A. Introduction

The Gulf of Maine is a marginal sea characterized by rugged bathymetry surrounding three major basins (Figure 1) and directly connected to the deep ocean only through the Northeast Channel. Tides, density contrasts between water masses, and winds play important roles in the dynamics of the circulation of the Gulf. From August 1986 through September 1987, an observational study of the variability of the thermohaline environment and associated large scale circulation of the Gulf was conducted. The field observation phase of this study included the deployment of moored temperature, conductivity (T/C) and bottom pressure instrumentation in the center of the major basins and the northern side of the Northeast Channel, and five seasonal hydrographic cruises (Table 1). The UNH observation effort, complemented by the work of D. Brooks (Texas A&M University), B. Butman (U.S. Geological Survey, Woods Hole), and C. Flagg (Brookhaven National Laboratory) will provide an improved understanding of some of the most important physical factors that control the thermohaline component of the subtidal circulation.

The temperature and salinity characteristics of the major basins and channels of the Gulf of Maine tend to be similar. To monitor changes in these regions, the moored temperature, conductivity, and pressure instrumentation was located in these key locations as shown in Figure 2 for the periods indicated in Table 2. The quasi real-time satellite telemetry of the moored information from the center of the basins in the Gulf permitted us to monitor the day to day changes in the temperature, salinity, and density properties at several depths as well as the engineering status of the data acquisition system. The hydrographic information, which was obtained during surveys in August 1986 (Garrison and Brown, 1987), February 1987, April 1987, July-August 1987, and September 1987 is being used to interpret the time series information from the moorings.

This report describes the hydrographic data from R/V Endeavor cruise EN-159, 4-18 April 1987. A total of 145 CTD stations were occupied at the locations listed in Table 3; Stations 1 - 19 were occupied during the mooring maintenance leg 4-9 April and the rest (stations 20 - 145) during the hydrography leg 9-18 April. The survey depicted in Figure 2 was designed to map the hydrography of the water of the Gulf with an emphasis on the basins

and water deeper than 100 m. Thus the cruise track consisted of radial lines centered on, and connecting, the centers of the major basins and the Northeast Channel.

B. Data Acquisition Methods

A prototype UNH internally recording CTD profiler was used for stations 1 – 19. This ocean profiling instrument is an internally recording data logger based on an INTERSIL 6100 microprocessor with 24 Kbytes of RAM storage and uses Sea Bird temperature and conductivity sensors and a Vibrotron pressure sensor. A ten-cell lithium battery pack will power the system continuously for about 1000 hours. Each sensor has a separate pressure case and is connected to the main pressure case containing the batteries and electronics. Thus, sensor problems can be diagnosed and easily corrected without complete system disassembly. The sensors are protected by a stainless steel cage attached to the main pressure case. Each sensor is sampled at about 5 Hz and recorded in RAM, which holds a maximum of 4096 samples. With a lowering rate of 30 meters per minute, a 300-meter profile can be taken during the 20 minutes it takes to fill the memory in its present configuration. When on deck, the data is dumped from the CTD to a PC. FORTRAN routines are used to normalize and plot the data. This prototype system demonstrated its feasibility, but its use during this cruise highlighted enough problems that a second-generation system is currently under development.

The model 8460 Vibrotron pressure sensor (serial number 280) (Lefcort, 1968) measures the depth of the instrument to a resolution of 0.03 dbars. The sensor has about 0.15 dbars of hysteresis over its entire range of 1000 dbars and another 0.2 dbars of temperature sensitivity, for a maximum expected uncertainty in depth of about 1/3 dbar. The Sea Bird SBE-3 temperature sensor (Pederson, 1969) used on the CTD has a pressure-protected 70 ms thermistor (serial number 483). Calibration history of slow 500 ms thermistor sensors shows a long-term drift of 3 to 5 millidegrees Centigrade per year with obtainable accuracies of 5 millidegrees (Irish, 1985). The faster thermistor should have similar stability. Temperature was measured to a 0.5 millidegree Centigrade resolution. The Sea Bird SBE-4 conductivity sensor (Pederson and Gregg, 1979) (serial number 85) used on the CTD was sampled to 0.0004 S/m resolution. The

sensor was calibrated in the spring of 1986 and the sensor flushed with fresh water regularly and kept wet at all times to prevent salt crystal formation in the platenizing. Standardization is normally done with water bottle samples; however, due to lack of time and equipment during the first leg of this cruise, no in situ calibration bottles were taken.

A Neil Brown (NB) Instrument Systems Mark III (serial number 1088) CTD was used for Stations 20 through 145. The NB CTD was mounted inside a General Oceanics rosette frame with six 5-liter Niskin bottles around the perimeter. An oxygen sensor was mounted on the NB CTD and a Sea Tech 25 cm path length transmissometer was mounted horizontally inside the frame. Data acquisition and display of the NB CTD was controlled by a Digital Equipment Corporation Microvax computer. The typical data scan of pressure, temperature, conductivity, oxygen current, oxygen temperature, and transmission was obtained 32 times a second and stored in computer memory and later stored on disk. Niskin bottle water sample salinity was measured on board with a Guildline Autosal 8400A. Dissolved oxygen was determined by the modified Winkler titration method of Carritt & Carpenter (1966). Position was measured by LORAN C using a Northstar 7000 and water depth by precision depth recorder Raytheon PTR LSR.

At each of stations 20 through 145, the instrument frame with NB CTD was lowered at 20–40 meters/minute to within 5 m of the bottom. Temperature, salinity, transmission, and dissolved oxygen profiles were displayed in real time on the lab computer's screen. Bottle samples were collected at the bottom and at 50 m intervals to the surface during the upcast. At some of the deeper stations the surface (seventh) sample had to be drawn from the ship's continuous sampler, and in this case the sampling line was allowed to flush for at least ten minutes before taking the sample. Dissolved oxygen samples were drawn first from all the Niskin bottles. Then salinity samples were taken from the bottom and surface bottles and nutrient samples were taken from all the bottles. The nutrient samples were frozen and taken back to UNH for post cruise analysis. The salinity and dissolved oxygen samples were analyzed on board.

C. Data Processing

The data from the UNH CTD for stations 1–19 were normalized to engineering units and edited by a "rolling filter" which retained data only when the CTD was falling at a constant rate (removing not only the upcast, but also the times when the instrument was not being lowered at a uniform rate). The Sea Bird conductivity sensor was not "pumped" so that its response time depended on the flushing rate of water due to the CTD's fall rate. When the ship rolled and slowed down or reversed the fall rate, the flushing rate was correspondingly modified, and the sensor response changed so that it did not match well with the temperature observations. This caused very observable and artificial spikes in the salinity record. Therefore, the data collected during these times were discarded. The resultant profiles do not have any obvious sensor time constant problems.

The first step in the processing of data from the Neil Brown CTD for stations 20–145 was to partition the raw CTD data from each station into downcast and upcast data files. Possible contamination due to ship roll was eliminated from both the downcast and upcast. On the downcast, data associated with decreasing pressure (due to ship roll) were discarded, and, on the upcast, data associated with increasing pressure were discarded. Further processing was done on the downcast data only.

For both CTDs, salinity was computed using the Practical Salinity Scale of 1980 (Lewis, 1980; Fofonoff and Millard, 1983) and corrected as discussed below. The edited and adjusted data were filtered from an equally spaced time series to an equally spaced spatial series with a 2 dbar long triangular filter advanced by one decibar increments. The 1 dbar averaged pressure, temperature and salinity data were used to calculate potential temperature, potential density anomaly (σ -theta), sound velocity, Brunt–Vaisala frequency, specific volume anomaly and dynamic height at 1 dbar intervals using algorithms of Fofonoff and Millard (1983). The uncertainty for each of the corrected data parameters is listed in Table 4.

1. UNH CTD Data Corrections; Stations 1 – 19

Pressure: At the start of the cast, the CTD was held about 1 meter below the surface for several hundred data scans. The average of the pressure data of these scans was subtracted from the pressure data of the cast. Typical adjustment values were about 0.8 dbars.

Temperature: The temperature sensor was calibrated in May 1986 at the Northwest Regional Calibration Center in Washington, and the calibration was checked after the cruise at UNH. Pre- and post-cruise values were consistent to $\pm 0.003^{\circ}\text{C}$, so no adjustments were made to the temperature data.

Salinity: The conductivity sensor was subject to some contamination and drift since its May 1986 calibration at the Northwest Regional Calibration Center. This drift was small, and we assumed that the sensitivity of the instrument was unaffected, and corrections could be made by applying a constant to the salinity data. This constant was determined from previous and post-cruise data and a comparison of the deep water T-S relation from the NB CTD cast 24 and the UNH CTD cast 15 which were obtained from the same Wilkinson Basin station about 32 hours apart.

The portions of the T-S curve for which $T > 6^{\circ}\text{C}$ are in water deeper than 190 meters where temperature and salinity gradients are small, and the T-S properties are observed to change more slowly than in shallow depths. Using the adjusted NB record (see below) as a standard, a constant adjustment of 0.059 ppt¹ was obtained and added to the UNH salinity so that the deep portions of the T-S curves coincided as shown in Figure 4. The discrepancy between the T-S relations at shallower depth is due to time variability. The hourly T-S obtained from the Wilkinson Basin T/C mooring during the 32-hour period before the mooring was recovered (prior to both stations 15 and 24) show that

¹Some investigators report salinity in psu. In this report, psu and ppt are equivalent.

the differences in T-S are typical of the time variability over this interval. The "clouds" of mooring data in Figure 4 are from T/C sensor pairs at 16, 66, 115, and 165 meters, respectively.

Comparisons of the UNH CTD with bottle samples from previous cruises and with the September 1987 cruise showed differences of 0.04 to 0.07 ppt. The value of 0.059 ppt was chosen as the best adjustment, and the resulting salinities are good to ± 0.01 ppt.

2. Neil Brown CTD Data Corrections; Stations 20 – 145

Pressure: At each of the stations, the pressure was recorded when the CTD was on the ship's deck just before the start of the cast. The average of these on deck pressure values, 5.2 db, was subtracted from the pressure data of casts 20–145.

Temperature: The pre-cruise calibration data of the instrument's temperature sensor showed an offset (standard-CTD temperature) of 0.0050°C at 0°C , decreasing to 0.0015°C at 20°C . Since these inaccuracies were within manufacturer's specified accuracy ($\pm 0.005^{\circ}\text{C}$) of the temperature sensor, the NB CTD temperature was not corrected.

Salinity: On almost every cast, bottom and surface salinity samples were collected for the purpose of correcting CTD salinity. Surface samples ranged from about 31–32.5 ppt and bottom samples from about 32.5–35 ppt. Bottle salinity was plotted versus CTD salinity, allowing spurious data points, due to leaking sample bottle, strong salinity gradient, incorrect sampling procedure, etc., to be rejected. A linear regression of bottle salinity on CTD salinity yielded a salinity correction equation for NB salinity $S_c = 0.10299 + 0.99687 * S$, where S is CTD salinity, and standard deviation of the discrepancies was ± 0.007 ppt. The difference between bottle data salinity and calculated salinity is shown in Figure 5. This equation was used to correct NB CTD salinity on casts 20 through 145.

D. Data Presentations

The 1 db averaged data are presented in this report in several ways: (1) station profile plots, station T-S diagrams, and data listings; (2) vertical section contour plots; and (3) horizontal section contour plots. The reader is referred to Figure 6 for purposes of interpreting the T-S diagrams.

Horizontal and vertical section contour plots were computer generated using the National Center for Atmospheric Research (NCAR) plot package. Unevenly spaced horizontal section data are interpolated by the triangularization method of Akima (1978) to produce the uniformly spaced grid of numbers which are contoured. The vertical section data are unevenly spaced in the horizontal direction and evenly spaced at 1 db intervals in the vertical direction. A linear interpolation was used to produce the uniformly spaced grid of numbers which are contoured.

Horizontal Sections: Horizontal sections of temperature, salinity, and sigma-theta at 2, 50, 100, 150, and 200 decibars were done using data from all appropriate stations. These sections are presented in Figures 7-21. The coastline and bathymetry were digitized from the Uchupi (1965) chart. The dots indicate the station location and as the sections go deeper the stations with data at that depth become fewer. Contour intervals are 1°C for temperature, 0.2 ppt for salinity, and 0.2 kg m⁻³ for sigma-theta. The surface dynamic height map relative to 100 decibars is presented in Figure 22. Contour interval is 1 dynamic centimeter.

Vertical Sections: Vertical sections of temperature, salinity, and sigma-theta for the sets of stations indicated in Figure 3 are presented in Figures 23-50. The vertical sections for all our cruises (Table 1) are numbered from 1 to 14, and corresponding sections of the different cruises are given the same number. On a particular cruise we might not have done all fourteen sections, so there will be gaps in the numbering. We did not do sections 8, 9, and 10 on this cruise. Contour intervals are 0.5°C for temperature, 0.2 ppt for salinity, and 0.25 kg m⁻³ for sigma-theta. The station numbers are indicated along the top horizontal axis.

Profiles, T-S Diagrams, and Data Listings: A profile plot, T-S diagram, and data listing is presented in Figures 51-195 for each of the 145 CTD stations. The 1 db averaged values are used for the profiles and for the T-S diagram. The data listing presents the 1 db average values of temperature (T), salinity (S), potential temperature (PT), density anomaly sigma-theta (STH), specific volume anomaly (SPVA), dynamic height with respect to surface (DH), sound velocity (SND V), and Brunt-Väisälä frequency (N) at 10 db intervals and at the surface and bottom.

E. Acknowledgements

The assistance of D. Ball, A. Benabdeljelil, R. Gelinas, D. Howard, E. Rose (all of UNH) on the cruise is gratefully acknowledged. The data acquisition went smoothly because of the help provided by the URI marine technicians L. Covington, J. Lewkowicz, and J. Szelag. We wish to thank the officers and crew of the R/V Endeavor for their assistance and enthusiasm in helping us gather data. We thank S. Palmer (UNH) for improving the quality of the computer generated graphics. This work was supported by funding from Sea Grant and National Science Foundation under grants No. R/FM-104 and OCE-8517274, respectively.

**Table 4. Estimated uncertainties in the measured parameters
after processing and corrections described in Section C.**

NB CTD instrument:	pressure	±0.2 dbar
	temperature	±0.005 °C
	salinity	±0.007 ppt
 UNH CTD instrument:	 pressure	 ±1 dbar
	temperature	±0.005 °C
	salinity	±0.01 ppt

GULF OF MAINE

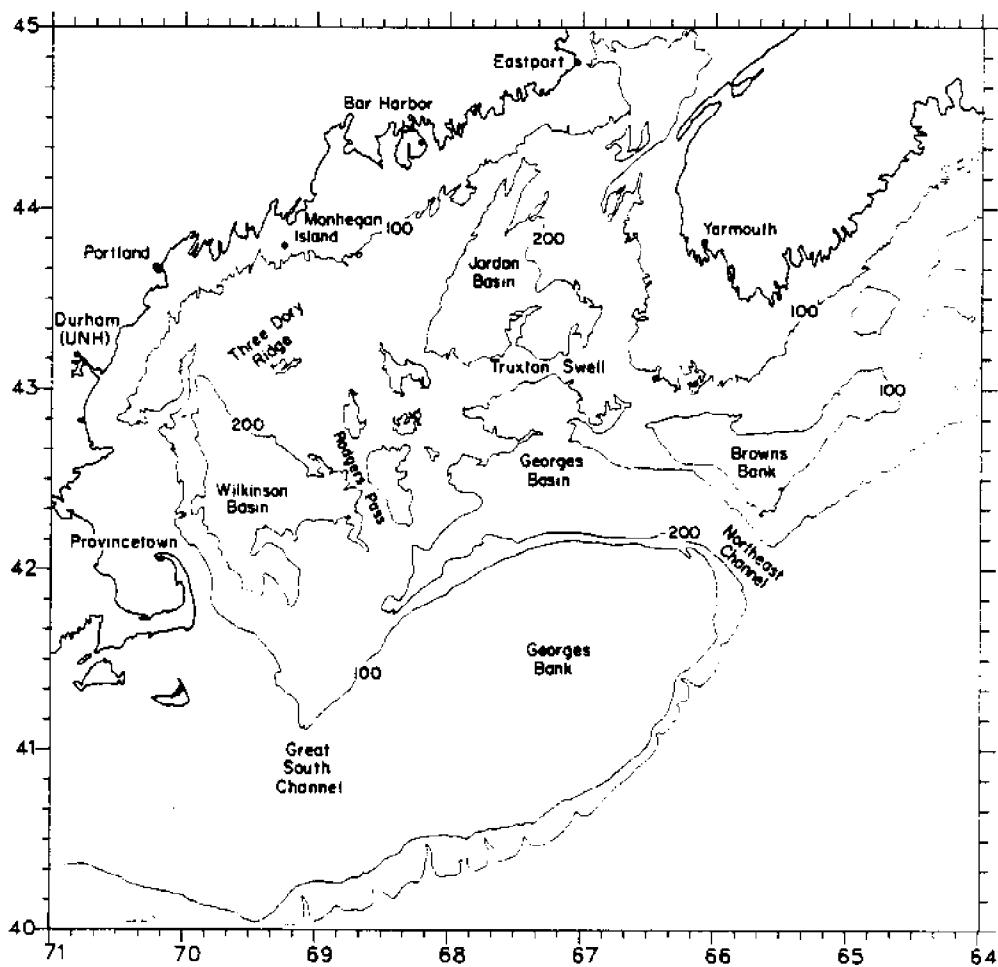

Figure 1. Location map of the Gulf of Maine. The 100 m and 200 m isobaths define the major bathymetric features.

GULF OF MAINE CTD STATION LOCATIONS APRIL 1987

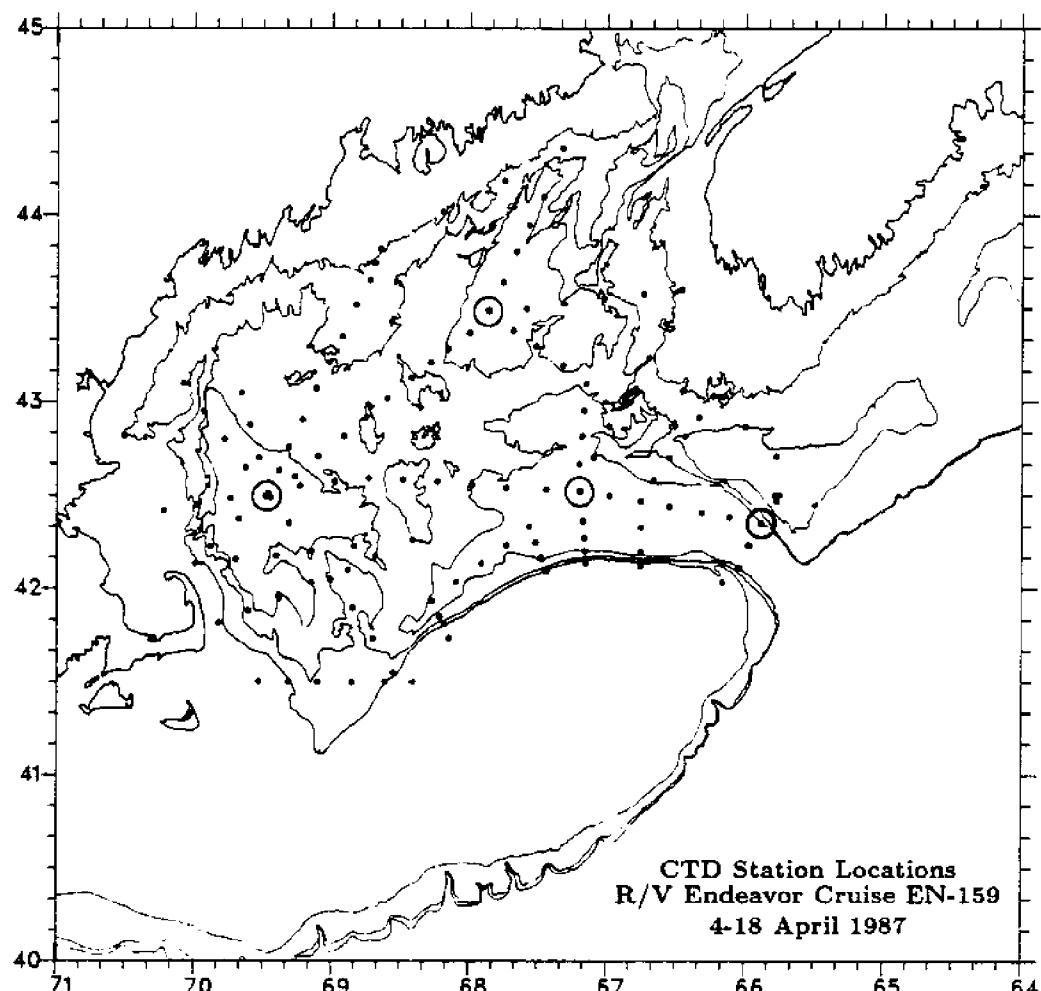

Figure 2. CTD station locations during the 4-18 April 1987 hydrographic survey on the R/V Endeavor cruise EN-159. Open circles locate the temperature, conductivity, and bottom pressure mooring sites.

GULF OF MAINE VERTICAL SECTION LINES APRIL 1987

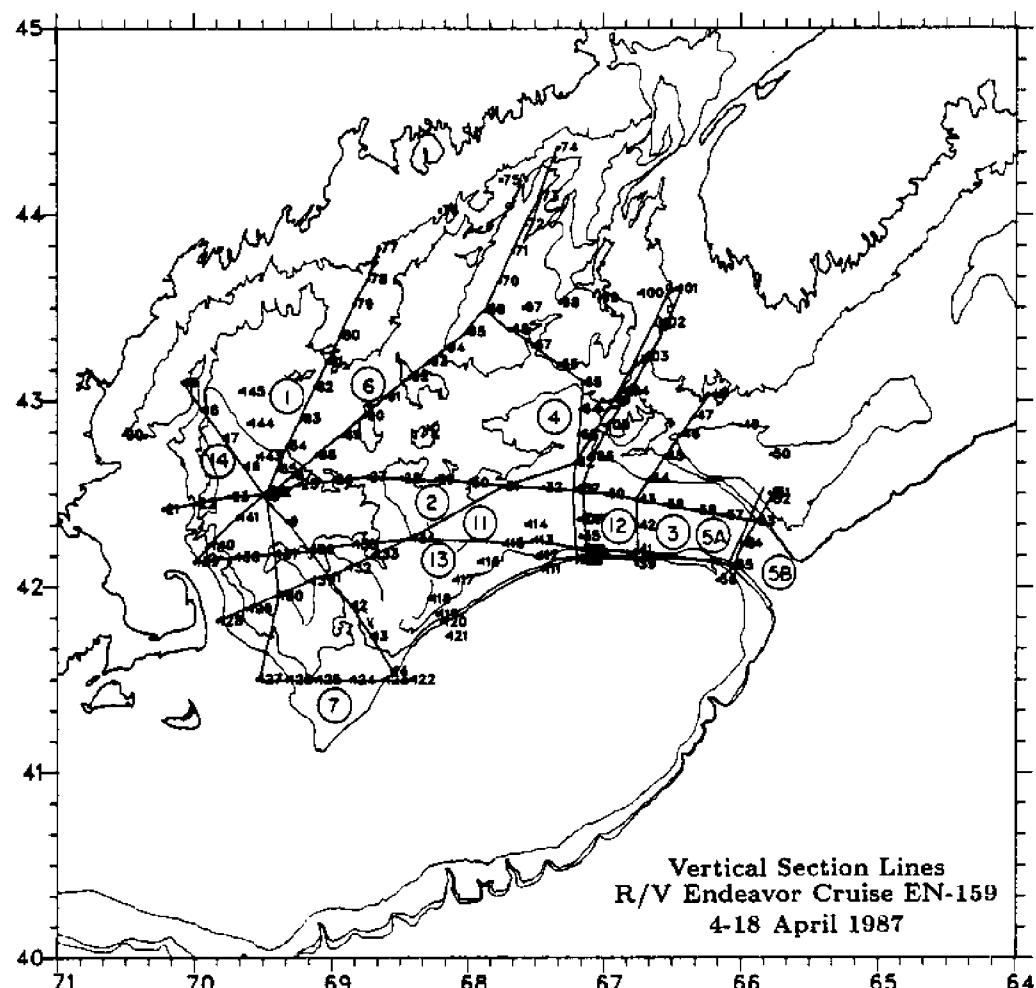

Figure 3. Vertical section locations during the 4-18 April 1987 hydrographic survey on the R/V Endeavor cruise EN-159.

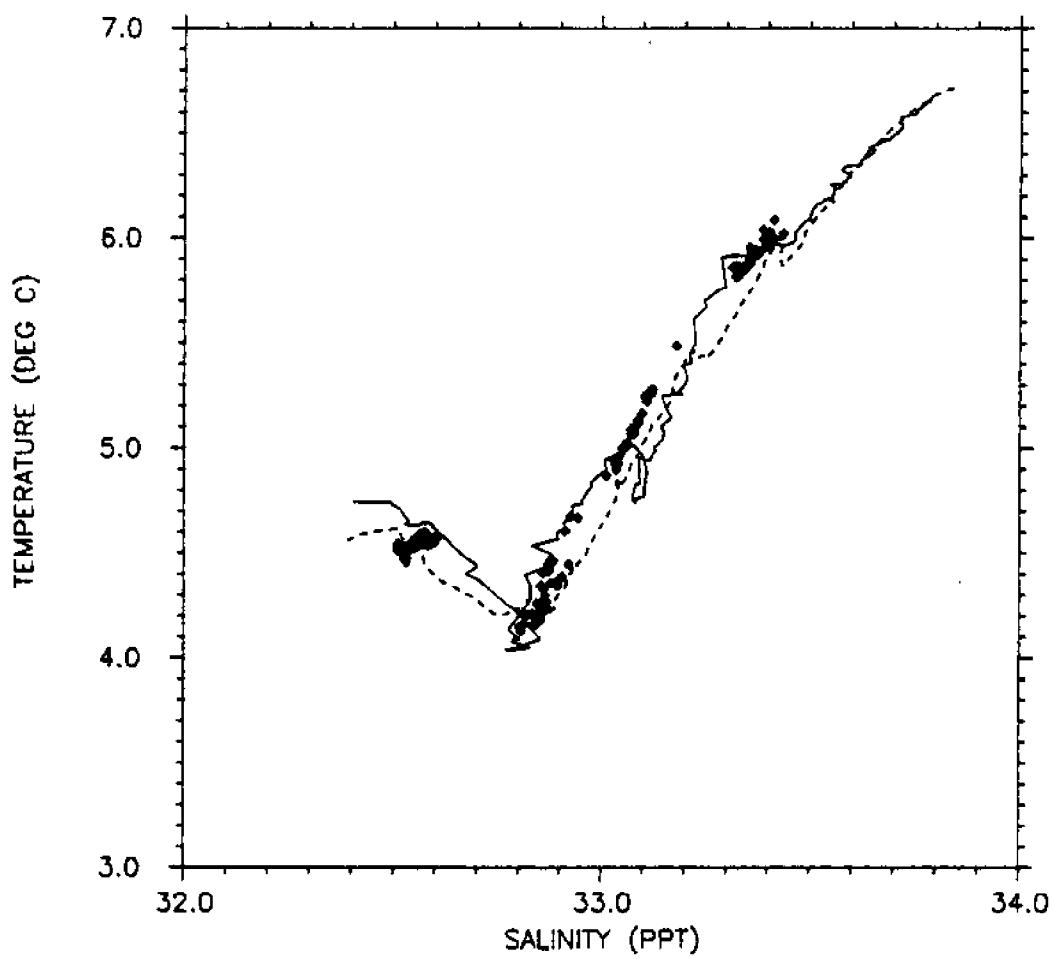

Figure 4. A T-S comparison of corrected data from the UNH CTD cast 15 (—) and Neil Brown CTD cast 24 (---). Hourly T-S observations from the Wilkinson Basin T/C mooring (\diamond) for a 32-hour period (6 April 1987, 0400, to 7 April 1987, 1200) are also presented.

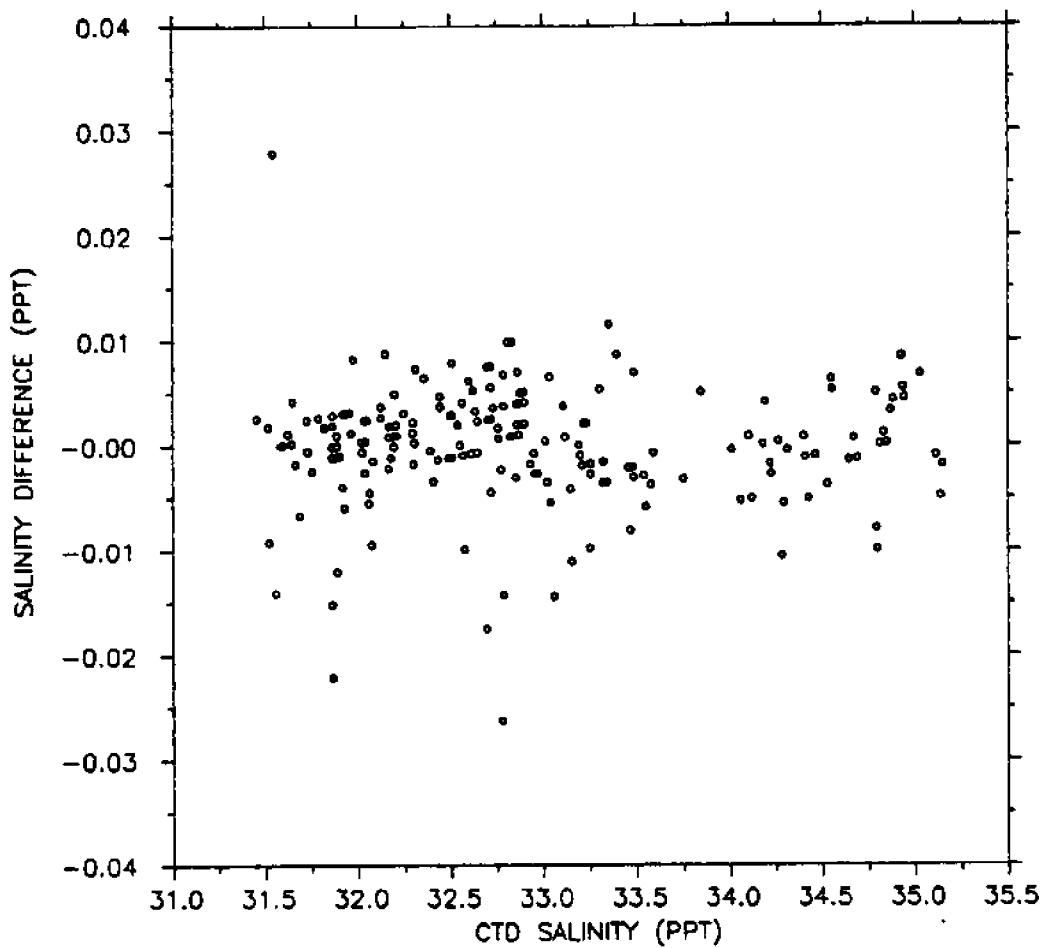

Figure 5. Deviations of bottle salinities for casts 20 through 145 from the linear fit between bottle and Neil Brown CTD salinities.

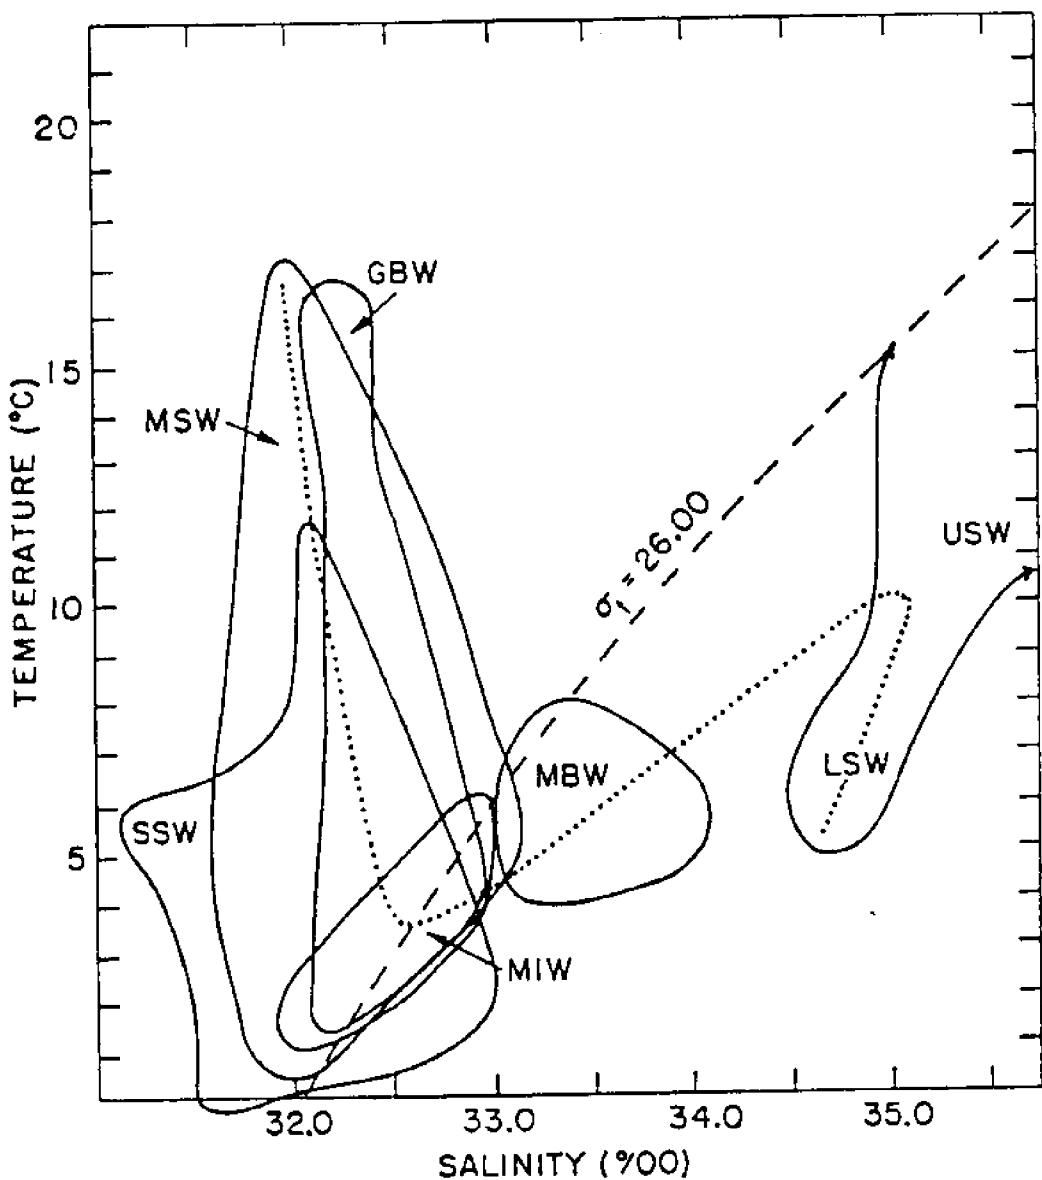

Figure 6. (from Hopkins and Garfield, 1979). T-S envelopes from a composite of the Colton et al. (1968) data from December 1965 to September 1966. The water mass abbreviations are MSW—Maine Surface Water; MIW—Maine Intermediate Water; MBW—Maine Bottom Water; SSW—Scotian Shelf Water; GBW—Georges Bank Water; USW—Upper Slope Water; and LSW—Lower Slope Water.

2 DECIBAR TEMPERATURE APRIL 1987

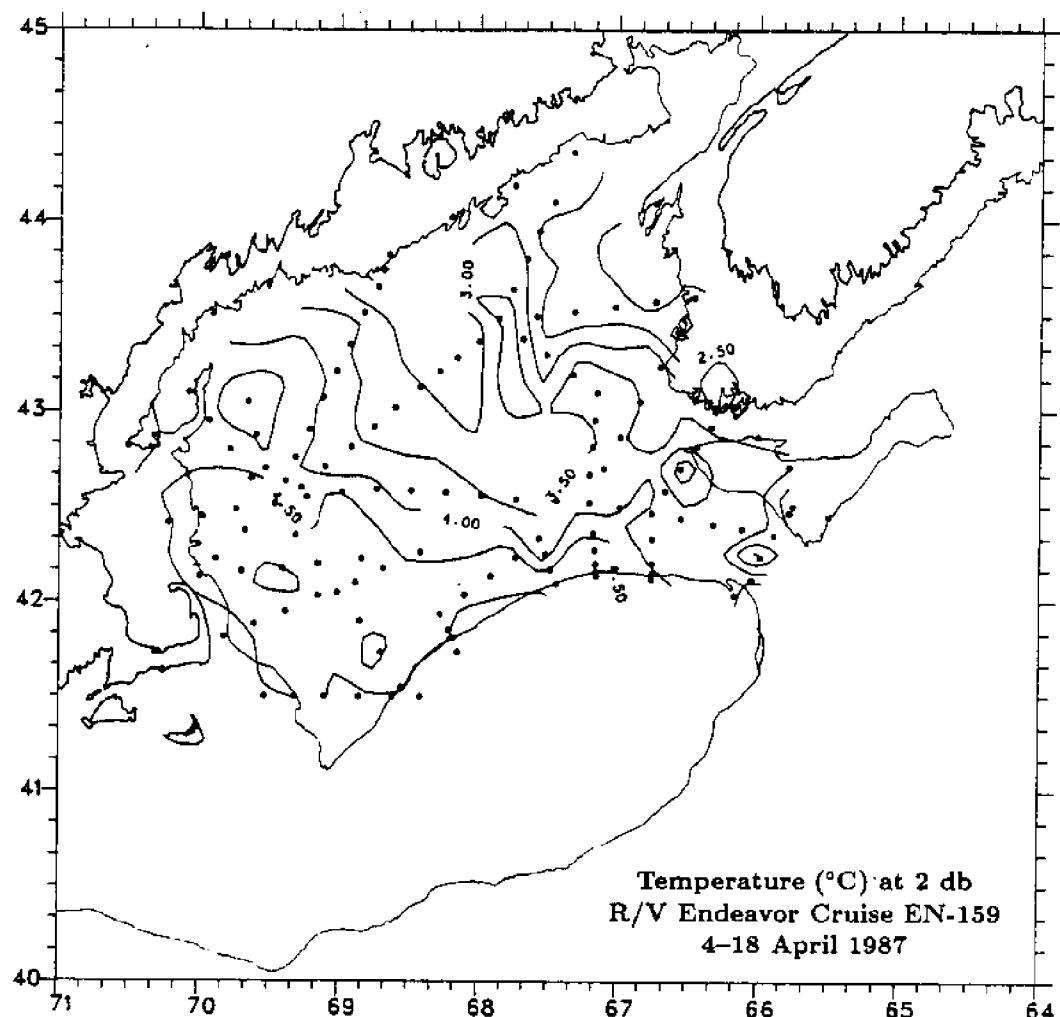

Figure 7. Horizontal section contour plot of 2 db temperature. Units are $^{\circ}\text{C}$ and contour interval is 0.5°C .

2 DECIBAR SALINITY APRIL 1987

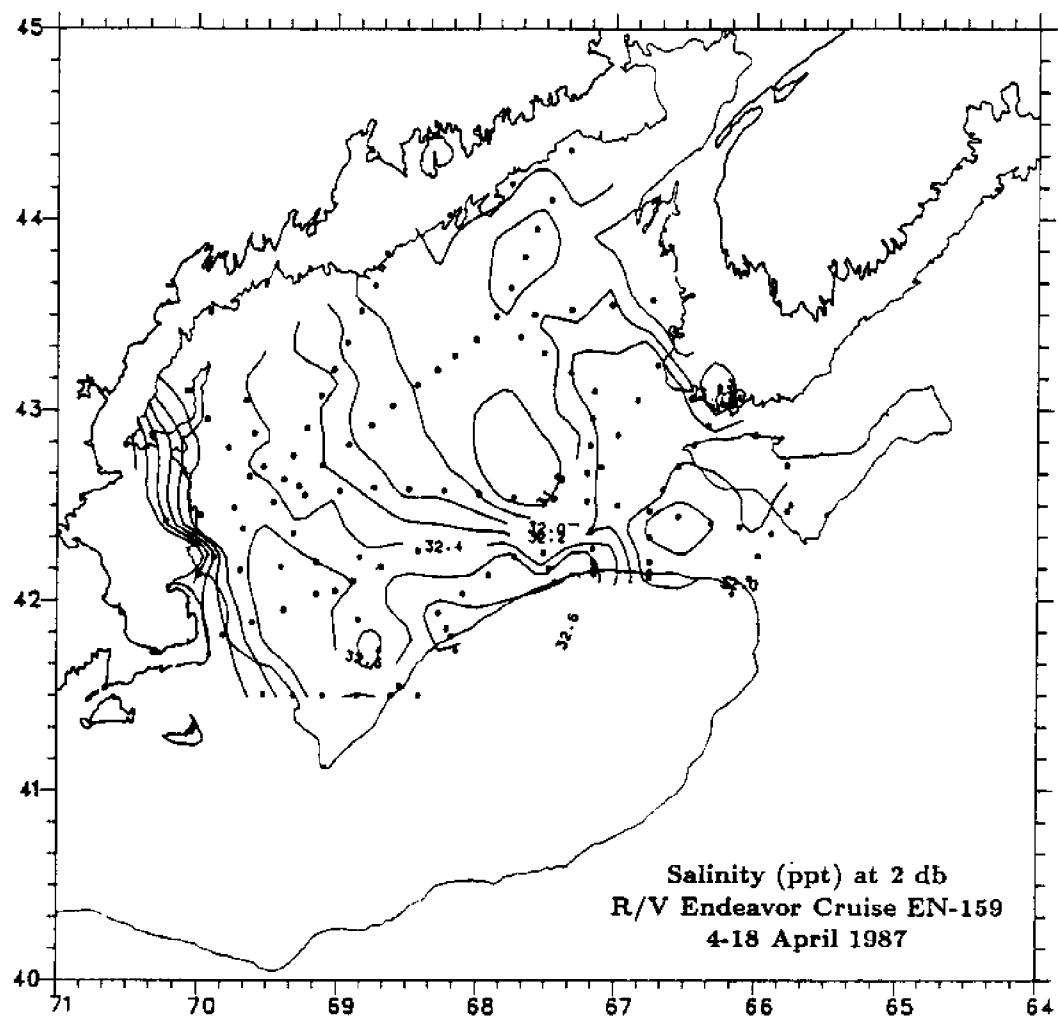

Figure 8. Horizontal section contour plot of 2 db salinity. Units are *ppt* and contour interval is 0.2 *ppt*.
