Ref.: SAJ-1995-03885 (SP-JPF), City of Cape Coral, Marina Renovation and Expansion, Cape Coral, Lee County, Florida

Dear John Policarpo,

The enclosed Biological Opinion (Opinion) was prepared by the National Marine Fisheries Service pursuant to Section 7(a)(2) of the Endangered Species Act (ESA). The Opinion considers the effects of a proposal by the Jacksonville District of the United States Army Corps of Engineers (USACE) to authorize Marina Renovation and Expansion. We base this Opinion on project-specific information provided in the consultation package, our review of published literature, and the best available data. This Opinion analyzes the potential for the project to affect the following ESA-listed species and critical habitat: green sea turtle (North Atlantic and South Atlantic Distinct Population Segments [DPSs]), hawksbill sea turtle, Kemp's ridley sea turtle, leatherback sea turtle, loggerhead sea turtle (Northwest Atlantic DPS), smalltooth sawfish (United States DPS), gulf sturgeon, giant manta ray, and smalltooth sawfish critical habitat.

We look forward to further cooperation with the USACE on other projects to ensure the conservation and recovery of our threatened and endangered marine species. This project has been assigned the tracking number SERO-2022-00902 in our Environmental Consultation Organizer (ECO). Please refer to the ECO number in all future inquiries regarding this consultation. Please direct questions regarding this Opinion to Karla Reece, Section 7 Team Lead, by email at [Karla.Reece@noaa.gov](mailto:Karla.Reece@noaa.gov).

Sincerely,

Andrew J. Strelcheck  
Regional Administrator

## INTRODUCTION

---

Section 7(a)(2) of the ESA of 1973, as amended (16 U.S.C. § 1531 et seq.), requires that each federal agency ensure that any action authorized, funded, or carried out by such agency is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of critical habitat of those species. Section 7(a)(2) requires federal agencies to consult with the appropriate Secretary in carrying out these responsibilities. The NOAA NMFS and the USFWS share responsibilities for administering the ESA.

Consultation is required when a federal action agency determines that a proposed action “may affect” listed species or designated critical habitat. Informal consultation is concluded after NMFS determines that the action is not likely to adversely affect listed species or critical habitat. Formal consultation is concluded after NMFS issues a Biological Opinion (hereafter, referred to as an/the Opinion) that identifies whether a proposed action is likely to jeopardize the continued existence of a listed species, or destroy or adversely modify critical habitat, in which case reasonable and prudent alternatives to the action as proposed must be identified to avoid these outcomes. The Opinion states the amount or extent of incidental take of the listed species that may occur, develops measures (i.e., reasonable and prudent measures) to reduce the effect of take, and recommends conservation measures to further the recovery of the species.

This document represents our Opinion based on our review of impacts associated with the proposed action to issue a permit within Lee County, Florida. This Opinion analyzes the proposed action’s effects on threatened and endangered species and designated critical habitat in accordance with Section 7 of the ESA. We based our Opinion on project information provided by the USACE, the SSRIT encounter database, the FWC, and the published literature cited herein.

On July 5, 2022, the U.S. District Court for the Northern District of California issued an order vacating the 2019 regulations that were revised or added to 50 CFR part 402 in 2019 (“2019 Regulations,” see 84 FR 44976, August 27, 2019) without making a finding on the merits. On September 21, 2022, the U.S. Court of Appeals for the Ninth Circuit granted a temporary stay of the district court’s July 5 order. On November 14, 2022, the Northern District of California issued an order granting the government’s request for voluntary remand without vacating the 2019 regulations. The District Court issued a slightly amended order two days later on November 16, 2022. As a result, the 2019 regulations remain in effect, and we are applying the 2019 regulations here. For purposes of this consultation and in an abundance of caution, we considered whether the substantive analysis and conclusions articulated in the Opinion and Incidental Take Statement would be any different under the pre-2019 regulations. We have determined that our analysis and conclusions would not be any different.

## 1 CONSULTATION HISTORY

---

The following is the consultation history for NMFS ECO tracking number SERO-2022-00902, Cape Coral Yacht Club Renovation.

On April 15, 2022, we received a request for formal consultation under Section 7 of the ESA from the USACE for construction permit application SAJ-1995-03885 (SP-JPF) in a letter dated April 15, 2022. The request was received with sufficient information to conduct consultation, and consultation was initiated on April 15, 2022.

On November 10, 2022 and February 8, 2023, we requested additional information during our internal quality control review process. We received a final response on February 13, 2023.

## **2 DESCRIPTION OF THE PROPOSED ACTION AND ACTION AREA**

---

### **2.1 Proposed Action**

The USACE proposes to permit the City of Cape Coral (the applicant) to renovate the existing marina and park at the Cape Coral Yacht Club (**Figure 2**).

Proposed work includes the following:

- Remove all of the existing docks (approximately 51,000 ft<sup>2</sup>) along the facility's shoreline in the basin and adjacent canals, including 117 existing boat slips;
- Remove all existing piles by pulling with heavy equipment;
- Construct new docking facilities, providing 162 slips (i.e., 117 existing slips plus an additional 45 new slips) consisting of 25,858 ft<sup>2</sup> of overwater structure (15,347 ft<sup>2</sup> of fixed wooden structure and 10,511 ft<sup>2</sup> of floating structure), a fuel dock, and wastewater pumpout slip;
- Install 621 wooden pilings (wrapped with PVC from 1 ft above MHW to 1 ft below the substrate) and 70 concrete pilings, all installed by jetting;
- Install 2,725 lin ft of new concrete panel seawall via jetting up to 18-in waterward of the existing seawall, with the existing wall remaining in place;
- Maintenance dredge 43,362 ft<sup>2</sup> (1,212 yd<sup>3</sup>) of material to a depth of -4 ft MLW within the marina basin and adjacent canals, done mechanically from a barge, with the spoil temporarily staged in the upland parking lot on the north side of the project site and then either used as beach fill onsite, if appropriate, or hauled to an upland disposal site if not appropriate as fill;
- Remove the existing boat ramp, including the adjacent docks;
- Fill in the ramp and access channel, including filling approximately 6,060 ft<sup>2</sup> (449 yd<sup>3</sup>) of material below MHW and approximately 2,284 ft<sup>2</sup> (114 yd<sup>3</sup>) of material along MHW and above to expand the beach area, using dredged material as described above, if appropriate;
- Refurbish the existing breakwater/groin structure on the west side of the current boat ramp area with a 16-in-wide by 26-ft-long steel panel with a concrete cap and 6 ft of riprap along the northwest side;
- Construct a new 83 ft by 79 ft, 2-lane boat ramp in the marina basin;
- Install two 8-ft-diameter flushing culverts from the canal to the north of the marina basin, with grating at both ends to prevent access by manatees, sawfish, or other marine species; and

The proposed action has the potential to impact 56,200 ft<sup>2</sup> of habitat as outlined in **Table 1**. Habitat between the MHW line and 3 ft measured at MLLW that may be affected by project components. below. Some maintenance dredging (up to 3,300 ft<sup>2</sup>) and seawall placement (260 lin ft up to 1.5 forward of the existing seawall, 390 ft<sup>2</sup>) will occur within the Cape Coral Smalltooth Sawfish Habitat Limited Exclusion Zone (hereafter, referred to as the Cape Coral Hotspot) as defined in the Biological Opinion for the authorization of minor in-water activities throughout the geographic area of jurisdiction of the U.S. Army Corps of Engineers Jacksonville District, including Florida and the U.S. Caribbean, SER-2015-17616 (hereafter, referred to as the JAXBO). Additionally, a 7-ft by 80-ft-marginal dock, 4-ft by 38-ft floating dock, and 4-ft by 38-ft dock will also be installed within the Cape Coral Hotspot.

**Table 1. Habitat between the MHW line and 3 ft measured at MLLW that may be affected by project components.**

<b>Project Action</b>	<b>Impact Area</b>
Seawall (2,725 lin ft installed up to 1.5 ft waterward of existing seawall, with approximately 260 lin ft within the Cape Coral Hotspot)	4,088 ft <sup>2</sup> (approximately 390 ft <sup>2</sup> within Cape Coral Hotspot)
Maintenance dredging	43,362 ft <sup>2</sup> (approximately 3,300 ft <sup>2</sup> within Cape Coral Hotspot)
Boat ramp removal, beach and channel fill	6,060 ft <sup>2</sup>
Breakwater reinforcement (steel plate and riprap)	190 ft <sup>2</sup>
New boat ramp	2,500 ft <sup>2</sup>
<b>Total</b>	<b>56,200 ft<sup>2</sup></b> <b>(3,690 within Cape Coral Hotspot)</b>

The USACE will ensure that the applicant will comply with the following Best Management Practices, Construction Conditions, and Project Design Criteria:

Work will be conducted by land and barge. The required minimum clearance for barges will be 12-18 inches; all barges will be secured by spudding.

Excavation, dredging, and grading will be completed using equipment such as excavators and front-end loaders. All construction debris and dredge materials unsuitable for reuse will be disposed of at an approved upland facility.

Stormwater outfalls will not be connected to the stormwater system until that system has been designed and constructed to meet all state and federal water quality standards.

No beach fill waterward of the MHW line will occur with the Cape Coral Hotspot.

In-water construction is expected to take 18 months to complete, during daylight hours only. The applicant has agreed to a construction moratorium within the Cape Coral Hotspot March 1 – July 1.

All contractors will comply with the NMFS [\*Protected Species Construction Conditions\*](#) (NMFS 2021), including the use of turbidity curtains. All turbidity curtains will have a minimum 1-ft clearance from the bottom to allow for the passage of juvenile smalltooth sawfish.

All contractors will comply with the NMFS [\*Vessel Strike Avoidance Measures\*](#).

All contractors will report all sightings of smalltooth sawfish during construction to the FWC via E-mail: [Sawfish@MyFWC.com](mailto:Sawfish@MyFWC.com) or telephone: 844-472-9347 (1-844-4SAWFISH). The applicant will report any future sightings of smalltooth sawfish at the property using the same information.

No recreational fishing will be allowed at the docks associated with the renovated marina. No Fishing signs will be posted in visible locations upon completion of the proposed action.

NMFS educational signs will be posted in a visible locations upon completion of the proposed action to alert boaters of ESA-listed species in the area: “Save Dolphins, Sea Turtles, Sawfish, and Manta Ray” and “Save Sawfish.” All NMFS-approved signs are available for download in English and Spanish at: <https://www.fisheries.noaa.gov/southeast/consultations/protected-species-educational-signs>.

Prior to project completion, the applicant will purchase at least one acoustic monitoring receiver suitable for collecting acoustic telemetry data for smalltooth sawfish. It will be made available to the FWC to assist their smalltooth sawfish monitoring efforts and will be compatible with their existing acoustic telemetry devices.

## 2.2 Action Area

The project site is located at the Cape Coral Yacht Club at 5819 Driftwood Parkway, Cape Coral, Lee County, Florida (26.543305°N, 81.950951°W NAD83). The project site is an existing marina and public park along the Caloosahatchee River, accessed via a man-made canal (**Figure 2**).

**Figure 2. The project site at 5819 Driftwood Parkway, Cape Coral, Lee County, Florida, on the Caloosahatchee River (©2022 Google Earth).**

The action area is defined by regulation as all areas to be affected by the federal action and not merely the immediate area involved in the action (50 CFR 402.02). For the purposes of this federal action, the action area includes the existing 2,725-lin ft of armored shoreline, marina basin, boat ramp channel, and submerged habitat within the immediate vicinity of the project site

that will be affected by the proposed action, including the submerged habitat within the boundary of the turbidity curtains (**Figure 3**). Substrate in the action area is sand and silt. The maximum depth where the turbidity curtains will be installed is approximately 6.5 ft at MLW. Depth where the replacement seawall, boat ramp, steel plate, and riprap will be placed is between 0 ft at MHW and 3 ft at MLLW. The action area is devoid of corals, SAV, and red mangroves. The action area occurs within the boundaries of critical habitat for smalltooth sawfish (CHEU). The action area also occurs within and directly adjacent to the boundaries of the Cape Coral Hotspot as defined in the JAXBO.

**Figure 3. The project site at 5819 Driftwood Parkway, Cape Coral, Lee County, Florida, along the Caloosahatchee River showing the project area in blue and the Cape Coral Hotspot exclusion zone with a border (©2022 Google Earth).**

### **3 STATUS OF LISTED SPECIES AND CRITICAL HABITAT**

**Table 1** provides the effect determinations for species the USACE and NMFS believe may be affected by the proposed action. Please note the following abbreviations are used only in the table below: E = endangered; T = threatened; LAA = likely to adversely affect; NLAA = may affect, not likely to adversely affect; NE = no effect.

**Table 2. Effects Determinations for Species the Action Agency and/or NMFS Believe May Be Affected by the Proposed Action**

Species	ESA Listing Status	Action Agency Effect Determination	NMFS Effect Determination
<b>Sea Turtles</b>			
Green (North Atlantic DPS)	T	NLAA	NLAA
Green (South Atlantic DPS)	T	NLAA	NLAA
Kemp's ridley	E	NLAA	NLAA
Leatherback	E	NLAA	NLAA
Loggerhead (Northwest Atlantic DPS)	T	NLAA	NLAA
Hawksbill	E	NLAA	NLAA
<b>Fish</b>			
Giant manta ray	T	NLAA	NLAA
Gulf sturgeon	T	NLAA	NE
Smalltooth sawfish (U.S. DPS)	E	LAA	NLAA

We believe the proposed action will have no effect on the hawksbill sea turtle or leatherback sea turtle due to the species' very specific life history strategies, which are not supported at the project site. Leatherback sea turtles have a pelagic, deepwater life history, where they forage primarily on jellyfish. Hawksbill sea turtles typically inhabit inshore reef and hard bottom areas where they forage primarily on encrusting sponges.

The proposed action will have no effect on Gulf sturgeon. Gulf sturgeon are typically found from the mouth of the Mississippi River to the mouth of Tampa Bay, which is outside of the action area.

**Table 2** provides the effects determinations for designated critical habitat occurring within the action area that the USACE and NMFS believe may be affected by the proposed action. Please note the following abbreviations are used only in the table below: LAA = likely to adversely affect, DAM = destroy or adversely modify.

**Table 3. Effects Determinations for Designated Critical Habitat the Action Agency and/or NMFS Believe May Be Affected by the Proposed Action**

Species	Critical Habitat Unit	Action Agency Effect Determination	NMFS Effect Determination
Smalltooth sawfish (U.S. DPS)	CHEU	LAA	LAA, not likely to DAM

As stated above, the action area occurs within and directly adjacent to the boundaries of the Cape Coral Hotspot as defined in the JAXBO. The Cape Coral Hotspot is one of the 4 areas within the CHEU that researchers have identified as disproportionately more important to juvenile smalltooth sawfish, based on intra- or inter-annual capture rates during random sampling events (Poulakis 2012; Poulakis et al. 2011). It also corresponds with an area where public encounters are more frequently reported (SSRIT encounter database).

### 3.1 Potential Routes of Effect Not Likely to Adversely Affect Listed Species

Sea turtles, smalltooth sawfish, and giant manta ray may be physically injured if struck by construction equipment, dredge equipment, support vessels, or placement of materials. We believe this is extremely unlikely to occur due to the species' ability to move away from the project site if disturbed. Mobile species, such as these, are able to avoid slow-moving equipment such as excavators and front-end loaders, support vessels such as barges, and the placement of material. In addition, the implementation of our *Protected Species Construction Conditions* will require all construction workers to observe in-water activities for the presence of these species. Operation of any mechanical construction equipment shall cease immediately if a protected species is seen within a 150-ft radius of the equipment. Activities may not resume until the protected species has departed the project area of its own volition or 20 minutes have passed since the animal was last seen in the area. Further, construction would be limited to daylight hours so construction workers are able to see protected species, if present, and avoid interactions with them.

The action area contains shallow-water habitat that may be used by sea turtles and giant manta ray for foraging and refuge. These species may be affected if they are temporarily unable to use the site for forage or refuge habitat due to avoidance of construction activities, related noise, and physical exclusion from the use of turbidity curtains. Although species will be unable to access the areas during construction, these effects will be insignificant given the project's limited footprint and availability of similar habitat nearby (unconsolidated shorelines within the canal system. Additionally, sea turtles (at the sizes that would be found in the action area) are highly mobile organisms, and because similar habitat is nearby, we expect these adjacent sites could provide short-term refuge or forage habitat.

The action area contains habitat that serves nursery area functions, including foraging and refuge, for juvenile smalltooth sawfish. Juvenile smalltooth sawfish may be affected by the permanent loss of habitat associated with the proposed action (up to 56,200 ft<sup>2</sup> of shallow euryhaline habitat, see **Table 1**). We believe this loss will be insignificant to the species given the relatively small amount of shallow euryhaline being lost and the availability of similar habitat nearby. There are unconsolidated shorelines and undisturbed habitat available downriver of the action area (e.g., within the CHPSP system), and extensive red mangrove and shallow, euryhaline habitat remaining within the CHEU.

A portion of the action area occurs within the boundaries of the Cape Coral Hotspot. Juvenile smalltooth sawfish may be affected by the temporary loss of access to habitat (due to the avoidance of construction activities) and the permanent removal of 3,690 ft<sup>2</sup> of habitat within the Cape Coral Hotspot (due to the seawall placement and maintenance dredging). As previously stated and restated below in stated below in Section 3.2.1, "hot spots" are areas disproportionately more important to juvenile smalltooth sawfish in terms of habitat use. We believe the loss of habitat (whether temporary or permanent) within the Cape Coral Hotspot will have an insignificant effect on juvenile smalltooth sawfish. The permanent loss of habitat within the Cape Coral Hotspot is limited to 260 lin ft of seawall replacement 18-inches-waterward of the existing seawall (390 ft<sup>2</sup>) in an area already armored and lacking red mangrove shoreline and 3,300 ft<sup>2</sup> of maintenance dredging (an area of up to 185 ft by 18 ft along the seawall within the Cape Coral Hotspot); no beach fill is proposed waterward of the MHW line within the Cape

Coral Hotspot. In addition, we believe that the construction methodologies proposed (i.e., installation of seawalls by jetting only, construction moratorium within the Cape Coral Hotspot from March 1 – July 1, minimum clearance for turbidity curtains and barges, and spudding required for all barges) will not appreciably block juvenile smalltooth sawfish from using the portion of the Cape Coral Hotspot within and adjacent to the action area. Further, there are unconsolidated shorelines and undisturbed habitat available in the Smalltooth Sawfish Habitat Limited Exclusion Zones located downriver of the Cape Coral Hotspot (i.e., in Glover Bight and Iona Cove).

An increase in recreational vessel traffic in the area may result from the construction of new moorage for 45 new vessels. Sea turtles, giant manta ray, and smalltooth sawfish could be affected by increased vessel traffic in the area as it may increase the risk of collisions with these species. We believe the risk of vessel interaction with sea turtles is extremely unlikely to occur. According to a NMFS Protected Resources Division analysis (Barnette 2018), it would take an introduction of at least 200 new vessels to an area to result in a take of 1 sea turtle in any single year. Because this project will result in far less than 200 new vessels, we believe it is extremely unlikely that sea turtles will be killed or injured by new or increased vessel traffic in the area. Due to the limited available information on the giant manta ray, the few instances of confirmed or suspected strandings of giant manta ray attributed to vessel strike injury, and because we expect the circumstances and factors resulting in vessel strike injury to be similar between sea turtles and the giant manta ray, we will rely on the more robust available data on sea turtle vessel strike injury to serve as a proxy for the giant manta ray. Therefore, we believe it is extremely unlikely that giant manta ray will be killed or injured by new or increased vessel traffic in the area. Smalltooth sawfish would rarely be at risk of being struck by recreational vessels because this species is primarily demersal (i.e., they live and feed on or near the bottom). Navigational markers throughout Florida alert boaters to shallow areas to prevent groundings. Recreational vessels rely on these markers to avoid shallow areas for safety reasons. Therefore, we believe it is extremely unlikely that smalltooth sawfish would be killed or injured by increased recreational vessel traffic in the area.

### **3.2 Status of Critical Habitat Likely to be Adversely Affected**

The term “critical habitat” is defined in Section 3(5)(A) of the ESA as (i) the specific areas within the geographic area occupied by a species, at the time it is listed in accordance with the Act, on which are found those physical or biological features (1) essential to the conservation of the species and (2) that may require special management considerations or protection; and (ii) specific areas outside the geographic area occupied by a species at the time it is listed, upon a determination that such areas are essential for the conservation of the species. “Conservation” is defined in Section 3(3) of the ESA as “...the use of all methods and procedures that are necessary to bring any endangered or threatened species to the point at which listing under the ESA is no longer necessary.”

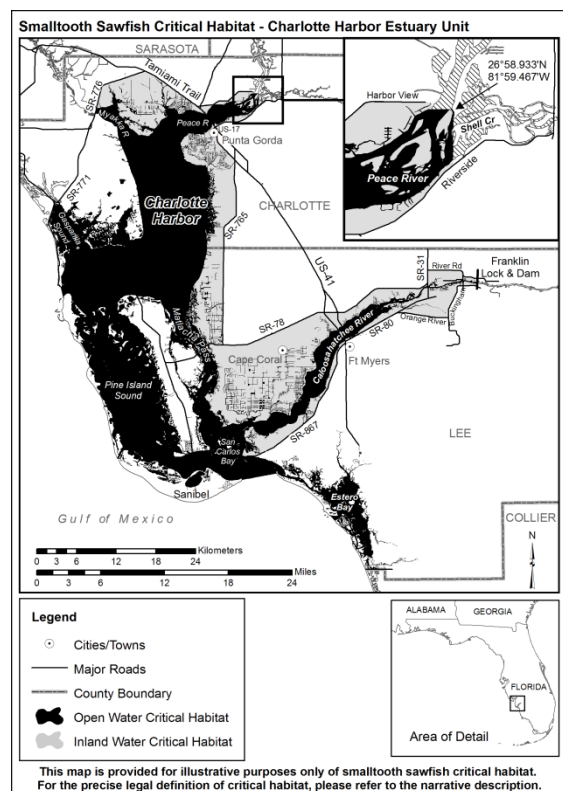

#### **3.2.1 *Smalltooth Sawfish Critical Habitat***

The U.S. DPS of smalltooth sawfish was listed as endangered on April 1, 2003; however, at that time, NMFS was unable to determine critical habitat. After funding additional studies necessary for the identification of specific habitats and environmental features important for the

conservation of the species, establishing a smalltooth sawfish recovery team, and reviewing the best scientific data available, NMFS issued a Final Rule (74 FR 45353; see also 50 CFR 226.218) to designate critical habitat for the U.S. DPS of smalltooth sawfish on September 2, 2009. Through the additional studies, researchers identified 2 primary nursery areas in southwest Florida and centered the critical habitat designations around these nurseries. The critical habitat consists of 2 units located along the southwestern coast of Florida: the CHEU, which is comprised of approximately 221,459 ac (346 mi<sup>2</sup>) of coastal habitat, and the TTIEU, which is comprised of approximately 619,013 ac (967 mi<sup>2</sup>) of coastal habitat.

#### *Critical Habitat Unit Affected by this Action*

This consultation focuses on an activity occurring in the CHEU, which encompasses portions of Charlotte and Lee Counties (**Figure 4**). The CHEU is comprised of Charlotte Harbor, Gasparilla Sound, Matlacha Pass, Pine Island Sound, San Carlos Bay, and Estero Bay. The unit is fed by the Myakka and Peace Rivers to the north and the Caloosahatchee River to the east. A series of passes between barrier islands connect the CHEU with the Gulf of Mexico. The CHEU is a relatively shallow estuary with large areas of SAV, oyster bars, saltwater marsh, freshwater wetlands, and mangroves. Freshwater flows from the Caloosahatchee River are controlled by the Franklin Lock and Dam, which periodically releases water, which thereby affects downstream salinity regimes. The CHEU boundaries are defined in detail in the Final Rule (74 FR 45353; see also 50 CFR 226.218).

**Figure 4. Map of smalltooth sawfish critical habitat – Charlotte Harbor Estuary Unit**

### *Essential Features of Critical Habitat*

The recovery plan developed for the smalltooth sawfish, which represents NMFS's best judgment about the objectives and actions necessary for the species' recovery, identified a need to increase the number of juvenile smalltooth sawfish developing into adulthood by protecting or restoring nursery habitat (NMFS 2009). NMFS determined that without sufficient habitat, the population was unlikely to increase to a level associated with low extinction risk and de-listing. Therefore, within the 2 critical habitat units NMFS identified 2 habitat features essential for the conservation of this species: (1) red mangroves, and (2) shallow, euryhaline habitats characterized by water depths between the MHW line and 3 ft (0.9 m) measured at MLLW (Final Rule, 74 FR 45353). These essential features of critical habitat provide juveniles refuge from predation and forage opportunities within their nursery habitat. One or both of these essential features must be present in an action area for it to function as critical habitat for smalltooth sawfish.

### *Habitat Use*

Juvenile smalltooth sawfish, identified as those up to 3 years of age or approximately 8 ft (2.4 m) in length (Simpfendorfer et al. 2008), inhabit the shallow waters of estuaries and can be found in sheltered bays, dredged canals, along banks and sandbars, and in rivers (NMFS 2000). Juvenile smalltooth sawfish occur in euryhaline waters (i.e., waters with a wide range of salinities) and are often closely associated with muddy or sandy substrates, and shorelines containing red mangroves (Simpfendorfer 2001; 2003). The structural complexity of red mangrove prop roots creates a unique habitat used by a variety of fish, invertebrates, and birds. Juvenile smalltooth sawfish, particularly YOY (measuring less than 39.4 in [100 cm] in length), use these areas as both refuge from predators and forage grounds, taking advantage of the large number of fish and invertebrates found there.

Tracking data from the Caloosahatchee River in Florida indicate very shallow depths and specific salinity ranges are important abiotic factors influencing juvenile smalltooth sawfish movement patterns, habitat use, and distribution (Simpfendorfer et al. 2011). An acoustic tagging study in a developed region of Charlotte Harbor, Florida, identified the importance of mangroves in close proximity to shallow-water habitat for juvenile smalltooth sawfish, stating that juveniles generally occur in shallow water within 328 ft (100 m) of mangrove shorelines (Simpfendorfer et al. 2010). Juvenile smalltooth sawfish spend the majority of their time in waters shallower than 13 ft (4 m) deep (Simpfendorfer et al. 2010) and are seldom found deeper than 32 ft (10 m) (Poulakis and Seitz 2004). Simpfendorfer et al. (2010) also indicated the following developmental differences in habitat use: the smallest YOY juveniles generally used water shallower than 1.6 ft (0.5 m), had small home ranges, and exhibited high levels of site fidelity. Although small juveniles exhibit high levels of site fidelity for specific nursery habitats for periods of time lasting up to 3 months (Wiley and Simpfendorfer 2007), they undergo small movements coinciding with changing tidal stages. These movements often involve moving from shallow sandbars at low tide and among red mangrove prop roots at higher tides (Simpfendorfer et al. 2010), behavior likely to reduce the risk of predation (Simpfendorfer 2006). As juveniles increase in size, they begin to expand their home ranges (Simpfendorfer et al. 2010; Simpfendorfer et al. 2011), eventually moving to more offshore habitats where they likely feed on larger prey and eventually reach sexual maturity.

Researchers have identified several areas within the Charlotte Harbor Estuary that are disproportionately more important to juvenile smalltooth sawfish, based on intra- or inter-annual capture rates during random sampling events within the estuary (Poulakis 2012; Poulakis et al. 2011). The areas, which were termed “hotspots” in Poulakis et al. (2011), correspond with areas where public encounters are most frequently reported. Use of these “hotspots” can be variable within and among years based on the amount and timing of freshwater inflow. Smalltooth sawfish use “hotspots” further upriver during drought (i.e., high salinity) conditions and areas closer to the mouth of the Caloosahatchee River during times of high freshwater inflow (Poulakis et al. 2011). At this time, researchers are unsure what specific biotic (e.g., presence or absence of predators and prey) or abiotic factors (e.g., flow rate, water temperature, etc.) influence this habitat selection. Still, they believe a variety of conditions in addition to salinity, such as temperature, dissolved oxygen, water depth, shoreline vegetation, and food availability, may influence smalltooth sawfish habitat selection (Poulakis et al. 2011).

### *Status and Threats to Critical Habitat*

Modification and loss of smalltooth sawfish critical habitat is an ongoing threat contributing to the current status of the species. Activities such as agricultural and urban development, commercial activities, dredge-and-fill operations, boating, erosion, and diversions of freshwater runoff contribute to these losses (South Atlantic Fishery Management Council 1998). Large areas of coastal habitat were modified or lost between the mid-1970s and mid-1980s within the United States (Dahl and Johnson 1991; USFWS 1999). Since then, rates of loss have decreased even though habitat loss continues. Between 1998 and 2004, approximately 2,450 ac (3.8 mi<sup>2</sup>) of intertidal wetlands consisting of mangroves or other estuarine shrubs were lost along the Atlantic and Gulf coasts of the United States (Stedman and Dahl 2008). In another study, Orlando Jr. et al. (1994) analyzed 18 major southeastern estuaries and recorded over 703 mi (1,131 kilometers [km]) of navigation channels and 9,844 mi (15,842 km) of shoreline with modifications. Additionally, changes to the natural freshwater flows into estuarine and marine waters through construction of canals and other water-control devices have altered the temperature, salinity, and nutrient regimes, reduced both wetlands and SAV coverage, and degraded vast areas of coastal habitat utilized by smalltooth sawfish (Gilmore 1995; Quigley and Flannery 2002; Reddering 1988; Whitfield and Bruton 1989). Juvenile sawfish and their critical habitat are particularly vulnerable to these kinds of habitat losses or alterations due to the juveniles’ affinity for (and developmental need of) shallow, estuarine systems. Although many forms of habitat modification are currently regulated, some permitted direct and/or indirect damage to habitat from increased urbanization still occurs and is expected to continue in the future.

In Florida, coastal development often involves the removal of mangroves, the armoring of shorelines through seawall construction, and the dredging of canals. This is especially apparent in master plan communities such as Cape Coral and Punta Gorda which are located within the Charlotte Harbor Estuary. These communities were created through dredge-and-fill projects to increase the amount of waterfront property available for development, but in doing so, developers removed the majority of red mangrove habitat from the area. The canals created by these communities require periodic dredging for boat access, further affecting the shallow, euryhaline essential feature of critical habitat. Development continues along the shorelines of Charlotte Harbor in the form of docks, boat ramps, shoreline armoring, utility projects, and navigation channel dredging.

To protect critical habitat, federal agencies must ensure that their activities are not likely to result in the destruction or adverse modification of the physical and biological features that are essential to the conservation of sawfish, or the species' ability to access and use these features (ESA Section 7(a)(2); see also 50 CFR 424.12(b) [discussing essential features]). Therefore, proposed actions that may impact critical habitat require an analysis of potential impacts to each essential feature. As mentioned previously, there are 2 essential features of smalltooth sawfish critical habitat: (1) red mangroves; and (2) shallow, euryhaline habitats characterized by water depths between the MHW line and 3 ft (0.9 m) measured at MLLW. The USACE oversees the permitting process for residential and commercial marine development in the CHEU. The FDEP and their designated authorities also regulate mangrove removal in Florida. All red mangrove removal permit requests within smalltooth sawfish critical habitat necessitate ESA Section 7 consultation. NMFS Protected Resources Division tracks the loss of these essential features of smalltooth sawfish critical habitat.

### *Threats to Critical Habitat*

#### Dock and Boat Ramp Construction

The USACE recommends that applicants construct docks in accordance with the NMFS-USACE *Dock Construction Guidelines in Florida for Docks or Other Minor Structures Constructed in or over Submerged Aquatic Vegetation (SAV), Marsh, or Mangrove Habitat* ("Dock Construction Guidelines") when possible. The current dock construction guidelines allow for some amount of mangrove removal; however, it is typically restricted to either (1) trimming to facilitate a dock, or (2) complete removal up to the width of the dock extending toward open water, which the guidelines define as a width of 4 ft.

Installation or replacement of boat ramps is often part of larger projects such as marinas, bridge approaches, and causeways where natural and previously created deepwater habitat access channels already exist. Boat ramps can result in the permanent loss of both the red mangrove and the shallow, euryhaline habitat features of critical habitat for smalltooth sawfish.

#### Marina Construction

Marinas have the potential to adversely affect aquatic habitats. Marinas are typically designed to be deeper than 3 ft MLLW to accommodate vessel traffic; therefore, most existing marinas lacking essential features are unlikely to function as critical habitat for smalltooth sawfish. The expansion of existing marinas and creation of new marinas can result in the permanent loss of large areas of this nursery habitat.

#### Bulkhead and Seawall Construction

Bulkheads and other shoreline stabilization structures are used to protect adjacent shorelines from wave and current action and to enhance water access. These projects may adversely impact critical habitat for smalltooth sawfish by removal of the essential features through direct filling and dredging to construct vertical or riprap seawalls. Generally, vegetation plantings, sloping riprap, or gabions are environmentally-preferred shoreline stabilization methods instead of vertical seawalls because they provide better quality fish and wildlife habitat. Nevertheless,

placement of riprap material removes more of the shallow euryhaline essential feature than a vertical seawall. Also, many seawalls built along unconsolidated shorelines require the removal of red mangroves to accommodate the seawalls.

#### Cable, Pipeline, and Transmission Line Construction

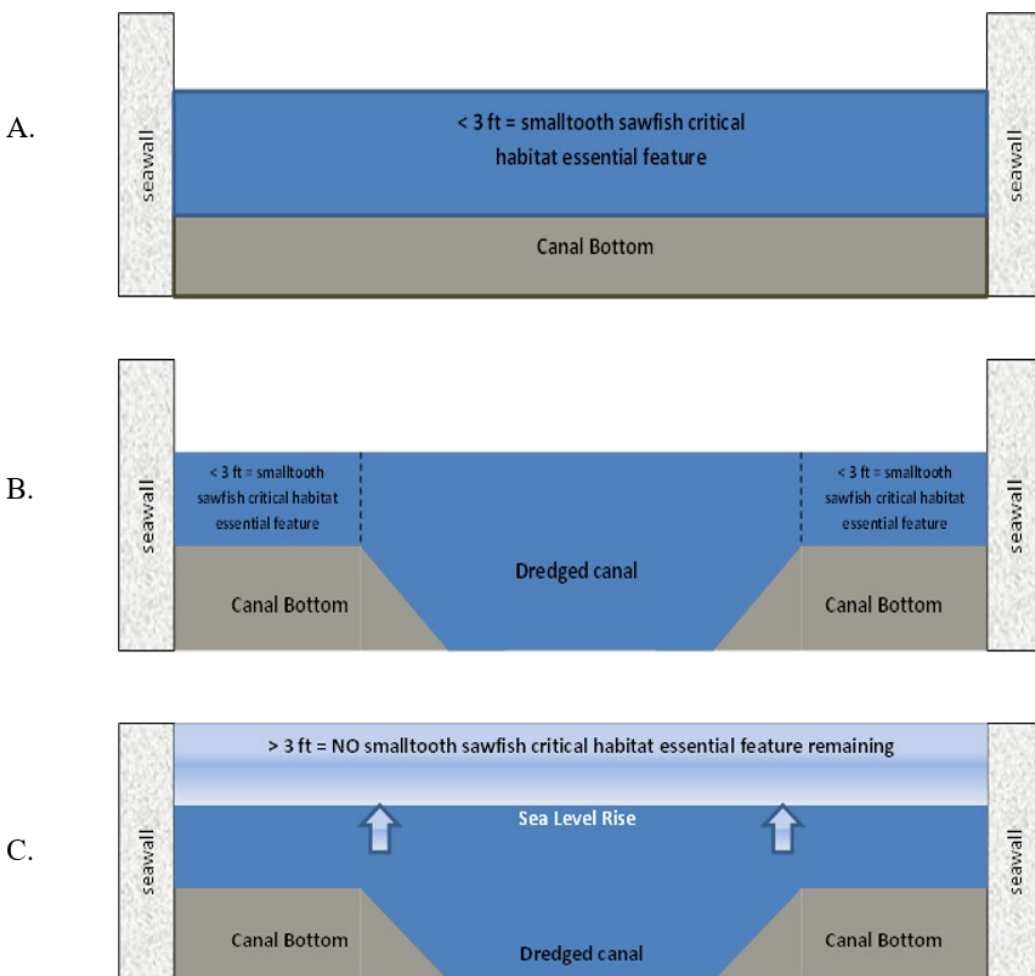

While not as common as other activities, excavation of submerged lands is sometimes required for installing cables, pipelines, and transmission lines. Construction may also require temporary or permanent filling of submerged habitats. Open-cut trenching and installation of aerial transmission line footers are activities that have the ability to temporarily or permanently impact critical habitat for smalltooth sawfish.

#### Transportation Infrastructure Construction

Potential adverse effects from federal transportation projects in smalltooth sawfish critical habitat (CHEU) include operations of the Federal Highway Administration, USACE, and the Federal Emergency Management Agency. Construction of road improvement projects typically follow the existing alignments and expand to compensate for the increase in public use. Transportation projects may impact critical habitat for smalltooth sawfish through installation of bridge footers, fenders, piles, and abutment armoring, or through removal of existing bridge materials by blasting or mechanical efforts.

#### Dredging

Riverine, nearshore, and offshore areas are dredged for navigation, construction of infrastructure, and marine mining. An analysis of 18 major southeastern estuaries conducted in 1993-1994 demonstrated that over 7,000 km of navigation channels have already been dredged (Orlando Jr. et al. 1994). Habitat effects of dredging include the loss of submerged habitats by disposal of excavated materials, turbidity and siltation effects, contaminant release, alteration of hydrodynamic regimes, and fragmentation of physical habitats (Gulf of Mexico Fishery Management Council 1998; Gulf of Mexico Fishery Management Council 2005; South Atlantic Fishery Management Council 1998). In the CHEU, dredging to maintain canals and channels constructed prior to the critical habitat designation, limits the amount of available shallow, euryhaline essential feature to the edges of waterways and these dredging activities can disturb juveniles that are using these areas. At the time of critical habitat designation, many previously dredged channels and canals existed within the boundaries of the critical habitat units; however, we are unsure which of those contained the shallow-water essential feature at that time. It is likely that many of these channels and canals were originally dredged deeper than 3 ft MLLW, but they have since shoaled in and now contain the essential feature of shallow, euryhaline habitat. Therefore, maintenance dredging impacts are counted as a loss to this essential feature, even though the areas may or may not have contained the essential feature at time of designation (see **Figure 5**, Diagrams A and B).

**Figure 5. Diagram A depicts a cross section of a historically dredged channel/canal within the boundaries of the critical habitat units that has not been maintained. Diagram B depicts the typical cross section of a maintenance-dredged channel/canal. Diagram C depicts a cross section of a maintained dredged channel/canal after sea level rise of > 1 ft.**

#### Construction, Operations and Maintenance of Impoundments and Other Water Level Controls

Federal agencies such as the USACE have historically been involved in large water control projects in Florida. Agencies sometimes propose impounding rivers and tributaries for such purposes as flood control, salt water intrusion prevention, or creation of industrial, municipal, and agricultural water supplies. Projects to repair or replace water control structures may affect smalltooth sawfish critical habitat by limiting sufficient freshwater discharge, which could alter the salinity of estuaries. The ability of an estuary to function as a nursery depends upon the quantity, timing, and input location of freshwater inflows (Garmestani and Percival 2005; Norton et al. 2012; USEPA 1994). Estuarine ecosystems are vulnerable to the following man-made disturbances: (1) decreases in seasonal inflow caused by the removal of freshwater upstream for agricultural, industrial, and domestic purposes; (2) contamination by industrial and sewage discharges; (3) agricultural runoff carrying pesticides, herbicides, and other toxic pollutants; and (4) eutrophication (e.g., influx of nutrients such as nitrates and phosphates most often from fertilizer runoff and sewage) caused by excessive nutrient inputs from a variety of nonpoint and

point sources. Additionally, rivers and their tributaries are susceptible to natural disturbances, such as floods and droughts, whose effects can be exacerbated by these man-made disturbances.

As stated above, smalltooth sawfish show an affinity for a particular salinity range, moving downriver during wetter months and upriver during drier months to remain within that range (Simpfendorfer et al. 2011). Therefore, water management decisions that affect salinity regimes may impact the functionality of critical habitat. This may result in smalltooth sawfish following specific salinity gradients into less advantageous habitats (e.g., areas with less shallow-water or red mangrove habitat). Furthermore, large changes in water flow over short durations would likely escalate movement patterns for smalltooth sawfish, thereby increasing predation risk and energy output. Researchers are currently looking into the effects of large-scale freshwater discharges on smalltooth sawfish and their designated critical habitat. The most vulnerable portion of the juvenile sawfish population to water-management outfall projects appears to be smalltooth sawfish in their first year of life. Newborn smalltooth sawfish remain in smaller areas irrespective of salinity, which potentially exposes them to greater osmotic stress (a sudden change in the solute concentration around a cell, causing a rapid change in the movement of water across its cell membrane), and impacts the nursery functions of sawfish critical habitat (Poulakis et al. 2013; Simpfendorfer et al. 2011).

### Climate Change Threats

The IPCC has stated that global climate change is unequivocal and its impacts to coastal resources may be significant (Intergovernmental Panel on Climate Change 2007). There is a large and growing body of literature on past, present, and future impacts of global climate change induced by human activities (i.e., global warming mostly driven by the burning of fossil fuels). The latest report by the Intergovernmental Panel on Climate Change (2013) is more explicit, stating that, “science now shows with 95% certainty that human activity is the dominant cause of observed warming since the mid-twentieth century.” Some of the anticipated outcomes are sea level rise, increased frequency of severe weather events, and changes in air and water temperatures. NOAA’s climate change web portal provides information on the climate-related variability and changes that are exacerbated by human activities (<http://www.climate.gov/#understandingClimate>).

Though the impacts on smalltooth sawfish cannot, for the most part, be predicted with any degree of certainty, we can project some effects to sawfish critical habitat. We know that both essential features (red mangroves and shallow, euryhaline waters less than 3 ft deep at MLLW) will be impacted by climate change. Sea level rise is expected to exceed 3.3 ft (1 m) globally by 2100, according to the most recent publications, exceeding the estimates of the Fourth Assessment of the IPCC (Meehl et al. 2007; Pfeffer et al. 2008; Rahmstorf et al. 2007). Mean sea level rise projections have increased since the Fourth Assessment because of the improved physical understanding of the components of sea level, the improved agreement of process-based models with observations, and the inclusion of ice-sheet dynamical changes (Intergovernmental Panel on Climate Change 2013). A 1-m sea level rise in the state of Florida is within the range of recent estimates by 2080 (Pfeffer et al. 2008; Rahmstorf et al. 2007).

Sea level increases would affect the shallow-water essential feature of smalltooth sawfish critical habitat within the CHEU. A 2010 climate change study by the MIT forecasted sea level rise in a

study area with significant overlap with the CHEU (Vargas-Moreno and Flaxman 2010). The study investigated possible trajectories of future transformation in Florida's Greater Everglades landscape relative to 4 main drivers: climate change, shifts in planning approaches and regulations, population change, and variations in financial resources. MIT used (Intergovernmental Panel on Climate Change 2007) sea level modeling data to forecast a range of sea level rise trajectories from low, to moderate, to high predictions (**Figure 6**). The effects of sea level rise on available shallow-water habitat for smalltooth sawfish would be exacerbated in areas where there is shoreline armoring (e.g., seawalls). This is especially true in canals where the centerlines are maintenance-dredged deeper than 3 ft (0.9 m) for boat accessibility. In these areas, the areas that currently contain the essential feature depth (less than 3 ft at MLLW) will be reduced along the edges of the canals as sea level rises (see previous **Figure 5** Diagram C).

**Figure 6. From left to right: current shoreline, + 3.5 in (+ 9 cm); + 18.5 in (+ 47 cm); and + 38.97 in (+ 99 cm) sea level rise by 2060.<sup>1</sup>**

Along the Gulf Coast of Florida, and south Florida in particular, rises in sea level will impact mangrove resources. As sea levels rise, mangroves will be forced landward in order to remain at a preferred water inundation level and sediment surface elevation, which is necessary for successful growth. This retreat landward will not keep pace with conservative projected rates of elevation in sea level (Gilman et al. 2008). This forced landward progression poses the greatest threat to mangroves in areas where there is limited or no room for landward or lateral migration (Semeniuk 1994). Such is the case in areas of the CHEU where landward mangrove growth is restricted by shoreline armoring and coastal development. This man-made barrier will prohibit mangroves from moving landward and will result in the loss of the mangrove essential feature.

Other threats to mangroves result from climate change: fluctuations in precipitation amounts and distribution, seawater temperature, CO<sub>2</sub> levels, and damage to mangroves from increasingly severe storms and hurricanes (McLeod and Salm 2006). A 25% increase in precipitation globally is predicted by 2050 (McLeod and Salm 2006), but the specific geographic distribution will vary, leading to increases and decreases in precipitation at the regional level. Changes in precipitation

<sup>1</sup> Adapted from Vargas-Moreno, J. C., and M. Flaxman. 2010. Addressing the challenges of climate change in the greater everglades landscape. Massachusetts Institute of Technology, Department of Urban Studies and Planning. Project Sheet November, 2010, Cambridge, MA.

patterns caused by climate change may adversely affect the growth of mangroves and their distribution (Field 1995; Snedaker 1995). Decreases in precipitation will increase salinity and inhibit mangrove productivity, growth, seedling survival, and spatial coverage (Burchett et al. 1984). Decreases in precipitation may also change mangrove species composition, favoring more salt-tolerant types (Ellison 2010). Increases in precipitation may benefit some species of mangroves, increasing spatial coverage and allowing them to out-compete other salt marsh vegetation (Harty 2004). Even so, potential mangrove expansion requires suitable habitat for mangroves to increase their range, which depends to a great extent on patterns and intensity of coastal development (i.e., bulkhead and seawall construction).

Seawater temperature changes will have potential adverse effects on mangroves as well. Many species of mangroves show an optimal shoot density in sediment temperatures between 59-77°F (15-25°C) (Hutchings and Saenger 1987). Yet, at temperatures between 77-95°F (25-35°C), many species begin to show a decline in leaf structure and root and leaf formation rates (Saenger and Moverley 1985). Temperatures above 95°F lead to adverse effects on root structure and survivability of seedlings (UNESCO 1991) and temperatures above 100.4°F (38°C) lead to a cessation of photosynthesis and mangrove mortality (Andrews et al. 1984). Although impossible to forecast precisely, sea surface ocean temperatures are predicted to increase 1.8-3.6°F (1-2°C) by 2060 (Chapter 11 (Intergovernmental Panel on Climate Change 2013)), which will in turn impact underlying sediment temperatures along the coast. If mangroves shift pole-ward in response to temperature increases, they will at some point be limited by temperatures at the lower end of their optimal range and available recruitment area. This is especially true when considering already armored shorelines in residential communities such as those within and surrounding the CHEU of critical habitat for smalltooth sawfish.

As atmospheric CO<sub>2</sub> levels increase, mostly resulting from man-made causes (e.g., burning of fossil fuels), the world's oceans will absorb much of this CO<sub>2</sub>, causing potential increases in photosynthesis and mangrove growth rates. This increase in growth rate, however, would be limited by lower salinities expected from CO<sub>2</sub> absorption in the oceans (Ball et al. 1997), and by the availability of undeveloped coastline for mangroves to expand their range. A secondary effect of increased CO<sub>2</sub> concentrations in the oceans is the deleterious effect on coral reefs' ability to absorb calcium carbonate (Hoegh-Guldberg et al. 2007), and subsequent reef erosion. Eroded reefs may not be able to buffer mangrove habitats from waves, especially during storm/hurricane events, causing additional physical effects.

Finally, the anticipated increase in the severity of storms and hurricanes may also impact mangroves. Tropical storms are expected to increase in intensity and/or frequency, which will directly impact existing mangroves that are already adversely impacted by increased seawater temperatures, CO<sub>2</sub>, and changes in precipitation (Cahoon et al. 2003; Trenberth 2005). The combination of all of these factors may lead to reduced mangrove height (Ning et al. 2003). Further, intense storms could result in more severe storm surges and lead to potential changes in mangrove community composition, mortality, and recruitment (Gilman et al. 2006). Increased storm surges and flooding events could also affect mangroves' ability to photosynthesize (Gilman et al. 2006) and the oxygen concentrations in the mangrove lenticels (Ellison 2010).

## 4 ENVIRONMENTAL BASELINE

---

This section describes the effects of past and ongoing human and natural factors contributing to the current status of the affected smalltooth sawfish critical habitat in the action area. The environmental baseline describes the critical habitat's health based on information available at the time of this consultation.

By regulation, the environmental baseline for an Opinion refers to the condition of the listed species or its designated critical habitat in the action area, without the consequences to the listed species or designated critical habitat caused by the proposed action. The environmental baseline includes the past and present impacts of all Federal, State, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early section 7 consultation, and the impact of State or private actions which are contemporaneous with the consultation in process. The consequences to listed species or designated critical habitat from ongoing agency activities or existing agency facilities that are not within the agency's discretion to modify are part of the environmental baseline (50 CFR 402.02).

Focusing on the current state of critical habitat is important because in some areas critical habitat features will commonly exhibit, or be more susceptible to, adverse responses to stressors than they would be in other areas, or may have been exposed to unique or disproportionate stresses. These localized stress responses or stressed baseline conditions may increase the severity of the adverse effects expected from the proposed action.

### 4.1 Status of Designated Critical Habitat within the Action Area

#### 4.1.1 *Smalltooth Sawfish Critical Habitat*

The action area is located within the boundaries of the CHEU of smalltooth sawfish designated critical habitat at the existing marina and park at the Cape Coral Yacht Club Cape Coral, Lee County, Florida. As stated above, the action area also occurs within and directly adjacent to the boundaries of the Cape Coral Hotspot as defined in the JAXBO, which is an area that researchers have identified as disproportionately more important to juvenile smalltooth sawfish, based on intra- or inter-annual capture rates during random sampling events (Poulakis 2012; Poulakis et al. 2011) and corresponds with an area where public encounters are more frequently reported. Water depths at the project site shoreline are approximately 6.5 ft at MLW. The action area is devoid of corals, SAV, and red mangroves. The entire action area is armored with vertical seawalls. There have been several sightings of smalltooth sawfish within the action area and numerous sightings of juvenile smalltooth sawfish at the entrance to the marina where it joins the Caloosahatchee River (SSRIT encounter database).

### 4.2 Factors Affecting Designated Critical Habitat within the Action Area

#### 4.2.1 *Federal Actions*

As per a review of our completed consultation database by the consulting biologist on February 22, 2022, there is 1 previous ESA Section 7 consultation in the action area with the potential to

adversely affect smalltooth sawfish critical habitat. SER-2011-2423 West Coast Inland Navigation District Normandy Canal and Everest Canal Dredge Projects ; we issued an Opinion on November 30, 2011, in which we estimated the loss of 89,000 ft<sup>2</sup> of shallow, euryhaline habitat due to maintenance dredging of existing canals at the mouth of the Caloosahatchee River and determined that the proposed action was likely to adversely affect, but would not destroy or adversely modify smalltooth sawfish critical habitat. These losses have already been accounted for in the “losses since critical habitat designation” in their respective sections of the Destruction and Adverse Modification analysis below (See Section 7.1 Line 3 in **Table 4**).

#### *4.2.2 State or Private Actions*

Examples of nonfederal activities that may adversely affect designated critical habitat for smalltooth sawfish in the action area include residential in-water activities that do not require federal permits or otherwise have a federal nexus. The direct and indirect impacts from these activities are difficult to quantify but may include loss or degradation of red mangroves or shallow, euryhaline habitat from unauthorized mangrove trimming, shoreline stabilization, or in-water construction. NMFS does not have any knowledge of state or private actions occurring in the action area that would not also require a federal permit; the likelihood of a project occurring in the action area that does not require a federal permit for in-water construction work is very small. Where possible, conservation actions in ESA Section 10 permits, ESA Section 6 cooperative agreements, and state permitting programs are being implemented or investigated to monitor or study impacts from these sources.

#### *4.2.3 Other Potential Sources of Impacts to the Environmental Baseline*

Stochastic events, such as hurricanes, are common throughout the range of smalltooth sawfish, especially in the current core of its range (i.e., south and southwest Florida). These events are by nature unpredictable and their effect on the survival and recovery of the species and on critical habitat are unknown; however, they have the potential to impede the survival and recovery directly if animals die as a result of them, or indirectly if habitat, especially critical habitat, is damaged as a result of these disturbances. Hurricane Irma likely damaged habitat, including mangroves, in and around the action area in 2017. Hurricane Ian likely damaged habitat, including mangroves, in and around the action area in 2022.

#### *4.2.4 Conservation and Recovery Actions Shaping the Environmental Baseline*

Federal EFH consultation requirements pursuant to the MSA can minimize and mitigate for losses of wetland and preserve valuable foraging and developmental habitat that is used by juvenile smalltooth sawfish, including areas that have been designated as smalltooth sawfish critical habitat. NMFS has designated mangrove and estuarine habitats as EFH as recommended by the Gulf of Mexico Fishery Management Council. Both essential features are critical components of areas designated as EFH and receive a basic level of protection under the MSA to the extent that the MSA requires minimization of impacts to EFH resources.

## **5 EFFECTS OF THE ACTION ON CRITICAL HABITAT**

---

Effects of the action are all consequences to listed species or critical habitat that are caused by the proposed action, including the consequences of other activities that are caused by the proposed action. A consequence is caused by the proposed action if it would not occur but for the proposed action and it is reasonably certain to occur. Effects of the action may occur later in time and may include consequences occurring outside the immediate area involved in the action (50 CFR 402.02)

The proposed action area is within the boundary of the CHEU of smalltooth sawfish designated critical habitat. The physical and biological features essential to the conservation of the U.S. DPS of smalltooth sawfish, which provide nursery area functions, are: (1) shallow, euryhaline habitats characterized by water depths between the MHW line and 3 ft (0.9 m) measured at MLLW, and (2) red mangroves. We believe the proposed action will affect the shallow, euryhaline habitat essential feature of smalltooth sawfish designated critical habitat as outlined below.

### **5.1 Effects of the Action on the Shallow, Euryhaline Habitat Essential Feature of Smalltooth Sawfish Designated Critical Habitat**

We believe the proposed action is likely to adversely affect smalltooth sawfish designated critical habitat due to the permanent removal of 56,200 ft<sup>2</sup> (see **Table 1**) of the shallow, euryhaline habitat essential feature, which provides forage, shelter, or other nursery habitat functions for juvenile smalltooth sawfish. Because we calculate and track losses to the shallow, euryhaline habitat essential feature of critical habitat in acres, we convert the project's effects from square feet to acres and use acres in the analyses below (i.e., 1.290172 ac, where 1 ft<sup>2</sup> = 0.0000229568 ac).

We estimated that the total amount of shallow, euryhaline habitat in CHEU at the effective date of species listing (May 1, 2003) was approximately 84,480 ac. While the available shallow, euryhaline essential feature will be diminished, the proposed action is not severing or preventing juvenile smalltooth sawfish access to alternate habitat with this essential feature in the surrounding area. Still, some ecological function provided to juvenile smalltooth sawfish currently using the area, and conservation benefits to future juvenile sawfish in terms of the shallow, euryhaline essential feature, will be lost; therefore, we believe the project is likely to adversely affect critical habitat in the CHEU.

### **5.2 Effects of the Action on the Red Mangrove Essential Feature of Smalltooth Sawfish Designated Critical Habitat**

Because the proposed action will not remove or permanently restrict access to red mangroves, there are no potential routes of adverse effects to the red mangrove essential feature of smalltooth sawfish designated critical habitat. In addition, there are no other potential routes of effect to the red mangrove essential feature.

## 6 CUMULATIVE EFFECTS

---

ESA Section 7 regulations require NMFS to consider cumulative effects in formulating its Opinions (50 CFR 402.14). Cumulative effects include the effects of future state, tribal, local, or private actions that are reasonably certain to occur in the action area considered in this Opinion (50 CFR 402.02).

Many threats to smalltooth sawfish critical habitat are expected to be exacerbated by the effects of global climate change. Potential increases in sea level may impact the availability of nursery habitat, particularly shallow, euryhaline habitat and red mangrove lined, low-lying coastal shorelines (Intergovernmental Panel on Climate Change 2014; Wanless et al. 2005). For example, nursery habitat could be negatively affected by increased temperatures, salinities, and acidification of coastal waters (Snedaker 1995), (Wanless et al. 2005), (Scavia et al. 2002), as well as increased runoff and erosion due to the expected increase in extreme storm events (Intergovernmental Panel on Climate Change 2014; Wanless et al. 2005). These alterations of the marine environment due to global climate change could affect the distribution of shallow, euryhaline habitat, which would ultimately affect the distribution, physiology, and growth rates of red mangroves. These alterations could potentially eliminate red mangroves from particular areas. The magnitude of the effects of global climate change on smalltooth sawfish critical habitat are difficult to predict, yet, when combined with the cyclical loss of habitat from extreme storm events, a decrease in the red mangrove essential feature of smalltooth sawfish critical habitat is likely (Norton et al. 2012; Scavia et al. 2002). However, the proposed action is of such a small scale, scope, and limited period that it is not very likely to contribute to, or be affected cumulatively by, climate change.

Smalltooth sawfish habitat, in general, and designated critical habitat, specifically, have been degraded or modified throughout the southeastern U.S. from agriculture, urban development, commercial activities, channel dredging, boating activities, and the diversion of freshwater runoff. No future actions with effects beyond those already described, and no other future state, tribal, or local private actions, are reasonably certain to occur in the action area. The habitat within the CHEU will likely continue to experience the same types of actions described in the Status of the Critical Habitat section. These threats include shoreline armoring, canal dredging, and dock construction.

## 7 DESTRUCTION AND ADVERSE MODIFICATION ANALYSIS

---

NMFS's regulations define *destruction or adverse modification* to mean "a direct or indirect alteration that appreciably diminishes the value of critical habitat as a whole for the conservation of a listed species" (50 CFR 402.02). Alterations that may destroy or adversely modify critical habitat may include impacts to the area itself, such as those that would impede access to or use of the essential features. NMFS will generally conclude that a federal action is likely to "destroy or adversely modify" critical habitat if the action results in an alteration of the quantity or quality of the essential physical or biological features of critical habitat and if the effect of the alteration is to appreciably diminish the value of critical habitat as a whole for the conservation of the species.

This analysis takes into account the geographic and temporal scope of the proposed action, recognizing that “functionality” of critical habitat necessarily means that it must now and must continue in the future to support the conservation of the species and progress toward recovery. The analysis takes into account any changes in amount, distribution, or characteristics of the critical habitat that will be required over time to support the successful recovery of the species. Destruction or adverse modification does not depend strictly on the size or proportion of the area adversely affected, but rather on the role the action area and the affected critical habitat serves with regard to the function of the overall critical habitat designation, and how that role is affected by the action.

The smalltooth sawfish recovery plan identifies 3 recovery objectives to help facilitate recruitment of juveniles into the recovering adult population (NMFS 2009). Recovery Objective #1 is to minimize human interactions and associated injury and mortality; this objective is not relevant to critical habitat. Recovery Objective #2 is to protect and/or restore smalltooth sawfish habitats. Recovery Objective #3 is to ensure smalltooth sawfish abundance increases substantially and the species reoccupies areas from which it had previously been extirpated. Our analysis evaluates whether the anticipated impacts to critical habitat associated with the proposed action would interfere with Recovery Objectives #2 and #3, and ultimately, the conservation objective behind the designated critical habitat—that is, facilitation of juvenile recruitment into a recovering adult population.

### **7.1 Protect and Restore Smalltooth Sawfish Habitat (Recovery Objective #2)**

In establishing Recovery Objective #2, we recognized that recovery and conservation of smalltooth sawfish depends on the availability and quality of nursery habitats. Historically, juvenile sawfish were documented in mangrove and non-mangrove habitat in the southeastern United States. Due to the protections provided by the Ten Thousand Islands National Wildlife Refuge, Everglades National Park, and the Florida Keys National Marine Sanctuary, much of the historic juvenile smalltooth sawfish habitat in southwest Florida has remained high-quality juvenile habitat. Recovery Regions G, H, and I in southwest Florida extend from the Manatee River on the west coast of Florida, south through Everglades National Park and the Florida Keys to Caesar Creek on the southeast coast of Florida. The CHEU is in Recovery Region G. While much of the CHEU is protected by the CHPSP system and the Estero Bay Aquatic Preserve, it is also highly anthropomorphically influenced.

The recovery plan states that for the 3 recovery regions with remaining high-quality habitats (i.e., Recovery Regions G, H, and I), juvenile habitats “must be maintained over the long term at or above 95% of the acreage available at the time of listing” (NMFS, 2009). To ensure that a proposed action will not impede Recovery Objective #2, we determine whether the critical habitat unit will be able to maintain 95% of the areas containing each essential feature after taking into account project impacts in the context of the status of the critical habitat, the environmental baseline, and cumulative effects. While the CHEU is only a part of the larger Recovery Region G, and the 95% protection threshold applies across not just Recovery Region G, but also Recovery Regions H and I, the threshold is still useful for evaluating the impacts at the individual recovery region level and for sub-units of the recovery regions. The CHEU contains the only known nursery areas within Recovery Region G; thus, we believe it is appropriate to evaluate impacts at the level of the unit. In addition, functioning critical habitat

contains either one or both of the essential features, and the essential features were selected based on their role in facilitating recruitment of juvenile animals into the adult population, which the recovery plan likewise seeks to conserve and protect. Consequently, we also believe it is appropriate to consider whether 95% of each of the essential features of critical habitat in the CHEU is maintained. Therefore, below we estimate the percent impact the proposed action will have on the shallow, euryhaline habitat essential feature of critical habitat within the CHEU. As stated above, the proposed action will not affect the red mangrove essential feature of smalltooth sawfish critical habitat.

#### 7.1.1 *Shallow, Euryhaline Essential Feature Impacts*

We estimated that 84,480 ac of shallow, euryhaline habitat (abbreviated SH throughout this section) was available within the CHEU at the effective date of species listing (i.e., May 1, 2003) (Table 4, Line 1). As discussed above, we must determine whether a proposed action's impact will interfere with long-term maintenance of this essential feature at or above 95% of the acreage available at the time of listing; however, loss of critical habitat was not formally monitored until the effective date of critical habitat designation (i.e., October 2, 2009). Therefore, we must estimate habitat loss that occurred during the period between the effective date of species listing and the effective date of critical habitat designation (i.e., May 1, 2003 – October 2, 2009).

To do this, we use an 84-month dataset of our completed Section 7 consultations (October 3, 2009 – September 30, 2016), including yearly losses due to programmatic consultations, to generate a rate of loss that can then be used to back-calculate the loss of SH between the effective date of species listing and the effective date of critical habitat designation. We rely on this dataset because using approximately 7 years of information helps avoid over- or under-estimating the rate of habitat loss due to any potential inter-annual variability associated with economic growth and contraction that may have occurred in that time. Our consultations completed during this time indicate that 17.60 ac of SH in the CHEU was lost due to federal agency actions.

Based on these losses, we estimate a monthly loss rate of SH in the CHEU using the following equation:

$$\begin{aligned} & \text{Monthly loss rate of SH (CHEU)} \\ &= \text{SH lost through federal agency actions} \div 84 \text{ months} \\ &= 17.60 \text{ ac} \div 84 \text{ months} \\ &= 0.21 \text{ ac per month} \end{aligned}$$

Assuming the same monthly loss rate, we back-calculate the loss of SH in the 77 months between the effective date of species listing and the effective date of critical habitat designation (i.e., May 1, 2003 – October 2, 2009) in the CHEU using the following equation:

$$\begin{aligned} & \text{SH lost prior to critical habitat designation (CHEU)} \\ &= 0.21 \text{ ac per month} \times 77 \text{ months} \\ &= 16.17 \text{ ac (Table 4, Line 2)} \end{aligned}$$

Next, we determine the loss of SH since the effective date of critical habitat designation. Due to the high frequency of relatively small projects affecting smalltooth sawfish critical habitat, we update the losses to the shallow, euryhaline habitat essential feature from federal actions every 6 months (i.e., January 1 and July 1). From the effective date of critical habitat designation through December 31, 2022, 71.96 ac of SH in the CHEU has been lost due to federal agency actions (**Table 4**, Line 3). While this amount of loss only takes into account projects with a federal nexus requiring ESA Section 7 consultation, there are very few projects without a federal nexus that could affect shallow, euryhaline habitat in the CHEU as most in-water construction projects require federal authorization.

Using this information, we calculate the SH currently available in CHEU using the following equation:

$$\begin{aligned}
 & \textit{SH currently available (CHEU)} \\
 &= \textit{SH at time of species listing} - (\textit{SH lost prior to critical habitat designation} \\
 &\quad + \textit{SH lost since critical habitat designation}) \\
 &= 84,480 \text{ ac} - (16.17 \text{ ac} + 71.96 \text{ ac}) \\
 &= 84,391.87 \text{ ac (Table 4, Line 4)}
 \end{aligned}$$

We calculate the amount of SH that must be maintained in the CHEU per Recovery Objective #2 using the following equation:

$$\begin{aligned}
 & \textit{SH that must be maintained (CHEU)} \\
 &= \textit{SH at time of species listing} \times 95\% \\
 &= 84,480 \text{ ac} \times 0.95 \\
 &= 80,256 \text{ ac (Table 4, Line 5)}
 \end{aligned}$$

The proposed action would result in the permanent loss of 1.290172 ac of SH (**Table 4**, Line 6). Using the above results, we estimate the total amount of SH lost in the CHEU since species listing, including losses from the proposed action using the following equation:

$$\begin{aligned}
 & \% \textit{SH lost since species listing (CHEU)} \\
 &= [(\textit{SH lost due to this project} + \textit{SH lost prior to critical habitat designation} \\
 &\quad + \textit{SH lost since critical habitat designation}) \\
 &\quad \div \textit{Total SH at time of species listing}] \times 100 \\
 &= [(1.290172 \text{ ac} + 16.17 \text{ ac} + 71.96 \text{ ac}) \div 84,480 \text{ ac}] \times 100 \\
 &= (89.420172 \text{ ac} \div 84,480 \text{ ac}) \times 100 \\
 &= 0.105848\% \text{ (Table 4, Line 7)}
 \end{aligned}$$

Thus, we estimate the percent of SH remaining within the CHEU as:

$$\begin{aligned}
 & \% \textit{SH remaining (CHEU)} \\
 &= 100\% - \% \textit{SH lost since species listing (CHEU)} \\
 &= 100\% - 0.105848\% \\
 &= 99.894152\% \text{ (Table 4, Line 8)}
 \end{aligned}$$

**Table 4. Summary of Impacts to the Shallow, Euryhaline Habitat Essential Feature**

<b>Shallow, Euryhaline Habitat in the CHEU</b>	<b>Acres</b>
1. Available at the time of species listing	84,480
2. Losses prior to critical habitat designation	16.17
3. Losses since critical habitat designation	71.96
4. Available as of January 1, 2023	84,391.87
5. Area that must be maintained per Recovery Plan	80,256 (95% of 84,480)
6. Affected by the proposed action	1.290172
7. Affected since species listing (including the proposed action)	89.420172 (0.105848% of 84,480)
8. Remaining	84,390.579828 (99.894152% of 84,480)

### *7.1.2 Summary of Impacts to the Essential Features*

Very small percentages of the essential features of smalltooth sawfish designated critical habitat have been affected by federal agency actions since the effective date of species listing. Including losses from the proposed action, 99.894152% of the SH essential feature (**Table 4**, Line 8) available at the time of species listing remain in the CHEU. Thus, the loss of essential features associated with the proposed action, in combination with losses since we listed the species, does not provide any impediment to effectively protecting 95% of juvenile habitat in the CHEU available at the effective date of species listing, and therefore will not be an impediment to Recovery Objective #2.

## **7.2 Ensure Smalltooth Sawfish Abundance Increases (Recovery Objective #3)**

In establishing Recovery Objective #3, we recognized that it was important that sufficient numbers of juvenile sawfish inhabit several nursery areas across a diverse geographic area to ensure survivorship and growth and to protect against the negative effects of stochastic events within parts of their range. To meet this objective, Recovery Region G (i.e., CHEU) must support sufficiently large numbers of juvenile sawfish to ensure that the species is viable in the long-term and can maintain genetic diversity. Recovery Objective #3 requires that the relative abundance of small juvenile sawfish (< 200 cm) either increases at an average annual rate of at least 5% over a 27-year period, or juvenile abundance is at greater than 80% of the carrying capacity of the recovery region.

Assessing the effect of the proposed action on small juvenile abundance is made difficult by the state of available data. Since the designation of critical habitat and the release of the recovery plan in 2009, ongoing studies have been in place to monitor the U.S. DPS of smalltooth sawfish. FWC FWRI is conducting a study in the CHEU that is supported primarily with funding provided by NMFS through the ESA Section 6 Species Recovery Grants Program, while Florida State University and the NOAA NMFS Southeast Fisheries Science Center Panama City Laboratory have focused studies in the TTIEU. The intent of these studies is to determine the abundance, distribution, habitat use, and movement of smalltooth sawfish. Early indications are

that juvenile sawfish are at least stable and likely increasing in the CHEU, due in large part to ESA-listing of the species and designation of critical habitat. While it may be too early to state definitively that juveniles within CHEU are surviving to adulthood, researchers consistently capture newborn smalltooth sawfish, particularly within “hotspots,” indicating adult smalltooth sawfish are pupping within Recovery Region G. Available data from the adjacent Recovery Region H (i.e., TTIEU) indicate that adult smalltooth sawfish are also reproducing within this recovery region and that the juvenile population trend is at least stable and possibly increasing—though variability is high (Carlson and Osborne 2012; Carlson et al. 2007). With no other data to consider, the abundance trend in the TTIEU represents the best data available for assessing the population trends in the CHEU. Therefore, we do not believe the loss of habitat associated with the proposed action, in combination with the losses to date, will impede the 5% annual growth objective for the juvenile population within Recovery Region G.

## **8 CONCLUSION**

---

After reviewing the current status of smalltooth sawfish critical habitat, the environmental baseline, and the cumulative effects, it is our opinion that the loss of 1.290172 ac (56,200 ft<sup>2</sup>) of shallow, euryhaline essential feature from the proposed action will not interfere with achieving the relevant habitat-based recovery objectives for smalltooth sawfish. Therefore, we conclude the proposed action will not impede the critical habitat’s ability to support the smalltooth sawfish’s conservation, despite permanent adverse effects. Given the nature of the proposed action and the information provided above, we conclude that the action, as proposed, is likely to adversely affect, but is not likely to destroy or adversely modify, smalltooth sawfish critical habitat.

## **9 INCIDENTAL TAKE STATEMENT**

---

NMFS does not anticipate that the proposed action will incidentally take any ESA-listed species under our purview and no take is authorized. Nonetheless, as soon as the USACE becomes aware of any take of an ESA-listed species under NMFS’s purview that occurs during the proposed action, the USACE shall report it to NMFS SERO PRD via the [NMFS SERO Endangered Species Take Report Form](#). This form shall be completed for each individual known reported capture, entanglement, stranding, or other take incident. Information provided via this form shall include the title, Cape Coral Yacht Club Renovations, the issuance date, and ECO tracking number, SERO-2022-00902, for this Opinion; the species name; the date and time of the incident; the general location and activity resulting in capture; condition of the species (i.e., alive, dead, sent to rehabilitation); size of the individual, behavior, identifying features (i.e., presence of tags, scars, or distinguishing marks), and any photos that may have been taken. At that time, consultation may need to be reinitiated.

## **10 CONSERVATION RECOMMENDATIONS**

---

Section 7(a)(1) of the ESA directs federal agencies to utilize their authority to further the purposes of the ESA by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations identified in an Opinion can assist action agencies in implementing their responsibilities under Section 7(a)(1). Conservation recommendations are discretionary activities designed to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to

develop information. The following conservation recommendations are discretionary measures that we believe are consistent with this obligation and therefore should be carried out by the federal action agency:

1. Continue public outreach and education on smalltooth sawfish and smalltooth sawfish critical habitat in an effort to minimize interactions, injury, and mortality.
2. Provide funding to conduct directed research on smalltooth sawfish that will help further our understanding about the species (e.g., implement a relative abundance monitoring program which will help define how spatial and temporal variability in the physical and biological environment influence smalltooth sawfish) in an effort to predict long-term changes in smalltooth sawfish distribution, abundance, extent, and timing of movements.
3. Fund surveys of detailed bathymetry and mangrove coverage within smalltooth sawfish critical habitat. Lee County and the USACE recently funded such surveys within the Cape Coral municipality. Data is needed from other municipalities within the CHEU to establish a more accurate baseline assessment of both critical habitat features (red mangroves and shallow-water areas).
4. Fund and support restoration efforts that rehabilitate and create shallow, euryhaline and mangrove fringe habitats within the range of smalltooth sawfish.

To stay abreast of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats, we request notification of the implementation of any conservation recommendations.

## **11 REINITIATION OF CONSULTATION**

---

This concludes NMFS's consultation on the proposed action. As provided in 50 CFR 402.16, reinitiation of formal consultation is required and shall be requested by USACE or by the Service, where discretionary federal action agency involvement or control over the action has been retained, or is authorized by law, and if: (a) the amount or extent of incidental take is exceeded, (b) new information reveals effects of the agency action on listed species or designated critical habitat in a manner or to an extent not considered in this Opinion, (c) the agency action is subsequently modified in a manner that causes an effect on the listed species or critical habitat not considered in this Opinion, or (d) a new species is listed or critical habitat designated that may be affected by the action.
