INTRODUCTION

Phytoplankton primary productivity was measured during three cooperative U.S.-U.S.S.R. MARMAP surveys of coastal waters between Cape Hatteras and Nova Scotia aboard the R. V. Belogorsk (78-01, 78-03, 78-04). Table 1 gives the dates of the three surveys and the number of stations where primary productivity was measured. Figures 1, 2, and 3 depict the cruise tracks and locations of stations sampled during these surveys. During the first survey (1 August - 4 September 1978, Belogorsk 78-01), primary production was measured at 44 stations extending from Nova Scotia south to Cape Hatteras. On the second survey (6 October - 1 November 1978, Belogorsk 78-03), primary production was measured at 42 stations from the Gulf of Maine to just south of Delaware Bay. The third survey (16 November - 29 November 1978, Belogorsk 78-04) was abbreviated. Productivity was measured at 24 stations from the Gulf of Maine to the eastern tip of Long Island.

Measurements of phytoplankton productivity were made in conjunction with measurements of chlorophyll a (Evans et al., 1979), nutrients (Draxler et al., 1979), temperature, salinity, dissolved oxygen, water transparency (Secchi disc and submersible photometer), daily photosynthetically active radiation, and collections of zooplankton, ichthyoplankton and phytoplankton.

METHODS

The details of the method used to measure primary productivity are given in a separate report (O'Reilly and Thomas, 1979) which describes submersible photometry, water sampling, ^{14}C incubations, filter fractionation, and calculations of daily rates of primary productivity ($\text{gC}/\text{m}^2/\text{d}$). Six to seven depths were sampled throughout the euphotic layer. During Belogorsk surveys 78-03 and 78-04 a submersible quantum photometer was used to determine the vertical extinction of photosynthetically active radiation (400-700 nanometers) as well as sampling depths corresponding to 100%, 69%, 46%, 25%, 10%, 3%, and 1% of subsurface light intensity. During the August survey (78-01) the submersible photometer did not operate properly. Consequently, Secchi disc disappearance-depths were used with the equation: ($K = 1.7/\text{Secchi depth}$) to estimate sampling depths.

Duplicate "light bottles" and one "dark bottle" were filled with seawater from each sampling depth. Zooplankton larger than 300 microns were removed from productivity bottles during filling. Approximately 15 $\mu\text{Ci}-^{14}\text{C}$ were added to each productivity sample. Alkalinity and pH were measured at surface and at the 10% light-depth.

Measurements of primary productivity were usually made at two stations each day of the cruise. Incubations lasted five hours with morning stations ending and afternoon stations commencing at approximately 1200 Eastern Standard Time (\sim local solar noon).

Following incubation under ambient light, the organic ^{14}C activity in productivity samples was filter-fractionated into netplankton (>20 microns), nanoplankton (<20 microns) and dissolved organic matter (<0.45 micron) released by phytoplankton. Rates of production for each size fraction ($\text{mgC}/\text{m}^3/\text{d}$) and daily integral rates of production ($\text{mgC}/\text{m}^2/\text{d}$) were calculated using our computer program PP1074 (O'Reilly and Thomas, 1979).

RESULTS

Average daily rates ($\text{mgC}/\text{m}^3/\text{d}$) of netplankton productivity, nanoplankton productivity, release of dissolved organic matter (DOM), and total productivity are given according to date, station, sampling depth, and percent light intensity in Tables 2, 3, and 4 (78-01, 78-03, 78-04, respectively). The percent of total carbon production by nanoplankton, netplankton and percent of released DOM is also given in these tables. Tables 2, 3, and 4 represent the output ("Section D") from our computer program PP1074 (O'Reilly and Thomas, 1979). Vertical profiles of productivity versus depth (percent light intensity) can be derived from these tables.

Many of the vertical profiles of total productivity in August (31 of 44) and October (37 of 42) indicate considerably less production at 100% light intensity than at 69% intensity, and may reflect "sunlight inhibition" of surface water productivity. During October, water samples for both the 100% and 69% sunlight incubations were frequently taken from the surface (1 m) Niskin bottle. Even though biomass was identical in both treatments, in 24 of 29 cases, considerably less

total productivity was measured at 100% intensity than at 69% intensity. During August and October, maximum total production frequently occurred at depths corresponding to 46% and 25% of surface light intensity (Table 2, Table 3). During the November survey, rates of total production progressively decreased with decreasing light intensity (Table 4). Maximum production usually occurred at 100% or 69% light intensity.

Daily integral rates of productivity ($\text{mgC}/\text{m}^2/\text{day}$) measured during the three surveys are given in Tables 5, 6, and 7 according to sampling date and station number. Secchi depth, percent light-depths, euphotic depth, incubation time, daily photosynthetically active radiation ($\text{Einsteins}/\text{m}^2/\text{d}$), PAR factor, and percent of total daily carbon production in netplankton, nanoplankton and DOM size fractions are also given in Tables 5, 6, and 7. These tables represent the output ("Section E") from our computer program PP1074.

The distribution of integral total daily productivity ($\text{gC}/\text{m}^2/\text{d}$), euphotic depth, percent of particulate production by nanoplankton, and euphotic percent extracellular release of DOM are depicted for each cruise in Figures 4, 5, 6, 7, 8, and 9.

In August, rates of total daily primary production ($\text{gC}/\text{m}^2/\text{d}$) were relatively high throughout the entire survey area. Daily production ranged between 0.6 and 3.7 $\text{gC}/\text{m}^2/\text{d}$. Productivity was greater than 1 $\text{gC}/\text{m}^2/\text{day}$ at 37 of 44 stations. Values were uniformly higher than 1 $\text{gC}/\text{m}^2/\text{day}$ from Nova Scotia to southern Delaware Bay, whereas south of Delaware, in waters off Maryland, Virginia and North Carolina, production was lowest with all values

less than $1\text{gC}/\text{m}^2/\text{day}$. Total daily primary production exceeded $3\text{gC}/\text{m}^2/\text{day}$ at three stations: one at the eastern tip of Long Island, a second south of Nantucket approaching the 200 m contour, and the third in the mid-western area of Georges Bank (Figure 4).

During October, total daily production throughout the survey area was also relatively high. Daily production ranged between 0.9 and $4.2\text{gC}/\text{m}^2/\text{d}$ with maxima of 4.1 and $4.2\text{gC}/\text{m}^2/\text{day}$ recorded at stations in the New York Bight and the eastern half of Georges Bank (Figure 6). Productivity was greater than $1\text{gC}/\text{m}^2/\text{d}$ at 40 of the 42 stations and greater than $2\text{gC}/\text{m}^2/\text{d}$ at 17 of the 42 stations.

During the November survey, productivity was relatively low. Daily production ranged between 0.2 and $2.3\text{gC}/\text{m}^2/\text{d}$ (Figure 8). Only 5 of the 24 stations surveyed produced more than $1\text{gC}/\text{m}^2/\text{d}$ (Figure 8). Highest production was observed over Georges Bank ($>2\text{gC}/\text{m}^2/\text{d}$).

Nannoplankton (less than 20 microns) were responsible for the majority of carbon produced during the August (78-01), October (78-03) and November (78-04) surveys (Figures 5, 7, and 9).

In August, netplankton species (greater than 20 microns) dominated over nannoplankton at only 2 stations (off the Delaware and Chesapeake estuaries). During the October survey, netplankton outproduced nannoplankton at only 9 of the 42 stations (off the New Jersey coast, one the central portion of Georges Bank, and in the northern portion of the Gulf of Maine) (Figure 7). In November (78-04), nannoplankton were the dominant photosynthesizers at 19 of 24 stations (Figure 9).

The dissolved organic carbon compounds (DOM) released by phytoplankton during photosynthesis are usually not measured when employing the ^{14}C method to measure productivity. Consequently, ^{14}C measurements reflect only particulate synthesis and are underestimates of total carbon photoassimilation. Our three MARMAP surveys of coastal waters demonstrate that the DOM fraction represents a significant portion of total production, and should be routinely measured. Euphotic percent extracellular release of DOM (EPER = Integral DOM release, $\text{mgC}/\text{m}^2/\text{d}$ \div integral total productivity, $\text{mgC}/\text{m}^2/\text{d}$) during August ranged between 5% and 44% of total production and averaged 19% (Figure 5).

In October, EPER ranged between 1 and 35% and averaged 9% (Figure 7). In November, EPER ranged between 4% and 33% and averaged 12% of total daily carbon productivity (Figure 9).

Our observations confirm earlier descriptions of Georges Bank and the New York Bight as regions of high productivity. Our observations also indicate that primary productivity of the Northwest Atlantic Continental Shelf may be higher than expected.

ACKNOWLEDGEMENTS

We wish to acknowledge Igor Krasovsky, Steve Ward, and Joe Kane for their assistance with shipboard measurements of primary productivity.
