.4.5.

4.11.8.5.4 Contribution of Alternative to Cumulative Effects

Use of alternative technologies would not influence the contribution of exploration activities to cumulative effects on water quality. Actions associated with Alternative 5 would cause temporary local impacts to water quality such as increases in temperature, turbidity, and concentrations of pollutants. Some actions associated with Alternative 6, such as discharges of cooling water and waste material, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to water quality. These interactions would be local and temporary and would represent only a small fraction of foreseeable cumulative impact.

4.11.8.5.5 Conclusion

The incremental contribution of activities associated with Alternative 6 to cumulative effects on water quality in the EIS project area would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with water quality were discussed under Alternative 2 (Section 4.11.4.5).

4.11.8.6 Environmental Contaminants and Ecosystem Functions

4.11.8.6.1 Summary of Direct and Indirect Effects

Direct and indirect impacts to environmental contaminants and ecosystem functions resulting from the implementation of Alternative 6 would be medium-intensity, temporary, and local. Regulation functions such as nutrient cycling and waste assimilation, which depend on biota and physical processes to facilitate storage and recycling of nutrients and breakdown or assimilation of contaminants, would be affected within the EIS project area. Habitat functions, particularly those related to benthic habitats, would be impacted as a result of discharges and other activities associated with exploratory drilling. Production functions including primary productivity and subsequent transfers to higher trophic levels could potentially be impacted as a result of activities associated with Alternative 6, while the effects of Alternative 6 on information ecosystem functions would depend upon interrelationships between impacts to cultural resources, social resources, and aesthetic resources, which are addressed in other sections of this EIS. Overall effects of Alternative 6 on ecosystem functions would be minor.

4.11.8.6.2 Past and Present Actions

Past and present actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.8.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting environmental contaminants and ecosystem functions within the EIS project area are discussed under Alternative 2, Section 4.11.4.6.

4.11.8.6.4 Contribution of Alternative to Cumulative Effects

Actions associated with Alternative 6 would cause localized minor impacts to environmental contaminants and ecosystem functions within the EIS project area. Some actions associated with Alternative 6, such as discharges from exploratory drilling operations, would interact with past, present, and reasonably foreseeable future actions resulting in both additive and synergistic impacts to ecosystem functions. The impacts resulting from such interactions would represent a relatively small fraction of foreseeable cumulative impact, and the accumulation of impacts is unlikely to be substantial. The use of alternative technologies associated with Alternative 6 could potentially decrease the accumulation of adverse impacts to habitat, production, and information functions within the EIS project area.

4.11.8.6.5 Conclusion

The incremental contribution of activities associated with Alternative 6 to cumulative effects on environmental contaminants and ecosystem functions in the EIS project area would be minor. Use of alternative technologies could potentially decrease the accumulation of adverse impacts to certain habitat functions within the EIS project area.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with environmental contaminants and ecosystem functions were discussed under Alternative 2 (Section 4.11.4.6).

4.11.8.7 Lower Trophic Levels

4.11.8.7.1 Summary of Direct and Indirect Effects

Activity levels in Alternative 6 are the same as in Alternative 4, with the addition of required measures that focus on alternative technologies for seismic exploration. This requirement does not affect lower trophic levels in the EIS project area, so the impacts discussed previously for Alternatives 2, 3, 4, and 5 are the same for Alternative 6; the overall impact to lower trophic levels would be minor.

4.11.8.7.2 Past and Present Actions

Past and present actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.8.7.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting lower trophic levels within the EIS project area are discussed under Alternative 2, Section 4.11.4.7.

4.11.8.7.4 Contribution of Alternative to Cumulative Effects

Alternative 6 would have the same types of effects as Alternative 2 with the addition of certain time/area closures. Therefore, the conclusions about Alternative 6 would be similar to Alternative 2 discussed in Section 4.10.4.7 and the overall impact would be moderate. The exploration activities authorized under Alternative 6 would have moderate contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on lower trophic levels.

4.11.8.7.5 Conclusion

Alternative 6 could have a minor contribution to cumulative effects on lower trophic organisms.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with lower trophic levels were discussed under Alternative 2 (Section 4.11.4.7).

4.11.8.8 Fish and Essential Fish Habitat

4.11.8.8.1 Summary of Direct and Indirect Effects

The effect of the alternative technologies outlined in Alternative 6 on fish resources and EFH are difficult to determine with any certainty but are anticipated to result in a reduction in the overall impact. Although the overall impact is considered to be minor based on Alternative 4 alone, replacement of airgun arrays with alternative technologies could potentially reduce adverse effects on fish. However, the limited number of airgun arrays that could be replaced by any of these technologies is fairly limited, thereby resulting in minimal reductions of overall impact levels. Therefore, there would be no measurable effect on the resource, and overall impact is considered to be minor.

4.11.8.8.2 Past and Present Actions

Past and present actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.8.8.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting fish and EFH within the EIS project area are discussed under Alternative 2, Section 4.11.4.8.

4.11.8.8.4 Contribution of Alternative to Cumulative Effects

Climate change is the only past, present, or reasonably foreseeable future action that is anticipated to have any measurable effect on fish and EFH within the EIS project area, and those effects are likely to be beneficial. As Arctic waters warm, productivity is likely to increase, thereby creating more favorable fish habitat throughout the region. The lack of measurable effect on fish and EFH resulting from the implementation of Alternative 6 would not add to any cumulative effects.

4.11.8.8.5 Conclusion

Direct and indirect effects associated with Alternative 6 on fish and EFH would be minor. The overall contribution of Alternative 6 to cumulative effects on fish and EFH would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with fish and EFH were discussed under Alternative 2 (Section 4.11.4.8).

4.11.8.9 Marine and Coastal Birds

4.11.8.9.1 Summary of Direct and Indirect Effects

As discussed in Section 4.9.2.3, the effects of disturbance, injury/mortality, and changes in habitat for marine and coastal birds would likely be temporary or short-term, localized, and not likely to have population-level effects for any species. In summary, the impact of Alternative 6 on marine and coastal birds would be considered negligible.

4.11.8.9.2 Past and Present Actions

Past and present actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.8.9.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting marine and coastal birds within the EIS project area are discussed under Alternative 2, Section 4.11.4.9.

4.11.8.9.4 Contribution of Alternative 6 to Cumulative Effects

Alternative 6 would have the same types and level of exploration activities as Alternative 4 with the gradual introduction of alternative seismic technologies. However, the potential reduction in sound levels during seismic surveys would not make much difference to birds so the effects are essentially the same as described for Alternative 4. In the absence of a very large oil spill (see below), the exploration activities authorized under Alternative 6 would have negligible contributions to the cumulative effects from past, present, and reasonably foreseeable future actions on marine and coastal birds.

4.11.8.9.5 Conclusion

Direct and indirect effects associated with Alternative 6 on marine and coastal birds would be negligible. The overall contribution of Alternative 6 to cumulative effects on marine and coastal birds would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with marine and coastal birds were discussed under Alternative 2 (Section 4.11.4.9).

4.11.8.10 Marine Mammals

4.11.8.10.1 Bowhead Whales

4.11.8.10.1.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 6 on bowhead whales are described in Section 4.9.2.4.1. Impacts of activities associated with oil and gas exploration in the EIS project area under Alternative 5 are similar to Alternative 4 (See Section 4.11.6.10.1).

Mitigating capabilities and effects of alternative technologies introduced under Alternative 6 on bowhead whales are difficult to determine, but could reduce adverse impacts associated with the use of airgun arrays. The overall reduction would likely be minimal. The gradual introduction of these alternative technologies could, ultimately, reduce the amount of seismic noise introduced into the marine environment. Airgun noise would not be eliminated, however, since these alternative technologies would not completely replace the existing technology, and what may be replaced is limited. In addition, surveys conducted with alternative technologies would still use marine vessels to tow or deploy equipment which could disturb bowhead whales. Effects of existing technology on bowhead whales would be mostly of medium intensity and temporary duration and range from localized to regional in extent. Alternative technologies could reduce the extent to localized areas on a small scale; it is not currently possible to assess potential behavioral reactions and determine if intensity level would change, as a result. Bowhead whales are considered a unique resource, since they are listed as endangered and are an essential subsistence resource for Iñupiat and Yupik Eskimos of the Arctic coast. Despite possible localized mitigating capabilities of using alternative technologies in lieu of limited numbers of airgun arrays, the overall impact of Alternative 6 on bowhead whales is considered to be moderate to major.

4.11.8.10.1.2 Past and Present Actions

Past and present actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.1.

4.11.8.10.1.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting bowhead whales within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.1.

4.11.8.10.1.4 Contribution of Alternative to Cumulative Effects

The contribution of the direct and indirect impacts resulting from Alternative 6, when combined with the past, present, and reasonably foreseeable future actions would, in many respects, be similar to Alternative 4 (Section 4.11.6.10.1). Since most potential impacts are due to acoustic disturbance that could, at least temporarily, disrupt or displace bowhead whales, the use of alternative technologies has the potential to reduce, but not eliminate, such effects. These technologies would gradually be introduced, would not completely replace airguns, and many are still in development with uncertain efficacy, so a thorough assessment of their effectiveness is not currently possible. Therefore, the contribution of activities authorized under Alternative 6 to cumulative effects on bowhead whales would be considered moderate.

4.11.8.10.1.5 Conclusion

Under Alternative 6, the direct and indirect effects to bowhead whales would be moderate. Alternative 6 would have a minor to moderate contribution to cumulative effects on bowhead whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with bowhead whales were discussed under Alternative 2 (Section 4.11.4.10.1).

4.11.8.10.2 Beluga Whales

4.11.8.10.2.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 6 on beluga whales are described in Section 4.9.2.4.2 and are summarized here. The additional oil and gas exploration activities proposed in Alternative 6 could directly and indirectly affect beluga whales by causing noise disturbance, habitat degradation, and potential ship strikes. Beluga whales disturbed by oil and gas exploration activities may move away from important habitats. The scale of the avoidance depends on the number and relative proximity of the surveys. Numerous simultaneous seismic activities could cause avoidance over large distances. Potential habitat degradation from drill cuttings or drilling mud discharges would be localized and temporary; the impact level would be negligible. While the incidence of ship strikes is currently low, it could rise with increasing vessel traffic.

The use of alternative technologies under Alternative 6 may reduce adverse impacts to beluga whales associated with the use of airgun arrays. Alternative technologies could reduce the extent of impacts to localized areas on a small scale. It is difficult to quantify the amount of impact reduction likely to occur due to the uncertainty in assessing potential behavioral reactions. Therefore there is no evidence to support a change in the expected impact intensity level. Despite possible localized impact reductions from using alternative technologies instead of airgun arrays, the overall impact of Alternative 6 on beluga whales is considered moderate.

The direct and indirect effects on beluga whales from the exploration activities under Alternative 5 would be low to medium intensity, short-term duration, local to regional extent, and would affect a unique resource. The summary impact level of Alternative 6 on beluga whales would be considered moderate.

4.11.8.10.2.2 Past and Present Actions

Past and present actions affecting beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.8.10.2.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions that would affect beluga whales in the EIS project area are discussed under Alternative 2, Section 4.11.4.10.2.

4.11.8.10.2.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 6 would add to the acoustic disturbance of beluga whales from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible since it would affect an extremely small proportion of habitat or prey base available to beluga whales. The exploration activities authorized under Alternative 6 would therefore have moderate additive contributions to the cumulative effects on beluga whales.

4.11.8.10.2.5 Conclusion

As stated above, most exploration activities authorized under Alternative 6 would result in minor to moderate contributions to cumulative effects on beluga whales.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with beluga whales were discussed under Alternative 2 (Section 4.11.4.10.2).

4.11.8.10.3 Other Cetaceans

4.11.8.10.3.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 6 on cetaceans are described in Section 4.9.2.4.3 and are summarized here. Evaluated collectively, the overall impact of Alternative 6 on other cetaceans is minor to moderate. Although the introduction of alternative technologies specified in Alternative 6 could incrementally mitigate adverse impacts into the future, the overall impact on other cetaceans of oil and gas exploration activities allowed under this alternative would be similar to Alternative 4. Due to the very small scale of any potential effects relative to overall population levels and available habitat, and the temporary nature of the majority of the activities associated with Alternative 6, impacts on the resource would be low in intensity, of short duration, and limited extent. Long term impacts are unknown, but anticipated to be minor.

Mitigating capabilities and effects of alternative technologies introduced under Alternative 6 on the cetaceans are difficult to determine, but could reduce adverse impacts associated with the use of airgun arrays. The overall reduction would likely be minimal. The gradual introduction of these alternative technologies could, ultimately, reduce the amount of seismic noise introduced into the marine environment. New alternative technologies may extend the transmission time of impulsive sounds and source signals could become less impulsive and could be reclassified as continuous noise that would be unlikely to affect fish. Airgun noise would not be eliminated, however, since these alternative technologies would not completely replace the existing technology and what may be replaced is limited. In addition, surveys conducted with alternative technologies would still use marine vessels to tow or deploy survey equipment.

4.11.8.10.3.2 Past and Present Actions

Past and present actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.8.10.3.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting other cetaceans within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.3.

4.11.8.10.3.4 Contribution of Alternative to Cumulative Effects

The oil and gas exploration activities authorized under Alternative 6 would add to the acoustic disturbance of other cetaceans from marine vessels, seismic sources, and aircraft traffic in the Beaufort and Chukchi seas. Although the introduction of the Alternative Technologies specified in Alternative 6 could incrementally mitigate adverse impacts into the future, the overall impact on other cetaceans of oil and gas exploration activities allowed under this alternative would be similar to Alternative 4. Most of this disturbance would occur during the open-water season and would be localized and temporary. Although ship strikes are possible with increased vessel activity associated with oil and gas exploration, the contribution to additional mortality would be negligible relative to the population level. Exploration activities could contribute to habitat alterations through icebreaking efforts and discharge of drilling muds. Effects would be localized and temporary. The contribution to habitat change would be negligible. The exploration activities authorized under Alternative 6 would therefore have minor additive contributions to the cumulative effects on other cetaceans.

4.11.8.10.3.5 Conclusion

As stated above, most exploration activities authorized under Alternative 6 would result in minor contributions to cumulative effects on other cetaceans.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with other cetaceans were discussed under Alternative 2 (Section 4.11.4.10.2).

4.11.8.10.4 Ice Seals

4.11.8.10.4.1 Summary of Direct and Indirect Effects

There are four species of seals considered in this section that are often collectively called "ice seals"; ringed seal, spotted seal, ribbon seal, and bearded seal. The direct and indirect effects of Alternative 6 on ice seals are described in Section 4.9.2.4.4 and are summarized here. Ringed seals and bearded seals have been the most commonly encountered species of any marine mammals in past offshore oil and gas exploration activities in the Alaskan Beaufort and Chukchi seas and would likely be affected more frequently by exploration activities authorized under Alternative 6 than either ribbon or spotted seals. Data from observers on board seismic source vessels and monitoring vessels indicate that seals tend to avoid on-coming vessels and active seismic arrays but they do not appear to react strongly even as ships pass fairly close with active arrays. They also do not appear to react strongly to icebreaking or on-ice surveys, keeping their distance or moving away at some point to an alternate breathing hole or haulout, but the scope of these behavioral responses appears to be within their natural abilities and responses to their naturally dynamic environment. None of the behavioral reactions observed to date indicate that any of the ice seal species would be displaced from key areas or resources for more than a few minutes or hours and they would be unlikely to experience any measurable effects on their reproductive success or survival. Ice seals are legally protected, have unique ecological roles in the Arctic, and are important subsistence resources and are therefore considered to be unique resources. Given the standard mitigation measures that have been required in the past, the effects of exploration activities that could be authorized under Alternative 6 on ice seals would likely be low in magnitude, distributed over a wide geographic area, and temporary to short-term in duration. The effects of Alternative 6 would therefore be considered minor to moderate for all ice seal species according to the criteria established in Section 4.1.3.

4.11.8.10.4.2 Past and Present Actions

Past and present actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.8.10.4.2 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting pinnipeds within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.4.

4.11.8.10.4.3 Contribution of Alternative 6 to Cumulative Effects

The exploration activities authorized under Alternative 6 would add to the disturbance of ice seals from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Very small numbers of ringed seals could be exposed to exploration activities during the denning season (winter-spring) when females with young are more susceptible to disturbance. Exploration activities would contribute negligible risk of additional mortality to any species, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 6 would therefore have minor contributions to the cumulative effects on the four species of ice seals considered.

4.11.8.10.4.4 Conclusion

Direct and indirect effects associated with Alternative 6 on pinnipeds would be minor to moderate. The overall contribution of Alternative 6 to cumulative effects on pinnipeds would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with pinnipeds were discussed under Alternative 2 (Section 4.11.4.10.4).

4.11.8.10.5 Walrus

4.11.8.10.5.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 6 on walrus are described in Section 4.9.2.4.5 and are summarized here. The types and levels of effects on Pacific walrus are essentially the same under Alternative 6 as for Alternative 4 (Section 4.7.2.4.5). Walrus have been regularly encountered during vessel-based exploration activities in the past, primarily in late summer as the pack ice recedes, as recorded by PSOs on board seismic source vessels and monitoring vessels. These data indicate that walrus do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than swimming away. They tend to dive into the water as icebreaking ships approach from some distance and are therefore not exposed to the loudest sounds generated by the ships. The gradual introduction of alternative technologies for seismic surveys would make very little difference to walrus because they are unlikely to be affected in any biologically meaningful way by seismic noise. Mitigation measures required for walrus by USFWS LOAs since the early 1990s have reduced the risk of close encounters with seismic and other exploration vessels and have reduced the risk of accidental spills that may affect walrus or their prey. None of the data collected to date on walrus reactions to exploration activities indicate that they would be displaced from key areas or resources for more than a few minutes or hours. Careful avoidance of vessel and aircraft traffic around walrus haulouts on land would be important to minimize the risk of calf and juvenile mortality from stampedes. Walrus are legally protected, fulfill an important ecological role in the Arctic, and are important subsistence resources and are therefore considered to be a unique resource for NEPA purposes. Given the level and type of exploration activities that would be authorized under Alternative 6, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on walrus would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 6 on Pacific walrus would therefore be considered minor.

4.11.8.10.5.2 Past and Present Actions

Past and present actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.8.10.5.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting Pacific walrus within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.5.

4.11.8.10.5.4 Contribution of Alternative 6 to Cumulative Effects

The exploration activities authorized under Alternative 6 would add to the disturbance of walrus from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to walrus, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 6 would therefore have negligible to minor contributions to the cumulative effects on Pacific walrus.

4.11.8.10.5.5 Conclusion

Direct and indirect effects associated with Alternative 6 on Pacific walrus would be minor. The overall contribution of Alternative 6 to cumulative effects on Pacific walrus would be negligible to minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with Pacific walrus were discussed under Alternative 2 (Section 4.11.4.10.5).

4.11.8.10.6 Polar Bears

4.11.8.10.6.1 Summary of Direct and Indirect Effects

The direct and indirect effects of Alternative 6 on polar bears are described in Section 4.9.2.4.6 and are summarized here. The types and levels of effects on polar bears are essentially the same under Alternative 6 as for Alternative 4 (Section 4.7.2.4.6). Polar bears have been infrequently encountered during vessel-based exploration activities in the past, as recorded by PSOs on board source vessels and monitoring vessels. These sparse data indicate that polar bears do not react strongly to vessels and active seismic arrays and their behavioral responses are often neutral rather than running or swimming away. The gradual introduction of alternative technologies for seismic surveys would make very little difference to polar bears because they are unlikely to be affected in any biologically meaningful way by seismic noise. They also do not appear to react strongly to icebreaking or on-ice surveys. Some bears keep their distance or move away at some point but others may approach vehicles and equipment out of curiosity. The types of effects of most concern for polar bears during exploration activities involve the risk of bear-human encounters. Mitigation measures and polar bear safety/interaction plans required by USFWS LOAs since the early 1990s have reduced the risk of these encounters for both people and bears. None of the data collected to date on polar bear reactions to exploration activities indicate that polar bears would be displaced from key areas or resources for more than a few minutes or hours and they are unlikely to experience any measurable effects on their reproductive success or survival as a result. Polar bears are legally protected, have a unique ecological role in the Arctic, and are important to subsistence cultures and are therefore considered a unique resource. Given the level and type of exploration activities that would be authorized under Alternative 6, and considering the mitigation measures that would be required by USFWS LOAs and NMFS in this EIS, the effects on polar bears would likely be low in magnitude, distributed over a wide geographic area, and temporary in duration. The effects of Alternative 6 on polar bears would therefore be considered minor.

4.11.8.10.6.2 Past and Present Actions

Past and present actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.8.10.6.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting polar bears within the EIS project area are discussed under Alternative 2, Section 4.11.4.10.6.

4.11.8.10.6.4 Contribution of Alternative 6 to Cumulative Effects

The exploration activities authorized under Alternative 6 would add to the disturbance of polar bears from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be temporary. Exploration activities would contribute negligible risk of additional mortality to polar bears, which would continue to be dominated by subsistence harvest. Exploration activities could contribute to habitat change through on-ice surveys, icebreaking efforts, and discharge of drilling muds but these effects would be localized and temporary or short-term. This contribution to habitat change would be negligible compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems due to ocean acidification. The exploration activities authorized under Alternative 6 would therefore have negligible to minor contributions to the cumulative effects on polar bears.

4.11.8.10.6.5 Conclusion

Direct and indirect effects associated with Alternative 6 on polar bears would be minor. The overall contribution of Alternative 6 to cumulative effects on polar bears would be negligible to minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with polar bears were discussed under Alternative 2 (Section 4.11.4.10.6).

4.11.8.11 Terrestrial Mammals

4.11.8.11.1 Summary of Direct and Indirect Effects

Activity levels in Alternative 6 are the same as in Alternative 4, and this alternative includes mitigation measures that focus on alternative technologies for seismic exploration. These mitigation measures do not affect terrestrial mammals in the EIS project area, so the impacts discussed for Alternatives 2 and 3 are the same for Alternative 6 and the overall impact to terrestrial mammals would be minor.

4.11.8.11.2 Past and Present Actions

Past and present actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.8.11.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting caribou within the EIS project area are discussed under Alternative 2, Section 4.11.4.11.

4.11.8.11.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.8.11.5 Conclusion

The incremental contribution of activities associated with Alternative 6 to cumulative effects on caribou would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with caribou were discussed under Alternative 2 (Section 4.11.4.11).

4.11.8.12 Time/Area Closures

The analysis of the cumulative effects under Alternative 6 associated with time/area closure locations can be found in Sections 4.11.8.10 (Marine Mammals), 4.11.8.9 (Marine and Coastal Birds) and 4.11.8.14 (Subsistence).

4.11.8.13 Socioeconomics

4.11.8.13.1 Summary of Direct and Indirect Effects

Direct and indirect effects associated with Alternative 6 are the similar to those described for Alternative 2. Alternative technologies may result in additional costs to lease holders due to increased time to complete surveys. To the extent that alternative technologies benefit to marine mammals and reduce net impacts to subsistence activities, there would be some potential socioeconomic benefits to the non-cash economy. The summary impact level for Socioeconomics under Alternative 6 is minor, not exceeding the significance threshold.

4.11.8.13.2 Past and Present Actions

Past and present actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13.

4.11.8.13.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting socioeconomics within the EIS project area are discussed under Alternative 2, Section 4.11.4.13. This analysis assumes current levels of oil and gas production and on-shore exploration would continue, but does not assume that offshore exploration associated with Alternative 6 would result in future oil and gas production.

4.11.8.13.4 Contribution of Alternative to Cumulative Effects

The incremental contribution of Alternative 6 to socioeconomic cumulative effects would be minor and positive. They differ from Alternative 2 by the potential for some lost productivity for lease holders due to alternative technologies and mitigation measures and countervailing positive impacts to subsistence resources and activities and therefore would have a countervailing positive impact to the non-cash economy. The summary contribution of these impacts to the cumulative effectives of socioeconomics is negligible to minor at a statewide and national level and minor at the local level.

4.11.8.13.5 Conclusion

The direct and indirect effects of Alternative 6 would be positive and minor. The contribution to cumulative effects of socioeconomics would be minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with socioeconomics were discussed under Alternative 2 (Section 4.11.4.13).

4.11.8.14 Subsistence

4.11.8.14.1 Summary of Direct and Indirect Effects

Using the impact criteria identified in Table 4.5-25, the direct and indirect effect of oil and gas exploration activities on subsistence resources and harvests resulting from implementation of Alternative 6 would be of low intensity, temporary in duration, local in extent, and the context would be common to unique. Protected resources (bowhead whales and polar bears are considered unique in context as these resources are protected by legislation (e.g. MMPA, ESA) or are considered an important subsistence resource (beluga whales). The impacts of implementing Alternative 6 could be considered beneficial to subsistence harvests and users as the implementation of new technologies could reduce the levels of noise introduced to the marine environment and then reduce the levels of noise disturbance to marine mammal subsistence resources. New alternative technologies may extend the transmission time of impulsive sounds and source signals could become less impulsive and could be reclassified as continuous noise that would be unlikely to affect subsistence resources. Direct and indirect impacts to subsistence harvest and subsistence resources are likely to be similar or less than those of Alternative 4 as discussed in Section 4.7.3.2 and Section 4.11.6.14. The summary impact to subsistence is therefore considered to range from negligible to moderate depending upon the specific subsistence resource affected and source of disturbance (Section 4.5.3.2 and Section 4.9.3.2).

4.11.8.14.2 Past and Present Actions

Past and present actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.8.14.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting subsistence resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.14.

4.11.8.14.4 Contribution of Alternatives to Cumulative Effects

The activities authorized under Alternative 6 would add to the disturbance of subsistence resources from marine vessels and aircraft traffic in the Alaskan Beaufort and Chukchi seas. Most of this disturbance would occur during the open-water season and would be low in intensity, temporary in duration and local in extent and affect subsistence resources that are common to unique in context. A low number of seals and polar bears could be disturbed during on-ice seismic surveys. Exploration activities would constitute a minor contribution to the disturbance of subsistence resources. Exploration activities could contribute to habitat change of subsistence resources through aircraft and vessel traffic, icebreaking efforts, on-ice surveys and discharge of drilling muds but these effects would be of low intensity, localized to regional in extent, temporary in duration, and affect subsistence resources that are common to unique in context. This contribution to habitat change would be negligible when compared to the potential for dramatic sea ice loss due to climate change and changes in ecosystems and resource abundance due to ocean acidification. The exploration activities authorized under Alternative 6 would therefore have a minor to moderate contribution to the cumulative effects on subsistence resources. Implementation of Alternative 6 would be considered beneficial to cumulative effects on subsistence resources.

The exploration activities authorized under Alternative 6 would occur at the same level as Alternative 4 but are considered beneficial to subsistence harvests and users as implementing new technologies that reduce the levels of noise into the marine environment could reduce the potential for disturbance to marine mammal subsistence resources. The exploration activities authorized under Alternative 6 would have a minor to moderate contribution to the cumulative effects on subsistence resources. Implementation of Alternative 6 would be considered beneficial to cumulative effects on subsistence resources.

4.11.8.14.5 Conclusion

Under Alternative 6, the direct and indirect effects to subsistence resources are considered low in intensity, temporary in duration, local in extent and affect subsistence resources that range from common to unique in context. Implementation of Alternative 6 would be a beneficial contribution to cumulative effects on subsistence resources as it would implement new technologies that would reduce the potential for disturbance to marine mammal subsistence resources. The contribution of the direct and indirect impacts in consideration of the past, present, and reasonably foreseeable future actions would be negligible to moderate on subsistence.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with subsistence resources were discussed under Alternative 2 (Section 4.11.4.14).

4.11.8.15 Public Health

4.11.8.15.1 Summary of Direct and Indirect Effects

As described in Section 4.9.3.3, anticipated direct and indirect effects on public health and safety as a result of Alternative 6 are expected to be similar to those expected under Alternative 4. Alternative 6 includes requirements for the use of alternative technologies. However, as discussed in Section 4.9.3.3, the effectiveness of these alternative technologies in reducing adverse impacts to subsistence uses is at present unknown, and thus the benefits of the additional measures are theoretical. Therefore, these additional mitigations do not affect the overall impact criteria rating for public health for Alternative 6. If, however, the alternative technologies are demonstrated to be effective and feasible to implement, there is the possibility that additional benefit to public health may accrue.

4.18.8.15.2 Past and Present Actions

The effects of past and present actions on public health and safety are the same as those described in Section 4.11.4.15.

4.11.8.15.3 Reasonably Foreseeable Future Actions

The effects of reasonably foreseeable future actions on public health and safety are the same as those described in Section 4.11.4.15.

4.11.8.15.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 6 to cumulative effects on public health and safety are the same as those for Alternative 2, described in Section 4.11.4.15.

4.11.8.15.5 Conclusion

Similar to the contribution of Alternative 2 described in Section 4.11.4.15, Alternative 6 contributes to cumulative impacts on public health and safety via the relatively small contribution of the direct and indirect impacts.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with public health and safety were discussed under Alternative 2 (Section 4.11.4.15).

4.11.8.16 Cultural Resources

4.11.8.16.1 Summary of Direct and Indirect Effects

Activity levels in Alternative 6 are the same as in Alternative 4, and this alternative includes mitigation measures that focus on alternative technologies for seismic exploration. These mitigation measures do not affect cultural resources in the EIS project area, so the impacts discussed for Alternatives 2 and 3 are the same for Alternative 6 and the overall impact to cultural resources would be minor.

4.11.8.16.2 Past and Present Actions

Past and present actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.8.16.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting cultural resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.16.

4.11.8.16.4 Contribution of Alternative to Cumulative Effects

The contribution of this alternative to cumulative effects is the same as described under Alternative 2.

4.11.8.16.5 Conclusion

The incremental contribution of activities associated with Alternative 6 to cumulative effects on cultural resources would be negligible.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with cultural resources were discussed under Alternative 2 (Section 4.11.4.16).

4.11.8.17 Land and Water Ownership, Use, and Management

4.11.8.17.1 Summary of Direct and Indirect Effects

As discussed in Section 4.9.3.5, the direct and indirect impacts on land and water ownership would be low magnitude, temporary duration, local extent, and common in context. The direct and indirect impacts on land and water use would have a high magnitude, be temporary in duration, local and common. The direct and indirect impacts to land and water management would be low intensity, temporary in nature, local, and common. In summary, the impacts of Alternative 6 on land and water ownership, use, and management would be negligible, moderate, and minor, respectively.

4.11.8.17.2 Past and Present Actions

Past and present actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.8.17.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting land and water ownership, use, and management within the EIS project area are discussed under Alternative 2, Section 4.11.4.17.

4.11.8.17.4 Contribution of Alternative to Cumulative Effects

Alternative 6 is the same as Alternative 4 except with use of alternative technologies. The cumulative effects discussed in Section 4.11.6.17 for Alternative 4 are applicable for this alternative. The conclusions for Alternative 4 are applicable to Alternative 6; the contribution of Alternative 6 to cumulative effects to land and water ownership, use, and management would be negligible, moderate, and minor, respectively.

4.11.8.17.5 Conclusion

Under Alternative 6, the levels of direct, indirect and cumulative impact for land and water ownership, use, and management are negligible, moderate, and minor, respectively. Based on this, the overall level of impact of Alternative 6 is considered minor.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with land and water ownership, use, and management were discussed under Alternative 2 (Section 4.11.4.17).

4.11.8.18 Transportation

4.11.8.18.1 Summary of Direct and Indirect Effects

Direct and indirect impacts on regional transportation systems and existing infrastructure would be expected to be the same as those discussed under Alternative 4 as discussed in Section 4.7.3.2. Alternative technologies are likely to use the same types of transportation equipment and infrastructure at the same levels as that currently used for seismic surveys, on-ice surveys and exploratory drilling as Alternatives 2, 3, 4, and 5.

4.11.8.18.2 Past and Present Actions

Past and present actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.8.18.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting transportation within the EIS project area are discussed under Alternative 2, Section 4.11.4.18.

4.11.8.18.4 Contribution of Alternative to Cumulative Effects

The contribution of impacts from Alternative 6 would be similar as those described for Alternative 4 in Section 4.11.6.18.

4.11.8.18.5 Conclusion

In summary, no concerns related to adverse cumulative impacts have been identified. Some cumulative impacts may exist if Alternative 6 overlaps with another large-scale development project but those impacts would be of low intensity, temporary in duration affecting local areas of common resources and are considered unlikely to have long-term impacts on regional transportation infrastructure.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with transportation were discussed under Alternative 2 (Section 4.11.4.18).

4.11.8.19 Recreation and Tourism

4.11.8.19.1 Summary of Direct and Indirect Effects

The direct impacts would be low intensity, temporary duration, local extent, and common in context. Indirect impacts would be the same levels as direct impacts, except that the geographic area would be broader, extending beyond the region to a state-wide level and potentially beyond. In summary, the impact of Alternative 6 on recreation and tourism would be minor.

4.11.8.19.2 Past and Present Actions

Past and present actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.8.19.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting recreation and tourism within the EIS project area are discussed under Alternative 2, Section 4.11.4.19.

4.11.8.19.4 Contribution of Alternative to Cumulative Effects

Activity levels in Alternative 6 are the same as in Alternative 4, and this alternative includes mitigation measures for that focus on alternative technologies for seismic exploration. These mitigation measures do not affect recreation or tourism in the EIS project area, so the cumulative effects discussed in Sections 4.11.4.19 and 4.11.5.19 for Alternatives 2 and 3 are the same for Alternative 6; the overall impact to recreation and tourism would be minor.

4.11.8.19.5 Conclusion

Alternative 6 would have a minor contribution to cumulative effects on recreation and tourism.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with recreation and tourism were discussed under Alternative 2 (Section 4.11.4.19).

4.11.8.20 Visual Resources

4.11.8.20.1 Summary of Direct and Indirect Effects

Direct and indirect effects of past and present actions are identical to those described in Section 4.11.6.20, Alternative 4.

4.11.8.20.2 Past and Present Actions

Past and present actions affecting visual resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.20.

4.11.8.20.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting visual resources within the EIS project area are discussed under Alternative 2, Section 4.11.4.20.

4.11.8.20.4 Contribution of Alternative to Cumulative Effects

The contribution of Alternative 6 to cumulative effects would be identical to that described in Section 4.11.6.20, Alternative 4.

4.11.8.20.5 Conclusion

Under Alternative 6, anticipated cumulative effects to visual resources are expected to be major. Impacts would be of high intensity, long-term in duration, regional in geographic extent and occurring in an important context.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with visual resources were discussed under Alternative 2 (Section 4.11.4.20).

4.11.8.21 Environmental Justice

4.11.8.21.1 Summary of Direct and Indirect Effects

Direct and indirect effects to subsistence and public health associated with Alternative 6 would be minor, similar to those described for Alternative 2. Alternative technologies may reduce the likelihood of disturbance to marine mammals which in turn could reduce detrimental impacts to subsistence users. However, the effectiveness of these alternative technologies in reducing adverse impacts to subsistence users is unknown and therefore the benefits of these technologies to lessen impacts to subsistence and public health are theoretical and do affect the overall impact criteria rating.

4.11.8.21.2 Past and Present Actions

Past and present actions affecting environmental justice within the EIS project area are discussed under Alternative 2, Section 4.11.4.21.

4.11.8.21.3 Reasonably Foreseeable Future Actions

Reasonably foreseeable future actions affecting environmental justice within the EIS project area are discussed under Alternative 2, Section 4.11.4.21.

4.11.8.21.4 Contribution of Alternative to Cumulative Effects

The incremental contribution of Alternative 6 to the overall industrial activity in the area would be similar that that described for Alternative 2. Therefore, the contribution of Alternative 6 to environmental justice indicator cumulative effects would be minor.

4.11.8.21.5 Conclusion

The direct and indirect effects of Alternative 6 would be minor. The contribution to the cumulative effect of environmental justice indicators would be minor. Therefore, there would be a disproportionate impact to Alaska Native communities in the EIS project area.

The additive effects resulting from a VLOS in the Beaufort or Chukchi seas associated with environmental justice were discussed under Alternative 2 (Section 4.11.4.21). A VLOS would have disproportionate adverse impacts to Alaska Natives living in the communities near the EIS project area.

4.12 Relationship Between Short-term Uses of the Environment and the Maintenance and Enhancement of Long-term Productivity

This section addresses this subject from a broad perspective incorporating the information and conclusions from detailed analysis provided in previous sections of the EIS (Sections 4.4-4.10). No construction activities are associated with the Proposed Action; therefore, short-term uses of the environment would primarily relate to seismic surveys and exploratory drilling operations. Short- and long-term commitments of labor and capital and the use of non-renewable materials for power and maintenance would be employed to achieve the short-term goal of discovering oil and gas resources and the long-term goal of developing oil and gas resources in the Beaufort and Chukchi seas.

Bowhead whales may be temporarily affected by noise from seismic surveys, exploratory drilling, vessel and aircraft traffic, and small oil spills on a short-term basis. Minor to moderate impacts are expected to occur to bowhead and beluga whales under the action alternatives. Polar bears could experience minor impacts through disturbance from vessel and aircraft traffic, ice breaking and an on-ice seismic survey in the Beaufort Sea. Steller's eiders and spectacled eiders may be negatively impacted by frequent vessel and aircraft disturbance and collisions with vessels and aircrafts, especially during molting. The impact to Steller's eiders and spectacled eiders are considered minor.

Short- and long-term effects on Iñupiat subsistence-harvest activities could be considered disproportionately adverse if seismic survey and exploratory drilling operations are not sufficiently mitigated. No unmitigable adverse impacts are expected to occur to subsistence resources and harvest. Short-term effects of seismic survey and exploratory drilling operations to social systems, cultural values, and institutional organization are not expected to have long-term adverse consequences. Archaeological resources finds discovered as a result of the seismic surveys could enhance long-term knowledge. Such finds could help fill gaps in knowledge of the history and early inhabitants of the area; but any destruction of archaeological sites or unauthorized removal of artifacts would represent long-term losses.

With respect to the short-term uses of the environment and the maintenance and enhancement of long-term productivity, the following could be expected to occur to the economy: federal revenues on offshore lease areas could increase; local and state employment could increase; and personal income could be generated.

In conclusion, the environmental effects of the proposed action alternatives would be temporary in nature and would have no adverse long-term impacts on the long-term productivity of the Beaufort and Chukchi seas, if properly mitigated as proposed. No losses of marine habitats are expected to occur from seismic survey activities. However, the quality of marine habitat surrounding seismic survey activities could be adversely affected in the short-term as airguns are fired to ensonify the area. Other noises originating from exploratory drilling operations (e.g. drilling, vessel traffic, the operation of ship-board equipment, and aircraft traffic) would also cause a temporary degradation of the marine environment, especially for marine mammals, marine birds, and fish unless mitigated as proposed. The benefits offered to the Nation by the long-term productivity of the Proposed Action are expected to offset the short-term use of the environment, if properly mitigated as proposed.

4.13 Irreversible and Irretrievable Commitments of Resources

This section describes the irreversible and irretrievable commitments of resources associated with implementing the alternatives of the Proposed Action. Irreversible and irretrievable commitment of resources refers to impacts or losses to resources that cannot be reversed or recovered. Resources include renewable and nonrenewable natural and mineral resources, including fish and wildlife habitat.

A commitment of resources is irreversible when a proposed action impacts limit the future options for a resource or cannot be reversed, except perhaps in the extreme long-term. It applies primarily to the effects of use of nonrenewable resources, which are those resources that cannot be replenished by natural means, such as oil, natural gas, iron ore, and cultural resources. An irretrievable commitment refers to the use or consumption of a resource that is neither renewable nor recoverable for use by future generations or is lost for a period of time. It applies to the loss of productivity, harvest, or use of natural resources.

No resources would be irreversibly and irretrievably committed (i.e. affected) by construction activities because none of the action alternatives have construction activities associated with them. Any irreversible and irretrievable commitments of resources would be limited to the implementation of seismic survey activities and exploratory drilling operations.

Irreversible and irretrievable nonrenewable resources committed for use by seismic survey vessels, support vessels, and support aircraft include any seismic survey or exploratory drilling equipment that could not be recovered or recycled, diesel fuel, gasoline, aviation fuel, lubricating oil, and drilling mud. The Proposed Action would also require a commitment of human and financial resources (time and labor). Water is the only renewable natural resource used to implement the alternatives. Water would be used on the seismic survey vessels, drilling rigs, and support vessels for cooking, drinking, and processing human wastes.

Any irretrievable or irreversible commitment of resources important to the long-term survival and recovery of threatened or endangered species would violate the Endangered Species Act and the Marine Mammal Protection Act, unless such commitment was made to help protect and aid in its conservation and recovery. Under certain circumstances bowhead whales, polar bears, Steller's eider, and spectacled eiders could be subjected to temporary non-lethal effects of disturbance due to noise from seismic survey activities, vessel and aircraft traffic and from small petroleum spills. It is unlikely that such effects could lead to permanent (irreversible) losses of these resources, particularly for the bowhead whale population, as their population is increasing.

This page intentionally left blank.

5.0 IMPLEMENTATION, MONITORING AND REPORTING, AND ADAPTIVE MANAGEMENT

The purpose of Chapter 5 is to describe certain procedures that are used to ensure NEPA and MMPA compliance for the issuance of G&G permits and authorizing ancillary activities by BOEM and MMPA ITAs by NMFS for Arctic oil and gas exploration activities. Specifically, this chapter describes and analyzes several issues:

(1) How the EIS will be used to support NMFS's and BOEM's NEPA compliance;

(2) How the MMPA has been implemented by NMFS in recent years for Arctic oil and gas activities and how it could be implemented in the future;

(3) The purposes, goals, and objectives of monitoring and reporting under the MMPA;

(4) Tools for mitigating impacts on the availability of marine mammals for subsistence uses; and

(5) Recommendations for adaptive management.

5.1 EIS Implementation and NEPA Compliance

5.1.1 Need for NEPA Compliance

NEPA was passed by Congress in 1969 and signed into law on January 1, 1970. Its primary focus is to ensure the incorporation of environmental planning into all major federal actions so that "environmental amenities and values may be given appropriate consideration in decision-making along with economic and technical considerations" (Sec. 102 [42 USC 4332] (b)). NEPA mandates that federal agencies prepare a detailed statement of the effects of "major Federal actions significantly affecting the quality of the human environment."

The CEQ is responsible for the development and oversight of regulations and procedures implementing NEPA. The CEQ regulations provide guidance for federal agencies regarding NEPA's requirements (40 CFR Part 1500). Federal agencies are required to produce their own regulations and guidance regarding NEPA implementation. U.S. Department of the Interior's (USDOI) NEPA procedures regulations are codified at 43 CFR Parts 46.10 to 46.450 and can be found at http://ecfr.gpoaccess.gov/cgi/t/text/text-idx?c=ecfr&tpl=/ecfrbrowse/Title43/43cfr46_main_02.tpl or http://www.doi.gov/oepc/nepafr.html. The BOEM NEPA procedures can be found in the USDOI Department Manual at http://elips.doi.gov/app_dm/index.cfm?fuseaction=home. The NOAA NEPA NAO 216-6 provides guidance on environmental review procedures for implementing NEPA. NAO 216-6 can be found at http://www.corporateservices.noaa.gov/ames/administrative_orders/chapter_216/216-6.html.

NMFS and BOEM staff, permit applicants, stakeholders, and the general public should understand how NMFS and BOEM will meet their obligations under NEPA. This EIS addresses Arctic oil and gas exploration activities (i.e. seismic surveys, site clearance and shallow hazards surveys, and exploratory drilling) that may occur. This EIS will inform BOEM decisions on specific G&G permit applications and ancillary activity surveys (i.e., not including drilling). This EIS will inform NMFS decisions on specific MMPA ITA requests related to G&G surveys, ancillary activity surveys, and exploratory drilling programs. BOEM will complete site-specific NEPA evaluation of proposed exploration drilling, incorporating the analyses in this EIS by reference, as appropriate.

5.1.2 NMFS NEPA Compliance

The Effects of Oil and Gas Activities in the Arctic Ocean Final EIS will cover oil and gas industry exploration activities that may impact the human environment in general, but it is not specific to the request for or issuance of any particular ITA. Thus, each project-specific authorization application will require its own NEPA compliance review. The form of this additional NEPA review will depend on the nature and scope of the proposed activity and may take the form of a Memorandum to the File, an EA, a supplemental EIS, or a new EIS.

In the future, NMFS anticipates receipt of applications to take marine mammals incidental to oil and gas industry exploration activities in both state and federal waters (i.e. G&G and ancillary surveys and exploratory drilling) pursuant to Sections 101(a)(5)(A) and (D) of the MMPA. There is no formal schedule for submission of ITA applications; however, Section 101(a)(5)(D) places a 120-day limit on the processing of an Incidental Harassment Authorization request. Therefore, requests can be submitted throughout the calendar year, meaning that the schedule is initiated and driven by the applicants. Each time an application is received, the request will be reviewed by NMFS to determine whether the proposed activity and its anticipated effects fall within the scope of the Effects of Oil and Gas Activities in the Arctic Ocean Final EIS.

The Effects of Oil and Gas Activities in the Arctic Ocean Final EIS will identify the Preferred Alternative, including an analysis of potential environmental consequences and mitigation measures. The ROD associated with the EIS will identify any conditions of approval that are relevant to Arctic oil and gas industry exploration authorization requests and will provide a listing of activities addressed by the Preferred Alternative. Proposed oil and gas exploration activities that are identified and analyzed within the Preferred Alternative will be reviewed to determine whether the proposed action and its anticipated effects fall within the scope of the Effects of Oil and Gas Activities in the Arctic Ocean Final EIS (see description of NMFS's NEPA compliance process below). Proposed oil and gas activities that are not identified and analyzed within the Preferred Alternative will undergo their own NEPA review, to be determined at the time the application is submitted.

New requests for the take of marine mammals incidental to seismic surveys, site clearance and shallow hazards surveys, and exploratory drilling activities will be reviewed by NMFS Permits and Conservation Division, Office of Protected Resources. NMFS will:

- Review the proposed ITA application to determine if the activities proposed by the applicant and the anticipated effects fall within the scope of the Preferred Alternative identified in the Effects of Oil and Gas Activities in the Arctic Ocean Final EIS. NMFS staff will conduct an internal review to determine whether or not the application falls within the scope of the Preferred Alternative.
- If NMFS determines the activities proposed by the applicant and the anticipated effects fall within the scope of the Preferred Alternative in the Effects of Oil and Gas Activities in the Arctic Ocean Final EIS, NMFS could develop a Memorandum to the File. The Memorandum would include a description of the proposed action, the anticipated effects, and include a discussion of the agency's rationale as to whether the proposed action and its anticipated effects are covered by the Effects of Oil and Gas Activities in the Arctic Ocean Final EIS. NMFS may, as appropriate, include any conditions of approval that apply as documented in the ROD.

If NMFS determines through the above process that the proposed activities were not analyzed within the Preferred Alternative, an additional NEPA compliance review (such as an Environmental Assessment) would be conducted. The NOAA NEPA Handbook and NAO 216-6 provide guidance for agency officials on this step of NEPA review, including the process for tiering analyses from a general or broad-scope EIS to a project-specific review, and incorporating by reference.

The EIS will also assist NMFS in carrying out other statutory responsibilities (e.g. assessing environmental impacts on listed species under the ESA [Section 7 consultation] and effects of the proposed action on EFH under the MSFCMA) and serve to support future decisions relating to the agency's role in authorizing the take of marine mammals incidental to deep penetration geophysical surveys, shallow hazards surveys, and exploratory drilling activities, as NMFS is required to ensure compliance with all applicable statutes when issuing an MMPA ITA.

Alternative 6 of this EIS analyzes the use of alternative technologies that could potentially augment or replace the use of airguns in traditional seismic surveys at some point in the future. Because the majority of these technologies have not yet been built and/or tested, it is difficult to fully analyze the level of impacts from these devices in this EIS. Additionally, the amount of reduction in impacts is dependent upon how many traditional seismic surveys (i.e. use of airgun arrays) can potentially be replaced or augmented by these alternative technologies, which is unknown at this time. This EIS examines a projected use of alternative technologies, but the actual amount that might be used during the timeframe of this EIS is not fully known at this time. Therefore, NMFS has determined that additional NEPA analyses would likely be required if applications are received requesting to use these technologies during seismic surveys. As described above, NMFS would review the application request to determine how much of the request is already described and analyzed by the Preferred Alternative and ROD. Because of the lack of details on these technologies, it is unlikely that a Memorandum to the File would be sufficient. Therefore, NMFS would likely tier from this EIS and prepare a supplemental NEPA document, incorporating key sections of this EIS by reference as appropriate and where relevant.

5.1.3 BOEM NEPA Compliance

BOEM anticipates receipt of applications to conduct exploration seismic surveys pursuant to the OCS Lands Act. Pursuant to 30 CFR Part 551.4, a G&G permit must be obtained from BOEM to conduct G&G exploration for oil, gas, and sulphur resources when operations occur on unleased lands or on lands leased to a third party. Ancillary activities are regulated under 30 CFR Part 550, which states that a notice must be submitted before conducting G&G data collection pursuant to a lease issued or maintained under the OCS Lands Act (30 CFR Part 550.208). BOEM will conduct site-specific NEPA reviews for G&G permit applications and proposed ancillary surveys. Proposed activities will be reviewed by BOEM to determine whether the activities are covered by the assessment of impacts contained in the Effects of Oil and Gas Activities in the Arctic Ocean Final EIS. The form of additional NEPA review will depend on the nature and scope of the proposed activity and may take the form of a Determination on NEPA Adequacy, a Categorical Exclusion Review, or an EA, a supplemental EIS, or a new EIS that tier from this EIS and incorporate information and analyses in this EIS by reference (see 40 CFR Part 1506.2). While this EIS is not being used by BOEM to analyze the approval of exploration drilling plans or by the Bureau of Safety and Environmental Enforcement (BSEE) for approval of applications for permits to drill, BOEM plans to incorporate by reference the content of this EIS into future site-specific NEPA and other environmental analyses for exploratory drilling, as appropriate. BOEM performs a site-specific NEPA compliance review (typically an EA) for exploratory drilling activities for each Exploration Plan to issue permits for on-lease exploration operations.

This EIS will also assist BOEM in carrying out other statutory responsibilities related to the issuance of G&G permits and ancillary activity notices, as discussed in Section 1.1 of this document. In accordance with applicable law and the need to conduct various consultations and analyses before issuing such permits, BOEM will coordinate closely with BSEE, NMFS, and the USFWS to verify compliance with the ESA, MSFCMA, NHPA, and, MMPA requirements. BOEM has the authority to modify permit conditions or lease operations, if necessary, to ensure OCS activities meet the requirements of the ESA or MMPA or other authorization.

5.2 MMPA Implementation and Compliance History and Process

Sections 101(a)(5)(A) and (D) of the MMPA (16 U.S.C. §1361 *et seq*.) direct the Secretary of Commerce to allow, upon request, the incidental, but not intentional taking of small numbers of marine mammals by U.S. citizens who engage in a specified activity (other than commercial fishing) within a specified geographical region if certain findings are made and either regulations are issued or, if the taking is limited to harassment, a notice of proposed authorization is provided to the public for review.

ITAs may be issued as either (1) regulations and associated LOAs or (2) IHAs. NMFS's implementing regulations state that an IHA can only be issued if the proposed action will not result in a potential for serious injury and/or mortality or where any such potential can be negated through required mitigation measures. Where the proposed activity has the potential to result in serious injury and/or mortality (that cannot be negated through mitigation measures), only regulations and associated LOAs may be used to authorize take. However, regulations and LOAs may also be issued when there is no potential for serious injury and/or mortality if the applicant requests it, which applicants sometimes do for multi-year activities because it offers some administrative streamlining benefits. IHAs cannot be valid for more than 12 consecutive months, whereas LOAs can be valid for up to five consecutive years. The Secretary of Commerce is required to authorize the take of small numbers of marine mammals incidental to a specified activity if the taking would have no more than a "negligible impact" on marine mammal species or stocks and not have an "unmitigable adverse impact" on the availability of such species or stocks for taking for subsistence uses.

Since 2006, NMFS has issued IHAs to various oil and gas industry or seismic operators for the take of marine mammals incidental to conducting seismic and site clearance and shallow hazards survey programs both on-ice and in open-water in the U.S. Beaufort and Chukchi seas. Between 2006 and 2012, NMFS issued 15 IHAs for open-water seismic and site clearance and shallow hazards survey programs and four IHAs for on-ice seismic surveys. NMFS also issued one IHA for the take of marine mammals incidental to an exploratory drilling program in the Beaufort Sea in 2007; however, the program was enjoined by a federal court. In 2012, NMFS issued two IHAs for exploratory drilling programs in the U.S. Arctic Ocean. However, only limited operations were conducted, with no drilling into hydrocarbon bearing zones. Starting in 2000, NMFS also issued several sets of five-year regulations and subsequent LOAs to BP for the take of marine mammals incidental to the construction and operation of its Northstar development and production facility in the Beaufort Sea. However, this type of production drilling activity is not covered by this EIS.

NMFS has explored the possibility of issuing regulations and associated LOAs to companies for oil and gas exploration activities in the Arctic. Doing so would provide some administrative streamlining. However, to date, regulations and LOAs have not been requested in the Arctic for oil and gas exploration activities. Because NMFS has determined in the past that the activities would not result in serious injury or mortality (or such impacts were negated through mitigation measures), NMFS has not required that applicants request regulations instead of IHAs. While past practice has been to issue IHAs for exploration activities instead of regulations and associated LOAs, NMFS could issue regulations and LOAs in the future. Therefore, through this EIS, NMFS is considering issuing either type of ITA (i.e. IHAs or LOAs) for oil and gas exploration activities in the Arctic.

5.3 Monitoring and Reporting

5.3.1 Purposes, Goals, and Objectives of MMPA Monitoring and Reporting Plans

The MMPA mandates that an authorization issued for the incidental take of marine mammals include requirements pertaining to the monitoring and reporting of the taking. The MMPA implementing regulations (50 CFR Part 216.104(a)(13)) further define the information that an applicant must provide when requesting an ITA, including the means of accomplishing monitoring and reporting that will result in increased knowledge of the species and the level of taking or impacts on populations of marine mammals that are expected to be present while conducting activities. The regulations further suggest that monitoring plans should include a description of the survey techniques that would be used to determine the movement and activity of marine mammals near the activity site(s), including migration and other habitat uses, such as feeding.

NMFS has developed more detailed guidance for applicants and analysts that further specifies the type of monitoring that can be used to comply with the broad goals outlined in the MMPA and its implementing regulations. Monitoring measures developed to comply with, and prescribed in, MMPA authorizations should be designed to accomplish or contribute to one or more of the following top-level goals:

(a) An increase in our understanding of the likely occurrence of marine mammal species in the vicinity of the action, i.e., presence, abundance, distribution, and/or density of species.

(b) An increase in our understanding of the nature, scope, or context of the likely exposure of marine mammal species to any of the potential stressor(s) associated with the action (e.g. sound or visual stimuli), through better understanding of one or more of the following:

    1. the action itself and its environment (e.g. sound source characterization, propagation, and ambient noise levels);
    2. the affected species (e.g. life history or dive patterns);
    3. the likely co-occurrence of marine mammal species with the action (in whole or part) associated with specific adverse effects; and/or
    4. the likely biological or behavioral context of exposure to the stressor for the marine mammal (e.g. age class of exposed animals or known pupping, calving or feeding areas).

(c) An increase in our understanding of how individual marine mammals respond (behaviorally or physiologically) to the specific stressors associated with the action (in specific contexts, where possible, e.g., at what distance or received level).

(d) An increase in our understanding of how anticipated individual responses, to individual stressors or anticipated combinations of stressors, may impact either: 1) the long-term fitness and survival of an individual; or 2) the population, species, or stock (e.g. through effects on annual rates of recruitment or survival).

(e) An increase in our understanding of how the activity affects marine mammal habitat, such as through effects on prey sources or acoustic habitat (e.g., through characterization of longer-term contributions of multiple sound sources to rising ambient noise levels and assessment of the potential chronic effects on marine mammals).

(f) An increase in understanding of the impacts of the activity on marine mammals in combination with the impacts of other anthropogenic activities or natural factors occurring in the region.

(g) An increase in our understanding of the effectiveness of mitigation and monitoring measures.

(h) A better understanding and record of the manner in which the authorized entity complies with the incidental take authorization and incidental take statement.

(i) An increase in the probability of detecting marine mammals (through improved technology or methodology), both specifically within the safety zone (thus allowing for more effective implementation of the mitigation) and in general, to better achieve the above goals.

Proposed Monitoring Plans are evaluated in the context of NMFS's implementing regulations and the above guidance, with consideration of the likelihood of effectively answering the questions that they have been designed to answer (e.g. what is the density of beluga whales in a given area; how do bowhead whales respond to drilling sounds at 160, 140, and 120 dB; how effective are forward looking infrared devices at detecting seals on the ice at night, etc.), given the proven success of the proposed methods in the past, as well as the proposed amount of effort. Efforts should be made to target questions that have been identified as priorities (i.e. to fill data gaps). Additionally, as described in Section 5.3.2 below, in the specific case of any activity that may affect the availability of marine mammals for subsistence uses and for which an IHA or LOA has been requested, MMPA implementing regulations require that monitoring plans or other research proposals undergo an independent peer review.

5.3.2 Monitoring Plan Peer Reviews

Prior to issuing an ITA for an activity that would occur in Arctic waters (i.e. north of 60º North latitude), and that may affect the availability of a species or stock for taking for subsistence purposes, the applicant's monitoring plan must be independently peer reviewed. The MMPA requires that in considering an application for an IHA, monitoring plans be independently peer reviewed "where the proposed activity may affect the availability of a species or stock for taking for subsistence uses" (16 U.S.C. 1371(a)(5)(D)(ii)(III)). Regarding this requirement, NMFS's implementing regulations state, "Upon receipt of a complete monitoring plan, and at its discretion, [NMFS] will either submit the plan to members of a peer review panel for review or within 60 days of receipt of the proposed monitoring plan, schedule a workshop to review the plan" (50 CFR § 216.108(d)). Although the MMPA only includes this requirement for IHAs, NMFS also requires independent peer review of monitoring plans as part of any petition for regulations and associated LOA(s) (50 CFR § 216.105(b)(3)).

As discussed in Section 5.3.1, an applicant's monitoring program should be designed to accomplish one or more of the following: document the effects of the activity on marine mammals; document or estimate the actual level of take as a result of the activity; increase the knowledge of the affected species; or increase knowledge of the anticipated impacts on marine mammal populations. Section 5.3.1 also discussed specific goals that should be accomplished by an applicant's monitoring program.

NMFS has hosted a one-to-two day Open Water Meeting each year since 1994. The purpose of these meetings is to bring together ITA applicants, subsistence hunters, agency scientists, and outside scientists with relevant expertise to review the design of industry monitoring plans for the upcoming open water season. Review of study results from the previous year's open water season is also undertaken. The inclusion of subsistence hunters in the review process ensures that both study designs and data interpretation are consistent with real-world observations of marine mammal behaviors and reactions to anthropogenic impacts. ITA applicants adjust their study designs and/or data interpretation techniques based on discussions in these meetings. In the early years, these meetings satisfied the requirement for an independent peer review via the workshop option described in the regulations.

Prior to 2006, the meetings were small with approximately 15 to 30 participants. The meetings from 2006 to 2012 drew approximately 150 to 250 participants each day of the two- to three-day meetings, thus making it difficult to achieve the focused and detailed reviews of the applicants' monitoring plans and reports provided in earlier meetings. Additional discussion about the Open Water Meeting is provided in Section 5.4.2.

In order to ensure the focused independent peer review of the monitoring plans prescribed by the regulations, in 2010, NMFS divided the annual meeting into two separate parts, one larger and more open stakeholder input meeting (discussed in Section 5.4.2), and one smaller meeting where a pre-selected group of scientists and affected subsistence hunters (who are available to answer questions and provide input) specifically gathers to review the proposed monitoring plans. In 2010, 2011, 2012, and 2013, after soliciting nominations from the industry ITA applicants, the Marine Mammal Commission, and the affected subsistence organizations, NMFS convened panels of approximately five to seven scientists to provide an independent scientific review of proposed monitoring plans.

During these reviews, NMFS charged the panel members with determining whether or not the monitoring plans, as put forth by the applicants, would accomplish the goals described earlier in this chapter. The panel members were asked to review the proposed monitoring plans, determine whether they were designed to accomplish their intended purpose - to document the effects of the activity on marine mammals, document or estimate the actual level of take as a result of the activity, increase the knowledge of the affected species, or increase knowledge of the anticipated impacts on marine mammal populations - and then make recommendations for how these goals could be better achieved. Panel members were provided the ITA applications and monitoring plans ahead of time in order to prepare for the discussions. Time was also set aside for the panel members to ask questions of the applicants in order to gain a better understanding of their proposal and what changes they may be able to implement. After the meetings, the panel members provided a final report to NMFS with their recommendations.

NMFS reviewed the final peer review panel report in the context of the applicants' activities and the requirements of the MMPA and selected recommendations that were appropriate for potential inclusion in the applicant's final monitoring plans. NMFS worked with the applicants regarding the feasibility of including these measures and protocols, and then included the selected measures as requirements in the issued ITAs.

This process is still developing, and some strengths and weaknesses have been identified. Utilizing a smaller group chosen from nominated scientists, with affected subsistence hunters available to share information and respond to questions, allows for a true scientific and independent review of the monitoring plans. The peer review panel report (which was not provided prior to 2010) provides NMFS with concrete recommendations that can be shared with the applicants and allows NMFS and the applicants to identify ways to improve the plans for current and future actions. However, panel members have suggested that the time allotted for interaction with the applicants in 2010 and 2011 was too short, so NMFS added additional time for interaction at the 2012 peer review panel meeting. Therefore, NMFS will strive to provide additional time for interaction where feasible. Also, at the request of the applicants, beginning in 2012, questions were provided to them in advance so that they could be prepared to discuss specific issues identified by the panel members. Generally, both scientist reviewers and applicants have indicated that this more focused method for peer review of the monitoring plans is more effective than the larger meeting format used in 2006 through 2009. However, it is an iterative process, and NMFS intends to continue modifying the methods as necessary to most effectively solicit input.

5.3.3 Potential Improvements for Monitoring and Reporting Plans

As described above, applicants for MMPA authorizations are required to include proposed monitoring plans. In the past, through the Open Water Meetings, public comments on NEPA and MMPA documents, POC meetings, etc., a broad range of recommendations have been made regarding monitoring plans for oil and gas exploration activities. In the last few years, more focused input has been provided via the new peer review format described above. However, in the former example (i.e. Open Water Meeting, public comments, etc.) input has often been unfocused and too broad to be effectively incorporated into MMPA authorizations, and in the latter example (i.e. independent peer review) much of the input is related to modifications to what a given company has already specifically proposed. What is missing is focused prioritization of needs and guidance to applicants in advance of their development of their initial applications.

In 2010 and 2011, the independent peer reviewers included in their report (in addition to specific comments on the applications that they are reviewing) additional recommendations (related to both the goals of monitoring, in addition to methodology) that could potentially be more broadly applied to multiple applicants, both in the present and the future. This sort of comprehensive consideration of multiple monitoring activities across multiple years could facilitate the most effective combined monitoring efforts in the Arctic.

In the interest of more comprehensive prioritization and planning of monitoring that could be required and implemented as part of MMPA ITAs, NMFS is considering the following:

- Developing and maintaining (on the NMFS website) a list of monitoring priorities and data gaps for Arctic oil and gas development projects;
- Soliciting input for this list from Open Water Meetings, peer review panels, public comment periods, or, potentially, a longer term panel convened specifically to develop these priorities;
- Including, in the above-mentioned list, specific recommendations for discrete monitoring projects (with suggested methodologies) that could be adopted by new applicants; and
- Considering and describing, in the list, how to best build on existing monitoring results and best integrate data collection, analysis, and reporting with simultaneous monitoring efforts.

Following are examples of some of the issues that have been identified as a priority for monitoring and reporting pursuant to MMPA ITAs for oil and gas exploration:

- Identification of presence, abundance, and distribution of multiple species in the winter months;
- Bowhead movement patterns following initial deflection from industry activities during fall migration;
- Development of a real-time monitoring approach that can adequately detect marine mammals during darkness or inclement weather;
- Results of impacts to marine mammals from oil and gas activities since 2006;
- Behavioral responses of bowheads, and other species, to acoustic exposure at specific levels (160 dB, 120 dB);
- Behavioral responses of bowhead cow-calf pairs to acoustic exposure at specific levels;
- Measurement of sound produced by icebreakers and the resulting impacts to marine mammals; and
- Industry information and data regarding their activities (e.g. specifically when and where a seismic or shallow hazards/site clearance survey was taking place and the times airguns or other devises were operating) and specific monitoring data not being publically available.

Building upon the existing public input tools, NMFS could develop an iterative and systematic annual means of identifying and prioritizing the monitoring goals for Arctic oil and gas exploration activities. These priorities could be available to potential applicants on the NMFS website along with specific methodology recommendations summarized from previous peer review recommendations. This would provide direction and guidance for applicants and allow for the most effective use of resources to answer the most pressing questions related to the effects of oil and gas exploration on marine mammals. NMFS intends to explore this way forward through public input on this EIS and at future Open Water Meetings.

5.3.4 BOEM Environmental Studies Program

The OCS Lands Act, as amended, established policy for the management of the OCS energy and mineral resources and for the protection of marine and coastal environments. Section 20 of the OCS Lands Act authorizes an Environmental Studies Program (ESP). The ESP aims to establish the information needed for assessment and management of environmental impacts on the human, marine, and coastal environments of the OCS and the potentially affected coastal areas, to predict impacts on the marine biota which may result from chronic, low level pollution or large spills associated with OCS production, from drilling fluids and cuttings discharges, pipeline emplacement, or onshore facilities, and to monitor human, marine, and coastal environments to provide time series and data trend information for identification of significant changes in the quality and productivity of these environments, and to identify the causes of these changes. Nationally, the applied research conducted through the ESP informs management decisions relating to OCS activities from the earliest stage of OCS planning through the final removal of the OCS structure at the end of its productive life.

The *Alaska Annual Studies Plan* complements and reinforces the goals of the ESP. The ESP is guided by several broad themes, which include:

- Monitoring Marine Environments
- Conducting Oil-Spill Fate and Effects Research
- Minimizing Seismic and Acoustic Impacts
- Understanding Social and Economic Impacts
- Maintaining Efficient and Effective Information Management

To be prepared to make decisions arising from activities associated with current oil and gas leases and potential future leasing and changing offshore technologies, the Alaska OCS Region continually proposes new studies and pursues information needs in conjunction with ESP goals. Due to the great differences that exist between Alaska environments and other OCS areas, the Alaska ESP remains especially flexible in planning and implementing needed studies. At each step of the offshore leasing and development process, a variety of potential issues or resource-use conflicts may be encountered. Two questions are fundamental:

- What is the expected change in the human, marine, and coastal environment due to offshore activity?
- Can undesirable change be minimized by mitigation measures?

Environmental studies are the primary means to provide information on these questions for use by decision-makers. Currently, the Alaska ESP is primarily focused on upcoming developments, exploration activities and existing leases, and potential future lease sales in the Beaufort Sea and Chukchi Sea Planning Areas. Current offshore oil and gas-related issues addressed by ongoing and proposed studies in the Beaufort Sea and the Chukchi Sea include, but are not limited to:

- What refinements are there to our knowledge of major oceanographic and meteorological processes and how they influence the human, marine, and coastal environment?
- What role will currents play in distribution of anthropogenic pollutants near development prospects?
- What long-term changes in heavy metal and hydrocarbon levels may occur near Beaufort Sea development prospects, such as Liberty, or regionally along the Beaufort Sea coast?
- How do we improve our model predictions regarding the fate of potential oil spills?
- If oil is spilled in broken ice, what will its fate be?
- What effects might pipeline construction have on nearby marine communities or organisms?
- What changes might occur in sensitive benthic communities such as the Stefansson Sound “Boulder Patch” and other Beaufort Sea kelp communities or fish habitats?
- What are the current spatial and temporal use patterns of these planning areas by species that are potentially sensitive, such as bowhead whales, polar bears, ice seals, walrus, other marine mammals, seabirds and other birds, or fish?
- What is the extent of endangered whale feeding in future proposed or potential lease sale areas?

- What changes might occur in habitat use, distribution, abundance, movement or health of potentially sensitive key species such as bowhead whales, polar bears, ice seals, walrus, other marine mammals, seabirds and other birds, or fish?
- What interactions between human activities and the physical environment have affected potentially sensitive species?
- What changes might occur in socioeconomics and subsistence lifestyles of coastal Alaska communities?
- What are current patterns of subsistence harvest, distribution, and consumption and what changes might occur in key social indicators as a result of offshore exploration and development?
- How can we continue to integrate local and/or traditional knowledge into studies related to the Alaska ESP?

Further information on Alaska Region's ESP and Studies Plan can be found at the BOEM website http://www.boem.gov/Environmental-Stewardship/Environmental-Studies/Alaska-Region/Index.aspx.

5.4 Tools for Mitigating Impacts on Subsistence

As discussed in Section 2.3.4 of this EIS, over the years, several processes and programs have evolved to facilitate interaction between the industry and the local communities to ensure that the Arctic subsistence culture can continue to thrive in conjunction with oil and gas exploration and development. Some of these processes are Federally-mandated while others have been voluntary between the industry and local communities. This section of the EIS discusses three of these tools in more detail: (1) POCs, which are required by NMFS's implementing regulations (50 CFR § 216.104(a)(12)); (2) Open Water Season CAAs, which are voluntary and not required by any statute or regulation; and (3) the annual Open Water Meeting. For each of these three tools, this section includes an examination and analysis of:

- what each one is and the purpose it has served;
- the process for developing and/or implementing the tool;
- the strengths and weaknesses of the tool; and
- how the tool can be modified or improved in order to aid NMFS in ensuring that the take of marine mammals incidental to oil and gas exploration activities has no unmitigable adverse impacts on the availability of marine mammals for subsistence uses.

5.4.1 Plan of Cooperation and Conflict Avoidance Agreement

In 1985, the Alaska Eskimo Whaling Commission (AEWC) and a number of arctic offshore oil and gas operators began working together to identify and mitigate sources of industrial interference with bowhead whale subsistence hunting. Recognizing the need to facilitate the co-existence of marine mammal subsistence uses and arctic offshore industrial activities, in 1986, Congress amended the MMPA to require that the issuance of ITAs rest on a Secretarial finding of "no unmitigable adverse impact to the availability" of marine mammal subsistence resources. The AEWC and offshore operators undertook an annual initiative to develop mitigation measures, which came to be known as the Open Water Season Conflict Avoidance Agreement (CAA) Process.

Regulations promulgated pursuant to the 1986 MMPA amendments, require that for an activity that will take place near a traditional Arctic hunting ground, or may affect the availability of marine mammals for subsistence uses, an applicant for MMPA authorization must either submit a POC or information that identifies the measures that have been taken to minimize adverse impacts on subsistence uses. The regulations provide that a POC must include the following:

- a statement that the applicant has notified the affected subsistence community and provided them a draft POC;
- a schedule for meeting with the communities to discuss proposed activities and resolve potential conflicts regarding any aspects of the operation or POC;
- a description of measures the applicant has taken or will take to ensure that proposed activities will not interfere with subsistence hunting; and
- what plans the applicant has to continue to meet with the communities, prior to and during the activity, to resolve conflicts and notify the community of any changes in the activity.

Input from the impacted bowhead whale subsistence communities indicates that they have historically found that the CAA process, through its highly interactive aspects, has effectively resulted in the development and implementation of measures that will ensure no unmitigable adverse impact. Based on this, for many years, NMFS generally found, after conducting an independent analysis, that if a company and the AEWC signed a CAA (which typically contained the components of a POC), then it was possible for a company to conduct their activity without having an unmitigable adverse impact on the subsistence hunt. However, in more recent years, some companies have become reluctant to sign a CAA with the AEWC. Additionally, some stakeholders have raised the issue that a CAA developed by the AEWC does not represent the interests of subsistence hunters of species other than bowhead whales. Last, NMFS and BOEM have no authority to require private agreements between third parties, and neither NMFS nor BOEM can enforce the provisions of CAAs because the federal government is not a party to the agreements. These concerns highlight NMFS' responsibility to conduct a rigorous and comprehensive independent analysis of the likely subsistence impacts and to specifically review the contents of each company's POC. However, the AEWC has raised concerns about the POCs, asserting that while the CAA process traditionally provided content for the regulatory POC process, the POC process as currently implemented by some companies takes place in a one-way fashion, i.e., the company develops a POC without meaningful input from the subsistence communities.

To date, individual companies conducting activities in a given year, as well as the impacted subsistence communities, are involved in meetings related to both the negotiation of CAAs (regardless of whether they are ultimately signed by either party) and the development of POCs. Participating in both of these processes necessitates a lot of work on the part of all parties. With input from both subsistence communities and the applicants for MMPA authorization, NMFS plans to explore methods of clarifying the requirements of the MMPA (as they relate to the POC and ensuring no unmitigable adverse impact) that would incorporate the effective pieces of the CAA negotiations, while continuing to ensure compliance with the MMPA as it relates to the subsistence hunt of all affected species.

5.4.2 Open Water Meeting

As mentioned in Section 5.3.2, during the 1980s and early 1990s, the monitoring plan peer review and Open Water Meeting were the same meeting. However, as attendance at the Open Water Meeting began to grow exponentially beginning in 2006, the need to split these processes into two separate meetings became apparent. The Open Water Meeting now refers to the open access stakeholder meeting (not the monitoring plan review) that is important to ensure NMFS' understanding, from the affected parties, of the effects of industry activity on the subsistence uses of marine mammals.

Since 2006, the Open Water Meeting has attracted members of industry, Federal, state, and local government officials and scientists, Native Alaskan marine mammal commissions, affected Native Alaskan hunters and community members, environmental non-governmental organizations, and other interested members of the public. Typically, each year, the industry presents the results of their marine mammal monitoring programs from the previous year and the suite of activities proposed for the upcoming season along with the associated monitoring plans. Native subsistence group representatives (e.g. whaling captains, AEWC members, etc.) present information related to impacts that industry activities may have had (either in the past year or historically) on their ability to effectively hunt a given species. There have also been presentations regarding ongoing western and traditional science programs conducted in the region. Many of these science programs are designed to gain knowledge about the physical and chemical properties of the ecosystem and distribution and abundance trend patterns of marine mammals and other species in the area.

Unlike the monitoring plan peer review, the Open Water Meeting is not specifically required by statute or regulation. However, because of the importance of stakeholder input and interaction in NMFS' determination of whether the take of marine mammals resulting from a specific activity will likely have an unmitigable adverse impact on subsistence uses, NMFS has continued to organize this annual meeting. The Open Water Meeting allows the public to provide input on industry proposals while the Federal agencies ultimately responsible for authorizing the activity itself and the incidental take of marine mammals can listen to those comments and participate in the interaction.

5.5 Adaptive Management

A simple definition of adaptive management is "a systematic process for continually improving management policies and practices by learning from the outcomes of operational programs" (Holling, 1978). The process basically involves the following steps: predict, mitigate, implement, monitor, and adapt.

Adaptive Management is a discretionary learning-based management approach to structured decision-making that may be used in conjunction with the NEPA process. Adaptive management considers appropriate adjustments to federal Actions (i.e. decisions related to the issuance of permits and authorizations under multiple statutes) and the associated required mitigation, monitoring, and reporting as the outcomes of previous proposed actions and required mitigation and monitoring, as well as new science, are better understood. NMFS and BOEM historically incorporated, and will continue to incorporate in the future, adaptive management principles in the issuance of permits and authorizations and any needed adjustments of mitigation and monitoring. The following are some of the specific sources of information upon which adaptive management decisions could be based during the life of this EIS:

(1) Results of monitoring required pursuant to MMPA ITAs or other Federal statutes for Arctic oil and gas development activities;

(2) Stakeholder input during the annual Open Water Meetings;

(3) Scientific input from the independent peer review;

(4) Public input during comment periods on MMPA authorizations;

(5) Results from BOEM's Environmental Studies Program;

(6) Results from general marine mammal and sound research;

(7) Results from the efforts of the NOAA Working Groups on Underwater Sound Mapping and Cetacean Mapping in the Arctic and elsewhere;

(8) Results of the BP Cumulative Impact modeling of multiple sound sources in the Beaufort Sea;

(9) Any information which reveals that marine mammals may have been taken in a manner, extent, or number not authorized; and

(10) Traditional ecological knowledge.

The intent of adaptive management is to ensure: (1) the minimization of adverse impacts to marine mammals, subsistence uses of marine mammals, endangered species, and other protected resources, within the context of the associated regulations and statutes; (2) the maximization of value of the information gathered via required monitoring; and (3) industry compliance with environmental protection statutes and regulations. NMFS will continuously consider adaptive management as the agency executes the ITA program and may seek to revise regulations in the future if they no longer are found to reflect the needs of management towards ensuring that takes are no more than negligible and subsistence needs are being properly addressed.

In the past few years, NMFS, BOEM, and USFWS reviewed operational and marine mammal observer reports at weekly environmental/regulatory compliance review meetings related to Arctic OCS activities during the open water season. The purpose of the meetings was to verify environmental/regulatory compliance by the operators during the activity and to determine whether federal decisions on monitoring, mitigation, and reporting were achieving the intended results. If the intended results were not being achieved, the agencies could modify the requirements for ongoing operations, as needed.

NMFS and BOEM intend to continue the review meetings, during OCS activities, with USFWS and BSEE. BSEE has the responsibility to verify that required environmental monitoring, mitigation, and reporting protocols (i.e. for protected species) are implemented during seismic surveying and drilling activities on the OCS. BSEE has the authority to enforce compliance with environmental requirements on all drilling operations. BOEM continues as the regulatory authority for G&G activities.

BOEM and BSEE will also conduct post-activity reviews. The reviews will be used to:

- document environmental compliance;
- determine whether reporting requirements provide sufficient information on operations and their effects;
- evaluate monitoring and mitigation effectiveness;
- improve site-specific monitoring and mitigation requirements, if needed; and
- support the incorporation of compliance, mitigation, and monitoring efforts into future programmatic and site-specific environmental analyses.

This page intentionally left blank.

6.0 CONSULTATION AND COORDINATION

6.1 Development of the EIS

The Notice of Intent (NOI) to prepare an EIS was published in the *Federal Register* on February 8, 2010 (75 FR 6175). The scoping period, during which issues and concerns are identified, was initiated February 8, 2010. This provided an opportunity for the oil industry, government organizations, tribal and local governments, environmental groups, the general public, and all other interested parties to comment on areas of interest or special concern regarding this EIS. The NOI also requested stakeholders to identify and provide information that should be considered by NMFS in preparation of the EIS. Scoping comments were received through April 9, 2010 as specified in the NOI and were used to identify issues of concern and develop the alternatives for this EIS. The scoping report summarizing the scoping comments and issues of concern is posted on the NMFS website at:

http://www.nmfs.noaa.gov/pr/permits/eis/arctic.htm.

On January 30, 2013, NMFS published an NOI to prepare a Supplemental DEIS (78 FR 6303). The public was afforded 60 days to provide comments on the DEIS, which went out for public comment on December 30, 2011 (76 FR 82275). The comment letters received during the DEIS public comment period, as well as the transcripts of the public meetings, can be found at the above mentioned website.

NMFS is the lead agency for this EIS and is responsible for the development of the EIS in collaboration with the cooperating agencies. BOEM and the NSB are participating as cooperating agencies. The EPA is participating as a consulting agency. NMFS is also working with the AEWC on the development of this EIS per our co-management agreement.

Executive Order 13175 (*Consultation and Coordination with Indian Tribal Governments*), states that the U.S. Government will "*work with Indian tribes on a government-to-government basis to address issues concerning Indian Tribal self-government, trust resources, and Indian Tribal treaty and other rights.*" For government-to-government consultation during the scoping process for this EIS and the public comment period for the DEIS, Tribal governments in each community, with the exception of Anchorage, were notified of the EIS process and invited to participate. The Tribal Organizations that received invitations to participate are listed below. Native Village of Point Hope declined to participate at the scoping stage because they received less than one month of prior notification.

- Native Village of Nuiqsut
- Iñupiat Community of the Arctic Slope
- Native Village of Point Hope
- Native Village of Point Lay
- Native Village of Barrow
- Native Village of Wainwright
- Native Village of Kotzebue

All of the above mentioned groups were also notified at the DEIS public comment stage, and the Native Village of Kivalina was also contacted at that time.

6.2 Consultation

Section 7(a)(2) of the ESA requires each federal agency to ensure that any action that it authorizes, funds, or carries out is not likely to jeopardize the continued existence of a listed species or result in the adverse modification of designated critical habitat. To satisfy its ESA obligations, NMFS will engage in the consultation and coordination processes with other regulatory agencies at the MMPA stage, and BOEM and BSEE will fulfill this requirement at the time of activity review.

6.3 Agencies and Organizations Contacted

The following are lists of the federal, state, Tribal and local government agencies; academic institutions; members of the oil and gas industry; special interest groups; and other organizations who were notified of the availability of the Supplemental DEIS.

Federal – Executive Branch	
Department of Commerce	National Marine Fisheries Service; Bowhead Whale Project, Alaska Regional Office, Anchorage National Oceanic and Atmospheric Administration; Policy and Strategic Planning, Information Services Division Office of the Assistant Secretary for Oceans and Atmosphere
Department of Defense	U.S. Army Corps of Engineers; Regulatory Branch, Alaska District U.S. Navy; NEPA Natural Resources
Department of Homeland Security	U.S. Coast Guard

6.4 List of Preparers

Representatives from NMFS, BOEM, EPA, and NSB reviewed draft documents. Earlier versions of chapters were drafted by contractors.

NOAA NMFS	Shane Guan; Fishery Biologist, Office of Protected Resources, Permits and Conservation Division, Silver Spring, MD Jolie Harrison; Supervisory Fishery Biologist, Office of Protected Resources, Permits and Conservation Division, Silver Spring, MD Candace Nachman; Fishery Biologist and EIS Project Manager, Office of Protected Resources, Permits and Conservation Division, Silver Spring, MD Jennifer Nist; Attorney-Advisor, Fisheries and Protected Resources Section, Silver Spring, MD P. Michael Payne; Division Chief, Office of Protected Resources Permits and Conservation Division, Silver Spring, MD Brad Smith; Supervisory Administrator, Protected Resources Division, Alaska Regional Office, Anchorage, Alaska
BOEM	Megan Butterworth; Biological Oceanographer, Headquarters, Herndon, VA Jill Lewandowski; Protected Species Biologist, Headquarters, Herndon, VA Kimberly Skrupky; Marine Biologist, Headquarters, Herndon, VA Sally Valdes; Aquatic Ecologist, Headquarters, Herndon, VA Eric Wolvovsky; Meteorologist, Herndon, VA Kelly Hammerle; Environmental Protection Specialist, Herndon, VA Brian Jordan; Archaeologist, Herndon, VA Tamara Arzt; Environmental Protection Specialist, Herndon, VA Keely Hite; Environmental Protection Specialist, Herndon, VA Susan Banet, Chief, Resource Analysis Section, Alaska Region, Anchorage, AK Mark Schroeder, Wildlife Biologist, Alaska Region, Anchorage, AK Pete Sloan, Geologist, Alaska Region, Anchorage, AK Sharon Warren, Deputy Regional Director, Alaska Region, Anchorage, AK Caryn Smith, Oceanographer, Alaska Region, Anchorage, AK Mary Cody, Wildlife Biologist, Alaska Region, Anchorage, AK Virginia Raps, Meteorologist, Alaska Region, Anchorage, AK Chris Crews, Wildlife Biologist, Alaska Region, Anchorage, AK Chris Campbell, Sociocultural Specialist, Alaska Region, Anchorage, AK

	Nancy Deschu, Fisheries Biologist, Alaska Region, Anchorage, AK Jerry Brian, Economist, Alaska Region, Anchorage, AK Bob Peterson, Chief, Resource and Economic Analysis Section, Alaska Region, Achorage, AK Scott Blackburn, NEPA Coordinator, Alaska Region, Anchorage, AK Jeff Denton, Wildlife Biologist, Alaska Region, Anchorage, AK Mike Routhier, Program Analysis Officer, Alaska Region, Anchorage, AK
EPA	Jennifer Curtis; NEPA Reviewer, EPA Alaska Operations, Anchorage, AK Hanh Shaw; Team Lead-NPDES Permits Unit, EPA Region 10, Seattle, WA Dianne Soderlund; Director, EPA-Alaska Operations, Anchorage, AK
NSB	Tom Lohman; Environmental Resource Specialist, North Slope Borough Department of Wildlife Management Robert Suydam; Wildlife Biologist, North Slope Borough Department of Wildlife Management
URS and Subcontractors	
URS	Jon Isaacs; Principal in Charge Amy Rosenthal; Project Manager Jack Colonell; Senior Review, Physical Environment Bridget Easley; Biological Environment Task Lead Joan Kluwe; Social Environment and Public Involvement Task Leads Dan LaPlant; Physical Environment Task Lead Taylor Breslford; Senior Review, Social Environment Tara Bellion; Administrative Record and Public Involvement Joanne Jones; Geographic Information Systems Linda Harriss; Word Processor Ida Krajsek; Word Processor Bill Loskutoff; Quality Controls and Quality Assurance
Subcontractors	Suzanne Ban; Cardno Entrix, Senior Review, Biological Environment David Hannay; Jasco Applied Sciences, Acoustics Murray Lee; Habitat, Health Impact Assessment Marla Orenstein; Habitat, Health Impact Assessment Paul Stang; Stang Consulting, Oil Spill Analysis Sheyna Wisdom; Fairweather Sciences, Acoustics, Marine Mammals

8.0 GLOSSARY

Acute—Sudden, short term, severe, critical, crucial, intense, but usually of short duration.

Anadromous fish—Fish that migrate up river from the sea to breed in fresh water.

Annelid—Worm with a cylindrical body segmented both internally and externally.

Annular preventer—A component of the pressure control system in the Blowout Preventer that forms a seal in the annular space around any object in the wellbore or upon itself, enabling well control operations to commence.

Anthropogenic—Coming from human sources, relating to the effect of humankind on nature.

Aphotic zone—Zone where the levels of light entering through the surface are not sufficient for photosynthesis or for animal response.

Archaeological resource—Any material remains of human life or activities that are at least fifty years of age and that are of archaeological interest.

Aromatic—Class of organic compounds containing benzene rings or benzenoid structures.

Attainment area—An area that is shown by monitored data or by air-quality modeling calculations to be in compliance with primary and secondary ambient air quality standards established by the USEPA.

Barrel (bbl)—A volumetric unit used in the petroleum industry; equivalent to 42 U.S. gallons or 158.99 liters.

Benthic—Literally, living on the bottom. Refers to material, especially sediment, at the bottom of an aquatic ecosystem, or it can be used to describe the organisms that live on, or in, the bottom of a water body or the sea.

Benthos—A region that includes the bottom of the sea and the littoral zone; also refers to the benthic invertebrate community, which is a group of animals that lives on or in the bottom sediments.

Biological Opinion—The FWS or NMFS evaluation of the impact of a proposed action on endangered and threatened species, in response to formal consultation under Section 7 or the endangered Species Act.

Block—A geographical area portrayed on official BOEMRE protraction diagrams or leasing maps that contains approximately 2,331 ha (9 mi2).

Blowout—An uncontrolled flow of fluids below the mudline from appurtenances on a wellhead or from a wellbore.

Blowout preventer (BOP)—One of several valves installed at the wellhead to prevent the escape of pressure either in the annular space between the casing and drill pipe or in open hole (i.e., hole with no drill pipe) during drilling completion operations. Blowout preventers on jackup or platform rigs are located at the water's surface; on floating offshore rigs, BOP's are located on the seafloor.

Brackish—Slightly salty water.

Cetacean—Large aquatic carnivorous mammal with fin-like forelimbs, no hind limbs includes whales, dolphins, porpoises, and narwhals. Also of or relating to these animals.

Chemosynthetic—Organisms that obtain their energy from the oxidation of various inorganic compounds rather than from light (photosynthesis).

Critical habitat—Specific areas within the geographical area occupied by the species at the time of listing (under the ESA), if they contain physical or biological features essential to conservation, and those features may require special management considerations or protection; and specific areas outside the geographical area occupied by the species if the agency (USFWS or NMFS) determines that the area itself is essential for conservation.

Coastal waters—Waters within the geographical areas defined by each State's Coastal Zone Management Program.

Coastal wetlands—Forested and nonforested habitats, mangroves, and marsh islands exposed to tidal activity. These areas directly contribute to the high biological productivity of coastal waters by input of detritus and nutrients, by providing nursery and feeding areas for shellfish and finfish, and by serving as habitat for birds and other animals.

Coastal zone—The coastal waters (including the lands therein and thereunder) and the adjacent shore lands (including the waters therein and thereunder) strongly influenced by each other and in proximity to the shorelines of the several coastal states; the zone includes islands, transitional and intertidal areas, salt marshes, wetlands, and beaches and extends seaward to the outer limit of the United States territorial sea. The zone extends inland from the shorelines only to the extent necessary to control shore lands, the uses of which have a direct and significant impact on the coastal waters. Excluded from the coastal zone are lands the use of which is by law subject to the discretion of or which is held in trust by the Federal Government, its officers, or agents. (The State land and water area officially designated by the State as "coastal zone" in its State coastal zone program as approved by the U.S. Department of Commerce under the Coastal Zone Management Act.)

Condensate—Liquid hydrocarbons produced with natural gas; they are separated from the gas by cooling and various other means. Condensates generally have an API gravity of 50o-120o.

Continental margin—The ocean floor that lies between the shoreline and the abyssal ocean floor, includes the continental shelf, continental slope, and continental rise.

Continental shelf—The gently seaward-sloping surface that extends between the shoreline and the top of the continental slope at about 150 meters (345 feet) depth. The average gradient of the shelf is between 1:500 and 1:1000 and, although it varies greatly, the average width is approximately 70 kilometers (44 miles). This can also be a judicial term; for example, the outer limit of the legal continental shelf is determined by reference to be a distance of 200 nautical miles (370 kilometers, 230 miles) or to the outer edge of the geological continental margin, wherever the margin extends beyond 200 nautical miles (370 kilometers; 230 miles).

Contingency Plan—A plan for possible offshore emergencies prepared and submitted by the oil or gas operator as part of the plan of development and production, and which may be required for part of the plan of exploration.

Continental slope—That part of the continental margin that lies between the continental shelf and the bottom of the ocean. Sunlight does not penetrate this area, and mostly it is home to scavengers. It is characterized by a relatively steep slope of 3 to 6 degrees.

Critical habitat—a designated area that is essential to the conservation of an endangered or threatened species that may require special management considerations or protection.

Crude oil—Petroleum in its natural state as it emerges from a well, or after it passes through a gas-oil separator but before refining or distillation. An oily, flammable, bituminous liquid that is essentially a complex mixture of hydrocarbons of different types with small amounts of other substances.

Crustacean—Includes a diversity of marine, freshwater, and terrestrial animals. All crustaceans have a head and five pairs of appendages, two of which are antennae. Many microscopic crustaceans, like krill and brine shrimp, are marine plankton, an important food source for other animals in the sea. Shrimp, lobsters, crabs, crayfish, and barnacles are crustaceans.

Deferral—Action taken by the Secretary of the Interior at the time of the Area Identification to remove certain areas/blocks from the proposed sale.

Delineation well—A well that is drilled for the purpose of determining the size and/or volume of an oil or gas reservoir.

***Deepwater Horizon* (DWH) event**—All actions stemming from the April 20, 2010, explosion and subsequent sinking of the Transocean drillship *Deepwater Horizon*, up to and including the Macondo well kill declaration on September 19, 2010.

Depleted species—Defined by the MMPA as any case in which: (a) the Secretary of Commerce, after consultation with the Marine Mammal Commission and the Committee of Scientific Advisors on Marine Mammals, determines that a species or population stock is below its optimum sustainable population; (b) a State determines that such species or stock is below its optimum sustainable population; or (c) a species or population stock is listed as a threatened species or endangered species under the ESA.

Demersal—Living near, deposited on, or sinking to the bottom of the sea.

Development—Activities that take place following discovery of economically recoverable mineral resources, including geophysical surveying, drilling, platform construction, operation of onshore support facilities, and other activities that are for the purpose of ultimately producing the resources.

Development Operations Coordination Document (DOCD)—A document that must be prepared by the operator and submitted to BOEMRE for approval before any development or production activities are conducted on a lease in the Western Gulf.

Diapause—A state of rest, halted development, or arrested development or growth, accompanied by greatly decreased metabolism, often correlated with the seasons, usually applied only to insects.

Dilution—The reduction in the concentration of dissolved or suspended substrates by mixing with water.

Direct employment—Consists of those workers involved the primary industries of oil and gas exploration, development, and production operations (Standard Industrial Classification Code 13—Oil and Gas Extraction).

Discharge—Something that is emitted; flow rate of a fluid at a given instant expressed as volume per unit of time.

Dispersant—A suite of chemicals and solvents used to break up an oil slick into small droplets, which increases the surface area of the oil and hastens the processes of weathering and microbial degradation.

Dispersion—A suspension of finely divided particles in a medium.

Distinct Population Segment (DPS)—A vertebrate population or group of populations that is discrete from other populations of the species and significant in relation to the entire species. Distinct population segments may be listed as threatened or endangered under the ESA.

Drilling mud—A mixture of clay, water or refined oil, and chemical additives pumped continuously downhole through the drill pipe and drill bit, and back up the annulus between the pipe and the walls of the borehole to a surface pit or tank. The mud lubricates and cools the drill bit, lubricates the drill pipe as it turns in the wellbore, carries rock cuttings to the surface, serves to keep the hole from crumbling or collapsing, and provides the weight or hydrostatic head to prevent extraneous fluids from entering the well bore and to downhole pressures; also called drilling fluid.

Drillship—A self-propelled, self-contained vessel equipped with a derrick amidships for drilling wells in deep water.

Effluent—A waste product that is discharged to the environment, usually used to mean treated wastewater discharged from a wastewater treatment plant, sewer, or industrial outfall.

Effluent limitations—Any restriction established by a State or the USEPA on quantities, rates, and concentrations of chemical, physical, biological, and other constituents discharged from point sources into U.S. waters, including schedules of compliance.

Endangered species—Defined under the ESA as "any species which is in danger of extinction throughout all or a significant portion of its range."

Environmental Assessment—A concise public document required by the National Environmental Policy Act of 1969 (NEPA). In the document, a Federal agency proposing (or reviewing) and action provides evidence and analysis for determining whether it must prepare an Environmental Impact Statement (EIS) or whether it finds there is no significant impact (i.e., Finding of No Significant Impact [FONSI]).

Environmental effect—A measurable alteration or change in environmental conditions.

Environmental Impact Statement (EIS)—A statement required by the National Environmental Policy Act of 1969 (NEPA) or similar State law in relation to any major action significantly affecting the environment; a NEPA document.

Epifaunal—Animals living on the surface of hard substrate.

Essential Fish Habitat (EFH)—Defined under the Magnuson-Stevens Fishery Conservation and Management Act as waters and substrate that are necessary to the fish species for spawning, breeding, feeding, or growth to maturity.

Estuary—Coastal semienclosed body of water that has a free connection with the open sea and where freshwater meets and mixes with seawater.

Eutrophication—The process whereby an aquatic environment becomes rich in dissolved nutrients, causing excessive growth and decomposition of oxygen-depleting plant life and resulting in injury or death to other organisms.

Exclusive Economic Zone (EEZ)—The maritime region extending 200 nmi from the baseline of the territorial sea, in which the United States has exclusive rights and jurisdiction over living and nonliving natural resources.

Exploration—The process of searching for minerals. Exploration activities include: (1) geophysical surveys where magnetic, gravity, seismic, or other systems are used to detect or infer the presence of such minerals; and (2) any drilling, except development drilling, whether on or off known geological structures. Exploration also includes the drilling of a well in which a discovery of oil or natural gas in paying quantities is made, and the drilling, after such a discovery, of any additional well that is needed to delineate a reservoir and to enable the lessee to determine whether to proceed with development and production.

Exploration Plan (EP)—A plan that must be prepared by the operator and submitted to BOEMRE for approval before any exploration or delineation drilling is conducted on a lease.

Exploration well—A well drilled in unproven or semi-proven territory to determining whether economic quantities of oil or natural gas deposit are present; exploratory well.

Fault—A fracture in the earth's crust accompanied by a displacement of one side of the fracture with respect to the other.

Field—An accumulation, pool, or group of pools of hydrocarbons in the subsurface. A hydrocarbon field consists of a reservoir in a shape that will trap hydrocarbons and that is covered by an impermeable, sealing rock.

Fixed or bottom founded—Permanently or temporarily attached to the seafloor.

Flyway—An established air route of migratory birds.

Formation—A bed or deposit sufficiently homogeneous to be distinctive as a unit. Each different formation is given a name, frequently as a result of the study of the formation outcrop at the surface and sometimes based on fossils found in the formation.

Fugitive emissions—Emission into the atmosphere that could not reasonably pass through a stack, chimney, vent or other functionally equivalent opening.

Gathering lines—A pipeline system used to bring oil or gas production from a number of separate wells or production facilities to a central trunk pipeline, storage facility, or processing terminal.

Geochemical—Of or relating to the science dealing with the chemical composition of and the actual or possible chemical changes in the crust of the earth.

Geologic hazard—A feature or condition that, if unmitigated, may seriously jeopardize offshore oil and gas exploration and development activities. Mitigation may necessitate special engineering procedures or relocation of a well.

Geophysical—Of or relating to the physics of the earth, especially the measurement and interpretation of geophysical properties of the rocks in an area.

Geophysical data—Facts, statistics, or samples that have not been analyzed or processed, pertaining to gravity, magnetic, seismic, or other surveys/systems.

Geophysical survey—A method of exploration in which geophysical properties and relationships are measured remotely by one or more geophysical methods.

Habitat—A specific type of environment that is occupied by an organism, a population, or a community.

Halophytic—A plant that can tolerate or thrive in alkaline soil rich in sodium or calcium salts; tolerant of saline (salty) conditions.

Harassment—Under the 1994 amendments to the MMPA, harassment is statutorily defined as any act of pursuit, torment, or annoyance which: has the potential to injure a marine mammal or marine mammal stock in the wild (Level A Harassment); or has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering but which does not have the potential to injure a marine mammal or marine mammal stock in the wild (Level B Harassment).

Haulout area—Specific locations where pinnipeds come ashore and concentrate in numbers to rest, breed, and/or bear young.

Holocene Epoch—A geologic time segment of the Quaternary Period, dating from the end of the Pleistocene Epoch, approximately 8,000 years ago until the present.

Hydrocarbons—Any of a large class of organic compounds containing primarily carbon and hydrogen. Hydrocarbon compounds are divided into two broad classes: aromatic and aliphatics. They occur primarily in petroleum, natural gas, coal, and bitumens.

Hypothermia—Condition in which body temperature drops below the level required for normal metabolism and/or bodily function to take place.

Hypoxia—Depressed levels of dissolved oxygen in water, usually resulting in decreased metabolism.

Incidental take—Takings that result from, but are not the purpose of, carrying out an otherwise lawful activity (e.g., fishing) conducted by a Federal agency or applicant (see Taking).

Indigenous—Originating where it is found. Refers to species or peoples found locally and from the local area.

Indirect effects—Effects caused by activities that are stimulated by an action but not directly related to it.

Industry infrastructure—The facilities associated with oil and gas development, e.g., refineries, gas processing plants, etc.

Indirect employment—Secondary or supporting oil- and gas-related industries, such as the processing of crude oil and gas in refineries, natural gas plants, and petrochemical plants.

Intertidal—The zone between the high and low water marks.

Invertebrate—An animal without a backbone or spinal column, such as an insect.

Isobath—Line connecting points of equal water depth on a nautical chart; a seabed contour.

Jackup rig—A barge-like, floating platform with legs at each corner that can be lowered to the sea bottom to raise the platform above the water.

Lagoon—A water body often separated from ocean water exchange, with enclosure as a defining characteristic.

Lease—Authorization that is issued under and that authorizes exploration for, and development and production of, minerals. Lease means an agreement that is issued under Section 8 or maintained under Section 6 of the Outer Continental Shelf Lands Act and that authorizes exploration for, and development and production of, minerals. The term also means the area covered by that authorization, whichever the context requires.

Lease sale—The competitive auction of leases granting companies or individuals the right to explore for and develop certain minerals under specified conditions and periods of time.

Lease term—The initial period for oil and gas leases, usually a period of 5, 8, or 10 years depending on water depth or potentially adverse conditions.

Lessee—A party who has entered into a lease with the United States to explore for, develop, and produce the leased minerals.

Lightering—Smaller boats supplying larger boats with supplies and/or carrying fuel; lightering operations include transfers within the vessel, to lightering barges, or if necessary, into the sea.

Lithic—Of or pertaining to stone.

Macondo Oil Spill—The name given to the oil spill that resulted from the explosion and sinking of the *Deepwater Horizon* rig from the period between April 24, 2010, when search and recovery vessels on site reported oil at the sea surface until uncontrolled flow from the Macondo well was capped.

Marshes—Persistent, emergent, nonforested wetlands characterized by predominantly cordgrasses, rushes, and cattails.

Migratory bird—Any mutation or hybrid of a listed species, as well as any part, egg, or nest of such bird. Protected under the Migratory Bird Treaty Act.

Minerals—As used in this document, minerals include oil, gas, sulphur, and associated resources, and all other minerals authorized by an Act of Congress to be produced from public lands as defined in Section 103 of the Federal Land Policy and Management Act of 1976.

Mollusk—An invertebrate having a soft unsegmented body, usually enclosed in a shell. Also a group of freshwater and saltwater animals, including oysters, clams, mussels, snails, conches, scallops, squid, and octopus.

Mysticete—A whale that has baleen (plates of keratinized tissue that hang from the upper jaw) instead of teeth (suborder Mysticeti). Examples include the humpback whale (*Megaptera novaeangliae*), gray whale (*Eschrichtius robustus*), and minke whale (*Balaenoptera acutorostrata*).

Nautical mile—A distance measurement equivalent to 1.15 statutory miles, or 1.8 kilometers.

Nearshore waters—Offshore open waters that extend from the shoreline out to the limit of the territorial seas (twelve nautical miles).

Nonattainment area—An area that is shown by monitoring data or by air-quality modeling calculations to exceed primary or secondary ambient air quality standards established by the USEPA.

Odontocete—Toothed marine mammals (suborder Odontoceti). Examples include the sperm whale (*Physeter macrocephalus*), beluga whale (*Delphinapterus leucas*), harbor porpoise (*Phocoena phocoena*), and bottlenose dolphin (*Tursiops truncatus*).

Offloading—Unloading liquid cargo, crude oil, or refined petroleum products.

Offshore—In beach terminology, the comparatively flat zone of variable width, extending from the shore to the edge of the continental shelf. It is continually submerged. Also the breaker zone directly seaward of the low tide line.

Oil spill contingency plan—A plan submitted by the lease or unit operator along with or prior to a submission of a plan of exploration or a development/production plan that details provisions for fully defined specific actions to be taken following discovery and notification of an oil spill occurrence.

Operational discharge—Any incidental pumping, pouring, emitting, emptying, or dumping of wastes generated during routine offshore drilling and production activities.

Operator—An individual, partnership, firm, or corporation having control or management of operations on a leased area or portion thereof. The operator may be a lessee, designated agent of the lessee, or holder of operating rights under an approved operating agreement.

Organic matter—Material derived from living plants or animals.

Outer Continental Shelf (OCS)—All submerged lands that comprise the continental margin adjacent to the United States and seaward of State offshore lands.

Pelagic—Of or pertaining to the open sea; associated with open water beyond the direct influence of coastal systems.

Perturbation—A secondary influence on a system that causes it to deviate.

Plankton—Passively floating or weakly motile aquatic plants (phytoplankton) and animals (zooplankton).

Pathology—The scientific study of the nature of disease and its causes, processes, development, and consequences.

Phocid—True or earless seals (family Phocidae). Examples include the bearded seal (*Erignathus barbatus*) and ringed seal (*Phoca hispida*).

Phytoplankton—Microscopic floating aquatic plants that produce their own nutrients through photosynthesis.

Pinniped—Aquatic carnivorous mammals having a streamlined body specialized for swimming with limbs modified as flippers, for example, seals.

Platform—A steel or concrete structure from which offshore development wells are drilled.

Plankton—Very small, free-floating organisms of the ocean or other aquatic systems, including phytoplankton and zooplankton, which get their nutrients from organisms.

Play—A prospective subsurface area for hydrocarbon accumulation that is characterized by a particular structural style or depositional relationship.

Plume—A narrow thermal feature, which can be either hot or cold, that rises or sinks because of its anomalous temperature compared to the surrounding fluid.

Polychaete—A class of mainly marine annelids, characterized by parapodia bearing numerous hairs; for example, bristle worm.

Polychlorinated Biphenyls (PCBs)—A group of toxic, carcinogenic organic compounds previously used for industrial purposes.

Polycyclic Aromatic Hydrocarbon (PAH)—Chemical compounds that consist of fused aromatic rings; many are known or suspected carcinogens.

Potential impact (effect)—The range of alterations or changes to environmental conditions that could be caused by an action.

Primary production—Organic material produced by photosynthetic or chemosynthetic organisms.

Produced water—Total water discharged from the oil and gas extraction process; production water or production brine.

Production—Activities that take place after the successful completion of any means for the extraction of resources, including bringing the resource to the surface, transferring the produced resource to shore, monitoring operations, and drilling additional wells or workovers.

Promulgated—Formally made public; published accounts.

Prospect—An untested geologic feature having the potential for trapping and accumulating hydrocarbons.

Province—A spatial entity with common geologic attributes. A province may include a single dominant structural element such as a basin or a fold belt, or a number of contiguous related elements.

Refining—Fractional distillation of petroleum, usually followed by other processing (for example, cracking).

Relief—The difference in elevation between the high and low points of a surface.

Reserves—Proved oil or gas resources.

Reservoir—A subsurface, porous, permeable rock boy in which hydrocarbons have accumulated.

Rig—A structure used for drilling an oil or gas well.

Right-of-way—A legal right of passage, an easement; the specific area or route for which permission has been granted to place a pipeline, (and) ancillary facilities, and for normal maintenance thereafter.

Rookery—The nesting or breeding grounds of gregarious (i.e., social) birds or mammals; also a colony of such birds or mammals.

Royalty—A share of the minerals produced from a lease paid in either money or "in-kind" to the landowner by the lessee.

Sale area—The geographic area of the Outer Continental Shelf (OCS) being offered for lease for the exploration, development, and production of mineral resources.

Scoping—The process prior to Environmental Impact Statement (EIS) preparation to determine the range and significance of issues to be addressed in the EIS for each proposed major federal action.

Seagrass beds—More or less continuous mats of submerged, rooted marine flowering vascular plants occurring in shallow tropical and temperate waters. Seagrass beds provide habitat, including breeding and feeding grounds, for adults and/or juveniles of many of the economically important shellfish and finfish.

Seismic—Pertaining to, characteristic of, or produced by water, earthquakes or earth vibration; having to do with elastic waves in the earth; also geophysical when applied to surveys.

Sediment—Material that has been transported and deposited by water, wind, glacier, precipitation, or gravity; a mass of deposited material.

Seeps (hydrocarbon)—Gas or oil that reaches the surface along bedding planes, fractures, unconformities, or fault planes.

Sensitive area—An area containing species, populations, communities, or assemblages of living resources, that is susceptible to damage from normal OCS-related activities. Damage includes interference with established ecological relationships.

Stranding—Defined under the MMPA as "an event in the wild in which (A) a marine mammal is dead and is (i) on a beach or shore of the United States; or (ii) in waters under the jurisdiction of the United States (including any navigable waters); or (B) a marine mammal is alive and is (i) on a beach or shore of the United States and is unable to return to the water; (ii) on a beach or shore of the United States and, although able to return to the water, is in need of apparent medical attention; or (iii) in the waters under the jurisdiction of the United States (including any navigable waters), but is unable to return to its natural habitat under its own power or without assistance."

Stipulations—Specific measures imposed upon a lessee that apply to a lease. Stipulations are attached as a provision of a lease; they may apply to some or all tracts in a sale. For example, a stipulation might limit drilling to a certain time period of the year or certain areas.

Subarea—A discrete analysis area.

Subsistence uses—The customary and traditional uses by rural residents of wild, renewable resources for direct personal or family consumption as food, shelter, fuel, clothing, tools, or transportation; for making and selling of handcraft articles out of nonedible byproducts of fish and wildlife resources take for personal or family consumption; for barter, or sharing for personal or family consumption; and for customary trade.

Substrate—Any stratum lying underneath another.

Supply vessel—A boat that ferries food, water, fuel, and drilling supplies and equipment to an offshore rig or platform and returns to land with refuse that cannot be disposed of at sea.

Take—In the Marine Mammal Protection Act, meaning "to harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal." In the Endangered Species Act, the definition includes to harass, harm, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct. A notable component of this definition is "harm," which means an act that actually kills or injures protected wildlife. Such acts may include significant habitat modification or degradation that actually kills or injures wildlife by significantly impairing essential behavior patterns, including breeding, feeding, or sheltering.

Tertiary—A geologic period dating from 63 million to 2 million years ago.

Threatened species—Defined under the Endangered Species Act as “any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.”

Total suspended solids—The total amount of suspended solids in water.

Turbidity—Reduced water clarity due to the presence of suspended matter.

Trawling—The operation of towing a net (trawl) to catch fish and/or shellfish. Trawls are towed either with bottom contact or in midwater. The towing speed varies, according to such factors as the type of trawl and trawling and the target species.

Trophic—Trophic levels refer to the hierarchy of organisms form photosynthetic plants to carnivores, such as man; feeding trophic levels refer to the hierarchy of organisms from photosynthetic plants to carnivores in which organisms at one level are fed upon by those at the next higher level (e.g., phytoplankton eaten by zooplankton eaten by fish).

Turbidity—Reduced water clarity resulting from the presence of suspended matter.

Upwelling—Divergence of water currents or the movement of surface water away from land, leading to upward movement of cold nutrient-rich water from the ocean depths; often associated with great production of fish and fisheries.

Volatile organic compound (VOC)—Any reactive organic compound that is emitted to the atmosphere as a vapor. The definition does not include methane.

Weathering (of oil)—The aging of oil due to its exposure to the atmosphere, causing marked alterations in its physical and chemical makeup.

CHAPTER 3 FIGURES

Figure 3.1-1 General circulation map of the Beaufort and Chukchi seas.
Source: Weingartner and Danielson 2010

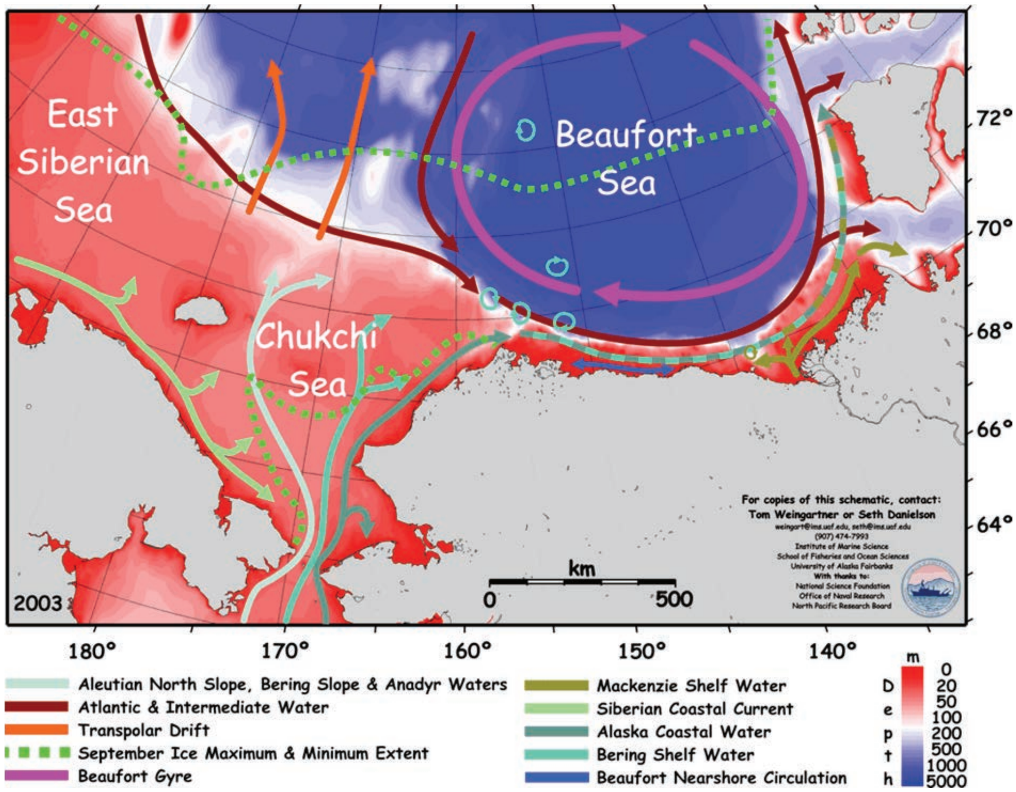

Figure 3.1-2 Bathymetry of the Beaufort Sea, with place names indicated.
Source: Weingartner 2008

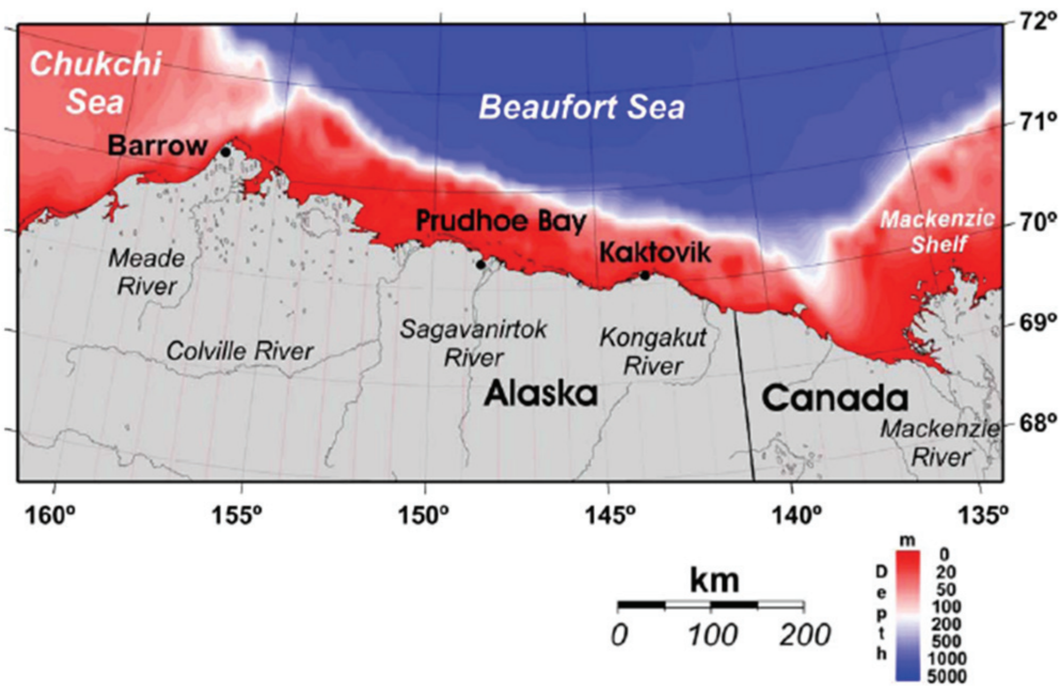

Figure 3.1-3 Schematic circulation map of the Beaufort and Chukchi shelves showing the flow of Bering Strait water through the Chukchi Sea along three principal pathways that are associated with distinct bathymetric features: the Herald Valley, the Central Channel, and Barrow Canyon.

Source: Weingartner and Danielson 2010

Three branches of the inflowing Pacific water are color-coded with navy blue (Anadyr Water) being the most nutrient-rich water and light blue (Alaska Coastal Water) being the least nutrient-rich. The Siberian Coastal Current (green) is present in summer and fall, but absent or weak in winter and spring. On the continental slope, the Pacific-origin water encounters Atlantic-origin Water (red) which is flowing counter-clockwise around the Arctic basin. Offshore of the slope, in the interior of the Canada Basin, is the clockwise wind-driven flow of the Beaufort Gyre (purple)

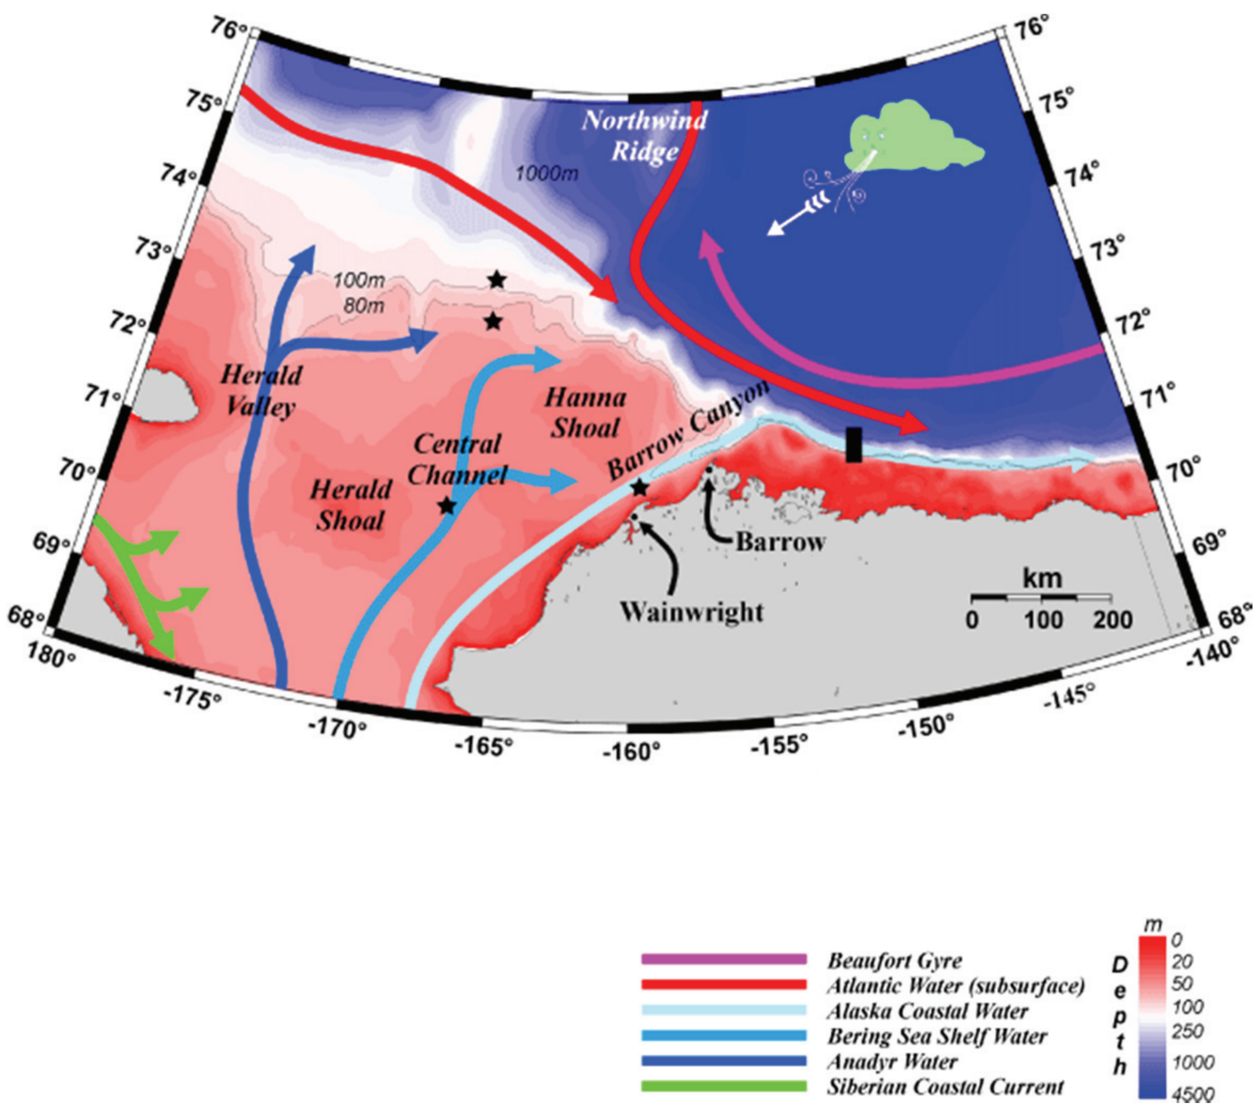

Figure 3.1-4 a) Sea Ice Extent March 2011 and September 2011. b) Average Monthly Arctic Sea Ice Extent March 1979 – 2011 and September 1979 – 2011.

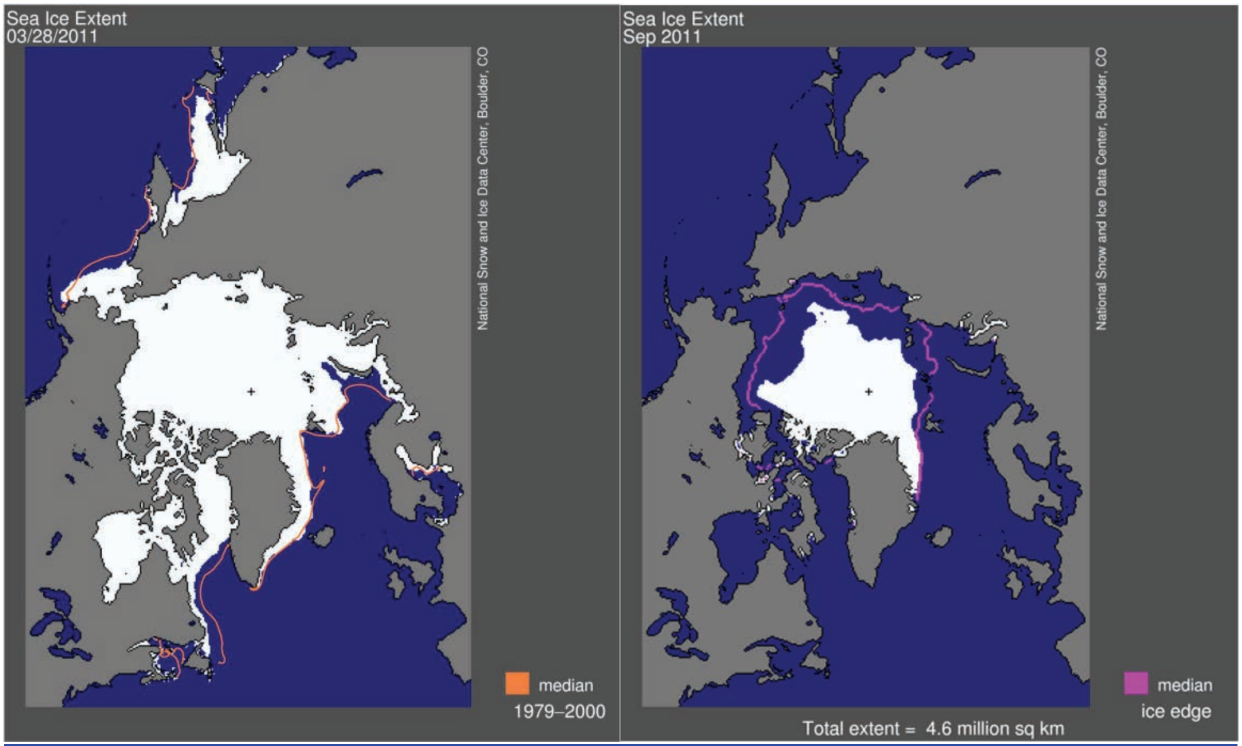
Sources: NSIDC, 2011a,b

a) Map shows the maximum sea ice extent (in white) for March 2011, and also the median sea ice extent (red line) for the period 1979–2000. Graph shows the average monthly sea ice extent over the period 1979–2011.



b) Map shows the minimum sea ice extent (in white) for September 2011, and the median sea ice extent (red line) for the period 1979–2000. Graph shows the average monthly sea ice extent over the period 1979–2011.

Source: Harris 1998

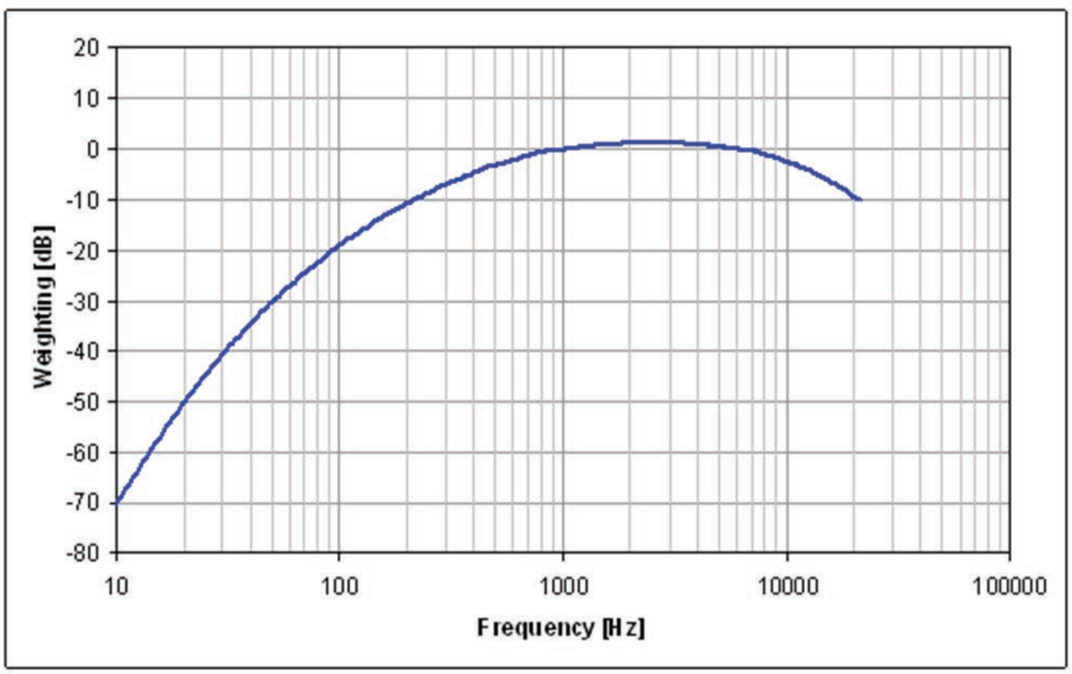

Figure 3.1-7 Hearing curves for some marine mammals in water and a typical human in air.

Source: Discovery of Sound in the Sea 2011

There are two sets of y-axes (vertical) because different reference pressures are used to measure sound in water (re 1 µPa; left axis) vs in air (re 20 µPa; right axis). Notice that the decibel values differ by 61.5 dB for the same value of intensity (watts/ m 2). The x-axis (horizontal) is the frequency of a sound on a logarithmic scale.

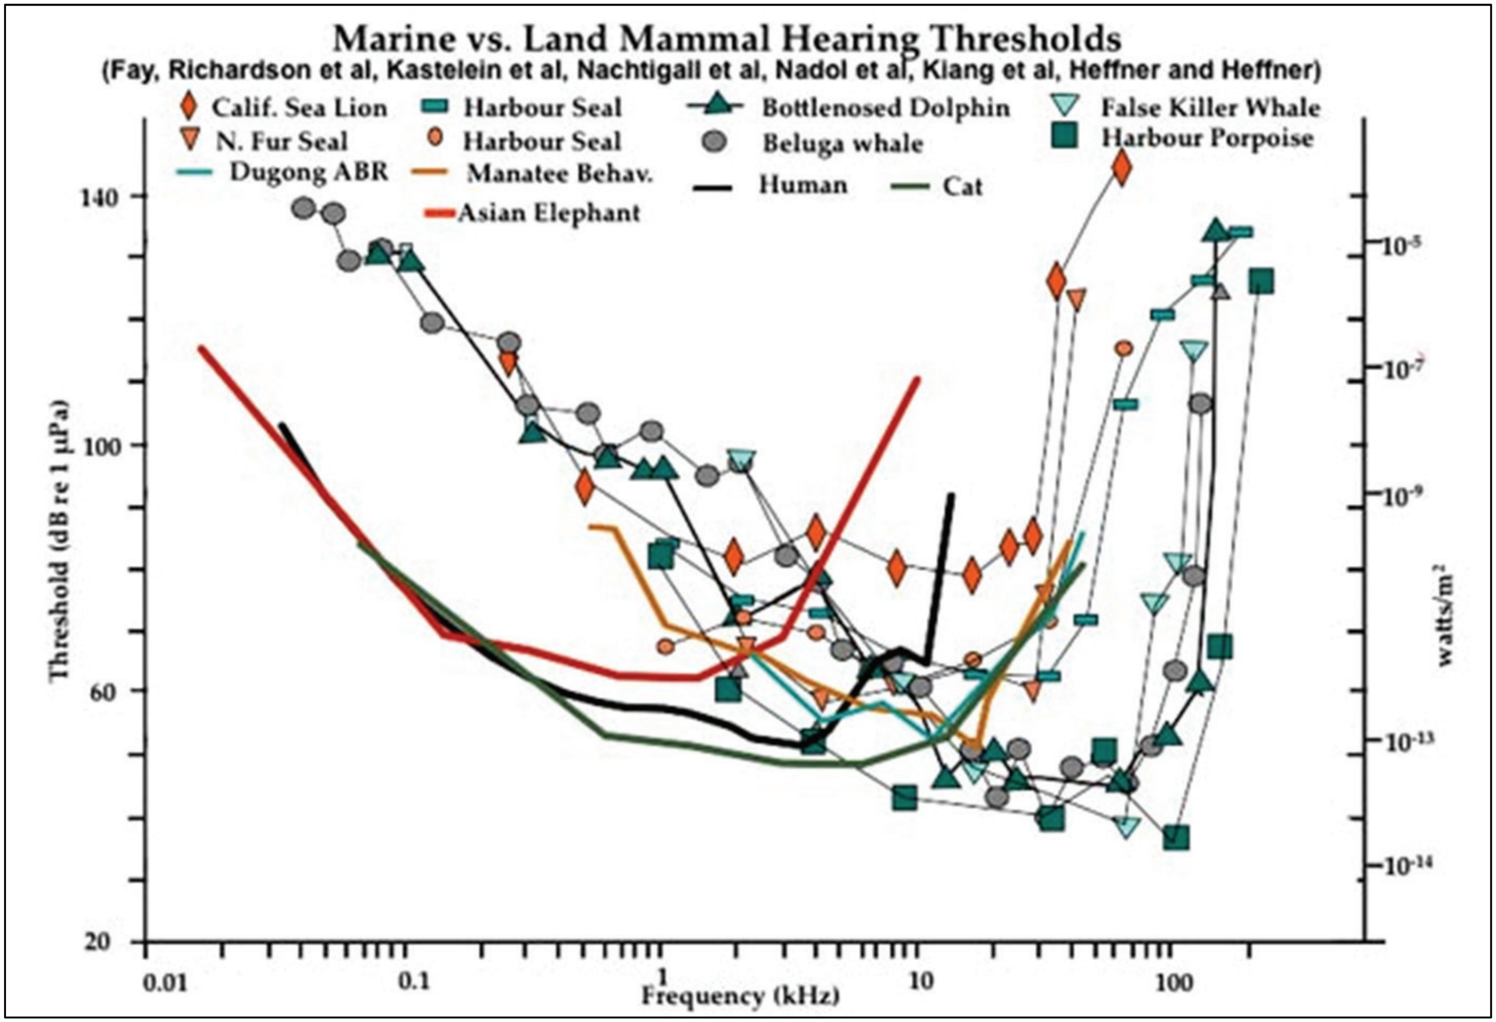

Figure 3.1-8 Graphic showing M-weighting functions for marine mammal hearing for (A) low, mid, and high frequency cetaceans, and (B) for pinnipeds in water and air.

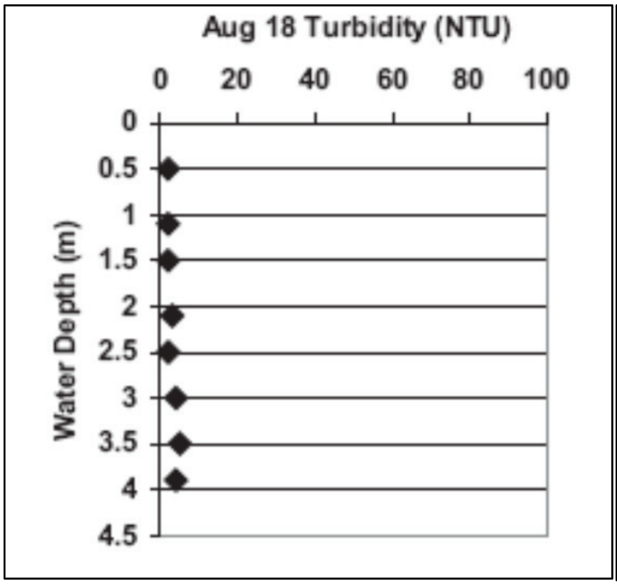
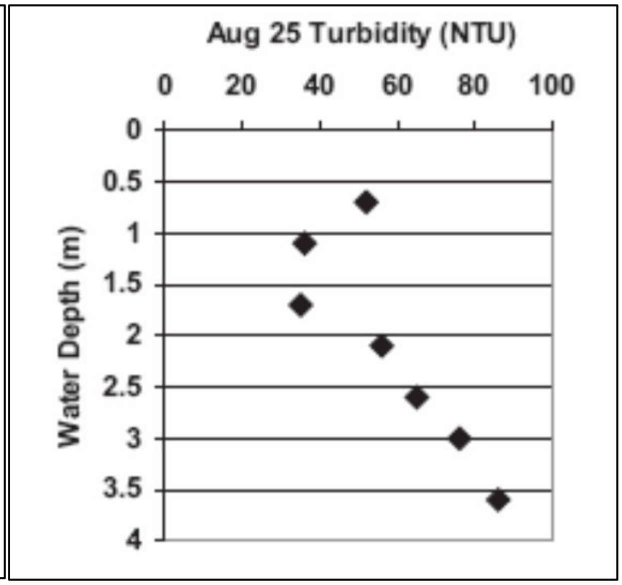
Source: Boehm 2001

Profile (a) shows turbidity levels before a storm event; profile (b) shows turbidity levels immediately following a storm event





(a) (b)

Figure 3.1-11 Levels of Ecological Organization.

The dose-response model traditionally used in environmental impact assessment only considers the effects of stressors on individuals or populations. However, the value of ecosystem goods and services is usually derived from interactions among physical, chemical, and biological ecosystem components.

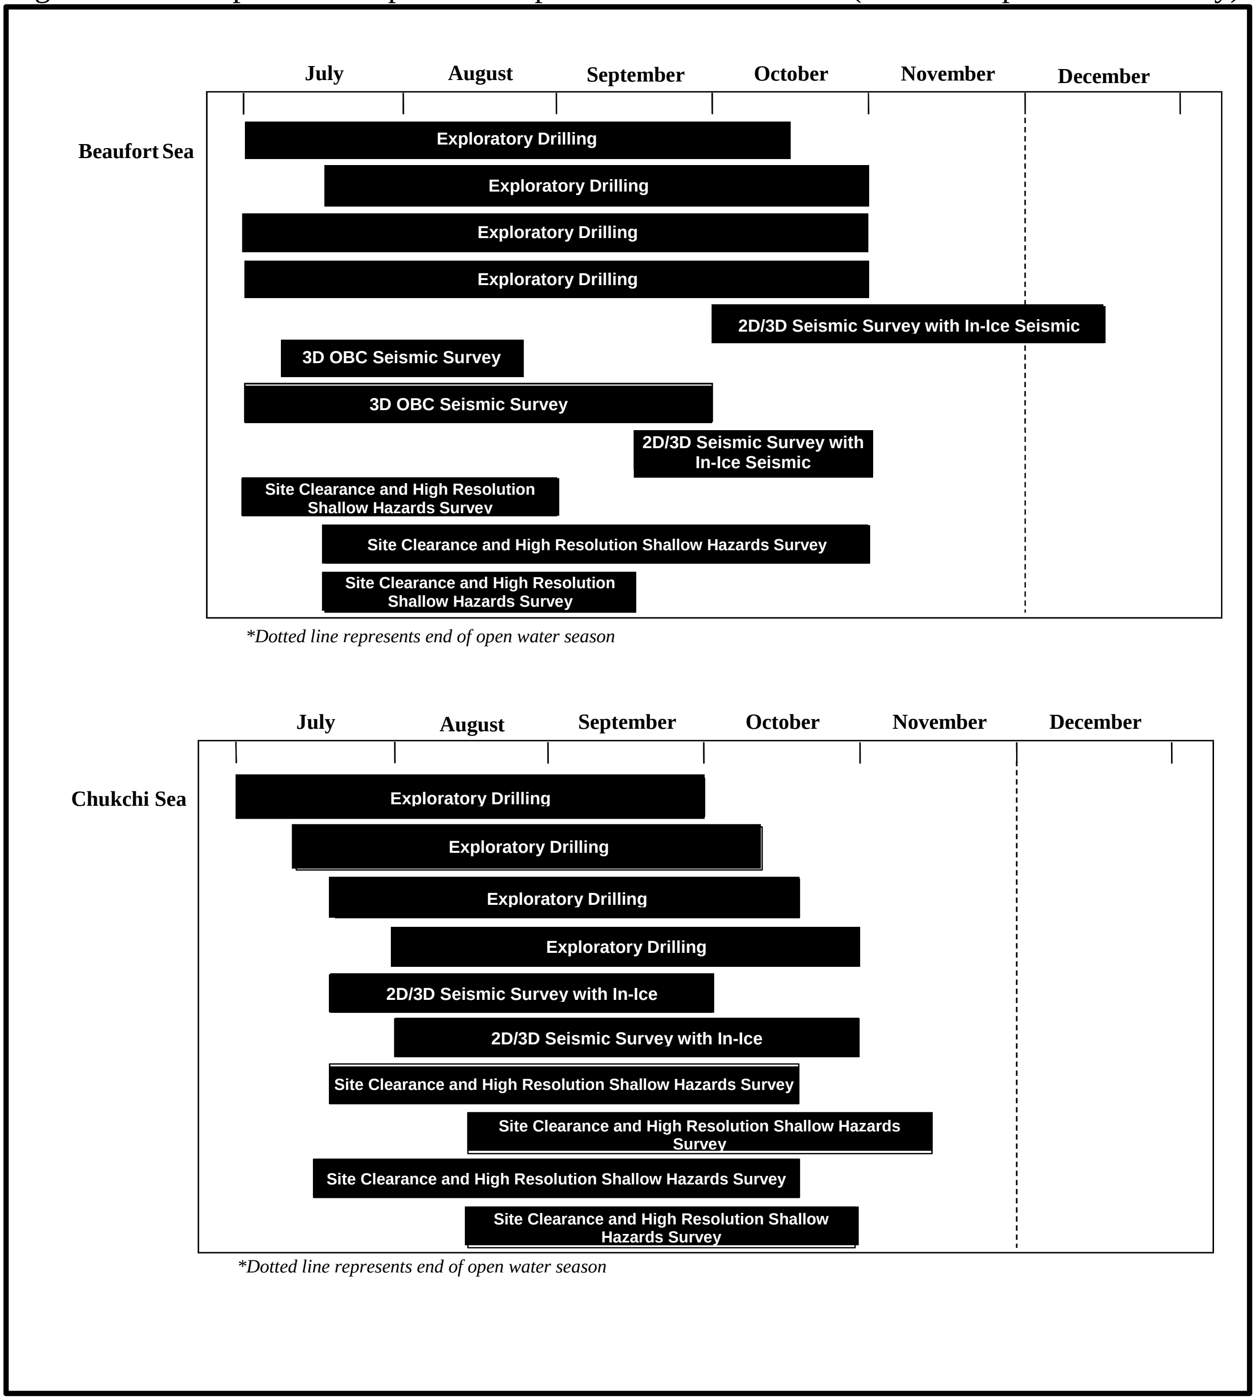

Figure 4.6-1 Example of dose-response curve used for Navy mid-frequency active sonar (Finneran and Jenkins 2012)

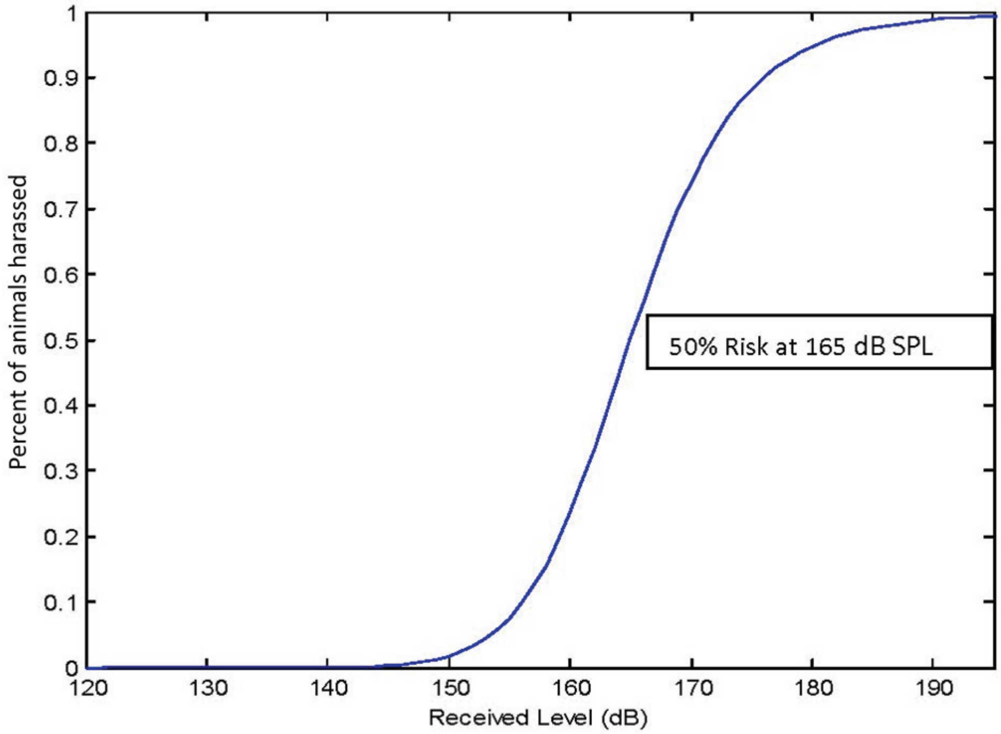

Figure 4.6-2 This graph illustrates proposed weighting functions that could be applied to cetaceans for the thresholds outlined above, if the methods outlined in Finneran and Jenkins (2012) were used. Note, in graphic LF = low frequency hearing specialists, MF = mid frequency hearing specialists, and HF = high frequency hearing specialists.

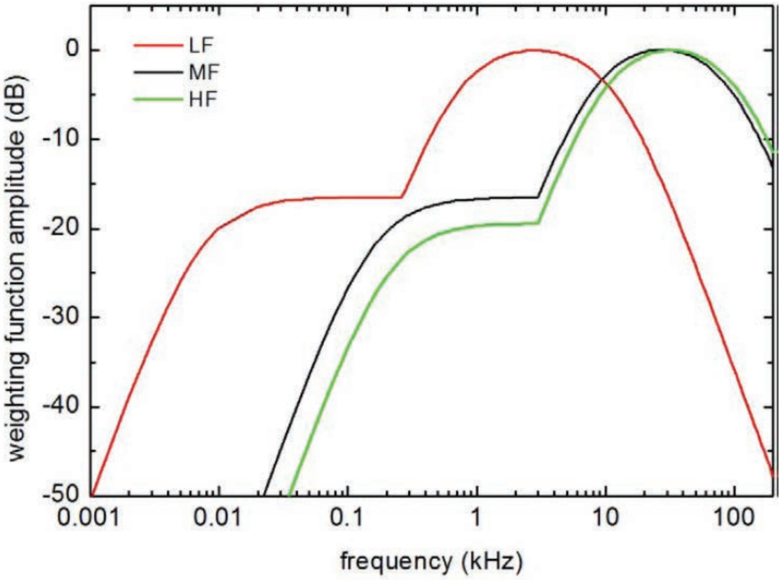

Figure 4.6-3 This graph illustrates the weighting functions that could be applied to pinnipeds for the thresholds outlined above (m-weighting, Southall et al., 2007, Finneran and Jenkins (2012)).

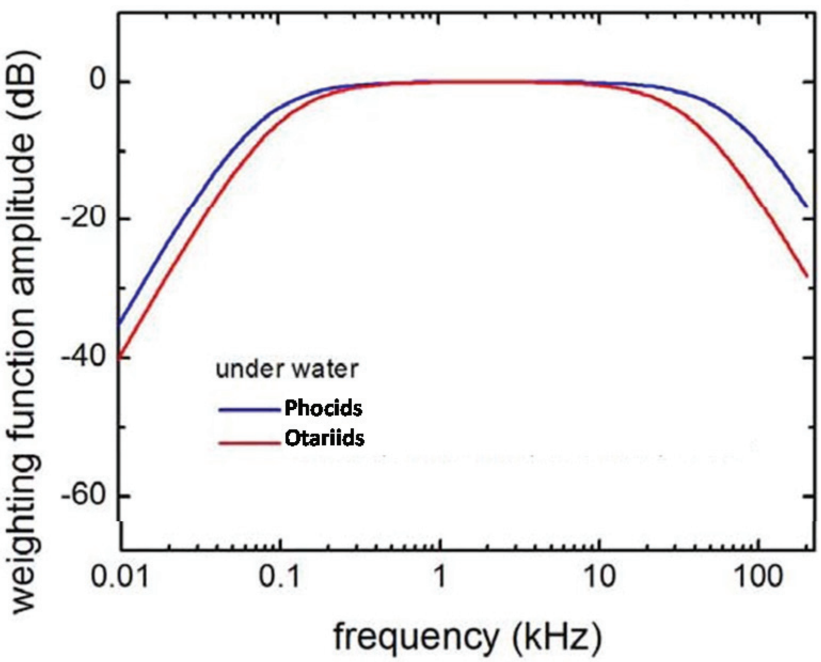

Figure 4.7-1 Dispersion and fate of water-based drill cuttings and drilling fluids discharged to the ocean. About 90% of the discharged solids settle rapidly and form a mud/cuttings pile within several hundred meters of the point of discharge.

Source: Neff 2005

This mud/cuttings pile would affect water depths near the drilling activity. The remaining 10% of the discharged solids remain suspended and drift with prevailing currents away from the drilling site to settle elsewhere.

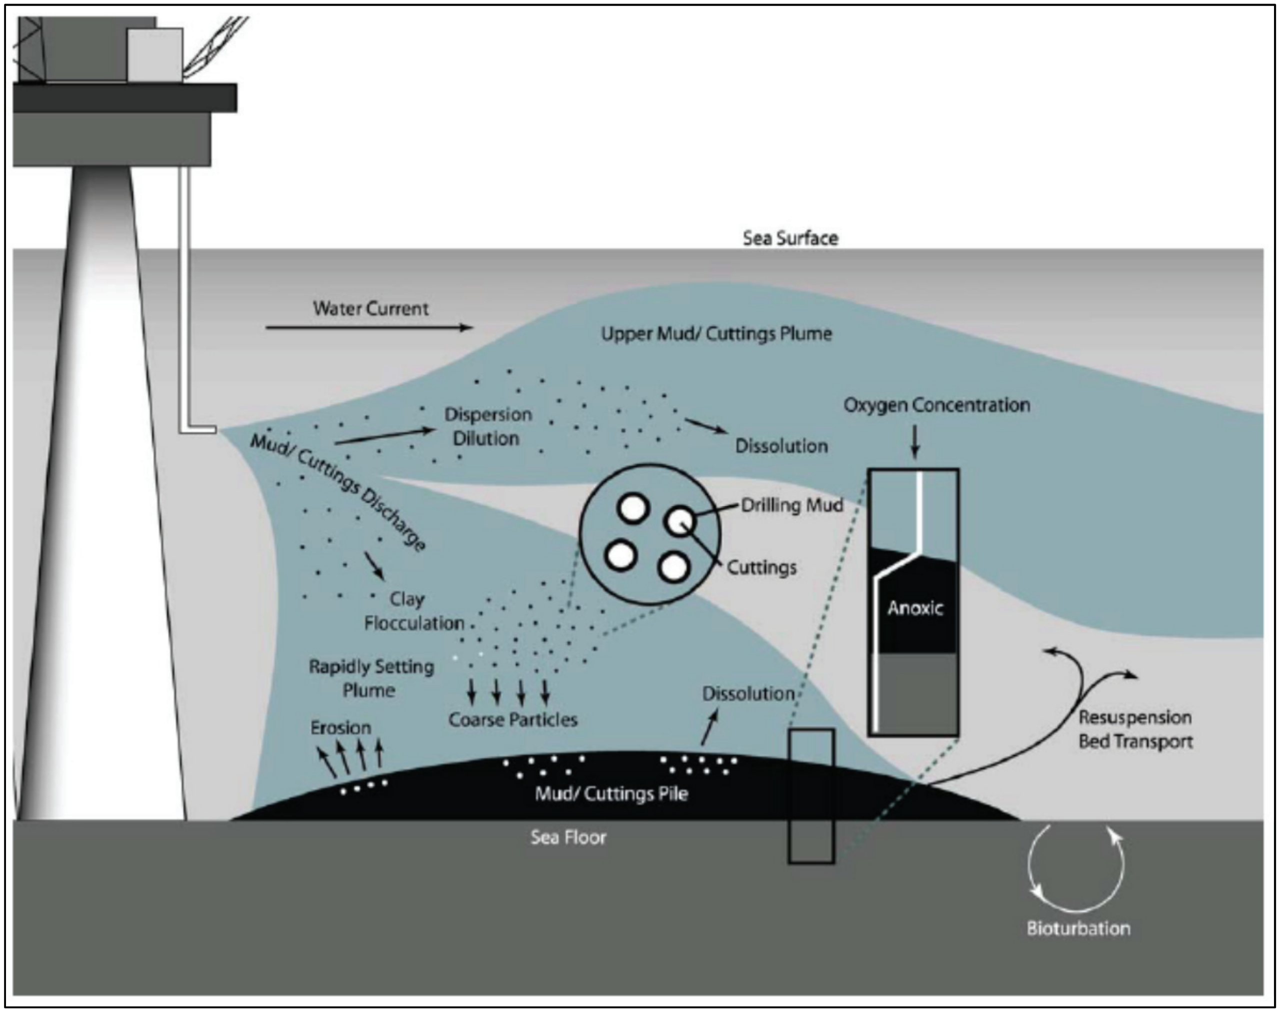

Figure 4.7-2 Logic framework for potential impacts to human health.

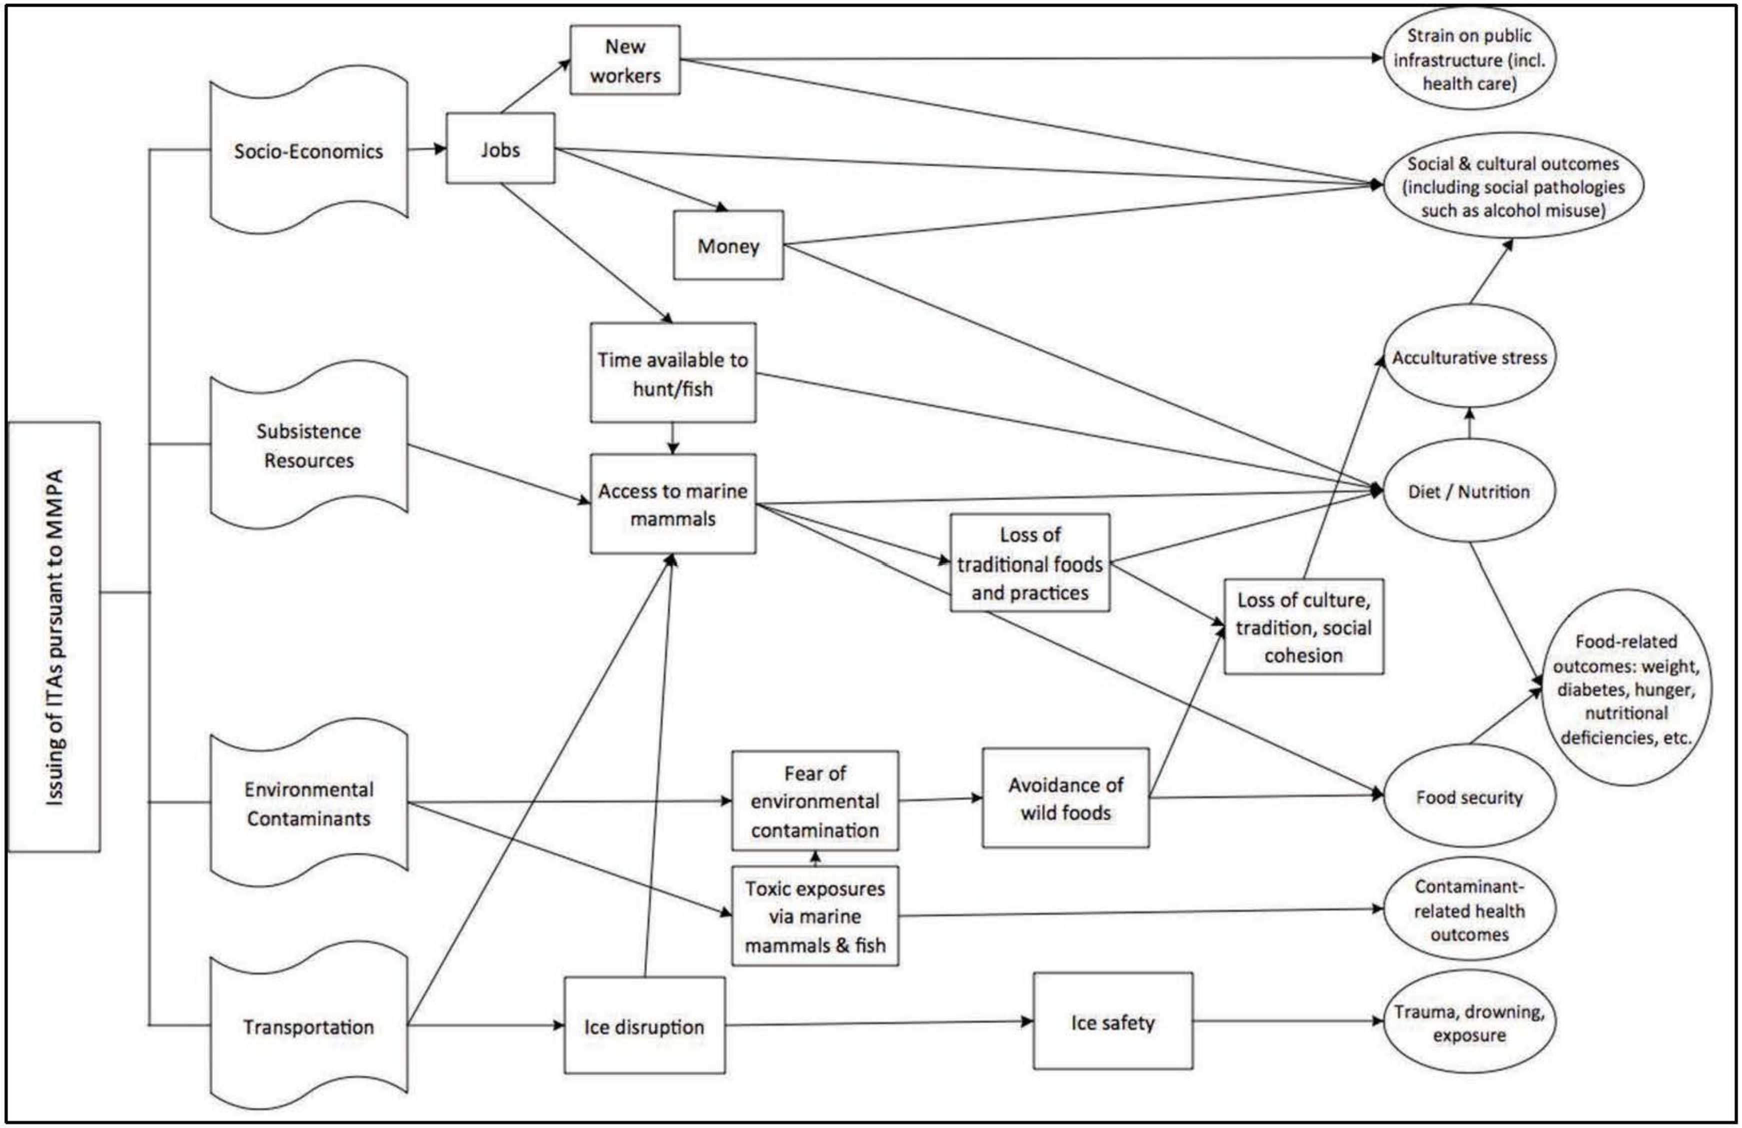

APPENDIX A

Standard and Additional Mitigation Measures

Table of Contents

Appendix A: Standard and Additional Mitigation Measures Addressing Impacts to Marine Mammals and Subsistence Activities

NMFS Standard Mitigation Measures

The mitigation measures[1] (and the identified mitigation monitoring needed to support them) listed below are planned for inclusion as a requirement under every MMPA ITA issued for the type of activity identified.

A. DETECTION-BASED MEASURES INTENDED TO REDUCE NEAR-SOURCE ACOUSTIC EXPOSURES AND IMPACTS ON MARINE MAMMALS WITHIN A GIVEN DISTANCE OF THE SOURCE

2D/3D and in-ice seismic surveys and site clearance and high resolution shallow hazards surveys

Mitigation Measure A1. Establishment and execution of 180 dB shutdown/power down radius for cetaceans and 190 dB shutdown/power down radius for ice seals.

NMFS has established acoustic thresholds that identify the received sound levels above which hearing impairment or other injury could potentially occur; these thresholds are 180 and 190 dB re 1 µPa (rms) for cetaceans and pinnipeds, respectively (NMFS 1995, 2000). All further received sound level criteria reported in this appendix will be re 1 µPa (rms). The established 180- and 190-dB re 1 µPa (rms) criteria are the received levels above which, in the view of a panel of bioacoustics specialists convened by NMFS before direct data on temporary threshold shift (TTS) (from which PTS is primarily extrapolated) for marine mammals became available, one could not be certain that there would be no injurious effects, auditory or otherwise, to marine mammals. Since the establishment of these acoustic criteria, NMFS has recommended and included shutdown/powerdown zones at the 180/190 dB isopleths as standard required mitigation measures in MMPA authorizations for seismic surveys. Typical language in past ITAs includes:

- Establish and have trained Protected Species Observers (PSOs) monitor a preliminary exclusion zone for cetaceans surrounding the airgun array on the source vessel where the received level would be 180 dB or greater. The radius for the zone will vary based on the airgun array used, water depth, and numerous other factors related to the water and seafloor properties. This final distance of the radius will be established by modeling and/or a sound source verification test.
- Establish and monitor a preliminary exclusion zone for pinnipeds surrounding the airgun array on the source vessel where the received level would be at or above 190 dB with trained PSOs. The radius for the zone will vary based on the airgun array used, water depth, and numerous other factors related to the water and seafloor properties. The final distance of the radius will be established by modeling and/or a sound source verification test.
- Immediately power-down the seismic airgun array and/or other acoustic sources, whenever any cetaceans or walrus are sighted approaching close to or within the area

[1] These measures have been included in past ITAs issued by NMFS in the Arctic Ocean.

delineated by the 180 dB, or pinnipeds or polar bears are sighted approaching close to or within the area delineated by the 190 dB isopleth.

- If the power-down operation cannot reduce the received sound pressure level at the cetacean or pinniped to less than 180 dB or 190 dB, respectively, then the holder of the ITA must immediately shutdown the seismic airgun array and/or other acoustic sources.
- The seismic airgun array cannot be powered up unless the marine mammal exclusion zones are visible and no marine mammals are detected within the appropriate safety zones for a minimum of 15 minutes (small odontocetes, pinnipeds) or 30 minutes (for mysticetes). The seismic array can be ramped up once the PSOs have no further visual detection of the animal(s) within the exclusion zone, and they are confident that no marine mammals remain within the appropriate exclusion zone.

Mitigation Measure A2. Specified ramp-up procedures for airgun arrays.

Ramp-up is the gradual introduction of sound to deter marine mammals from potentially damaging sound intensities and from approaching the exclusion zone. This technique involves the gradual increase (usually approximately 5-6 dB per 5-minute increment) in emitted sound levels, beginning with firing a single airgun and gradually adding airguns over a period of 20 to 40 minutes, until the desired operating level of the full array is obtained. Ramp-up procedures are instituted based on the assumption that any marine mammals in the vicinity of seismic operations will become aware of the noise source before it rises to potentially harmful levels and to leave the area. The 180- and 190-dB exclusion zones described in the previous measure are used for the ramp-up procedures as well. Typical language in past ITAs includes:

- Conduct a 30-minute period of marine mammal observations by at least two trained PSOs to verify that the exclusion zone is clear prior to commencing ramp-up at the commencement of seismic operations and at any time the airgun array has been shut down for a certain period of time. The period of shutdown requiring a full ramp-up is based on the size of the airgun array but is typically between 8 and 10 minutes.
- Do not commence ramp-up if the entire exclusion zones are not visible for at least 30 minutes prior to ramp-up in either daylight or nighttime and do not commence ramp-up at night unless the seismic source has maintained a sound pressure level at the source of at least 180 dB during the interruption of full seismic survey operations. If a sound source of at least 180 dB has been maintained during the interruption of seismic operations, then the 30 minute pre-ramp-up visual survey is waived.
- Ramp-up the airgun arrays at no greater than 6 dB per 5-minute period starting with the smallest airgun in the array and then adding additional guns in sequence until the full array is firing if no marine mammals are observed in the safety zones and periods specified above. Ramp-up procedures should be used at the commencement of seismic operations and any time after the airgun array has been shut down for a certain period of time.

Mitigation Measure A3. Protected Species Observers (PSOs) required on all seismic source vessels and ice breakers, as well as on dedicated monitoring vessels.

PSOs are a key component both for the purposes of implementing mitigation measures, such as shutdowns and ramp-ups, and for gathering information pursuant to the monitoring requirements of the ITA (latter addressed separately). Some of the mitigation monitoring requirements in past ITAs include:

- The holder of the ITA must designate trained, NMFS-approved, individuals (PSOs) to be onboard the source vessel to conduct the visual monitoring programs required under this Authorization and to record the effects of seismic surveys and the resulting noise on marine mammals.
- To the extent possible, PSOs should be on duty for four consecutive hours or less, although more than-one four-hour shift per day is acceptable. PSOs will not work more than three shifts in a 24-hour period (i.e. 12 hours total per 24-hour period).
- Monitoring is to be conducted by the PSOs onboard the active seismic vessel (including in-ice surveys), to (A) ensure that no marine mammals enter the appropriate exclusion zone whenever the seismic sources are on, and (B) to record marine mammal activity. At least two observers must be on watch the 30 minutes prior to full ramp up, during ramp ups, and for as much of the other operating hours as possible. At all other times, at least one observer must be on active watch (1) whenever the seismic source is operating during the daytime; (2) during any nighttime power-ups of the airguns; and (3) at night, whenever one or more power-down situations the preceding day were due to marine mammal presence.
- At all times, the crew must be instructed to keep watch for marine mammals. If any are sighted, the bridge watch-stander must immediately notify the PSO(s) on-watch. If a marine mammal is within or closely approaching its designated exclusion zone, the seismic acoustic sources must be immediately powered down or shutdown.
- Monitoring will consist of recording: (A) the species, group size, age/size/sex categories (if determinable), the general behavioral activity, heading (if consistent), bearing and distance from seismic vessel, sighting cue, behavioral pace, and apparent reaction of all marine mammals seen near the seismic vessel and/or its airgun array (e.g. none, avoidance, approach, paralleling, etc.); (B) the time, location, heading, speed, and activity of the vessel (shooting or not), along with sea state, visibility, cloud cover and sun glare at (1) any time a marine mammal is sighted, (2) at the start and end of each watch, and (3) during a watch (whenever there is a change in one or more variable); and, (C) the identification of all vessels that are visible within 5 km (3.1 mi) of the seismic-vessel whenever a marine mammal is sighted, and the time observed, bearing, distance, heading, speed and activity of the other vessel(s).

On-ice Seismic Surveys

Mitigation Measure A4. All activities must be conducted at least 152 m (500 ft) from any observed ringed seal lair.

- This measure requires survey crews to be trained in seal detection and to search for ringed seal lairs around intended seismic survey operation sites and prohibits seismic activities within a 152 m (500 ft) radius of ringed seal lairs. Additionally, while traveling on ice roads, the area shall be monitored for marine mammals, especially ringed seal lairs.
- No ice roads may be built between the mobile camp and work site. Travel between mobile camp and work site shall also be monitored for marine mammals and be done by vehicles driving through on a snow road. Vehicles must avoid any pressure ridges, ice ridges, and ice deformation areas where seal structures are likely to be present.

Mitigation Measure A5. No energy source may be placed over a ringed seal lair.

- A 152 m (500 ft) exclusion zone must be established around all located active subnivean seal structures, within which no seismic or impact work may be conducted.

Exploratory Drilling Activities

Mitigation Measure A6. PSOs required on all drill ships (including rigs and ships) and ice management vessels.

- PSO requirements would be the same as those identified for Standard Mitigation Measure A3. PSOs are required on all types of drilling units and all support vessels. PSOs will watch during active drilling operations and transits.

B. NON-DETECTION-BASED MEASURES INTENDED TO MORE BROADLY LESSEN THE SEVERITY OF ACOUSTIC IMPACTS ON MARINE MAMMALS OR REDUCE OVERALL NUMBERS TAKEN BY ACOUSTIC SOURCE

This measure would be required for all activities that occur during the open-water season (i.e. 2D/3D seismic including in-ice surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities).

Mitigation Measure B1. Specified flight altitudes for all support aircraft except for take-off, landing, and emergency situations.

- Aircraft shall not operate below 457 m (1,500 ft) unless the aircraft is engaged in approaching, landing or taking off, or unless engaged in providing assistance to a whaler or in poor weather (low ceilings) or any other emergency situations. Aircraft shall not operate below 305 m (1,000 ft) during marine mammal monitoring when operating outside of active subsistence areas. Aircraft engaged in marine mammal monitoring shall not operate below 457 m (1,500 ft) in areas of active subsistence use; such areas are to be identified through communications with the Communication Centers.
- Except for airplanes engaged in marine mammal monitoring, aircraft shall use a flight path that keeps the aircraft at least five miles inland until the aircraft is directly (south) of its offshore destination, then at that point it shall fly directly to its destination. This is applicable to the Beaufort Sea only.
- Helicopters shall not hover or circle above groups of marine mammals or within 457 m (1,500 ft) of such groups.

C. MEASURES INTENDED TO REDUCE/LESSEN NON-ACOUSTIC IMPACTS ON MARINE MAMMALS

These measures would be required for all activities that occur during the open-water season (i.e. 2D/3D seismic including in-ice surveys, CSEM surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities).

Mitigation Measure C1. Specified procedures for changing vessel speed and/or direction to avoid collisions with marine mammals.

General operation conditions include:

- Reduce vessel speed when within 274 m (900 ft) of whales and those vessels capable of steering around such groups should do so. Vessels may not be operated in such a way as to separate members of a group of whales from other members of the group.
- Avoid multiple changes in direction and speed when within 274 m (900 ft) of whales. In addition, operators should check the waters immediately adjacent to a vessel to ensure that no whales will be injured when the vessel's propellers (or screws) are engaged.
- Do not operate support vessels (including small boats), to the extent that they are being used, at a speed that would make collisions with whales likely. Vessel speeds shall be less than 10 knots in the proximity of feeding whales or whale aggregations.
- When weather conditions require, such as when visibility drops, adjust vessel speed accordingly to avoid the likelihood of injury to whales. Vessel speeds should be reduced to at least 10 knots.

D. MEASURES INTENDED TO ENSURE NO UNMITIGABLE ADVERSE IMPACT TO SUBSISTENCE USES

These measures would be required for all activities that occur during the open-water season and in-ice (i.e. 2D/3D seismic including in-ice surveys, CSEM surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities).

Mitigation Measure D1. Shutdown of exploration activities occurring in specific areas of the Beaufort Sea corresponding to the start and conclusion of the fall bowhead whale hunts in Nuiqsut (Cross Island) and Kaktovik beginning on August 25. The following includes typical language from recent IHAs that required shutdown in the Beaufort Sea to account for fall bowhead whaling.

- No geophysical activity from the Canadian Border to the Canning River (146 deg. 4 min. W) beginning on or around August 25 to close of the Kaktovik's and Nuiqsut's fall bowhead whale.
- The bowhead whale subsistence hunt will be considered closed for a particular village when the village Whaling Captains' Association declares the hunt ended or the village quota has been exhausted (as announced by the village Whaling Captains' Association or the Alaska Eskimo Whaling Commission [AEWC]), whichever occurs earlier.
- From Pt. Storkerson (~148 deg. 42 min. W) to Thetis Island (~150 deg. 10.2 min. W);
    - Inside the Barrier Islands: No geophysical activity prior to August 5. Geophysical activity is allowed from August 5 until completion of operations. Geophysical activity allowed in this area after August 25 shall include a source array of no more than 12 airguns, a source layout no greater than 8 m x 6 m (26.2 ft x 19.7 ft), and a single source volume no greater than 14.4 liters (880 in^3).
    - Outside the Barrier Islands: No geophysical activity from August 25 to close of fall bowhead whale hunting in Nuiqsut. Geophysical activity is allowed at all other times.
- From Canning River (~146 deg. 4 min. W) to Pt. Storkerson (~148 deg. 42 min. W), no geophysical activity from August 25 to the close of bowhead whale subsistence hunting in Nuiqsut.
- Around Barrow, no geophysical activity from Pitt Point on the east side of Smith Bay (~152 deg. 15 min. W) to a location about half way between Barrow and Peard Bay

(~157 deg. 20 min. W) from September 15 to the close of the fall bowhead whale hunt in Barrow.

Mitigation Measure D2. Establishment and utilization of Communication Centers in subsistence communities to address potential interference with marine mammal hunts on a real-time basis throughout the season.

To address potential interference with marine mammal hunts on a real-time basis, exploration companies have been required to participate in the establishment and interaction with Communication Centers in affected subsistence communities. The Communication Centers are to be operated on a 24-hour basis during the fall bowhead whale hunt.

- Upon notification by a Communication Center operator of an at-sea emergency, the holder of the ITA shall provide such assistance as necessary to prevent the loss of life, if conditions allow the holder of the ITA to safely do so.
- Upon request for emergency assistance made by a subsistence whale hunting organization, or by a member of such an organization, in order to prevent the loss of a whale, the holder of the ITA shall assist towing of a whale taken in a traditional subsistence whale hunt, if conditions allow the holder of the ITA to safely do so.

Mitigation Measure D3. Required flight altitudes and paths for all support aircraft in areas where subsistence occurs, except during take-off, landing, and emergency situations.

Aircraft shall avoid concentrations or groups of whales. Operators shall, at all times, conduct their activities at a maximum distance from such concentrations of whales.

- Aircraft shall not operate below 457 m (1,500 ft) unless the aircraft is engaged in, approaching, landing or taking off, or unless engaged in providing assistance to a whaler or in poor weather (low ceilings) or any other emergency situations.
- Aircraft engaged in marine mammal monitoring shall not operate below 457 m (1,500 ft).
- Except for airplanes engaged in marine mammal monitoring, aircraft operating in the Beaufort Sea shall use a flight path that keeps the aircraft at least five miles inland until the aircraft is directly (south) of its offshore destination, then at that point it shall fly directly (north) to its destination.
- When weather conditions do not allow a 457 m (1,500 ft) flying altitude, such as during severe storms or when cloud cover is low, aircraft may be operated below the 457 m (1,500 ft) altitude. However, when aircraft are operated at altitudes below 457 m (1,500 ft) because of weather conditions, the operator must avoid whale concentrations and concentration areas and should take precautions to avoid flying directly over or within 1,372 m (4,501 ft) of groups of whales.

BOEM Standard Mitigation Measures

The following measures are typically required by BOEM in G&G permits issued under the OCS Lands Act. These measures are not standardized in regulations. However, they have typically been required in recent years and are adjusted periodically, as needed.

- No solid or liquid explosives shall be used without specific approval.
- Permittee operations shall be conducted in a manner to ensure that they will not cause pollution, cause undue harm to aquatic life, create hazardous or unsafe conditions, or unreasonably interfere with other uses of the area. If any difficulties are encountered with other uses of the area or any of

the above mentioned scenarios occur during operations under this permit, they shall be reported to the Regional Supervisor, Resource Evaluation. Serious or emergency conditions shall be reported without delay.

- The Permittee shall maintain a minimum spacing of 15 miles between their deep penetration seismic-source vessels and any other concurrently operating deep penetration seismic-source vessel. If there is not 15 miles between seismic-source vessels, one source vessel must cease operations. The BOEM must be notified by means of the weekly report whenever a shutdown of operations occurs in order to maintain this minimum distance.
- Permittee operators shall use the lowest sound levels feasible to accomplish their data-collection needs.
- When any operator becomes aware of the potentially harassing effects of operations on whales, or when any operator is unsure of the best course of action to avoid harassment of whales, every measure to avoid further harassment shall be taken until NMFS is consulted for instructions or directions. However, human safety shall take precedence at all times over the guidelines and distances recommended herein for the avoidance of disturbance and harassment of whales.
- The Permittee shall notify BOEM, NMFS, and U.S. Fish and Wildlife Service (USFWS) in the event of any loss of cable, streamer, or other equipment that could pose a danger to marine mammals and other wildlife resources.
- To help avoid causing bird collisions with seismic survey and support vessels, seismic and surface support vessels will minimize the use of high-intensity work lights, especially within the 20-meter-bathymetric contour. High-intensity lights will be used only as necessary to illuminate active, on-deck work areas during periods of darkness or inclement weather (such as rain or fog), otherwise they shall be turned off. Deck lights, interior lights, and lights used during navigation could remain on for safety. Nothing in this mitigation measure is intended to reduce personnel safety or prevent compliance with other regulatory requirements (e.g., U.S. Coast Guard or Occupational Safety and Health Administration) for marking or lighting of equipment and work areas.
- All bird collisions (with vessels and aircraft) shall be documented and reported within 3 days to BOEM. Minimum information shall include species, date, time, location and weather, identification of the vessel or aircraft involved, and its operational status when the strike occurred. Bird photographs are not required, but would be helpful in verifying species. Permittees/operators are advised that the USFWS does not recommend recovery or transport of dead or injured birds due to avian influenza concerns.

Additional Mitigation Measures

The following mitigation measures (and mitigation monitoring needed to support them) will be evaluated in Chapter 4 and may be required by NMFS in ITAs or by BOEM in G&G permits or ancillary activity notices to make the necessary findings under the MMPA and OCS Lands Act, respectively, for the type of activity identified.

A. DETECTION-BASED MEASURES INTENDED TO REDUCE NEAR-ARRAY ACOUSTIC EXPOSURES AND IMPACTS ON MARINE MAMMALS WITHIN A GIVEN DISTANCE OF THE SOURCE

Additional Mitigation Measure A1. Prior to conducting the authorized survey, the seismic array operator shall conduct SSV tests for their airgun array configurations in the area in which the survey is proposed to occur.

This measure would be implemented for seismic, including in-ice, and site clearance and high resolution shallow hazards surveys. Before conducting the activity, the operators shall conduct sound source verification (SSV) tests to verify the radii of the safety and monitoring zones within real-time conditions in the field, providing for more accurate radii to be used. When moving an operation into a new area, the operator shall re-verify the new radii of the exclusion zones. The purpose of this mitigation measure is to establish and monitor more accurate safety zones based on empirical measurements, as compared to the zones based on modeling and extrapolation from different datasets. Using a hydrophone system, the vessel operator is required to conduct SSV tests for all airgun arrays and vessels and, at a minimum, report the following results to NMFS within five days of completing the test:

- The empirical distances from the airgun array and other acoustic sources utilized during the effectiveness of the ITA to broadband received levels of 190 dB down to 120 dB in 10 dB increments and the radiated sounds vs. distance from the source vessel.
- Measurements are to be made at the beginning of the survey for locations not previously modeled in the Arctic Seas.

Additional Mitigation Measure A2. All PSOs shall be provided with and use appropriate night-vision devices (e.g. Forward Looking Infrared [FLIR] imaging devices, 360° thermal imaging devices), Big Eyes, and reticulated and/or laser range finding binoculars in order to detect marine mammals within the exclusion zones.

- This measure would be required for all activities requiring the use of PSOs.
- All PSOs could be provided with and use appropriate night-vision devices, Big Eyes, and reticulated and/or laser range finding binoculars in order to detect marine mammals within the Exclusion Zone.

Additional Mitigation Measure A3. Operators shall limit seismic airgun operations in situations of low visibility when the entire safety radius cannot be observed (e.g., nighttime or bad weather). These limitations could mean cease airgun operations entirely, reduce the time that operations are conducted in this limited visibility situation, or reduce the number of airguns operating so that the exclusion radius is entirely visible.

- This measure would be implemented for seismic, including in-ice, and site clearance and high resolution shallow hazards surveys.

Additional Mitigation Measure A4. Seismic operators shall use passive (or active) acoustic monitoring systems, in addition to visual monitoring, to detect marine mammals approaching or within the exclusion zone and trigger the shutdown of airguns.

- This measure would be implemented for seismic, including in-ice, and site clearance and high resolution shallow hazards surveys.

Additional Mitigation Measure A5. Enhancement of monitoring protocols and mitigation shutdown zones to minimize impacts in specific biologic situations (e.g. expansion of shutdown zone to 120 dB or 160 dB when cow/calf groups and feeding or resting aggregations are detected, respectively).

This measure would be implemented for any activity that implements standard shutdown zones. Some characteristic mitigation language that has been used in past ITAs for these measures include:

- For seismic activities (including shallow hazards and site clearance and other marine surveys where active acoustic sources will be employed) in the Beaufort Sea after August 25, a 120-dB monitoring zone for bowhead whales will be established and monitored for the next 24 hours if four or more bowhead whale cow/calf pairs are observed at the surface during an aerial monitoring program within the area where an ensonified 120-dB zone around the vessel's track is projected. To the extent practicable, such monitoring should focus on areas upstream (eastward) of the bowhead migration. No seismic surveying shall occur within the 120-dB safety zone around the area where these whale cow-calf pairs were observed, until two consecutive surveys (aerial or vessel) indicate they are no longer present within the 120-dB safety zone of seismic-surveying operations.
- A 160-dB vessel monitoring zone for bowhead and gray whales will be established and monitored in the Chukchi Sea and after August 25 in the Beaufort Sea during all seismic surveys. Whenever an aggregation of bowhead whales or gray whales (12 or more whales of any age/sex class that appear to be engaged in a non-migratory, significant biological behavior (e.g. feeding, socializing)) are observed during an aerial or vessel monitoring program within the 160-dB safety zone around the seismic activity, the seismic operation will not commence or will shut down, until two consecutive surveys (aerial or vessel) indicate they are no longer present within the 160-dB safety zone of seismic-surveying operations.

B. NON-DETECTION-BASED MEASURES INTENDED TO MORE BROADLY LESSEN THE SEVERITY OF ACOUSTIC IMPACTS ON MARINE MAMMALS OR REDUCE OVERALL NUMBERS TAKEN BY ACOUSTIC SOURCE

These measures would be required for all activities that occur during the open-water season (i.e. 2D/3D seismic surveys including in-ice seismic, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities).

Additional Mitigation Measure B1. Temporal/spatial limitations to minimize impacts in particular important habitats, including Kaktovik, Barrow Canyon, Hanna Shoal, the shelf break of the Beaufort Sea, Kasegaluk Lagoon, and Ledyard Bay.

All, or a subset of, oil and gas activities would be limited (e.g., either completely prohibited, or the overall time reduced) in the areas specified here during the listed timeframes. Additionally, buffer zones around these time/area closures could potentially be included. Buffer zones would require that activities emitting pulsed sounds would need to operate far enough away from these closure areas so that sounds at 160 dB do not propagate into the area or that activities emitting continuous sounds would need to operate far enough away from these closure areas so that sounds at 120 dB do not propagate into the area. In the event that a buffer zone of this size was impracticable, a buffer zone avoiding the ensonification of the important habitat above 180 dB could be used. Table A-1 below outlines the time/area closure locations, dates, and species or subsistence hunts that would be protected by the closures.

2D/3D Seismic Surveys, Including In-Ice Surveys ONLY

Additional Mitigation Measure B2. Restriction of number of surveys (of same level of detail) that can be conducted in the same area in a given amount of time (i.e. to avoid needless collection of identical data).

- Require industry to organize a way to interact with one another to identify when and if duplicative surveys are likely to occur (survey type to gather same type of data within five years) and outline efforts to avoid or describe justification.

Additional Mitigation Measure B3. Separate seismic surveys are prohibited from operating within 145 km (90 mi) of one another.

C. MEASURES INTENDED TO REDUCE/LESSEN NON-ACOUSTIC IMPACTS ON MARINE MAMMALS

These measures would be required for all activities that occur during the open-water season (i.e. 2D/3D seismic surveys including in-ice seismic, CSEM surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities).

Additional Mitigation Measure C1. Vessels and aircraft avoidance of concentrations of groups of ice seals by 0.8 km (0.5 mi).

- Seismic survey and associated support vessels shall observe a 0.8 km (0.5 mi) safety radius around ice seal or Pacific walrus groups hauled out onto land or ice.
- Vessels must reduce speed when walruses are observed in the water. Vessels capable of steering around these animals must do so. Vessels may not be operated in such a manner as to separate members of a group of ice seals or walruses from other members of a group. Vessels should avoid multiple changes in direction and speed when ice seals or walruses are present.
- Under no circumstances, other than an emergency, should aircraft be operated at an altitude lower than 457 m (1,500 ft) when within 0.8 km (0.5 mi) of ice seal or Pacific walrus groups.
- Helicopters may not hover or circle above such areas or within 762 m (2,500 lateral ft) of such areas.

- Seismic survey operators shall adhere to any mitigation measures identified by the USFWS to protect polar bears from being harassed and/or injured.
- Vessels must reduce speed when polar bears are observed in the water. Vessels capable of steering around these animals must do so. Vessels may not be operated in such a manner as to separate members of a group of polar bears from other members of a group. Vessels should avoid multiple changes in direction and speed when polar bears are present.
- Currently, proposed polar bear critical habitat mitigation includes a 1.6 km (1 mi) no disturbance zone around the barrier islands, and sea ice habitat.

Additional Mitigation Measure C2. Specified shipping or transit routes to avoid important habitat in areas where marine mammals may occur in high densities.

Exploratory Drilling Activities ONLY

Additional Mitigation Measure C3. Requirements to ensure reduced, limited, or zero discharge of any or all of the specific discharge streams identified with potential impacts to marine mammals or marine mammal prey or habitat.

Discharge streams identified with potential impacts to marine mammals or marine mammal habitat include the following:

- Drill cuttings;
- Drilling fluids;
- Sanitary waste;
- Bilge water;
- Ballast water; and
- Domestic waste (i.e. gray water).

Additional Mitigation Measure C4. Operators are required to recycle drilling muds.

- Operators are required to recycle drilling muds (e.g. use those muds on multiple wells) based on operational considerations to reduce discharges.

On-ice Seismic Surveys

Additional Mitigation Measure C5. Use trained seal-lair sniffing dogs for areas with water deeper than 3 m (9.8 ft) depth contour to locate seal structures under snow in the work area and camp site before initiation of activities.

- Seal lairs are to be avoided by 152 m (500 ft).

Additional Mitigation Measure C6. Use trained seal-lair sniffing dogs to survey the ice road and establish a route where no ringed seal structures are present.

D. MEASURES INTENDED TO ENSURE NO UNMITIGABLE ADVERSE IMPACT TO SUBSISTENCE USES

These measures would be required for all activities that occur during the open-water season (i.e. 2D/3D seismic surveys, including in-ice seismic, CSEM surveys, site clearance and high resolution shallow hazards surveys, and exploratory drilling activities).

Additional Mitigation Measure D1. No transit of exploration vessels into the Chukchi Sea prior to July 15 or until the beluga hunt is completed at Point Lay.

- Any vessel conducting geophysical work in the Chukchi Sea should remain at least 8 km (5 mi) offshore during transit except for emergencies or human/navigation safety.
- Geophysical activity shall not be conducted within 96.5 km (60 mi) of any point on the Chukchi Sea coast.

Additional Mitigation Measure D2. Vessels transiting east of Bullen Point to the Canadian border should remain at least 8 km (5 mi) offshore during transit along the coast, except for emergencies or human/navigation safety.

Additional Mitigation Measure D3. Shutdown of exploration activities in the Beaufort Sea for the Nuiqsut (Cross Island) and Kaktovik bowhead whale hunts based on real-time reporting of whale presence and hunting activity rather than a fixed date.

Additional Mitigation Measure D4. Shutdown of exploration activities in the Beaufort Sea for the Barrow bowhead whale hunts from Pitt Point on the east side of Smith Bay to a location about half way between Barrow and Peard Bay from September 15 to the close of the fall bowhead whale hunt in Barrow.

Additional Mitigation Measure D5. Shutdown of exploration activities in the Chukchi Sea for the Barrow (the area circumscribed from the mouth of Tuapaktushak Creek due north to the coastal zone boundary, to Cape Halkett due east to the coastal zone boundary) and Wainwright (the area circumscribed from Point Franklin due north to the coastal zone boundary, to the Kuk River mouth due west to the coastal zone boundary) bowhead whale hunts based on real-time reporting of whale presence and hunting activity rather than a fixed date.

Additional Mitigation Measure D6. Shutdown of exploration activities in the Chukchi Sea for the Point Hope and Point Lay bowhead whale hunts based on real-time reporting of whale presence and hunting activity rather than a fixed date.

Additional Mitigation Measure D7. Transit restrictions into the Chukchi Sea modified to allow offshore travel under certain conditions (e.g. 32 km [20 mi] from the coast) if beluga whale, fall bowhead whale (Barrow and Wainwright), and other marine mammal hunts would not be affected.

Exploratory Drilling Activities ONLY

Additional Mitigation Measure D8. For exploratory drilling operations in the Beaufort Sea west of Cross Island, no drilling equipment or related vessels used for at-sea oil and gas operations shall be moved onsite at any location outside the barrier islands west of Cross Island until the close of the bowhead whale hunt in Barrow.

Table A-1. Proposed Time/Area closure locations under Additional Mitigation Measure B1. This table identifies the species and subsistence hunts that would be mitigated by implementing these closures.

	Kaktovik	Barrow Canyon and the Western Beaufort Sea	Beaufort Sea Shelf Break	Hanna Shoal	Kasegaluk Lagoon and Ledyard Bay
Proposed closure period	August 25 - September 15	Mid-July - October	Mid-July - late September	September 15 - early October	Mid-June - mid-July for the Lagoon and July 1 – November 15 for the LBCHU
Bowhead Whale	Migrating and feeding: late August - October	Migrating and feeding: late August - October	Migrating: late August - October	Part of migratory corridor: September - October	Do not occur (migrate offshore)
Beluga Whale	Uncommon	Migrating and feeding: mid-July - late August	Feeding: mid-July - late September	Unknown	Feeding, molting, calving: June and July
Spotted Seal	Present	Present	Present	Present	Present; Some feeding habitat
Walrus	Not present	Not present	Not Present	Feeding: July - August	Resting habitat: Spring and early winter
Whaling Hunts	bowheads: late August - mid-September	bowheads: September - October	Uncommon	None	belugas: mid-June - mid-July in the Lagoon only
Sealing Hunts	Mostly October - June	Mostly November - January and spring	Uncommon	None	Mostly October - June

Criteria and Thresholds for U.S. Navy Acoustic and Explosive Effects Analysis

April 2012

Criteria and Thresholds for U.S. Navy Acoustic and Explosive Effects Analysis

J. J. Finneran and A. K. Jenkins
SSC Pacific

SSC Pacific

ACKNOWLEDGMENTS

This technical report relies heavily upon two prior documents:

OPNAV Recommended Phase II Threshold Criteria, dated 20 January 2012.

Marine Mammal and Sea Turtle Criteria and Thresholds for Navy Effects Analyses, dated August 2010

We wish to thank the following individuals whom contributed to the aforementioned documents and to the completion of this technical report: Chip Johnson, Julie Rivers and Roy Sokolowski (COMPACFLT); Sean Hanser (NAVFAC Pacific); Dorian Houser, Sarah Kotecki, and Jason Mulsow (Navy Marine Mammal Program); Danielle Buonantony, Anurag Kumar, and Mandy Shoemaker (NAVFAC Atlantic), Amy Farak, Peter Hulton, and Stephanie Watwood (NUWC Newport); Robert Gisiner and Heather Havens (OPNAV N45); Jene Nissen (USFF).

CONTENTS

ACRONYMS AND ABBREVIATIONS

dB	decibel
dB re 1 μPa	decibels referenced to 1 microPascal
dB re 1 $\mu Pa^2 \cdot s$	decibels referenced to 1 microPascal- squared – seconds
GI	gastrointestinal
HF	high-frequency
Hz	hertz
kHz	kilohertz
LF	low-frequency
MF	mid-frequency
psi	pounds per square inch
PTS	permanent threshold shift
SEL	sound exposure level
SPL	sound pressure level
TM	tympanic membrane
TTS	temporary threshold shift

1 INTRODUCTION

The U.S. Navy is required to assess the potential impacts to marine species from training and testing activities to remain in compliance with a suite of Federal environmental laws and regulations including, but not limited to, the Marine Mammal Protection Act, Endangered Species Act, and the National Environmental Policy Act. In cases where these activities introduce high-levels of sound or explosive energy into the marine environment, an effects analysis must be conducted. The acoustic effects analysis begins with mathematical modeling to predict the sound transmission patterns from Navy sources. These data are then coupled with marine species distribution and abundance data to determine the sound levels likely to be received by various marine species. Finally, criteria and thresholds are applied to estimate the specific effects that animals exposed to Navy-generated sound may experience.

Sounds produced from naval activities can be divided into seven categories: (1) Sonars and other active acoustic sources; (2) Explosive detonations; (3) Ship noise; (4) Aircraft noise; (5) Gunfire and other launch noise; (6) Pile driving; and (7) Airguns. This report summarizes the criteria and thresholds for marine mammals and sea turtles exposed to underwater explosive detonations and sonars and other acoustic sources. Pile driving and seismic airguns, although impulsive sources, lack the potential for shock wave generation and are therefore not treated as explosives, but rather rely on unique criteria and thresholds agreed upon by Navy and NMFS. The criteria and thresholds for pile driving and airguns are therefore not included in this document.

2 CRITERIA AND THRESHOLDS FOR MARINE MAMMALS

2.1 INTRODUCTION

The criteria and thresholds for marine mammals are similar to those proposed by Southall et al. (2007): Marine mammal species are divided into a number of functional hearing groups, with all species in the same group assumed to be equally susceptible to noise. Within each functional hearing group, auditory weighting functions are used to emphasize frequencies where sensitivity to noise is high and de-emphasize frequencies where sensitivity is low. Individual criteria and thresholds are defined for explosive and (non-explosive) acoustic sources. The criteria and thresholds presented here for explosive sources are similar to those proposed by Southall et al. (2007) for impulsive sources, and the criteria and thresholds presented here for acoustic sources are similar to the Southall et al. (2007) non-impulsive criteria.

2.2 FUNCTIONAL HEARING GROUPS

To facilitate the acoustic and explosive effects analyses, marine mammals are divided into eight functional hearing groups, and the same criteria and thresholds are used for all species within a group. Species were grouped by considering their known or suspected auditory sensitivity, ear anatomy, and acoustic ecology (i.e., how they use sounds), as has been done previously (e.g., Ketten, 2000; Southall *et al.*, 2007). Appendix A summarizes the specific families and subfamilies contained in each functional hearing group.

2.2.1 Low-frequency (LF) cetaceans

Low-frequency cetaceans include all of the mysticetes.

No direct measurements of hearing sensitivity in any LF cetacean are available. Sensitivity to LF sound by baleen whales has been inferred from observed vocalization frequencies, observed reactions to playback of sounds, and anatomical analyses of the auditory system (Houser et al., 2001; Parks et al., 2007). Baleen whales are estimated to hear from 15 Hz – 20 kHz, with good sensitivity from 20 Hz – 2 kHz (Ketten, 1998). Mathematical models of the humpback whale's ear developed from anatomical features and optimization techniques (Houser *et al.*, 2001) suggest that humpbacks are sensitive to frequencies between 40 Hz and 16 kHz, but best sensitivity is likely to occur between 100 Hz and 8 kHz. Based on these data, functional hearing limits for LF cetaceans are defined as 7 Hz – 22 kHz.

2.2.2 Mid-frequency (MF) cetaceans

Mid-frequency cetaceans include most delphinid species (e.g., bottlenose dolphin, common dolphin, killer whale, pilot whale; see high-frequency cetacean list for exceptions), beaked whales, bottlenose whales, and sperm whales (but not pygmy and dwarf sperm whales of the genus *Kogia*, which are treated as high-frequency species).

Hearing sensitivity has been directly measured for a number of species within this group, including Atlantic bottlenose dolphins (Johnson, 1967), belugas (Finneran et al., 2005; White, 1977), Indo-Pacific bottlenose dolphins (Houser et al., 2008), Black Sea bottlenose dolphins

(Popov et al., 2007), striped dolphins (Kastelein et al., 2003), white-beaked dolphins (Nachtigall et al., 2008), Risso's dolphins (Nachtigall et al., 2005), killer whales (Szymanski et al., 1999), false killer whales (Yuen et al., 2005), common dolphins (Touhey-Moore et al., unpublished), Atlantic white-sided dolphins (Touhey-Moore et al., unpublished), Gervais' beaked whales (Finneran et al., 2009), Blainville's beaked whale (Pacini et al., 2011), short-finned pilot whales (Schlundt et al., 2011), and long-finned pilot whales (Pacini et al., 2010). All audiograms exhibit the same general U-shape, with a nominal hearing range between approximately 150 Hz and up to 160 kHz; these two frequencies were used as the lower and upper cutoff frequencies for the functional hearing limits.

2.2.3 High-frequency (HF) cetaceans

High-frequency cetaceans include the porpoises (genus *Phocoena*, *Neophocaena*, *Phocoenoides*), river dolphins, *Kogia* species, and *Cephalorhynchus* species.

Hearing has been tested for harbor porpoises (Kastelein et al., 2002a), Yangtze finless porpoises (Popov et al., 2005), Amazon River dolphins (Popov and Supin, 1990b), and Tucuxi dolphins (Popov and Supin, 1990a). All audiograms exhibit the same general U-shape with nominal hearing range between 200 Hz and 180 kHz; these two frequencies were used as the lower and upper cutoff frequencies for the functional hearing limits.

2.2.4 Phocids

Phocids include all earless seals or "true seals," including the ice seals (harp, hooded, bearded, ringed, ribbon, spotted, Weddell, leopard, Ross, and crabeater seals); harbor or common seals; gray seals; inland seals (e.g., Caspian and Baikal seals); elephant seals (northern and southern); and monk seals (Hawaiian and Mediterranean). Since these animals are amphibious, separate criteria and thresholds are included for airborne and underwater exposure.

Phocid hearing limits are estimated to be 75 Hz – 30 kHz and 75 Hz – 75 kHz in air and water, respectively (Kastak and Schusterman, 1999; Kastelein et al., 2009; Møhl, 1968; Reichmuth, 2008; Terhune and Ronald, 1971; 1972).

2.2.5 Otariids and Odobenids

Otariids include all eared seals (fur seals and sea lions) and odobenids are walruses (the only extant species). Separate criteria/thresholds are included for airborne and underwater exposure. Since these animals are amphibious, separate criteria and thresholds are included for airborne and underwater exposure.

Otariid hearing limits are estimated to be 100 Hz – 35 kHz and 100 Hz – 50 kHz in air and water, respectively (Babushina et al., 1991; Kastak and Schusterman, 1998; Kastelein et al., 2005b; Moore and Schusterman, 1987; Mulsow and Reichmuth, 2007; Mulsow et al., 2011a; Mulsow et al., 2011b; Schusterman et al., 1972).

The ear morphology of the walrus is intermediate between the otariid and phocid ear; however, current data indicate that the hearing of the walrus is more similar to that of otariids (Kastelein et al., 2002c). Therefore, the hearing limits defined for otariids are also applied to walruses.

2.2.6 Mustelids

Mustelids include sea otters (in air and under water). Since these animals are amphibious, separate criteria and thresholds are included for airborne and underwater exposure.

Like the pinnipeds, sea otters are amphibious mammals in the order Carnivora. No published data are available for sea otter hearing, though it is reasonable to expect hearing ability similar to other mustelids (otters). Behavioral measures of hearing in air for two North American river otters indicate a functional hearing of approximately 450 Hz – 35 kHz (Gunn, 1988), which is similar to the in-air hearing range of otariids. Based on the limited available information and the fact that the otariid ear is very similar to the ear of other carnivores (Nummela, 2008), the functional hearing limits for otariid are used for sea otters.

2.2.7 Ursids

Ursids include polar bears (in air and under water). Since these animals are amphibious, separate criteria and thresholds are included for airborne and underwater exposure.

Like the pinnipeds and sea otters, polar bears are amphibious mammals in the order Carnivora. Hearing threshold measurements of polar bears (in air) have shown good sensitivity up to approximately 20 kHz, with a rapid decline in sensitivity above 20 kHz (Bowles et al., 2008; Nachtigall et al., 2007). Based on the limited available information and the fact that the otariid ear is very similar to the ear of other carnivores (Nummela, 2008), the functional hearing limits for otariid are used for polar bears.

2.2.8 Sirenians

Sirenians contain manatees and dugongs.

Gerstein et al. (1999) obtained behavioral audiograms for two West Indian manatees and found an underwater hearing range of approximately 400 Hz – 76 kHz, with best sensitivity around 16 – 18 kHz. Mann et al. (2009) obtained masked behavioral audiograms from two manatees; sensitivity was shown to range from 250 Hz – 90 kHz, although the detection level at 90 kHz was 80 dB above the manatee’s frequency of best sensitivity (16 kHz). This audible frequency range is similar to that of phocids (Gerstein *et al.*, 1999; Southall *et al.*, 2007), therefore the functional hearing range for phocids (75 Hz – 75 kHz) was applied to the Sirenians.

2.3 AUDITORY WEIGHTING FUNCTIONS

Human occupational noise exposure guidelines rely on numeric thresholds based on “weighted” noise levels. Weighted noise levels are calculated by applying frequency-dependent filters, or “weighting functions,” to the noise sound pressure measured in the workplace. The weighting functions are designed to emphasize frequencies (i.e., to add “weight”) where people are sensitive to noise and to de-emphasize frequencies (i.e., subtract weight) where people are not very sensitive. The weighted noise levels at each frequency are then combined to generate a single, weighted exposure value. This technique allows the use of a single, weighted threshold value, regardless of the noise frequency. The alternative would be to have a large number of individual threshold values, one for every frequency that might be encountered.

Weighting functions for humans were derived from equal loudness contours — graphs representing the sound pressure levels (SPLs) that give rise to a sensation of equal loudness magnitude in a human listener as a function of sound frequency (Suzuki and Takeshima, 2004). Equal loudness contours are in turn derived from subjective loudness experiments, where human listeners are asked to judge the relative loudness of two tones with different frequencies (e.g., Fletcher and Munson, 1933; Robinson and Dadson, 1956). For humans, the most commonly encountered weighting functions are the “A-weighting” and “C-weighting” functions. A-weighting resembles the human auditory sensitivity curve, and is the most common weighting function prescribed in noise regulations. The C-weighting curve is flatter, subtracts less energy at the extreme high and low frequencies, and better matches human sensitivity to louder sounds.

For marine mammals, several approaches have been used to define auditory weighting functions. See Appendix B for a summary of weighting functions and parameters specific for each functional hearing group.

2.3.1 Development of marine mammal auditory weighting functions

The first broadly applied marine mammal weighting functions were developed by Southall et al. (2007). Cetaceans and pinnipeds were divided into five functional hearing groups: LF cetaceans, MF cetaceans, HF cetaceans, pinnipeds in air, and pinnipeds in water. At the time, there were no equal loudness data for marine mammals. Although the use of species’ hearing sensitivities as weighting functions seems logical, existing audiograms for odontocetes typically possessed a much steeper reduction in sensitivity at low-frequencies compared to the dolphin and beluga temporary threshold shift (TTS) data, which showed little variation between 3 and 20 kHz. For these reasons, Southall et al. based their proposed weighting functions on the shape of the human “C-weighting” network, with the parameters adjusted so the weighting function shape better matched the known or suspected hearing range for each species group. The group of resulting weighting functions was referred to as the “M-weighting” functions (Southall *et al.*, 2007).

The “M-weighting” functions are described by the equation:

$$W(f) = K + 20\log_{10}\left[\frac{b^2 f^2}{(a^2 + f^2)(b^2 + f^2)}\right], \qquad (1)$$

where *f* is the frequency (Hz), $W(f)$ is the weighting function amplitude (dB) at each frequency, *a* and *b* are constants related to the upper and lower hearing limits, respectively, and *K* is a constant used to normalize the equation at a particular frequency. Specific values for the constants *a* and *b* are given in Table 1 (Southall *et al.*, 2007). Figure 1 shows the resulting weighting functions. The M-weighting functions are nearly flat between the lower and upper cutoff frequencies (*a* and *b*, respectively) specified in Table 1. For this reason, they were believed to over-estimate the effects of noise at high and low frequencies and thus to be protective (Southall *et al.*, 2007).

Table 1. Parameters for the "M-weighting" functions defined by Southall et al. (2007).

Species Group	*K*	*a* (Hz)	*b* (Hz)
LF cetaceans	0	7	22,000
MF cetaceans	0	150	160,000
HF cetaceans	0	200	180,000
Pinnipeds in water	0	75	75,000
Pinnipeds in air	0	75	30,000

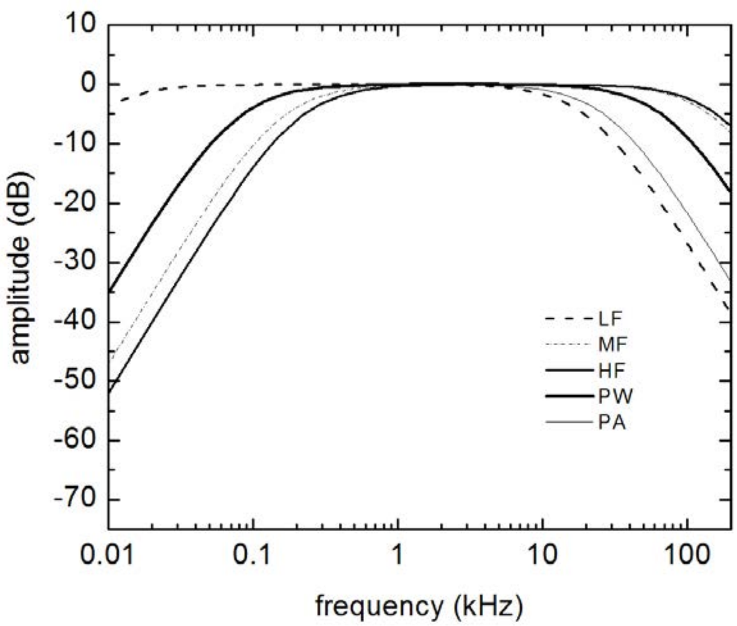

Figure 1. Marine mammal auditory weighting functions proposed by Southall et al. (2007). LF – low-frequency cetacean, MF – mid-frequency cetacean, HF – high-frequency cetacean, PW – pinnipeds in water, PA – pinnipeds in air.

The next advancement of marine mammal weighting functions occurred in 2011, when subjective loudness measurements were made with a bottlenose dolphin, the first time such an experiment has been conducted with a non-human animal (Finneran and Schlundt, 2011). From the subjective loudness data, equal loudness contours were derived, using the same procedures as those used to derive human equal loudness contours (e.g., Suzuki and Takeshima, 2004). Finally, Eq. (1) was fit to the equal loudness contour data, providing a set of auditory weighting functions. Three weighting functions based on equal loudness contours (the “EQL weighting functions”) were presented by Finneran and Schlundt (2011); the functions were based on the equal loudness contours passing through 90, 105, and 115 dB re 1 µPa at 10 kHz.

Figure 2 compares the Finneran and Schlundt (2011) bottlenose dolphin EQL weighting functions with the Southall et al. (2007) M-weighting function for MF cetaceans. Also shown in Fig. 2 is the relative susceptibility to noise, based on the TTS onset data for dolphins (Finneran, 2010; Finneran and Schlundt, 2009). In contrast to the onset of TTS, which represents an exposure threshold, the hazardousness of a noise exposure can also be described by the *susceptibility* of the listener, which represents the listener’s sensitivity to noise. The *relative susceptibility* is obtained by negating the onset TTS levels (in dB), then normalizing these data at some frequency. High values of susceptibility therefore indicate frequencies where noise is more hazardous. The susceptibility data can be directly compared to auditory weighting functions, which preferentially emphasize (apply larger weight to) frequencies where noise is more hazardous and de-emphasize those frequencies where noise is less hazardous. In Fig. 2, the EQL weighting functions, M-weighting function, and susceptibility data are all normalized at 3 kHz.

At frequencies above 3 kHz, the dolphin susceptibility to TTS increases (the TTS onset is lower); however, the MF cetacean weighting function proposed by Southall et al. (2007) is flat between 3 and 20 kHz and does not reflect the dependence of TTS on exposure frequency. In contrast, the EQL weighting functions predict larger effects from noise than the MF cetacean M-weighting function above 3 kHz, and better match the susceptibility data. The best fit to the susceptibility data is found with the EQL weighting function based on the 90-dB re 1 µPa equal loudness contour (adjusted $R^2 = 0.831$). Below 3 kHz, the EQL weighting functions are similar and predict increasingly lower effects compared to the MF cetacean M-weighting function. No MF cetacean TTS data exist for frequencies below 3 kHz and the equal loudness data only extend down to 2.5 kHz, therefore the accuracy of the EQL weighting functions at lower frequencies is unknown.

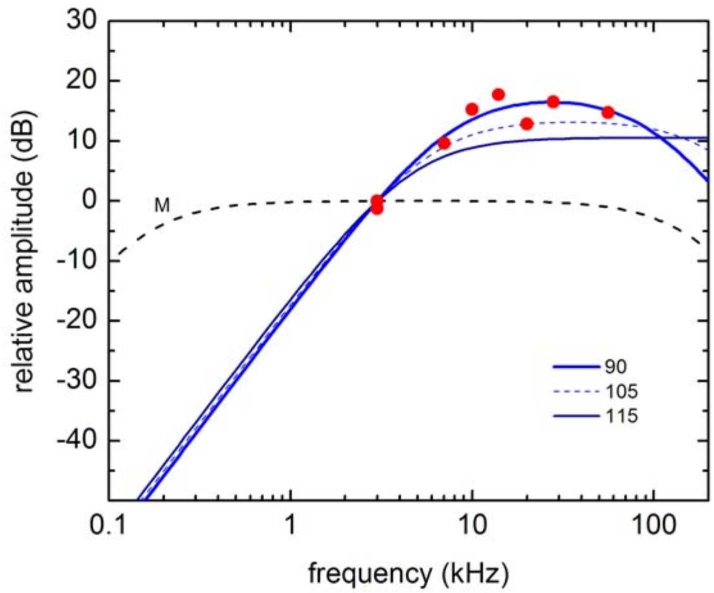

Figure 2. Comparison of dolphin auditory weighting function (solid lines), relative susceptibility to noise measured in a bottlenose dolphin (symbols), and Southall et al. mid-frequency cetacean “M-weighting” (dashed line).

2.3.1.1 Estimating EQL weighting functions for LF and HF cetaceans

Although equal loudness data only exist for bottlenose dolphins, EQL weighting functions can be estimated for other species by adjusting the parameters for Eq. (1), on a relative basis, to fit the known or suspected hearing range of each species group. This process can only be used for functional hearing groups that are closely related to the MF cetaceans (the group for whom the EQL functions exist) — the LF and HF cetaceans.

Because the frequency excitation pattern within the mammalian ear is organized logarithmically, not linearly (Ketten, 2000), the adjustment of the parameters *a* and *b* is done on a logarithmic basis. Specifically, the parameters *a* and *b* are adjusted so that the relationship, in terms of octaves, between *a* and *b* for the EQL weighting function and the functional hearing limits is preserved between the MF cetacean group and the other species groups. The extrapolation is performed using:

$$\frac{\log_2 a' - \log_2 f'_L}{\log_2 f'_U - \log_2 f'_L} = \frac{\log_2 a - \log_2 f_L}{\log_2 f_U - \log_2 f_L}, \tag{2}$$

and

$$\frac{\log_2 b' - \log_2 f'_L}{\log_2 f'_U - \log_2 f'_L} = \frac{\log_2 b - \log_2 f_L}{\log_2 f_U - \log_2 f_L}, \tag{3}$$

where a and b are the EQL weighting function parameters for MF cetaceans, a' and b' are the (extrapolated) parameters for the LF or HF species group, f_L and f_U are the lower and upper frequency limits for MF cetaceans (150 Hz and 160 kHz, respectively), and f'_L and f'_U are the lower and upper frequency limits for LF cetaceans or HF cetaceans. Taking the logarithm to the base 2 ($\log_2$) converts each frequency to octave spacing (re 1 Hz); this is done because the frequency organization of the inner ear is logarithmically spaced, not linearly (Ketten, 2000).

For low-frequency cetaceans, f'_L = 7 Hz and f'_U = 22 kHz, so application of Eqs. (2) and (3) yields a' = 674 Hz and b' = 12,130 Hz. A value of K = 0.94 is needed to normalize the peak of the curve to 0 dB.

For high-frequency cetaceans, f'_L = 200 Hz and f'_U = 180 kHz, so application of Eqs. (2) and (3) yields a' = 9,480 Hz and b' = 108,820 Hz. A value of K = 1.4 is needed to normalize the peak of the curve to 0 dB.

Parameters used to generate the LF, MF, and HF cetacean EQL weighting functions from Eq. (1) are given in Table 2. Graphs of the EQL weighting functions for the LF, MF, and HF cetaceans are shown in Fig. 3.

Table 2. Parameters for the EQL weighting functions for the LF, MF, and HF cetaceans. The MF cetacean function is based on the 90 dB re 1 µPa equal loudness contour for dolphins (Finneran and Schlundt, 2011). The LF and HF functions were extrapolated form the MF function based on the functional hearing limits for the LF and HF cetacean groups. The value of K was adjusted for each function to set the peak amplitude to 0 dB.

Functional Hearing Group	*K*	*a* (Hz)	*b* (Hz)
LF cetacean (extrapolated)	0.9	674	12,130
MF cetacean (based on dolphin 90-dB re 1 µPa equal loudness function)	1.4	7,829	95,520
HF cetacean (extrapolated)	1.4	9,480	108,820

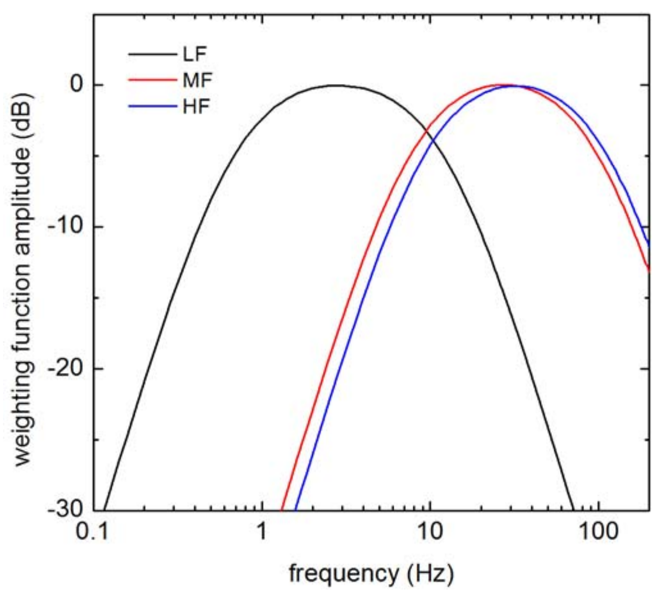

Figure 3. EQL weighting functions for the LF, MF, and HF cetaceans. The MF cetacean function is based on the 90 dB re 1 µPa equal loudness contour for dolphins (Finneran and Schlundt, 2011). The LF and HF functions were extrapolated form the MF function based on the functional hearing limits for the LF and HF cetacean groups.

2.3.2 Navy marine mammal weighting functions

Auditory weighting functions developed for Navy acoustics effects analyses utilize features of both the M-weighting functions and the EQL weighting functions. Two types of Navy weighting functions are defined: Type I weighting functions and Type II weighting functions.

Type I weighting functions are similar to the M-weighting functions and have two parameters (*a*, *b*) that define the lower and upper frequencies where the amplitude begins to decline (the “rolloff” or “cutoff” frequencies), and one parameter (*K*) that defines the amplitude of the flat portion of the curve. Type I functions are flat over a broad range of frequencies. As with the M-weighting functions, the cutoff frequencies are based on the known or estimated hearing range for each functional hearing group. The equation for the Type I weighting function is

$$W_I(f) = K + 20\log_{10}\left[\frac{b^2 f^2}{\left(a^2 + f^2\right)\left(b^2 + f^2\right)}\right], \quad (4)$$

where $W_I(f)$ is the weighting function amplitude (in dB) at the frequency f (in Hz), and *a*, *b*, and *K* are constants defining the shape of the function for each functional hearing group.

Table 3 lists the parameters used to generate the Type I weighting functions from Eq. (4) for each functional hearing group defined in Section 2-2. The weighting functions are displayed in Fig. 4. The Navy Type I weighting functions for the cetaceans are identical to the Southall et al. (2007) M-weighting functions. The Type I weighting functions (in air and underwater) for the phocids are identical to the Southall et al. (2007) M-weighting functions for pinnipeds (the pinniped M-weighting functions were based on the hearing ranges for phocids seals). The Type I functions for otariids, odobenids, mustelids, ursids, and sirenians are based on the estimated functional hearing limits for these functional groups as defined in Section 2.2.

Table 3. Parameters for the Navy marine mammal Type I weighting functions.

Functional Hearing Group	*K*	*a* (Hz)	*b* (Hz)
LF cetaceans	0	7	22,000
MF cetaceans	0	150	160,000
HF cetaceans	0	200	180,000
Phocids (in water), Sirenians	0	75	75,000
Phocids (in air)	0	75	30,000
Otariids, Odobenids, Mustelids, Ursids (in water)	0	100	40,000
Otariids, Odobenids, Mustelids (in air)	0	100	30,000

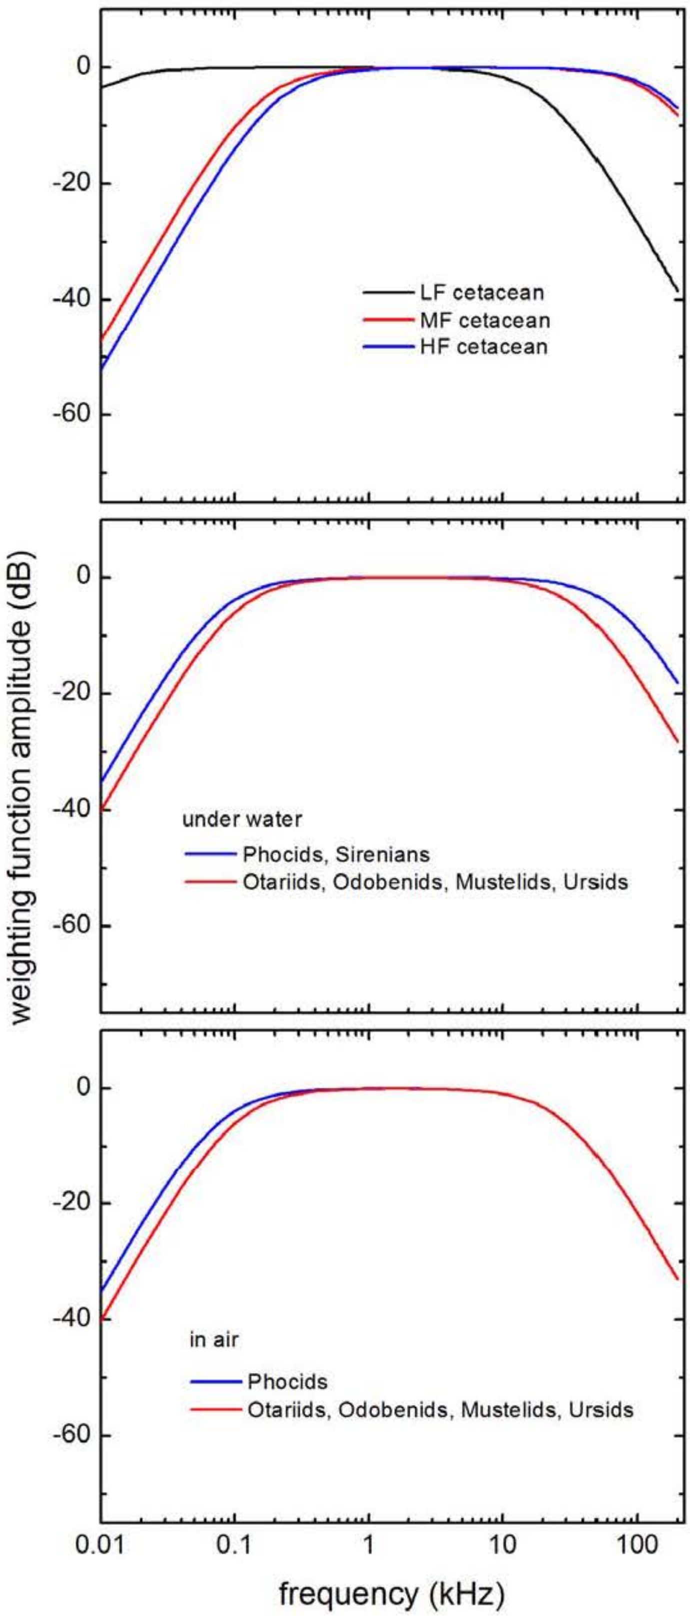

Figure 4. Navy Type I weighting functions.

Type II weighting functions modify the Type I functions (or M-weighting functions) by including a region of increased amplitude (increased susceptibility) based on the EQL weighting functions. Type II functions are only derived for the cetaceans, because the underlying data necessary for the functions are only available for bottlenose dolphins (MF cetaceans). Although TTS data exist for three pinniped species (harbor seal, California sea lion, northern elephant seal), most exposures consisted of octave band noise centered at 2.5 kHz, thus data are insufficient to either derive weighting functions in a manner analogous to that used for MF cetaceans or to verify the effectiveness of extrapolations from the MF cetacean group.

Type II functions are defined using two component curves: one based on the Type I weighting function and the other based on the EQL weighting function. At each frequency, the amplitude of the weighting function is defined using the larger value from the two component curves, as illustrated in Fig. 5. In practice, the Type I component will dominate below some frequency, denoted as the “inflection point” frequency, and the EQL component will dominate above the inflection point. The idea behind the Type II function is to enhance the Type I weighting function by accounting for the increased susceptibility to noise seen in the bottlenose dolphin TTS data at frequencies above 3 kHz. The EQL weighting functions are not used by themselves because of the uncertainty regarding the weighting function amplitude at low frequencies, below the range of the TTS and equal loudness data. The Type I function is used at lower frequencies as a protective approach since there are no TTS or equal loudness data below 2.5 – 3 kHz. The Type II weighting function represents a way to incorporate new data showing increased susceptibility to noise at higher frequencies with the broad, protective weighting functions proposed by Southall et al. (2007).

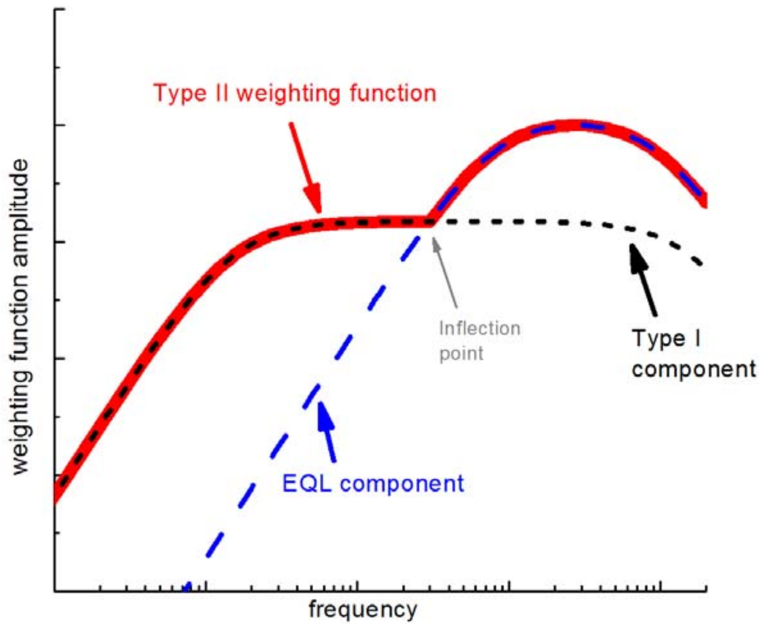

Figure 5. Illustration of the Type II weighting function concept. Below the inflection point frequency, the Type II weighting function matches the shape of the Type I function. Above the inflection point, the Type II function matches the EQL-based weighting function.

The Type II weighting functions are mathematically defined as:

$$W_{II}(f) = \text{maximum}\{G_1(f), G_2(f)\}, \tag{5}$$

where $W_{II}(f)$ is the weighting function amplitude (dB) at the frequency f (Hz),

$$G_1(f) = K_1 + 20\log_{10}\left[\frac{b_1^2 f^2}{(a_1^2 + f^2)(b_1^2 + f^2)}\right], \tag{6}$$

$$G_2(f) = K_2 + 20\log_{10}\left[\frac{b_2^2 f^2}{(a_2^2 + f^2)(b_2^2 + f^2)}\right], \tag{7}$$

the parameters a_1, b_1, and K_1 define the Type I component of the function and a_2, b_2, and K_2 define the EQL component of the function. The specific parameters for the LF, MF, and HF cetaceans are given in Table 4. Note that the values for a_1, b_1 match the parameters *a* and *b* for the Type I (and M-weighting) functions and a_2, b_2 match the parameters for the EQL weighting functions. The values for K_2 match the values for *K* for the EQL weighting function, so the Type II functions also have their peak amplitudes at 0 dB. The values for K_1 are adjusted from the Type I functions so that the MF and HF cetaceans have the inflection point at 3 kHz. For the LF cetaceans, *K* is adjusted so that the flat portion of the Type I component is 16.5 dB below the peak, identical to the value for the MF cetaceans. This places the inflection point for the LF cetacean function at 267 Hz. The Type II weighting functions are shown graphically in Fig. 6.

Table 4. Marine mammal Type II weighting function parameters for use in Eq. (5).

Functional Hearing Group	K_1 (dB)	a_1 (Hz)	b_1 (Hz)	K_2 (dB)	a_2 (Hz)	b_2 (Hz)	Inflection point (Hz)
LF cetaceans	-16.5	7	22,000	0.9	674	12,130	267
MF cetaceans	-16.5	150	160,000	1.4	7,829	95,520	3,000
HF cetaceans	-19.4	200	180,000	1.4	9,480	108,820	3,000

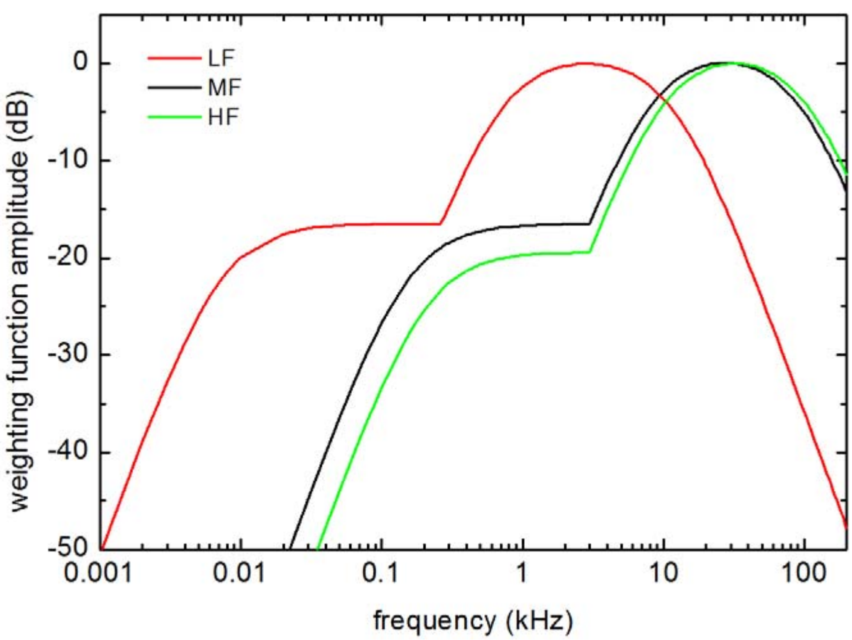

Figure 6. Navy Type II weighting functions for LF, MF, and HF cetaceans.

2.4 CRITERIA AND THRESHOLDS FOR SONARS AND OTHER ACTIVE ACOUSTIC SOURCES

2.4.1 Introduction

Criteria for marine mammals exposed to sonars and other active acoustic sources are divided into physiological effects and behavioral effects. Physiological effects criteria and thresholds are based on temporary and permanent threshold shift (TTS and PTS). Behavioral thresholds are based on observational data documenting the reactions of various marine mammal species to sound. For TTS, PTS, and behavioral responses, criteria and thresholds are provided for each functional hearing group. A summary of the various criteria and thresholds is provided in Appendix C.

2.4.2 Criteria and thresholds for TTS

TTS criteria and thresholds are based on TTS onset values obtained from representative species of MF and HF cetaceans and pinnipeds. The data obtained from MF and HF cetaceans and pinnipeds were then extrapolated to the other functional hearing groups.

Criteria for TTS are based on the sound exposure level (SEL) received by the animal. SEL is used, rather than sound pressure level (SPL), because SEL includes the effect of the exposure duration, which is a key factor is the likelihood that a noise exposure will produce TTS.

The threshold value for TTS for each functional hearing group is defined in terms of the *weighted* SEL. This means that the SEL corresponding to the onset of TTS is “weighted” by the appropriate weighting function. For cetaceans, Type II weighting functions are used for sonars and other active acoustic sources, since the EQL portion of the Type II functions are based on tonal noise exposures most closely related to sonars. For the other functional hearing groups, where Type II weighting functions do not exist, Type I functions are used instead.

For meaningful comparison to the weighted SEL threshold value, the SEL received by an animal must also be weighted by the same function. To determine if a TTS occurs, the frequency content of the SEL is first determined. The appropriate weighting function is then used to weight each frequency band. Then, the total, weighted SEL is calculated by integrating the weighted frequency content. Finally, the weighted exposure is compared to the weighted threshold value for TTS. If the weighted exposure SEL meets or exceeds the weighted SEL threshold value, then TTS is assumed to occur.

2.4.2.1 Low-Frequency Cetaceans

No direct measurements of TTS are available for any LF cetaceans. For this reason, the MF criteria and thresholds are also applied to LF cetaceans; however, exposures and threshold SEL values are weighted using the Type II LF cetacean weighting function rather than the MF cetacean function. This provides higher susceptibility to low frequency sound, consistent with the inferred frequencies of best hearing for LF cetaceans. The resulting (Type II) weighted exposure SEL for LF cetaceans is 178 dB re 1 $\mu Pa^2 \cdot s$.

2.4.2.2 Mid-Frequency Cetaceans

To date, TTS data has been collected for bottlenose dolphins and belugas, two diverse odontocetes. Both species had similar TTS thresholds (Schlundt et al., 2000). Due to the similarity in the known audiograms and TTS thresholds, the TTS thresholds for dolphins and belugas are applied to all MF cetaceans.

A number of studies have shown that an SEL of 195 dB re 1 µPa^2·s is a reasonable threshold for TTS in dolphins and belugas exposed to 3 kHz tones (Finneran, 2005; Finneran et al., 2010; Mooney et al., 2009; Nachtigall et al., 2004; Schlundt *et al.*, 2000). This threshold was also supported by Southall et al. (2007) as the best estimate of onset-TTS for non-impulsive noise exposure in cetaceans. For the MF cetacean Type II weighting function, the weighting function amplitude at 3 kHz is -16.5 dB. This means that the (Type II) weighted exposure SEL for MF cetaceans is 178 dB re 1 µPa^2·s.

2.4.2.3 High-Frequency Cetaceans

At the time the Navy criteria were developed, no direct measurements of TTS were available for any HF cetacean exposed to non-impulsive sound (such as that produced by sonars). TTS thresholds for HF cetaceans were therefore based on data published by Lucke et al. (2009), who measured TTS in a harbor porpoise exposed to impulses produced by a small seismic air gun. The TTS threshold for impulsive noise obtained from the airgun TTS data was adjusted to estimate the TTS threshold for sonars and other active acoustic sources (which are non-impulsive sources) using the method outlined by Southall et al. (2007) (Type II weighted SEL = 146 dB re 1 µPa^2·s). This method relies on the relationship between impulsive and non-impulsive TTS onset values for MF cetaceans, which means that the non-impulsive threshold is 6 dB higher than the impulsive threshold (Southall *et al.*, 2007). For the harbor porpoise, this results in a non-impulsive, (Type II) weighted TTS threshold of 152 dB re 1 µPa^2·s.

Due to the similarities in the known audiograms, the TTS threshold derived for harbor porpoises is used for all HF cetaceans. Newly published TTS data for the Yangtze finless porpoise (Popov et al., 2011) were not directly used to derive threshold values, although this study supports the concept that the HF cetacean thresholds are significantly lower than those for the MF cetaceans. Kastelein et al. (2011) have also presented results of TTS experiments with harbor porpoise, though, at present, these data have not been published.

2.4.2.4 Phocids (in water)

TTS thresholds for phocids exposed to underwater sonars and other active acoustics are based on data reported by Kastak et al. (2005), who provided estimates of the average SEL for onset-TTS for a harbor seal, sea lion, and Northern elephant seal exposed to underwater, octave-band noise centered at 2.5 kHz. The most sensitive of the two phocids was the harbor seal, with a TTS onset threshold of 183 dB re 1 µPa^2·s. For phocids, only a Type I weighting function is used; the weighting function amplitude at 2.5 kHz is 0 dB. This means the (Type I) weighted exposure SEL for harbor seals under water is 183 dB re 1 µPa^2·s.

Due to the similarities in the known audiograms, and the fact that the only other phocid for whom TTS data are available had a higher TTS onset threshold (Northern elephant seal, with

TTS onset 204 dB SEL), the underwater TTS threshold for the harbor seal is used for all phocids seals. Recently, Kastelein et al. (2011) have presented results of TTS experiments with harbor seals exposed to underwater noise, though, at present, these data have not been published.

2.4.2.5 Phocids (in air)

TTS thresholds for phocids exposed to acoustic sources in-air are based on data reported by Kastak et al. (2004), who provided estimates of the average SEL for onset-TTS for a harbor seal, sea lion, and Northern elephant seal exposed to in-air, octave-band noise centered at 2.5 kHz. The most sensitive of the two phocids was the harbor seal, with a TTS onset threshold of 131 dB re $(20\ \mu Pa)^2 \cdot s$. For phocids, only a Type I weighting function is used; the weighting function amplitude at 2.5 kHz is 0 dB. This means the (Type I) weighted exposure SEL for harbor seals in air is 131 dB re $(20\ \mu Pa)^2 \cdot s$.

Due to the similarities in the known audiograms, and the fact that the only other phocid for whom TTS data are available had a higher TTS onset threshold [northern elephant seal, with TTS onset 163 dB re $(20\ \mu Pa)^2 \cdot s$], the in-air TTS threshold for the harbor seal is used for all phocids seals.

2.4.2.6 Otariids and odobenids (in water)

TTS thresholds for otariids exposed to underwater sonars and other active acoustics are based on data reported by Kastak et al. (2005), who provided estimates of the average SEL for onset-TTS for a harbor seal, sea lion, and Northern elephant seal exposed to underwater, octave-band noise centered at 2.5 kHz. The California sea lion TTS onset threshold was 206 dB SEL. For otariids, only a Type I weighting function is used; the weighting function amplitude at 2.5 kHz is 0 dB. This means the (Type I) weighted exposure SEL for California sea lions exposed under water is 206 dB re 1 $\mu Pa^2 \cdot s$.

As the only otariid species for whom TTS data are available, the California sea lion TTS threshold is used for all otariids. No TTS data exist for the walrus; however, underwater audiograms (Kastelein et al., 2002b) for the walrus show a strong similarity to those of other otariids, therefore, the otariid TTS threshold is also used for odobenids.

2.4.2.7 Otariids and odobenids (in air)

TTS thresholds for otariids exposed to acoustic sources in-air are based on data reported by Kastak et al. (2007; 2004), who provided estimates of the average SEL for onset-TTS for a California sea lion exposed to in-air, octave-band noise centered at 2.5 kHz. The California sea lion TTS onset threshold was 154 dB re $(20\ \mu Pa)^2 \cdot s$. For otariids, only a Type I weighting function is used; the weighting function amplitude at 2.5 kHz is 0 dB. This means the (Type I) weighted exposure SEL for California sea lions exposed in air is 154 dB re $(20\ \mu Pa)^2 \cdot s$.

As the only otariid species for whom TTS data are available, the California sea lion TTS threshold is used for all otariids. No TTS data exist for the walrus; however, underwater audiograms (Kastelein *et al.*, 2002b) for the walrus show a strong similarity to those of other otariids, therefore, the otariid TTS threshold is also used for odobenids.

2.4.2.8 Mustelids

Based on the limited data available for sea otters and the similarities between these species and pinnipeds, the otariid TTS criteria and thresholds are used for mustelids.

2.4.2.9 Ursids

Based on the limited data available for polar bears and the similarities between these species and pinnipeds, the otariid TTS criteria and thresholds are used for polar bears.

2.4.2.10 Sirenians

No TTS data for manatees and dugongs exist; however, because the hearing ranges of phocids and sirenians are roughly equivalent, the phocid TTS threshold (the lowest of any of the pinnipeds), is used for sirenians.

2.4.3 Criteria and thresholds for PTS

In contrast to TTS, which represents a temporary reduction of hearing sensitivity, PTS represents tissue damage that does not recover and leads to a permanent reduced sensitivity to sounds over specific frequency ranges. Since no studies have been designed to intentionally induce PTS in marine mammals, onset-PTS levels for marine mammals must be estimated using available information. TTS data are available for some marine mammal species, and a large amount of TTS and PTS data exist for terrestrial mammals. Differences in auditory structures and sound propagation and interaction with tissues prevent direct application of numerical thresholds for PTS in terrestrial mammals to marine mammals. However, the inner ears of marine and terrestrial mammals are analogous and certain relationships are expected to relate to both groups of mammals. Experiments with marine mammals have revealed similarities between marine and terrestrial mammals with respect to features such as TTS, age-related hearing loss, ototoxic drug-induced hearing loss, masking, and frequency selectivity (e.g., Finneran, 2012; Finneran *et al.*, 2005; Nachtigall et al., 2000). For this reason, relationships between TTS and PTS from human and terrestrial mammal data can be used, along with TTS onset values for marine mammals, to estimate exposures likely to produce PTS in marine mammals (Southall *et al.*, 2007).

A variety of terrestrial and marine mammal data sources indicate that threshold shifts up to 40 to 50 dB may be induced without PTS, and that 40 dB is a reasonable upper limit for threshold shift to prevent PTS (e.g., Kryter et al., 1966; Miller et al., 1963; Ward, 1960; Ward et al., 1958; Ward et al., 1959). A conservative assumption is that 40 dB of TTS is an upper limit for reversibility and that any additional exposure will result in some PTS. This means that 40 dB of TTS essentially defines the onset of PTS. To estimate the exposure necessary to induce 40 dB of TTS (and thus PTS), TTS growth rates from marine and terrestrial mammals are used to estimate the additional exposure required to “grow” TTS from the onset value (6 dB of TTS) to the point of the onset of PTS (40 dB of TTS) — a 34 dB difference.

Data from Ward et al. (1958) reveal a linear relationship between TTS and SEL with growth rates of 1.5 to 1.6 dB TTS per dB increase in SEL. This value for the TTS growth rate is larger than those experimentally measured in a dolphin exposed to 3 and 20 kHz tones (Finneran and Schlundt, 2010), and so appears to be a protective value to use for cetaceans. The additional exposure above onset-TTS that is required to reach PTS is therefore 34 dB divided by 1.6 dB, or approximately 20 dB. For cetaceans, exposure to sonars and other active acoustics sources with an SEL 20 dB above that producing TTS may be assumed to produce a PTS. For example, an onset-TTS threshold of 195 dB re 1 μPa^2·s would have a corresponding onset-PTS threshold of 215 dB re 1 μPa^2·s. This extrapolation process is identical to that recently proposed by Southall et al. (2007).

Kastak et al. (2007) reported a TTS growth rate of 2.5 TTS per dB increase in SEL for a California sea lion. This growth rate results in a 14 dB difference between TTS onset and PTS onset. Since this results in a more protective approach, this value is used for all pinnipeds, not just the otariids. The same 14 dB difference is also used for the functional groups that utilize the same thresholds as the pinnipeds: the odobenids, mustelids, ursids, and sirenians..

2.4.3.1 LF Cetaceans

PTS onset for LF cetaceans is defined as the exposure 20 dB above TTS onset: a (Type II) weighted SEL of 198 dB re 1 μPa^2·s.

2.4.3.2 MF Cetaceans

PTS onset for MF cetaceans is defined as the exposure 20 dB above TTS onset: a (Type II) weighted SEL of 198 dB re 1 μPa^2·s.

2.4.3.3 HF Cetaceans

PTS onset for HF cetaceans is defined as the exposure 20 dB above TTS onset: a (Type II) weighted SEL of 172 dB re 1 μPa^2·s.

2.4.3.4 Phocids (in water)

PTS onset for phocids seals is defined as the exposure 14 dB above TTS onset: a (Type I) weighted SEL of 197 dB re 1 μPa^2·s.

2.4.3.5 Phocids (in air)

PTS onset for phocids seals is defined as the exposure 14 dB above TTS onset: a (Type I) weighted SEL of 145 dB re (20 μPa)^2·s.

2.4.3.6 Otariids and odobenids (in water)

PTS onset for otariids and odobenids is defined as the exposure 14 dB above TTS onset: a (Type I) weighted SEL of 220 dB re 1 μPa^2·s.

2.4.3.7 Otariids and odobenids (in air)

PTS onset for otariids and odobenids is defined as the exposure 14 dB above TTS onset: a (Type I) weighted SEL of 168 dB re (20 μPa)^2·s.

2.4.3.8 Mustelids

Based on the limited data available for sea otters and the similarities between these species and pinnipeds, the otariid PTS criteria and thresholds are used for mustelids: a (Type I) weighted SEL of 220 dB re 1 $\mu Pa^2 \cdot s$ in water and 168 dB re $(20\ \mu Pa)^2 \cdot s$ in-air.

2.4.3.9 Ursids

Based on the limited data available for polar bears and the similarities between these species and pinnipeds, the otariid PTS criteria and thresholds are used for polar bears: a (Type I) weighted SEL of 220 dB re 1 $\mu Pa^2 \cdot s$ in water and 168 dB re $(20\ \mu Pa)^2 \cdot s$ in-air.

2.4.3.10 Sirenians

Because the hearing ranges of the phocids and sirenians are roughly equivalent, the phocid PTS threshold (the lowest of any of the pinnipeds), is used for sirenians: a (Type I) weighted SEL of 197 dB re 1 $\mu Pa^2 \cdot s$.

2.4.4 Criteria and thresholds for behavioral effects

Marine animals are likely to exhibit any of a suite of potential behavioral responses or combinations of behavioral responses upon exposure to sonars and other active acoustic sources. Potential behavioral responses include, but are not limited to, avoiding exposure or continued exposure, behavioral disturbance (including distress or disruption of social or foraging activity), habituation to the sound, becoming sensitized to the sound, or not responding to the sound.

In Navy acoustic impact analyses, two types of criteria/thresholds are utilized to estimate behavioral effects of noise:

(1) In cases where a specific taxonomic group's behavioral responses to sound have been well documented, a single sound pressure level (SPL) threshold has been provided to predict the number of behavioral disturbances. As an example, for harbor porpoises (but not other HF cetaceans), a behavioral response threshold of 120 dB SPL (no weighting function) is used for sonars and other active acoustic sources because of the demonstrated high behavioral sensitivity of harbor porpoises to these types of sounds.

(2) For all other taxa, the likelihood of behavioral effects is based on a probabilistic function (termed a behavioral response function – BRF), that relates the likelihood (i.e, probability) of a behavioral response to the received SPL. The BRF is used to estimate the percentage of an exposed population that is likely to exhibit altered behaviors or behavioral disturbance at a given exposure SPL. The BRF relies on the assumption that sound poses a negligible risk to marine mammals if they are exposed to SPL below a certain "basement" value. Above the basement exposure SPL, the probability of a response increases with increasing SPL.

Two BRFs are used in Navy acoustic impact analyses: BRF_1 for LF cetaceans and BRF_2 for all other functional hearing groups (i.e., MF and HF cetaceans, pinnipeds, mustelids, ursids, and sirenians). The BRF functions are based on three sources of data: behavioral observations during TTS experiments conducted at the US Navy Marine Mammal Program (Finneran and Schlundt, 2004); reconstruction of sound fields produced by the USS Shoup associated with the behavioral responses of killer whales observed in Haro Strait (Department of the Navy, 2003; Fromm, 2009); and observations of the behavioral response of North Atlantic right whales exposed to alert stimuli containing mid-frequency components (Nowacek et al., 2004). For a detailed discussion of the derivation of the BRFs, see Department of the Navy (2008a).

The BRFs are calculated using:

$$R(L) = \frac{1 - \left(\frac{L-B}{K}\right)^{-A}}{1 - \left(\frac{L-B}{K}\right)^{-2A}}, \qquad (8)$$

where $R(L)$ is the probability of a response, L is the received SPL, and B and K are parameters that define the shape of the curve. For both BRFs, the "basement" parameter B = 120 dB re 1 μPa and the factor K = 45. For the BRF_1, A = 8; for BRF_2, A = 10. Both functions are illustrated in Fig. 7. Note that the received SPL is weighted using the Type I weighting functions when applying the BRFs.

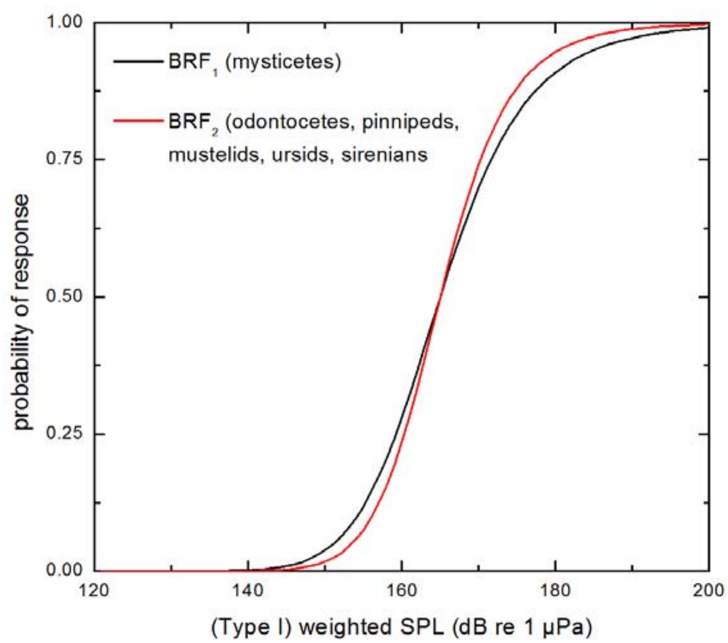

Figure 7. Navy Behavioral response functions (BRFs).

2.4.4.1 LF cetaceans

BRF_1 is used to assess behavioral effects from sonars and other active acoustic sources for all LF cetaceans. The LF cetacean Type I weighting function is used when determining the received SPL to use with the BRF.

2.4.4.2 MF cetaceans

To assess behavioral effects from sonars and other active acoustic sources to all MF cetaceans *except beaked whales*, BRF_2 is used, with the exposure weighted using the Type I weighting function for MF cetaceans.

Data obtained from *Mesoplodon densirostris* suggest greater responsiveness of beaked whales to a variety of sonars and active acoustic sources compared to other species exposed to the same or similar sounds (Tyack et al., 2011). For this reason, an (unweighted) SPL of 140 dB re 1µPa is used for beaked whales as a threshold to predict behavioral disturbance when exposed to sonars or other active acoustic sources.

2.4.4.3 HF cetaceans

To assess behavioral effects from sonars and other active acoustic sources to all HF cetaceans *except harbor porpoises*, BRF_2 is used, with the exposure weighted using the Type I weighting function for HF cetaceans.

For harbor porpoises, the information currently available suggests a very low threshold level of response for both captive and wild animals. Threshold levels at which both captive (Kastelein et al., 2005a; Kastelein et al., 2000) and wild harbor porpoises (Johnston, 2002) responded to sound (e.g. acoustic harassment devices, acoustic deterrent devices, or other non-impulsive sound sources) is very low (e.g. an SPL of approximately 120 dB re 1 µPa), although the biological significance of the disturbance is uncertain. Therefore, an (unweighted) SPL of 120 dB re 1µPa is used for harbor porpoises as a threshold to predict behavioral disturbance.

2.4.4.4 Phocids (in water)

To assess behavioral effects from sonars and other active acoustic sources to all phocids in water, BRF_2 is used, with the exposure weighted using the Type I weighting function for phocids.

2.4.4.5 Phocids (in air)

A number of investigators have studied pinniped reactions to rocket launches (Berg et al., 2004; Berg et al., 2002; Berg et al., 2001; Holst et al., 2005; Thorson et al., 2000a; b; Thorson et al., 1999; Thorson et al., 1998). In some cases severe reactions such as stampeding were recorded by pinnipeds exposed to rocket launch noise with SPLs of approximately 110–120 dB re 20 µPa. Distant rocket launches with received SPLs of approximately 60-70 dB re 20 µPa tended to be ignored by hauled-out pinnipeds. Southall et al. (2007) reviewed these studies and recommended an (unweighted) SEL of 100 dB re $(20\ \mu Pa)^2\cdot s$ as the threshold to predict effects to pinnipeds in air. Despite this threshold being based on reactions to launch noise, not sonars or other active acoustics, Navy uses this threshold as a protective measure for pinnipeds exposed to in-air acoustic sources. Therefore, the behavioral response threshold for phocids exposed to acoustic sources in-air is an (unweighted) SEL of 100 dB re (20 µPa)^2·s.

2.4.4.6 Otariids and odobenids (in water)

To assess behavioral effects from sonars and other active acoustic sources to all otariids and odobenids in water, BRF_2 is used, with the exposure weighted using the Type I weighting function for otariids.

2.4.4.7 Otariids and odobenids (in air)

Similar to phocids seals, the behavioral response threshold for otariids and odobenids exposed to acoustic sources in-air is an (unweighted) SEL of 100 dB re (20 µPa)^2·s.

2.4.4.8 Mustelids

Due to a lack of specific data regarding sea otter reactions to sound, and the phylogenetic and audiometric similarities between these amphibious carnivores and pinnipeds, the pinniped behavioral thresholds are also used to assess the potential behavioral effects to mustelids.

Therefore, to assess behavioral effects from in-water sonars and other active acoustic sources on sea otters, BRF_2 is used, with the exposure weighted using the Type I weighting function for mustelids. For in-air sounds, an (unweighted) SEL of 100 dB re (20 µPa)^2·s is used as a threshold for behavioral reactions in sea otters.

2.4.4.9 Ursids

Due to a lack of specific data regarding polar bear reactions to sound, and the phylogenetic and audiometric similarities between these amphibious carnivores and pinnipeds, the pinniped behavioral thresholds are also used to assess the potential behavioral effects to ursids.

Therefore, to assess behavioral effects from in-water sonars and other active acoustic sources on polar bears, BRF_2 is used, with the exposure weighted using the Type I weighting function for ursids. For in-air sounds, an (unweighted) SEL of 100 dB re (20 µPa)^2·s is used as a threshold for behavioral reactions in polar bears.

2.4.4.10 Sirenians

Due to a lack of specific data regarding sirenian reactions to sound, and the audiometric similarities between these animals and phocid pinnipeds, the phocid behavioral thresholds are also used to assess the potential behavioral effects to sirenians.

Therefore, to assess behavioral effects from in-water sonars and other active acoustic sources on sirenians (manatees and dugongs), BRF_2 is used, with the exposure weighted using the Type I weighting function for sirenians.

2.5 CRITERIA AND THRESHOLDS FOR EXPLOSIVE SOURCES

2.5.1 Introduction

Criteria and thresholds for predicting physical and behavioral effects to marine mammals exposed to underwater explosive detonations were initially developed for the U.S. Navy shock trials of the SEAWOLF submarine (Department of the Navy, 1998) and WINSTON S. CHURCHILL guided missile destroyer (Department of the Navy, 2001). After the SEAWOLF and CHURCHILL shock trials, additional data became available regarding the auditory effects of impulsive sounds, similar to underwater detonations, on marine mammals (e.g., Finneran, 2002). These data were incorporated into the analysis for the shock trial of the MESA VERDE amphibious transport dock ship (Department of the Navy, 2008b). The present US Navy criteria and thresholds for explosive sources follow the a similar approach to that used for the MESA VERDE acoustic impact analysis (Department of the Navy, 2008b).

Similarly to the criteria and thresholds for marine mammals exposed to sonars and other active acoustic sources, criteria and thresholds for explosive sources are divided into physiological effects and behavioral effects. Because of the increased hazardousness of the shock wave associated with underwater detonations, physiological effects not only include auditory effects (PTS and TTS), but also mortality and direct (i.e., non-auditory) tissue damage known as primary blast injury. Criteria and thresholds for physiological effects are presented in order of decreasing severity (i.e., mortality and most serious injuries first). These are followed by criteria and thresholds for PTS, TTS, and behavioral reactions for each functional hearing group. A summary of the various criteria and thresholds is provided in Appendix D.

2.5.2 Mortality and primary (non-auditory) blast injury

A considerable body of laboratory data exist on injuries from impulsive sound exposure, usually from explosive pulses, obtained from tests with a variety of lab animals (mice, rats, dogs, pigs, sheep and other species). Primary blast injuries from explosive detonations are the result of differential compression and rapid re-expansion of adjacent tissues of different acoustic properties (e.g., between gas-filled and fluid-filled tissues or between bone and soft tissues). These injuries usually manifest themselves in the gas-containing organs (lung and gut) and auditory structures (e.g., rupture of the eardrum across the gas-filled spaces of the outer and inner ear). This section describes criteria and thresholds for primary blast injury to non-auditory tissues such as the lungs and gastrointestinal (GI) tract.

2.5.2.1 Mortality

An analysis of potential mortality of submerged terrestrial mammals exposed to small explosive charges has been conducted and used to define Navy thresholds for mortality for marine mammals exposed to underwater detonations (U.S. Navy, 2001; Yelverton, 1981). These analyses found the most common injuries to submerged mammals exposed to underwater detonations to be hemorrhaging in the fine structure of the lungs, and that lung damage is governed by the magnitude of the acoustic impulse (the time integral of the instantaneous sound pressure) of the underwater blast, not the peak pressure or sound exposure level (Richmond et al., 1973; Yelverton, 1981; Yelverton et al., 1973; Yelverton et al., 1975). Therefore, Navy analyses use the value of the acoustic impulse to determine if mortality or slight lung injury occurs. This approach is consistent with other efforts to predict the effects of underwater detonations (Department of the Navy, 1998; 2001; 2008b).

Mortality thresholds resulting from studies of injuries to submerged terrestrial mammals exposed to underwater blasts were based on the occurrence of "extensive lung injury" resulting in "1% Mortality," defined as an exposure where most animals may have moderate blast injuries to the lungs but 99% would survive. The minimum acoustic impulse for predicting the onset of mortality (I_M) is defined as:

$$I_M(M,D) = 91.4M^{1/3}\left(1+\frac{D}{10.1}\right)^{1/2}, \qquad (9)$$

where M is the animal mass (kg), D is the animal depth (m), and the units of I_M are Pa·s. This equation is based on the Goertner injury model (Goertner, 1982), corrected for atmospheric and hydrostatic pressures and based on the cube root scaling of body mass (Richmond *et al.*, 1973; U.S. Navy, 2001). The impulse required for mortality is assumed to increase proportionally to the square root of the ratio of the combined atmospheric and hydrostatic pressures at a specific depth to the atmospheric pressure at the surface. The critical value is assumed to be delivered during a time period that is the lesser of the positive pressure duration, or 20% of the natural period of the assumed-spherical lung adjusted for the size and depth of the animal. As depth increases, the impulse delivery time decreases (Goertner, 1982).

The impact analyses completed for the SEAWOLF and CHURCHILL shock trials (Department of the Navy, 1998; 2001) and other Navy compliance documents used a single body mass, that of a dolphin calf (12.2 kg), to represent all marine mammals for the derivation of the mortality threshold; however, thresholds based on the mass of a dolphin calf may underestimate mortality in smaller marine mammals and may overestimate mortality in larger marine mammals. Species-specific masses are therefore used for determining mortality thresholds because they most closely represent effects to individual species. Table D-2, in Appendix D, provides a nominal body mass for each species based on newborn individuals, a protective approach since the impulse threshold is lower for smaller masses and only a small percentage of a marine mammal population would consist of newborns (i.e., most would be larger and therefore have a higher threshold for mortality). In some cases, body masses were not available for the listed species and were therefore extrapolated from similar species.

2.5.2.2 Slight lung injury

Thresholds for slight lung injury to marine mammals exposed to underwater blasts were based on the occurrence of "slight lung injury" resulting in "0% Mortality," defined as an exposure where most animals may have slight blast injuries to the lungs but all would survive. The minimum acoustic impulse for predicting the onset of slight lung injury (I_S) is defined as:

$$I_S(M,D) = 39.1M^{1/3}\left(1+\frac{D}{10.1}\right)^{1/2}, \quad (10)$$

where M is the animal mass (kg), D is the animal depth (m), and the units of I_S are Pa·s. This equation is based on the Goertner injury model (Goertner, 1982), corrected for atmospheric and hydrostatic pressures and based on the cube root scaling of body mass (Richmond *et al.*, 1973; U.S. Navy, 2001). The impulse required for a slight lung injury is assumed to increase proportionally to the square root of the ratio of the combined atmospheric and hydrostatic pressures at a specific depth to the atmospheric pressure at the surface. As with the mortality thresholds, species-specific masses (see Table D-2, in Appendix D) are used for determining thresholds for slight lung injury.

In-air mortality and slight lung injury criteria and thresholds for pinnipeds (i.e., otariids, phocids, and odobenids) were not developed. Navy explosive training and testing activities do not normally coincide with pinniped, polar bear, or sea otter terrestrial habitat and therefore exposure to explosive energy on land that could cause mortality and slight lung injury is unlikely.

2.5.2.3 GI tract injury

Slight injury to the GI tract appears to be better correlated with the peak sound pressure of the shock wave rather than the acoustic impulse and is independent of the animal's size and mass (Goertner, 1982). Slight contusions to the GI tract were reported during small charge tests (Richmond *et al.*, 1973), when the (unweighted) peak SPL was 237 dB re 1µPa, therefore an unweighted peak SPL of 237 dB re 1 µPa is used as a threshold for slight injury to the GI tract for all marine mammals exposed to underwater explosions.

In-air GI tract injury criteria and thresholds for pinnipeds (i.e., otariids, phocids, and odobenids) were not developed. Navy explosive training and testing activities do not normally coincide with pinniped, polar bear, or sea otter terrestrial habitat and therefore exposure to explosive energy on land that could cause GI tract injury is unlikely.

2.5.3 Auditory Effects (TTS and PTS)

Navy environmental analyses for auditory effects (TTS and PTS) from underwater detonations follow the approach proposed by Southall et al. (2007) and used in the MESA VERDE acoustic impact analysis (Department of the Navy, 2008b), where a weighted SEL threshold is used in conjunction with an unweighted peak SPL threshold. The threshold producing the greater range for effect is then used because it is the more protective of the dual thresholds. In most cases, a total weighted SEL is more conservative than the largest SEL in any single 1/3-octave band, which was used for some earlier ship shock trials (e.g., Department of the Navy, 2001). Type II weighting functions for each functional hearing group are used, when available, to determine the auditory effects of explosions. If a Type II weighting function is not available for a functional hearing group, the Type I function for the group is used.

SEL and peak SPL thresholds for TTS are based on TTS data from impulsive sound exposures when available. If impulsive TTS data are not available, but TTS data from non-impulsive exposures are available, the onset of TTS is estimated from the TTS onset for non-impulsive sound and the relationship between impulse and non-impulse TTS observed in dolphins and belugas. For those species for whom no TTS data exist, TTS onset thresholds are based on the most closely related species for whom TTS data exist.

Since marine mammal PTS data from impulsive noise exposures do not exist, onset-PTS levels for these animals are estimated by adding 15 dB to the SEL-based TTS threshold and adding 6 dB to the peak pressure based thresholds. These relationships were derived by Southall et al. (2007) from impulse noise TTS growth rates in chinchillas. The appropriate frequency weighting function (i.e., Type II when available, otherwise Type I) for each functional hearing group is applied when using the SEL-based thresholds to predict PTS. The peak SPL thresholds are not weighted.

The specific thresholds for TTS and PTS for each marine mammal functional hearing group are detailed below and summarized in Appendix D.

2.5.3.1 LF Cetaceans

No TTS data are available for LF cetaceans, so the MF cetacean TTS onset values are used for LF cetaceans as well. The dual TTS thresholds for LF cetaceans therefore consist of a (Type II) weighted SEL of 172 dB re 1 $\mu Pa^2 \cdot s$ and a peak SPL of 224 dB re 1 μPa.

The PTS thresholds for LF cetaceans consist of a total (Type II) weighted SEL of 187 dB re 1 $\mu Pa^2 \cdot s$ and a peak SPL of 230 dB re 1 μPa.

2.5.3.2 MF Cetaceans

The TTS onset thresholds for MF cetaceans are based on TTS data from a beluga exposed to an underwater impulse produced from a seismic watergun (Finneran et al., 2002). These thresholds were also recommended by Southall et al. (2007). The numeric thresholds for MF cetaceans consist of a (Type II) weighted SEL of 172 dB re 1 $\mu Pa^2 \cdot s$ and a peak SPL of 224 dB re 1 μPa.

The PTS thresholds for MF cetaceans consist of a total (Type II) weighted SEL of 187 dB re 1 $\mu Pa^2 \cdot s$ and a peak SPL of 230 dB re 1 μPa.

2.5.3.3 HF Cetaceans

The TTS onset thresholds for HF cetaceans are based on TTS data from a harbor porpoise exposed to an underwater impulse produced from a seismic airgun (Lucke *et al.*, 2009). The numeric thresholds for HF cetaceans consist of a (Type II) weighted SEL of 146 dB re 1 $\mu Pa^2 \cdot s$ and a peak SPL of 195 dB re 1 μPa are used for HF cetaceans.

The PTS thresholds for HF cetaceans consist of a (Type II) weighted SEL of 161 dB re 1 $\mu Pa^2 \cdot s$ and a peak SPL of 201 dB re 1 μPa.

2.5.3.4 Phocids (in water)

Criteria for predicting TTS in phocid seals exposed to underwater pulses were based on underwater TTS data from a harbor seal exposed to octave band noise (Kastak *et al.*, 2005) and the extrapolation procedures described by Southall et al. (2007). The resulting TTS threshold values are: a (Type I) weighted SEL of 177 dB re 1 μPa^2·s and a peak SPL of 212 dB re 1 μPa.

The PTS thresholds for phocid seals exposed to underwater explosives consist of a total (Type I) weighted SEL of 192 dB re 1 μPa^2·s and a peak SPL of 218 dB re 1 μPa.

2.5.3.5 Phocids (in air)

The only known data regarding TTS in pinnipeds exposed to in-air impulse noise are from an unpublished report [Bowles et al. (unpublished data), as cited by Southall et al. (2007)] of TTS in harbor seals exposed to simulated sonic booms. The report cites onset-TTS at a peak SPL of 143 dB re 20 μPa or 129 dB re (20 μPa)^2·s. Southall et al. 2007 also reported that Bowles tested other pinnipeds whose TTS thresholds were higher, but actual numeric thresholds were not reported. Based on the only available TTS data for pinnipeds exposed to in-air impulsive noise, TTS thresholds for phocid seals exposed to in-air blasts consist of a (Type I) weighted SEL of 129 dB re (20 μPa)^2·s and a peak SPL of 143 dB re 20 μPa.

The PTS thresholds for phocid seals exposed to in-air explosives consist of a (Type I) weighted SEL of 144 dB re (20 μPa)^2·s and a peak SPL of 149 dB re 20 μPa.

2.5.3.6 Otariids and odobenids (in water)

Criteria for predicting TTS in otariids and odobenids exposed to underwater pulses were based on underwater TTS data from a California sea lion exposed to octave band noise (Kastak *et al.*, 2005) and the extrapolation procedures described by Southall et al. (2007). The resulting threshold values are: a (Type I) weighted SEL of 200 dB re 1 μPa^2·s and a peak SPL of 212 dB re 1 μPa.

The PTS thresholds for otariids and odobenids exposed to underwater explosives consist of a (Type I) weighted SEL of 215 dB re 1 μPa^2·s and a peak SPL of 218 dB re 1 μPa.

2.5.3.7 Otariids and odobenids (in air)

Based on the only available TTS data for pinnipeds exposed to in-air impulsive noise [Bowles et al., as cited by Southall et al. (2007)], TTS thresholds for otariids and odobenids exposed to in-air blasts consist of a (Type I) weighted SEL of 129 dB re (20 μPa)^2·s and a peak SPL of 143 dB re 20 μPa.

The PTS thresholds for otariids and odobenids exposed to in-air explosives consist of a (Type I) weighted SEL of 144 dB re (20 μPa)^2·s and a peak SPL of 149 dB re 20 μPa.

2.5.3.8 Mustelids

The explosive TTS and PTS thresholds for otariids are also used for sea otters because of the close taxonomic relationships and the similarities between audiograms. Therefore, for underwater exposures, the TTS threshold values for explosives consist of a (Type I) weighted

SEL of 200 dB re 1 µPa^2·s and a peak SPL of 212 dB re 1 µPa. For in-air exposures, a (Type I) weighted SEL of 129 dB re (20 µPa)^2·s and a peak SPL of 143 dB re 20 µPa are used.

The PTS threshold values for mustelids exposed to underwater explosives consist of a (Type I) weighted SEL of 215 dB re 1 µPa^2·s and a peak SPL of 218 dB re 1 µPa. For in-air exposures, mustelid PTS thresholds consist of a (Type I) weighted SEL of 144 dB re (20 µPa)^2·s and a peak SPL of 149 dB re 20 µPa.

2.5.3.9 Ursids

The explosive TTS and PTS thresholds for otariids are also used for polar bears because of the close taxonomic relationships and the similarities between audiograms. Therefore, for underwater exposures, the TTS threshold values for explosives consist of a (Type I) weighted SEL of 200 dB re 1 µPa^2·s and a peak SPL of 212 dB re 1 µPa. For in-air exposures, a (Type I) weighted SEL of 129 dB re (20 µPa)^2·s and a peak SPL of 143 dB re 20 µPa are used.

Similarly, the PTS threshold values for ursids exposed to underwater explosives consist of a (Type I) weighted SEL of 215 dB re 1 µPa^2·s and a peak SPL of 218 dB re 1 µPa. For in-air exposures, ursid PTS thresholds consist of a (Type I) weighted SEL of 144 dB re (20 µPa)^2·s and a peak SPL of 149 dB re 20 µPa.

2.5.3.10 Sirenians

The explosive TTS and PTS thresholds for phocid seals are also used for sirenians because of the similarities between the hearing ranges of phocids and manatees/dugongs. Therefore, for underwater exposures, the TTS threshold values for explosives consist of a (Type I) weighted SEL of 177 dB re 1 µPa^2·s and a peak SPL of 212 dB re 1 µPa.

The PTS thresholds for sirenians exposed to underwater explosives consist of a total (Type I) weighted SEL of 192 dB re 1 µPa^2·s and a peak SPL of 218 dB re 1 µPa.

2.5.4 Behavioral Effects

For single detonations, behavioral disturbance is likely to be limited to a short-lived startle reaction; therefore, Navy does not use any unique behavioral disturbance thresholds for marine mammals exposed to single explosive events.

For multiple, successive detonations (i.e., detonations happening at the same location within a 24-hour period), the threshold for behavioral disturbance is set 5 dB below the SEL-based TTS threshold, unless there are species or group specific data indicating that a lower threshold should be used. This is based on observations of behavioral reactions in captive dolphins and belugas occurring at exposure levels ~ 5 dB below those causing TTS after exposure to pure tones (Finneran and Schlundt, 2004; Schlundt *et al.*, 2000). The appropriate frequency weighting function (i.e., Type II when available, otherwise Type I) for each functional hearing group is applied when using the SEL-based disturbance thresholds.

The specific behavioral disturbance thresholds for the marine mammal functional hearing groups are detailed below and summarized in Appendix D.

2.5.4.1 LF Cetaceans

Specific data are lacking on the levels of sound that may illicit a behavioral reaction in LF cetaceans. Therefore, the disturbance threshold for LF cetaceans exposed to multiple, successive detonations is the TTS SEL-based threshold minus 5 dB: a (Type II) weighted SEL of 167 dB re 1 $\mu Pa^2 \cdot s$.

2.5.4.2 MF Cetaceans

The disturbance threshold for MF cetaceans exposed to multiple, successive detonations is a (Type II) weighted SEL of 167 dB re 1 $\mu Pa^2 \cdot s$, based on observations of behavioral reactions in captive dolphins and belugas occurring at exposure levels ~ 5 dB below those causing TTS after exposure to pure tones (Finneran and Schlundt, 2004; Schlundt *et al.*, 2000).

2.5.4.3 HF Cetaceans

Specific data are lacking on the levels of sound that may illicit a behavioral reaction in HF cetaceans. Therefore, the disturbance threshold for HF cetaceans exposed to multiple, successive detonations is the TTS SEL-based threshold minus 5 dB: a (Type II) weighted SEL of 141 dB re 1 $\mu Pa^2 \cdot s$.

2.5.4.4 Phocids (in water)

Specific data are lacking on the levels of sound that may illicit a behavioral reaction in phocid seals. Therefore, the disturbance threshold for phocids exposed to multiple, successive detonations is the TTS SEL-based threshold minus 5 dB: a (Type I) weighted SEL of 172 dB re 1 $\mu Pa^2 \cdot s$.

2.5.4.5 Phocids (in air)

As described in Section 2.4.4.5, a (Type I) weighted SEL of 100 dB re $(20\ \mu Pa)^2 \cdot s$ as the behavioral disturbance threshold for phocids exposed to multiple, successive, in-air blasts.

2.5.4.6 Otariids/odobenids (in water)

As with the phocids, the Navy the disturbance threshold for otariids and odobenids exposed to multiple, successive underwater detonations is the TTS SEL-based threshold minus 5 dB: a (Type I) weighted SEL of 195 dB re 1 $\mu Pa^2 \cdot s$.

2.5.4.7 Otariids/odobenids (in air)

As with the phocids, the Navy thresholds for otariids/odobenids exposed to multiple, successive explosive detonations in-air follows the Southall et al. (2007) recommendations: a (Type I) weighted SEL of 100 dB re $(20\ \mu Pa)^2 \cdot s$.

2.5.4.8 Mustelids

Specific data are lacking on the levels of sound that may illicit a behavioral reaction in sea otters. In light of the close taxonomic relationships and the similarities between the audiograms of otariids and mustelids, the behavioral disturbance thresholds for otariids exposed to multiple detonations are also used for sea otters. Therefore, the Navy the disturbance threshold for mustelids exposed to multiple, successive underwater detonations is a (Type I) weighted SEL of 195 dB re 1 $\mu Pa^2 \cdot s$.

For in-air exposures, the disturbance thresholds for mustelids exposed to multiple, successive explosive detonations consists of a (Type I) weighted SEL of 100 dB re (20 μPa)^2·s.

2.5.4.9 Ursids

Specific data are lacking on the levels of sound that may illicit a behavioral reaction in polar bears. In light of the close taxonomic relationships and the similarities between the audiograms of otariids and ursids, the behavioral disturbance thresholds for otariids are also used for polar bears. Therefore, the Navy the disturbance threshold for ursids exposed to multiple, successive underwater detonations is a (Type I) weighted SEL of 195 dB re 1 μPa^2·s.

For in-air exposures, the disturbance thresholds for ursids exposed to multiple, successive explosive detonations consists of a (Type I) weighted SEL of 100 dB re (20 μPa)^2·s.

2.5.4.10 Sirenians

The behavioral disturbance thresholds for phocid seals exposed to multiple, successive detonations are also used for sirenians because of the similarities between the hearing ranges of phocids and manatees/dugongs. Therefore, the disturbance threshold for sirenians exposed to multiple, successive detonations consists of a (Type I) weighted SEL of 172 dB re 1 μPa^2·s.

3 CRITERIA AND THRESHOLDS FOR SEA TURTLES

3.1 INTRODUCTION

The criteria and thresholds for sea turtles are similar to those proposed by Southall et al. (2007) for marine mammals: All sea turtles are placed into a single functional hearing group, and an auditory weighting function is used to emphasize frequencies where sensitivity to noise is high and de-emphasize frequencies where sensitivity is low. Individual criteria and thresholds are defined for sonars and other active acoustic sources and explosives.

3.2 FUNCTIONAL HEARING GROUP

To facilitate the acoustic and explosive effects analyses, animals are divided into functional hearing groups, and the same criteria and thresholds used for all species within a group. Several studies using green, loggerhead, and Kemp's ridley turtles suggest sea turtles are most sensitive to low-frequency sounds (Bartol and Ketten, 2006; Bartol et al., 1999; Lenhardt, 1994; Ridgway et al., 1969). Although hearing sensitivity varies slightly by species and age class, because of the similarities across the available data, all sea turtles are placed into a single functional hearing group.

3.3 AUDITORY WEIGHTING FUNCTION

Auditory weighting functions are used to emphasize frequencies where sensitivity to noise is high and to de-emphasize frequencies where sensitivity is low. The weighted noise levels at each frequency are then combined to generate a single, weighted exposure value. This technique allows the use of a single, weighted threshold value, regardless of the noise frequency.

For humans, weighting functions are based on subjective loudness data. Analogous data for dolphins was used to derive the Type II weighting functions for MF cetaceans, and by extrapolation, for the other cetaceans. For the other marine mammal functional groups, only Type I weighting functions, based on functional hearing limits, are used. Since there are no equal loudness data for sea turtles and the differences between turtles and cetaceans preclude extrapolation to derive a Type II function for turtles, only a Type I weighting function is used for sea turtles.

The sea turtle weighting function amplitude is calculated using Eq. (4). The parameters for the weighting function are provided in Table 5; these are based on the functional hearing range for sea turtles of approximately 100 Hz to 1 kHz, with an upper frequency limit of 2 kHz (Bartol and Ketten, 2006; Bartol *et al.*, 1999; Lenhardt, 1994; Ridgway *et al.*, 1969). Figure 8 shows the sea turtle weighting function. The sea turtle (Type I) weighting function is used with all sea turtle SEL-based thresholds.

Table 5. Parameters for the Navy sea turtle (Type I) weighting function.

Functional Hearing Group	*K*	*a* (Hz)	*b* (Hz)
Sea turtles	0	10	2,000

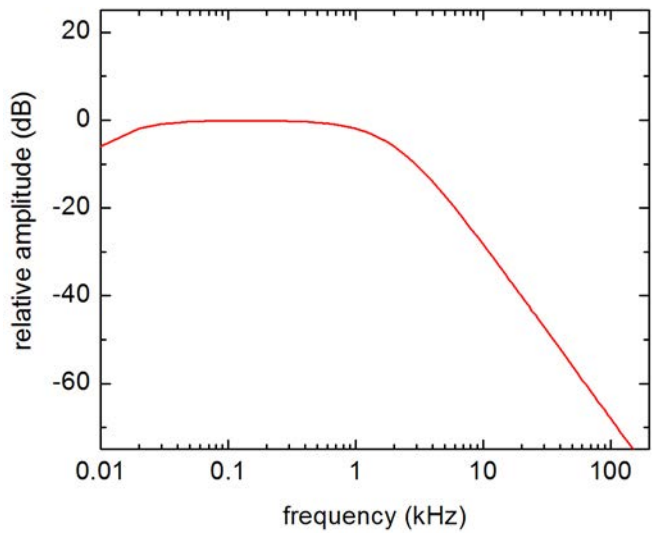

Figure 8. Auditory weighting function for sea turtles.

3.4 CRITERIA AND THRESHOLDS FOR SONARS AND OTHER ACTIVE ACOUSTIC SOURCES

3.4.1 Introduction

Criteria for sea turtles exposed to sonars and other active acoustic sources are divided into physiological effects and behavioral effects. Physiological effects criteria and thresholds are based on temporary and permanent threshold shift (TTS and PTS). Behavioral thresholds are based on experimental and observational data documenting the reactions of sea turtles to sound. A summary of the various criteria/thresholds and the sea turtle weighting function is provided in Appendix C.

3.4.2 Criteria and thresholds for TTS

To date, no known data are available on potential hearing impairments (i.e., TTS and PTS) in aquatic turtles. Sea turtles, based on their auditory anatomy (Bartol and Musick, 2003; Lenhardt et al., 1985; Wartzok and Ketten, 1999; Wever, 1978; Wyneken, 2001), are believed to have lower absolute sensitivity (i.e., higher thresholds) compared to cetaceans. Because of this, and the lack of data specific to sea turtles, previous Navy environmental analyses (e.g., Department of the Navy, 1998; 2001; 2008b), used the cetacean TTS threshold to define the sea turtle threshold. Since sea turtles have best sensitivity at low frequencies, similar to the LF cetaceans, the LF cetacean TTS threshold is applied to sea turtles. Therefore, the TTS threshold for sea turtles exposed to sonars and other active acoustic sources is a (Type I) weighted SEL of 178 dB re 1 $\mu Pa^2 \cdot s$.

3.4.3 Criteria and thresholds for PTS

As with the marine mammals, the PTS threshold for sea turtles exposed to sonars and other active acoustic sources is estimated as being 20 dB above the TTS threshold. This results in a PTS threshold consisting of a (Type I) weighted SEL of 198 dB re 1 $\mu Pa^2 \cdot s$.

3.4.4 Criteria and thresholds for behavioral effects

Potential behavioral changes could include a startle reaction, avoiding the sound source, increased swimming speed, increased surfacing time, and decreased foraging. No known studies have examined the reactions of sea turtles to sonars or other active acoustic sources. However, several studies have investigated the behavioral responses of sea turtles to impulsive sounds produced by seismic airguns. O’Hara and Wilcox (1990) reported that loggerhead turtles kept in a 300 × 45 m enclosure in a 10 m deep canal maintained a standoff range of 30 m from three small airguns fired simultaneously at 15-s internals (O'Hara and Wilcox, 1990). Although O’Hara and Wilcox did not report the actual received sound levels, McCauley et al. (2000) have estimated the received SPL for avoidance to be 175–176 dB re 1 μPa.

Moein et al. (1994) investigated the use of airguns to repel juvenile loggerhead sea turtles from hopper dredges. The results from all turtles tested (11 individuals, six trials each) indicated avoidance was seen during the first presentation of the air gun exposure at a mean range of 24 m; however, details of the airgun, its operational pressure, deployment depth, and the sound levels received by the turtles throughout the cage were not provided.

McCauley et al. (2000) measured behavioral responses in captive green and loggerhead turtles exposed to airgun impulses. The results showed that above a received SPL of 166 dB re 1 μPa the turtles noticeably increased their swimming activity compared to non airgun operation periods. Above 175 dB re 1 μPa, behavior became more erratic possibly indicating the turtles were in an agitated state (McCauley *et al.*, 2000). The authors noted that the point at which the turtles showed the more erratic behavior would be expected to approximately equal the point at which avoidance would occur for unrestrained turtles (McCauley *et al.*, 2000).

Cumulatively, these studies indicate that behavioral disturbance may occur in sea turtles exposed to impulsive noise with SPLs greater than 166 dB re 1 μPa and that more erratic behavior and avoidance may begin at SPLs of 175–179 dB re 1 μPa, with 175 dB re 1 μPa more likely to be the point at which avoidance may occur in unrestrained turtles (McCauley *et al.*, 2000). Navy effects analyses use the lower range of SPLs that caused avoidance as the behavioral disturbance threshold for sea turtles: a (Type I) weighted SPL of 175 dB re 1 μPa.

3.5 CRITERIA AND THRESHOLDS FOR EXPLOSIVE SOURCES

3.5.1 Introduction

Similarly to the marine mammal criteria and thresholds for sonars and other active acoustic exposures, criteria and thresholds for explosive sources are divided into physiological effects and behavioral effects. Because of the increased hazardousness of the shock wave associated with underwater detonations, physiological effects not only include auditory effects (PTS and TTS), but also mortality and direct (i.e., non-auditory) tissue damage known as primary blast injury. Criteria and thresholds for physiological effects are presented in order of decreasing severity (i.e., mortality and most serious injuries first). These are followed by criteria and thresholds for PTS, TTS, and behavioral reactions. A summary of the various criteria and thresholds is provided in Appendix D.

3.5.2 Mortality and primary (non-auditory) blast injury

Very little information exists regarding the impacts of underwater detonations on sea turtles. Impacts to sea turtles from explosive removal operations have ranged from non-injurious effects (e.g., acoustic annoyance, mild tactile detection or physical discomfort) to varying levels of injury (i.e., non-lethal and lethal injuries). Often, effects of explosive events on turtles must be inferred from documented effects to other vertebrates with lungs or other-gas containing organs, such as mammals and fish (Viada et al., 2008). As with marine mammals, primary blast injury almost exclusively affects the gas-containing organs: the lung and the ear. For this reason, the general principles of the Goertner injury model are applicable; however, since it is not known what degree of protection from a shock wave is provided by a turtle's shell, application of the Goertner injury model is believed to be protective (Viada *et al.*, 2008). Therefore, Eqs. (9) and (10) are used to calculate the mortality and slight lung injury thresholds, respectively, for sea turtles exposed to underwater detonations. Sea turtle body masses for use in Eqs. (9) and (10) are provided in Table D-2, in Appendix D. Since sea turtle hatchlings can weigh less than 0.5% of their adult mass, juvenile masses are used to avoid greatly over-estimating the potential effects of detonations.

Although the lungs and auditory system are considered to be the most likely site of injury to sea turtles exposed to underwater detonations, as a protective measure, the GI tract injury threshold used for marine mammals is also applied to sea turtles: an (unweighted) SPL of 237 dB re 1 μPa.

3.5.3 Auditory Effects (TTS and PTS)

No data exist to correlate the sensitivity of the sea turtle tympanum and middle and inner ear to trauma associated with the shock waves associated with underwater explosions (Viada *et al.*, 2008). Thus, similar to the turtle sonar and other active acoustic thresholds, sea turtle thresholds for TTS and PTS after exposure to underwater detonations are identical to the values for LF cetaceans.

Therefore, the dual TTS thresholds for sea turtles consist of a (Type I) weighted SEL of 172 dB re 1 $\mu Pa^2 \cdot s$ and a peak SPL of 224 dB re 1 μPa.

The PTS thresholds for sea turtles consist of a (Type I) weighted SEL of 187 dB re 1 μPa^2·s and a peak SPL of 230 dB re 1 μPa.

3.5.4 Behavioral Effects

As discussed in Section 3.4.4, several authors have investigated the behavioral responses of sea turtles to impulsive sounds produced by airguns (McCauley et al., 2000; Moein et al., 1994; O'Hara and Wilcox, 1990). Cumulatively, these studies indicate that a behavioral reaction to a sound may occur with SPLs greater than 166 dB re 1 μPa, and that more erratic behavior and avoidance, which may be indicative of a behavioral disturbance in wild animals, may occur at SPLs of 175–179 dB re 1 μPa. McCauley et al. determined that these SPLs would result in an SEL 11.4–14.6 dB lower than the SPL. For an SPL of 175 dB re 1 μPa, the comparable SEL would therefore be 163.6–160.4 dB re 1 μPa^2·s.

For Navy environmental documents, the sea turtle behavioral disturbance threshold after exposure to multiple, successive underwater impulses therefore consists of a (Type I) weighted SEL of 160 dB re 1 μPa^2·s.

APPENDIX A. FUNCTIONAL HEARING GROUPS

Table A-1. Functional hearing groups used in Navy acoustic impact analyses.

Functional Hearing Group	Description
LF cetaceans	Suborder Mysticeti (baleen whales)
MF cetaceans	Family Ziphiidae (beaked whales) Family Physeteridae (Sperm whale) Family Monodontidae (Irrawaddy dolphin, beluga, narwhal) Subfamily Delphininae (white-beaked/white-sided/ Risso's/bottlenose/spotted/spinner/striped/common dolphins) Subfamily Steninae (rough-toothed/humpback dolphins) Subfamily Globicephalinae (melon-headed whales, false/pygmy killer whale, killer whale, pilot whales) Subfamily Lissodelphinae (right whale dolphins)
HF cetaceans	Family Phocoenidae (porpoises) Family Platanistidae (Indus/Ganges river dolphins) Family Iniidae (Amazon river dolphins) Family Pontoporiidae (Baiji/ La Plata river dolphins) Family Kogiidae (Pygmy/dwarf sperm whales) Subfamily Cephalorhynchinae (Commersen's, Black, Heaviside's, Hector's dolphins)
Phocids	Family Phocidae (earless seals)
Otariids and Odobenids	Family Otaridae (fur seals/sea lions) Family Odobenidae (walrus)
Mustelids	Family Mustelidae (sea otters)
Ursids	Family Ursidae (polar bears)
Sirenians	Order Sirenia (mantees/dugongs)
Sea turtles	Family Cheloniidae (loggerhead, green, hawksbill, Kemp's ridley, olive ridley, flatback sea turtle) Family Dermochelyidae (leatherback sea turtle)

APPENDIX B. AUDITORY WEIGHTING FUNCTIONS

B.1 TYPE I WEIGHTING FUNCTIONS

$$W_I(f) = K + 20\log_{10}\left[\frac{b^2 f^2}{(a^2 + f^2)(b^2 + f^2)}\right] \tag{B-1}$$

$W_I(f)$ weighting function amplitude (dB)

f sound frequency (Hz)

a lower cutoff frequency (Table B-1)

b upper cutoff frequency (Table B-1)

K gain (Table B-1)

Table B-1. Parameters for the Navy Type I weighting functions.

Functional Hearing Group	*K* (dB)	*a* (Hz)	*b* (Hz)
LF cetaceans	0	7	22,000
MF cetaceans	0	150	160,000
HF cetaceans	0	200	180,000
Phocids (in water), Sirenians	0	75	75,000
Phocids (in air)	0	75	30,000
Otariids, Odobenids, Mustelids, Ursids (in water)	0	100	40,000
Otariids, Odobenids, Mustelids, Ursids (in air)	0	100	30,000
Sea turtles	0	10	2,000

B.2 TYPE II WEIGHTING FUNCTIONS

$$W_{II}(f) = \text{maximum}\{G_1(f), G_2(f)\}, \quad \text{(B-2)}$$

$W_{II}(f)$ weighting function amplitude (dB)

f sound frequency (Hz)

$$G_1(f) = K_1 + 20\log_{10}\left[\frac{b_1^2 f^2}{(a_1^2 + f^2)(b_1^2 + f^2)}\right] \quad \text{(B-3)}$$

$G_1(f)$ amplitude of Type I function component (dB)

a_1 Type I component lower cutoff frequency (Table B-2)

b_1 Type I component upper cutoff frequency (Table B-2)

K_1 Type I component gain (Table B-2)

$$G_2(f) = K_2 + 20\log_{10}\left[\frac{b_2^2 f^2}{(a_2^2 + f^2)(b_2^2 + f^2)}\right] \quad \text{(B-4)}$$

$G_2(f)$ amplitude of EQL function component (dB)

a_2 EQL component lower cutoff frequency (Table B-2)

b_2 EQL component upper cutoff frequency (Table B-2)

K_2 EQL component gain (Table B-2)

Table B-2. Parameters for the Navy (cetacean) Type II weighting functions.

Functional Hearing Group	K_1 (dB)	a_1 (Hz)	b_1 (Hz)	K_2 (dB)	a_2 (Hz)	b_2 (Hz)	Inflection point (Hz)
LF cetaceans	-16.5	7	22,000	0.9	674	12,130	267
MF cetaceans	-16.5	150	160,000	1.4	7,829	95,520	3,000
HF cetaceans	-19.4	200	180,000	1.4	9,480	108,820	3,000

APPENDIX C. CRITERIA AND THRESHOLDS FOR SONARS AND OTHER ACTIVE ACOUSTIC SOURCES

Table C-1. Navy criteria and thresholds for marine mammals and sea turtles exposed to sonars and other active acoustic sources

Functional Hearing Group or Species	PTS Threshold (all weighted SEL)	TTS Threshold (all weighted SEL)	Behavioral Threshold
LF Cetaceans	(Type II) SEL: 198 dB re 1 μPa^2·s	(Type II) SEL: 178 dB re 1 μPa^2·s	(Type I) SPL: BRF_1
MF Cetaceans (*except beaked whales*)	(Type II) SEL: 198 dB re 1 μPa^2·s	(Type II) SEL: 178 dB re 1 μPa^2·s	(Type I) SPL: BRF_2
Beaked whales	(Type II) SEL: 198 dB re 1 μPa^2·s	(Type II) SEL: 178 dB re 1 μPa^2·s	(unweighted) SPL: 140 dB re 1 μPa
HF Cetaceans (*except harbor porpoises*)	(Type II) SEL: 172 dB re 1 μPa^2·s	(Type II) SEL: 152 dB re 1 μPa^2·s	(Type I) SPL: BRF_2
Harbor porpoises	(Type II) SEL: 172 dB re 1 μPa^2·s	(Type II) SEL: 152 dB re 1 μPa^2·s	(unweighted) SPL: 120 dB re 1 μPa
Phocids Sirenians (in water)	(Type I) SEL: 197 dB re 1 μPa^2·s	(Type I) SEL: 183 dB re 1 μPa^2·s	(Type I) SPL: BRF_2
Phocids (in air)	(Type I) SEL: 145 dB re (20 μPa)^2·s	(Type I) SEL: 131 dB re (20 μPa)^2·s	(unweighted) SEL: 100 dB re (20 μPa)^2·s
Otariids Odobenids Mustelids Ursids (in water)	(Type I) SEL: 220 dB re 1 μPa^2·s	(Type I) SEL: 206 dB re 1 μPa^2·s	(Type I) SPL: BRF_2
Otariids Odobenids Mustelids Ursids (in air)	(Type I) SEL: 168 dB re (20 μPa)^2·s	(Type I) SEL: 154 dB re (20 μPa)^2·s	(unweighted) SEL: 100 dB re (20 μPa)^2·s
Sea Turtles	(Type I) SEL: 198 dB re 1 μPa^2·s	(Type I) SEL: 178 dB re 1 μPa^2·s	(Type I) SPL: 175 dB re 1 μPa

APPENDIX D. CRITERIA AND THRESHOLDS FOR EXPLOSIVES

Table D-1. Navy criteria and thresholds for marine mammals and sea turtles exposed to explosive detonations.

Functional Hearing Group or Species	Mortality	Slight Lung Injury	GI tract injury	PTS Threshold	TTS Threshold	Behavioral Threshold
LF Cetaceans	Modified Goertner model, Eq. (D-1) Mass from Table D-2	Modified Goertner model, Eq. (D-2) Mass from Table D-2	(unweighted) SPL: 237 dB re 1 μPa	(Type II) SEL: 187 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 230 dB re 1 μPa	(Type II) SEL: 172 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 224 dB re 1 μPa	(Type II) SEL: 167 dB re 1 $\mu Pa^2 \cdot s$
MF Cetaceans	Modified Goertner model, Eq. (D-1) Mass from Table D-2	Modified Goertner model, Eq. (D-2) Mass from Table D-2	(unweighted) SPL: 237 dB re 1 μPa	(Type II) SEL: 187 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 230 dB re 1 μPa	(Type II) SEL: 172 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 224 dB re 1 μPa	(Type II) SEL: 167 dB re 1 $\mu Pa^2 \cdot s$
HF Cetaceans	Modified Goertner model, Eq. (D-1) Mass from Table D-2	Modified Goertner model, Eq. (D-2) Mass from Table D-2	(unweighted) SPL: 237 dB re 1 μPa	(Type II) SEL: 161 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 201 dB re 1 μPa	(Type II) SEL: 146 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 195 dB re 1 μPa	(Type II) SEL: 141 dB re 1 $\mu Pa^2 \cdot s$
Phocids Sirenians (in water)	Modified Goertner model, Eq. (D-1) Mass from Table D-2	Modified Goertner model, Eq. (D-2) Mass from Table D-2	(unweighted) SPL: 237 dB re 1 μPa	(Type I) SEL: 192 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 218 dB re 1 μPa	(Type I) SEL: 177 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) peak SPL: 212 dB re 1 μPa	(Type I) SEL: 172 dB re 1 $\mu Pa^2 \cdot s$

Functional Hearing Group or Species	Mortality	Slight Lung Injury	GI tract injury	PTS Threshold	TTS Threshold	Behavioral Threshold
Phocids (in air)	See Note 1	See Note 1	See Note 1	(Type I) SEL: 144 dB re (20 µPa)^2·s (unweighted) peak SPL: 149 dB re 20 µPa	(Type I) SEL: 129 dB re (20 µPa)^2·s (unweighted) peak SPL: 143 dB re 20 µPa	(Type I) SEL: 100 dB re (20 µPa)^2·s
Otariids Odobenids Mustelids Ursids (in water)	Modified Goertner model, Eq. (D-1) Mass from Table D-2	Modified Goertner model, Eq. (D-2) Mass from Table D-2	(unweighted) SPL: 237 dB re 1 µPa	(Type I) SEL: 215 dB re 1 µPa^2·s (unweighted) peak SPL: 218 dB re 1 µPa	(Type I) SEL: 200 dB re 1 µPa^2·s (unweighted) peak SPL: 212 dB re 1 µPa	(Type I) SEL: 195 dB re 1 µPa^2·s
Otariids Odobenids Mustelids Ursids (in air)	See Note 1	See Note 1	See Note 1	(Type I) SEL: 144 dB re (20 µPa)^2·s (unweighted) peak SPL: 149 dB re 20 µPa	(Type I) SEL: 129 dB re (20 µPa)^2·s (unweighted) peak SPL: 143 dB re 20 µPa	(Type I) SEL: 100 dB re (20 µPa)^2·s
Sea Turtles	Modified Goertner model, Eq. (D-1) Mass from Table D-2	Modified Goertner model, Eq. (D-2) Mass from Table D-2	(unweighted) SPL: 237 dB re 1 µPa	(Type I) SEL: 187 dB re 1 µPa^2·s (unweighted) peak SPL: 230 dB re 1 µPa	(Type I) SEL: 172 dB re 1 µPa^2·s (unweighted) peak SPL: 224 dB re 1 µPa	(Type I) SEL: 160 dB re 1 µPa^2·s

1 - In-air GI tract injury, slight lung injury, and mortality criteria and thresholds for pinnipeds (i.e., otariids, phocids, and odobenids) were not developed. Navy explosive training and testing activities do not normally coincide with pinniped, polar bear, or sea otter terrestrial habitat and therefore exposure to explosive energy on land that could cause these injuries is unlikely.

$$I_M(M,D) = 91.4 M^{1/3}\left(1+\frac{D}{10.1}\right)^{1/2} \qquad \text{(D-1)}$$

$I_M(M,D)$	mortality threshold, expressed in terms of acoustic impulse (Pa·s)
M	Animal mass (Table D-1)
D	Water depth (m)

$$I_S(M,D) = 39.1 M^{1/3}\left(1+\frac{D}{10.1}\right)^{1/2} \qquad \text{(D-2)}$$

$I_S(M,D)$	slight lung injury threshold, expressed in terms of acoustic impulse (Pa·s)
M	Animal mass (Table D-1)
D	Water depth (m)

Table D-2. Representative animal masses for use in Eqs. (D-1) and (D-2).

Species Name	Common Name	Newborn Calf / Pup Mass (kg)	Reference
Cetaceans			
Family Balaenidae			
Eubalaena glacialis	North Atlantic right whale	910	Reeves et al. (2002)
Eubalaena japonica	North Pacific right whale	910	Reeves et al. (2002)
Family Balaenopteridae			
Balaenoptera acutorostrata	Minke whale	200	Mann et al. (2000)
Balaenoptera borealis	Sei whale	650	Gambell (1985)
Balaenoptera edeni	Bryde's whale	680	Reeves et al. (2002)
Balaenoptera musculus	Blue whale	2,000	Reidenberg and Laitman (2002)
Balaenoptera physalus	Fin whale	1,750	Reidenberg and Laitman (2002)
Megaptera novaeangliae	Humpback whale	680	Reeves et al. (2002)
Family Delphinidae			
Delphinus capensis	Long-beaked common dolphin	7	Surrogate: striped dolphin
Delphinus delphis	Short-beaked common dolphin	7	Surrogate: striped dolphin
Feresa attenuata	Pygmy killer whale	7	Surrogate: striped dolphin
Globicephala macrorhynchus	Short-finned pilot whale	37	Reeves et al. (2002)
Globicephala melas	Long-finned pilot whale	70	Reidenberg and Laitman (2002)
Grampus griseus	Risso's dolphin	47	Nachtigall et al. (2005)
Lagenodelphis hosei	Fraser's dolphin	19	Reeves et al. (2002)
Lagenorhynchus acutus	Atlantic white-sided dolphin	20	Reeves et al. (2002)
Lagenorhynchus albirostris	White-beaked dolphin	40	Reidenberg and Laitman (2002)
Lagenorhynchus obliquidens	Pacific white-sided dolphin	12	Heise (1997)
Lissodelphis borealis	Northern right whale dolphin	15	Surrogate: bottlenose dolphin/melon-headed whale
Orcinus orca	Killer whale	160	Reeves et al. (2002)
Peponocephala electra	Melon-headed whale	15	Reeves et al. (2002)
Pseudorca crassidens	False killer whale	80	Mann et al. (2000)
Stenella attenuata	Pantropical spotted dolphin	7	Surrogate: striped dolphin
Stenella clymene	Clymene dolphin	7	Surrogate: striped dolphin
Stenella coeruleoalba	Striped dolphin	7	Reeves et al. (2002)
Stenella frontalis	Atlantic spotted dolphin	7	Surrogate: striped dolphin
Stenella longirostris	Spinner dolphin	7	Surrogate: striped dolphin
Steno bredanensis	Rough-toothed dolphin	14	Surrogate: humpbacked dolphin
Tursiops aduncus	Indo-Pacific bottlenose dolphin	9	Reeves et al. (2002)
Tursiops truncatus	Common bottlenose dolphin	14	Reeves et al. (2002)
Family Eschrisctiidae			

Species Name	Common Name	Newborn Calf / Pup Mass (kg)	Reference
Eschrichtius robustus	Gray whale	500	Reidenberg and Laitman (2002)
Family Kogiidae			
Kogia breviceps	Pygmy sperm whale	23	Reeves et al. (2002)
Kogia sima	Dwarf sperm whale	14	Plön (2004)
Family Monodontidae			
Delphinapterus leucas	Beluga whale	80	Reeves et al. (2002) and Reidenberg and Laitman (2002)
Monodon monoceros	Narwhal	80	Reeves et al. (2002)
Family Phocoenidae			
Phocoenoides dalli	Dall's Porpoise	6	Ferrero and Walker (1999)
Phocoena phocoena	Harbor porpoise	5	Reeves et al. (2002) and Reidenberg and Laitman (2002)
Family Physeteridae			
Physeter macrocephalus	Sperm whale	1000	Reeves et al. (2002) and Reidenberg and Laitman (2002)
Family Ziphiidae			
Berardius arnouxii	Arnoux's beaked whale	250	Surrogate: Cuvier's beaked whale
Berardius berardii	Baird's beaked whale	250	Surrogate: Cuvier's beaked whale
Hyperoodon ampullatus	Northern bottlenose whale	250	Surrogate: Cuvier's beaked whale
Indopacetus pacificus	Longman's beaked whale	228	Dalebout et al (2003)
Mesoplodon bidens	Sowerby's beaked whale	170	Reeves et al. (2002)
Mesoplodon carlhubbsi	Hubb's beaked whale	170	Surrogate: Sowerby's beaked whale
Mesoplodon densirostris	Blainville's beaked whale	60	Reeves et al. (2002) and Reidenberg and Laitman (2002)
Mesoplodon europaeus	Gervais' beaked whale	49	Reidenberg and Laitman (2002)
Mesoplodon ginkgodens	Ginkgo-toothed beaked whale	170	Surrogate: Sowerby's beaked whale
Meosplodon hectori	Hector's beaked whale	60	Surrogate: Blainville's beaked whale
Mesoplodon layardii	Strap-toothed whale	136	Surrogate: True's beaked whale
Mesoplodon mirus	True's beaked whale	136	Reidenberg and Laitman (2002)
Mesoplodon perrini	Perrin's beaked whale	60	Surrogate: Blainville's beaked whale
Mesoplodon peruvianus	Pygmy beaked whale	49	Surrogate: Gervais' beaked whale
Mesoplodon stejnegeri	Stejneger's beaked whale	60	Surrogate: Blainville's beaked whale

Species Name	Common Name	Newborn Calf / Pup Mass (kg)	Reference
Tasmacetus shepherdi	Shepherd's beaked whale	250	Surrogate: Cuvier's beaked whale
Ziphius cavirostris	Cuvier's beaked whale	250	Reeves et al. (2002)
Carnivores			
Family Mustelidae			
Enhydra lutris	Sea otter	2	Reeves et al. (2002)
Family Phocidae			
Cystophora cristata	Hooded seal	11	Reeves et al. (2002)
Erignathus barbatus	Bearded seal	29	Lydersen et al. (2002)
Halichoerus grypus	Gray seal	13	Iverson et al. (1993)
Histriophoca fasciata	Ribbon seal	9	Reeves et al. (2002)
Mirounga angustirostris	Northern elephant seal	22	Le Boeuf et al. (1972)
Monachus schauinslandi	Hawaiian monk seal	10	Wirtz (1968)
Pagophilus groenlandicus	Harp seal	7	Reeves et al. (2002)
Phoca vitulina	Harbor seal	7	Ellis et al. (2000)
Pusa hispida	Ringed seal	4	Reeves et al. (2002)
Family Otariidae			
Arctocephalus townsendi	Guadalupe fur seal	2	Reeves et al. (2002)
Callorhinus ursinus	Northern fur seal	4	Reeves et al. (2002)
Eumetopias jubatus	Steller sea lion	16	Reeves et al. (2002)
Zalophus californianus	California sea lion	6	Reeves et al. (2002)
Family Ursidae			
*Ursinus maritimus**	Polar bear	10	DeMaster and Stirling (1981)
Sirenians			
Family Dugonginae			
Dugong dugong	Dugong	25	Reeves et al. (2002)
Family Trichechidae			
Trichechus manatus	West Indian manatee	27	Caldwell and Caldwell (1985)
Sea Turtles			
Family Cheloniidae			
Caretta caretta	Loggerhead turtle	8.7	Southwood, Higgins et al. (2007)
Chelonia mydas	Green turtle	8.7	Wood and Wood (1993)
Eretmochelys imbricata	Hawksbill turtle	7.4	Okuyama, Shimizu et al. (2010)
Lepidochelys kempii	Kemp's ridley turtle	6.25	McVey and Wibbels (1984) and Caillouet, Koi et al. (1986)
Lepidochelys olivacea	Olive ridley turtle	7.15	Rajagopalan (1984)
Family Dermochelyidae			
Dermochelys coriacea	Leatherback turtle	35.18	Jones (2009)
