This section evaluates potential entanglement impacts of various types of expended materials used by the Navy during training and testing activities within the Study Area. The likelihood of fish being affected by an entanglement stressor is a function of the physical properties, location, and buoyancy of the object and the behavior of the fish as described in Section 3.0.5.7.4 (Conceptual Framework for Assessing Effects from Entanglement). Two types of military expended materials are considered here: (1) fiber optic cables and guidance wires, and (2) parachutes.

Most entanglement observations involve abandoned or discarded nets, lines, and other materials that form loops or incorporate rings (Derraik 2002; Keller et al. 2010; Laist 1987; Macfadyen et al. 2009). A 25-year dataset assembled by the Ocean Conservancy reported that fishing line, rope, and fishing nets accounted for approximately 68 percent of fish entanglements, with the remainder due to encounters with various items such as bottles, cans, and plastic bags (Ocean Conservancy 2010). No occurrences involving military expended materials were documented.

Fish entanglement occurs most frequently at or just below the surface or in the water column where objects are suspended. A smaller number involve objects on the seafloor, particularly abandoned fishing gear designed to catch bottom fish or invertebrates (Ocean Conservancy 2010). More fish species are entangled in coastal waters and the continental shelf than elsewhere in the marine environment because of higher concentrations of human activity (e.g., fishing, sources of entangling debris), higher fish abundances, and greater species diversity (Helfman et al. 2009b; Macfadyen et al. 2009). The consequences of entanglement range from temporary and inconsequential to major physiological stress or mortality.

Some fish are more susceptible to entanglement in derelict fishing gear and other marine debris, compared to other fish groups. Physical features, such as rigid or protruding snouts of some elasmobranchs (e.g., the wide heads of hammerhead sharks), increase the risk of entanglement compared to fish with smoother, more streamlined bodies (e.g., lamprey and eels). Most other fish, except for jawless fish and eels that are too smooth and slippery to become entangled, are susceptible to entanglement gear specifically designed for that purpose (e.g., gillnets); however, the Navy does not expend any items that are designed to function as entanglement objects.

The overall effects of entanglement are highly variable, ranging from temporary disorientation to mortality due to predation or physical injury. The evaluation of a species' entanglement potential should consider the size, location, and buoyancy of an object as well as the behavior of the fish species.

The following sections seek to identify entanglement potential due to military expended material. Where appropriate, specific geographic areas (open ocean areas, range complexes, testing ranges, and bays and inland waters) of potential impact are identified.

3.9.3.4.1 Impacts from Fiber Optic Cables and Guidance Wires

Fiber optic cables and guidance wires are used during training and testing activities. A discussion of the types of activities, physical characteristics, location of use, and the number of items expended under each alternative is presented in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires).

Marine fish groups identified in Sections 3.9.2 (Affected Environment), that could be susceptible to entanglement in expended cables and wires are those with elongated snouts lined with tooth-like structures that easily snag on other similar marine debris, such as derelict fishing gear (Macfadyen et al. 2009). Some elasmobranchs (hammerhead sharks) and billfish occurring within the offshore and continental shelf portions of the range complexes (where the potential for entanglement would occur) could be susceptible to entanglement in cables and wires. Species occurring outside the specified areas within these range complexes would not be exposed to fiber optic cables or guidance wires.

Once a guidance wire is released, it is likely to sink immediately and remain on the seafloor. In some cases, the wire may snag on a hard structure near the bottom and remain partially or completely suspended. The types of fish that encounter any given wire would depend, in part, on its geographic location and vertical location in the water column. In any situation, the most likely mechanism for entanglement would involve fish swimming through loops in the wire that tighten around it; however, loops are unlikely to form in guidance wire (Environmental Sciences Group 2005).

Because of their physical characteristics, guidance wires and fiber optic cables pose a potential, though unlikely, entanglement risk to susceptible fish. Potential entanglement scenarios are based on fish behavior in abandoned monofilament, nylon, and polypropylene lines used in commercial nets. Such derelict fishing gear is abundant in the ocean (Macfadyen et al. 2009) and pose a greater hazard to fish than the very thin wire expended by the Navy. Fishing gear materials often have breaking strengths that can be up to orders of magnitude greater than that of guidance wire and fiber optic cables (Environmental Sciences Group 2005), and are far more prone to tangling, as discussed in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires). Fiber optic cables do not easily form loops, are brittle, and break easily if bent, so they pose a negligible entanglement risk. Additionally, the encounter rate and probability of impact from guidance wires and fiber optic cables are low, as few are expended.

3.9.3.4.1.1 No Action Alternative – Training Activities

Tables 3.0-80 and 3.0-83 list the number and locations of activities that expend fiber optic cables and guidance wires. As indicated in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires), under the No Action Alternative, activities that expend fiber optic cables occur in the SOCAL Range Complex and the SSTC, while expended guidance wires would occur in the Hawaii and SOCAL Range Complexes. While individual fish susceptible to entanglement could encounter guidance wires and cables, the long-term consequences of entanglement are unlikely for either individuals or populations because: (1) the encounter rate is low given the low number of items expended, (2) the types of fish that are susceptible to these items is limited, (3) the restricted overlap with susceptible fish, and (4) the properties of guidance wires and fiber optic cables reduce entanglement risk to fish. Potential impacts from exposure to guidance wires and fiber optic cables are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

Expended torpedo guidance wire would not co-occur with the distribution and habitat of steelhead trout. The sink rates of these guidance wires would rule out the possibility of it drifting great distances into nearshore and coastal areas where steelhead trout are found, or into designated river or estuarine critical habitat.

Pursuant to the ESA, the use of fiber optic cables and guidance wires for training activities under the No Action Alternative would have no effect on ESA-listed steelhead trout.

The use of fiber optic cables and guidance wires for training activities under the No Action Alternative would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.1.2 No Action Alternative - Testing Activities

Tables 3.0-80 and 3.0-83 list the number and locations of activities that expend fiber optic cables and guidance wires. As indicated in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires), under the No Action Alternative, activities that expend fiber optic cables occur only in the SOCAL Range Complex, while expended guidance wires would occur in the Hawaii and SOCAL Range Complexes. Risk of entanglement resulting from proposed testing activities would be low as described in the analysis for the No Action Alternative – Training Activities; therefore, testing activities are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

Pursuant to the ESA, the use of fiber optic cables and guidance wires for testing activities under the No Action Alternative would have no effect on ESA-listed steelhead trout.

The use of fiber optic cables and guidance wires for testing activities under the No Action Alternative would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.1.3 Alternative 1 – Training Activities

Tables 3.0-80 and 3.0-83 list the number and locations of activities that expend fiber optic cables and guidance wires. As indicated in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires), under Alternative 1, activities that expend fiber optic cables occur in the SOCAL Range Complex and the SSTC, while expended guidance wires would occur in the Hawaii and SOCAL Range Complexes. Despite the slight increase from the No Action Alternative, the risk of entanglement resulting from proposed training activities would be low as described in the analysis for the No Action Alternative – Training Activities; therefore, training activities are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

Pursuant to the ESA, the use of fiber optic cables and guidance wires for training activities under Alternative 1 would have no effect on ESA-listed steelhead trout.

The use of fiber optic cables and guidance wires for training activities under Alternative 1 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.1.4 Alternative 1 – Testing Activities

Tables 3.0-80 and 3.0-83 list the number and locations of activities that expend fiber optic cables and guidance wires. As indicated in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires), under Alternative 1, activities that expend fiber optic cables occur only in the SOCAL Range Complex, while expended guidance wires would occur in the Hawaii and SOCAL Range Complexes. Despite the approximately 20 percent increase from the No Action Alternative, the risk of entanglement resulting from proposed testing activities would be low as described in the analysis for the No Action Alternative – Training Activities; therefore, testing activities are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

Pursuant to the ESA, the use of fiber optic cables and guidance wires for testing activities under Alternative 1 would have no effect on ESA-listed steelhead trout.

The use of fiber optic cables and guidance wires for testing activities under Alternative 1 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.1.5 Alternative 2 – Training Activities

The number and location of training activities under Alternative 2 are identical to training activities under Alternative 1. Therefore, impacts and comparisons to the No Action Alternative would also be identical as described in Section 3.9.3.4.1.2 (Alternative 1 – Training). Despite the slight increase from the No Action Alternative, the risk of entanglement resulting from proposed training activities would be low as described in the analysis for the No Action Alternative – Training Activities; therefore, training activities are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

Pursuant to the ESA, the use of fiber optic cables and guidance wires for training activities under Alternative 2 would have no effect on ESA-listed steelhead trout.

The use of fiber optic cables and guidance wires for training activities under Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.1.6 Alternative 2 – Testing Activities

Tables 3.0-80 and 3.0-83 list the number and locations of activities that expend fiber optic cables and guidance wires. As indicated in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires), under Alternative 2, activities that expend fiber optic cables occur only in the SOCAL Range Complex, while expended guidance wires would occur in the Hawaii and SOCAL Range Complexes. As indicated in Section 3.0.5.3.4.1 (Fiber Optic Cables and Guidance Wires) under Alternative 2, the number of activities that expend fiber optic cables is nearly the same as that of the No Action Alternative. The activities using fiber optic cables under Alternative 2 would occur in the same geographic locations as the No Action Alternative. The number of torpedo activities that expend guidance wire is nearly two times that of the No Action Alternative. These activities under Alternative 2 would occur in the same geographic locations as the No Action Alternative. Despite the increase from the No Action Alternative, the risk of entanglement resulting from proposed testing activities would be low as described in the analysis for the No Action Alternative – Training Activities; therefore, testing activities are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

Pursuant to the ESA, the use of fiber optic cables and guidance wires for testing activities under Alternative 2 would have no effect on ESA-listed steelhead trout.

The use of fiber optic cables and guidance wires for testing activities under Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.2 Impacts from Parachutes

Parachutes of varying sizes are used during training and testing activities. The types of activities that use parachutes, physical characteristics and size of parachutes, locations where parachutes are used, and the number of parachute activities proposed under each alternative are presented in Section 3.0.5.3.4.2 (Parachutes).

Fish face many potential entanglement scenarios in abandoned monofilament, nylon, polypropylene line, and other derelict fishing gear in the nearshore and offshore marine habitats of the Study Area (Macfadyen et al. 2009; Ocean Conservancy 2010). Abandoned fishing gear is dangerous to fish because it is abundant, essentially invisible, strong, and easily tangled. In contrast, parachutes are rare, highly visible, and not designed to capture fish. The combination of low encounter rates and weak entangling features reduce the risk that steelhead trout would be adversely impacted by parachutes.

Once a parachute has been released to the water, it poses a potential entanglement risk to fish. The Naval Ocean Systems Center identified the potential impacts of torpedo air launch accessories, including parachutes, on fish (U.S. Department of the Navy 1996). Unlike other materials in which fish become entangled (such as gill nets and nylon fishing line), the parachute is relatively large and visible, reducing the chance that visually oriented fish would accidentally become entangled in it. No cases of fish entanglement have been reported for parachutes (Ocean Conservancy 2010,U.S. Department of the Navy 2001a). Entanglement in a newly-expended parachute while it is in the water column is unlikely because fish generally react to sound and motion at the surface with a behavioral reaction by swimming away from the source (see Section 3.9.3.3.2, Impacts from Military Expended Material Strikes) and would detect the oncoming parachute in time to avoid contact. While the parachute is sinking, fish would have ample opportunity to swim away from the large moving object. Even if the parachute landed directly on a fish, it would likely be able to swim away faster than the parachute would sink because the resistance of the water would slow the parachute’s downward motion.

Once the parachute is on the bottom, however, it is feasible that a fish could become entangled in the parachute or its suspension lines while diving and feeding, especially in deeper waters where it is dark. If the parachute dropped in an area of strong bottom currents, it could billow open and pose a short-term entanglement threat to large fish feeding on the bottom. Benthic fish with elongated spines could become caught on the parachute or lines. Most sharks and other smooth-bodied fish are not expected to become entangled because their soft, streamlined bodies can more easily slip through potential snares. A fish with spines or protrusions (e.g., some sharks, billfish, sturgeon, or sawfish) on its body that swam into the parachute or a loop in the lines, and then struggled, could become bound tightly enough to prevent escape. Although this scenario is possible based on the structure of the materials and the shape and behavior of fish, it is not considered a likely event.

Aerial-launched sonobuoys are deployed with a parachute. The sonobuoy itself is not considered an entanglement hazard for upon deployment (Environmental Sciences Group 2005), but their components may pose an entanglement hazard once released into the ocean. Sonobuoys contain cords, electronic components, and plastic mesh that may entangle fish (Environmental Sciences Group 2005). Open-ocean filter feeding species, such as basking sharks, whale sharks, and manta rays could become entangled in these items, whereas smaller species could become entangled in the plastic mesh in the same manner as a small gillnet. Since most sonobuoys are expended in offshore areas, many coastal fish would not encounter or have any opportunity to become entangled in materials associated with sonobuoys, apart from the risk of entanglement in parachutes described above.

3.9.3.4.2.1 No Action Alternative – Training Activities

Table 3.0-84 lists the number and locations of activities that expend parachutes. The number and footprint of parachutes are detailed in Table 3.3-5 (Marine Habitats). As indicated in Section 3.0.5.3.4.2 (Parachutes) under the No Action Alternative, activities involving parachute use would occur in the open ocean portions of the Study Area. Given the size of the range complexes and the resulting widely scattered parachutes (0.12 per nm^2), it would be very unlikely that fishes would encounter and become entangled in any parachutes or sonobuoy accessories. If a fish were to encounter and become entangled in any of these items, the growth, survival, annual reproductive success, or lifetime reproductive success of populations would not be impacted directly or indirectly.

Expended parachutes generally would not co-occur with the distribution and critical habitat of steelhead trout. However, if an expended parachute were encountered, the steelhead trout, like all salmonids, is a strong swimmer with a streamlined body that is unlikely to become entangled in parachutes or lines, but there would be the potential for effect.

Pursuant to the ESA, the use of parachutes for training activities under the No Action Alternative may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of parachutes for training activities under the No Action Alternative would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.2.2 No Action Alternative – Testing Activities

Table 3.0-84 lists the number and locations of activities that expend parachutes. The number and footprint of parachutes are detailed in Table 3.3-5. As indicated in Section 3.0.5.3.4.2 (Parachutes) under the No Action Alternative, activities involving parachute use would occur in the open ocean portions of the Hawaii and SOCAL Range Complexes. Given the size of the range complexes and the resulting widely scattered parachutes (0.02 per nm^2), it would be very unlikely that fishes would encounter and become entangled in any parachutes or sonobuoy accessories. If a fish were to encounter and become entangled in any of these items, the growth, survival, annual reproductive success, or lifetime reproductive success of populations would not be impacted directly or indirectly.

Expended parachutes generally would not co-occur with the distribution and critical habitat of steelhead trout. However, if an expended parachute were encountered, the steelhead trout, like all salmonids, is a strong swimmer with a streamlined body that is unlikely to become entangled in parachutes or lines, but there would be the potential for effect.

Pursuant to the ESA, the use of parachutes for testing activities under the No Action Alternative may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of parachutes for testing activities under the No Action Alternative would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.2.3 Alternative 1 – Training Activities

Table 3.0-84 lists the number and locations of activities that expend parachutes. The number and footprint of parachutes are detailed in Table 3.3-6. As indicated in Section 3.0.5.3.4.2 (Parachutes) under Alternative 1, activities involving parachute use would occur in the open ocean portions of the Study Area. Given the size of the range complexes and the resulting widely scattered parachutes (0.14 per nm^2), it would be very unlikely that fishes would encounter and become entangled in any parachutes or sonobuoy accessories. If a fish were to encounter and become entangled in any of these items, the growth, survival, annual reproductive success, or lifetime reproductive success of populations would not be impacted directly or indirectly.

Expended parachutes generally would not co-occur with the distribution and critical habitat of steelhead trout. However, if an expended parachute were encountered, the steelhead trout, like all salmonids, is a strong swimmer with a streamlined body that is unlikely to become entangled in parachutes or lines, but there would be the potential for effect.

Pursuant to the ESA, the use of parachutes for training activities under Alternative 1 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of parachutes for training activities under Alternative 1 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.2.4 Alternative 1 – Testing Activities

Table 3.0-84 lists the number and locations of activities that expend parachutes. The number and footprint of parachutes are detailed in Table 3.3-6. As indicated in Section 3.0.5.3.4.2, (Parachutes) under Alternative 1, activities involving parachute use would occur in the open ocean portions of the Hawaii and SOCAL Range Complexes, with the number of activities involving the use of parachutes being approximately two times that of the No Action Alternative. The activities using parachutes under Alternative 1 would occur in the same geographic locations as the No Action Alternative. Given the size of the range complexes and the resulting widely scattered parachutes (0.03 per nm^2), it would be very unlikely that fishes would encounter and become entangled in any parachutes or sonobuoy accessories. If a fish were to encounter and become entangled in any of these items, the growth, survival, annual reproductive success, or lifetime reproductive success of populations would not be impacted directly or indirectly.

Expended parachutes generally would not co-occur with the distribution and critical habitat of steelhead trout. However, if an expended parachute were encountered, the steelhead trout, like all salmonids, is a strong swimmer with a streamlined body that is unlikely to become entangled in parachutes or lines, but there would be the potential for effect.

Pursuant to the ESA, the use of parachutes for testing activities under Alternative 1 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of parachutes for testing activities under Alternative 1 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.2.5 Alternative 2 – Training Activities

The number and location of training activities under Alternative 2 are identical to training activities under Alternative 1. Therefore, impacts and comparisons to the No Action Alternative would also be identical as described in Section 3.9.3.4.2.2, Alternative 1.

Pursuant to the ESA, the use of parachutes for training activities under Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of parachutes for training activities under Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.2.6 Alternative 2 – Testing Activities

Table 3.0-84 lists the number and locations of activities that expend parachutes. The number and footprint of parachutes are detailed in Table 3.3-7. As indicated in Section 3.0.5.3.4.2 (Parachutes) under Alternative 2, activities involving parachute use would occur in the open ocean portions of the Hawaii and SOCAL Range Complexes, with the number of activities involving the use of parachutes being approximately two times that of the No Action Alternative. The activities using parachutes under Alternative 2 would occur in the same geographic locations as the No Action Alternative. Given the size of the range complexes and the resulting widely scattered parachutes (0.03 per nm^2), it would be very unlikely that fishes would encounter and become entangled in any parachutes or sonobuoy accessories. If a fish were to encounter and become entangled in any of these items, the growth, survival, annual reproductive success, or lifetime reproductive success of populations would not be impacted directly or indirectly.

Expended parachutes generally would not co-occur with the distribution and critical habitat of steelhead trout. However, if an expended parachute were encountered, the steelhead trout, like all salmonids, is a strong swimmer with a streamlined body that is unlikely to become entangled in parachutes or lines, but there would be the potential for effect.

Pursuant to the ESA, the use of parachutes for testing activities under Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of parachutes for testing activities under Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.4.3 Summary and Conclusions of Entanglement Impacts

While most fish species are susceptible to entanglement in fishing gear that is designed to entangle a fish by trapping a fish by its gills or spines (e.g., gill nets), only a limited number of fish species that possess certain features such as an irregular shaped or rigid rostrum (snout) (e.g., billfish) are susceptible to entanglement by military expended materials. A survey of marine debris entanglements found no fish entanglements in military expended materials in a 25-year dataset (Ocean Conservancy 2010).

3.9.3.4.3.1 Combined Entanglement Stressors

An individual fish could experience the following consequences of entanglement stressors: displacement, stress, avoidance response, behavioral changes, entanglement causing injury, and entanglement causing mortality. If entanglement results in mortality, it cannot act in combination because mortal injuries occur with the first instance. Therefore, there is no possibility for the occurrence of this consequence to increase if sub-stressors are combined.

Sub-lethal consequences may result in delayed mortality because they cause irrecoverable injury or alter the individual's ability to feed or detect and avoid predation. Sub-lethal effects resulting in mortality could be more likely if the activities occurred in essentially the same location and occurred within the individual's recovery time from the first disturbance. This circumstance is only likely to arise during training and testing activities that cause frequent and recurring entanglement stressors to essentially the same location (e.g., torpedoes expended at the same location as sonobuoys). In these specific circumstances the potential consequences to fishes from combinations of entanglement stressors may be greater than the sum of their individual consequences.

These specific circumstances that could multiply the consequences of entanglement stressors are highly unlikely to occur for two reasons. First, it is highly unlikely that torpedo guidance wires and sonobuoy parachutes would impact essentially the same space because most of these sub-stressors are widely dispersed in time and space. Because the risk of injury or mortality is extremely low for each sub-stressor independently, the combined impact of these sub-stressors does not increase the risk in a meaningful way. Furthermore, while it is conceivable that interaction between sub-stressors could magnify their combined risks, the necessary circumstances are highly unlikely to overlap.

Interaction between entanglement sub-stressors is likely to have neutral consequences for fishes. There is no potential for these entangling objects to combine in a way that would multiply their impact, as is the case with derelict (abandoned or discarded) fishing nets that commonly occur in the Study Area (Macfadyen et al. 2009) and entangle fish by design. Fish entangled in derelict nets attract scavengers and predators that may themselves become entangled in an ongoing cycle (Morgan and Chuenpagdee 2003). Guidance wires and parachutes are used relatively infrequently over a wide area, and are mobile for only a short time. Therefore, unlike discarded fishing gear, it is extremely unlikely that guidance wires and parachutes could interact.

3.9.3.4.3.2 Summary of Entanglement Stressors

The Navy identified and analyzed three military expended materials types that have potential to entangle fishes: fiber-optic cables, guidance wires, and parachutes. Other military expended materials types such as bomb or missile fragments do not have the physical characteristics to entangle fishes in the marine environment and were not analyzed. Even for fishes that might encounter and become entangled in an expended guidance wire, the breaking strength of that wire is low enough that the impact would be only temporary and not likely to impact the individual.

Pursuant to the ESA, entanglement stressors used under the No Action Alternative, Alternative 1, and Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

Entanglement stressors used under the No Action Alternative, Alternative 1, and Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5 Ingestion Stressors

This section analyzes the potential ingestion impacts of the various types of munitions and military expended materials other than munitions used by the Navy during training and testing activities within the Study Area. Aspects of ingestion stressors that are applicable to marine organisms in general are presented in Section 3.0.5.7.5 (Conceptual Framework for Assessing Effects from Ingestion). Ingestion of expended materials by fishes could occur in coastal and open ocean areas, and can occur at the surface, in the water column, or at the seafloor depending on the size and buoyancy of the expended object and the feeding behavior of the fish. Floating material is more likely to be eaten by fishes that feed at or near the water surface (e.g., ocean sunfishes, basking sharks, manta rays, etc.), while materials that sink to the seafloor present a higher risk to bottom-feeding fishes (e.g., rockfish, hammerhead sharks, skates/rays, flounders).

It is reasonable to assume that any item of a size that can be swallowed by a fish could be eaten at some time; this analysis focuses on ingestion of materials in two locations: (1) at the surface or water column, and (2) at the seafloor. Open-ocean predators and open-ocean planktivores are most likely to ingest materials in the water column. Coastal bottom-dwelling predators and estuarine bottom-dwelling predators could ingest materials from the seafloor. The potential for fish, including the ESA-listed fish species, to encounter and ingest expended materials is evaluated with respect to their feeding group and geographic range, which influence the probability that they would eat military expended materials.

The Navy expends the following types of materials during training and testing in the Study Area that could become ingestion stressors: non-explosive practice munitions (small- and medium-caliber), fragments from high-explosives, fragments from targets, chaff, flare casings (including plastic end caps and pistons), and small parachutes. The activities that expend these items and their general distribution are detailed in Section 3.0.5.3.5 (Ingestion Stressors). Metal items eaten by marine fish are generally small (such as fishhooks, bottle caps, and metal springs), suggesting that small- and medium-caliber projectiles, pistons, or end caps (from chaff canisters or flares) are more likely to be ingested. Both physical and toxicological impacts could occur as a result of consuming metal or plastic materials. Items of concern are those of ingestible size that either drift at or just below the surface (or in the water column) for a time or sink immediately to the seafloor. The likelihood that expended items would cause a potential impact on a given fish species depends on the size and feeding habits of the fish and the rate at which the fish encounters the item and the composition of the item. In this analysis only small- and medium-caliber munitions (or small fragments from larger munitions), chaff, small parachutes, and end caps and pistons from flares and chaff cartridges are considered to be of ingestible size for a fish.

The analysis of ingestion impacts on fish is structured around the following feeding strategies:

Feeding at or Just Below the Surface or Within the Water Column

- **Open-Ocean Predators.** Large, migratory, open-ocean fishes, such as tuna, dorado, sharks, and billfishes, feed on fast-swimming prey in the water column of the Study Area. These fishes range widely in search of unevenly distributed food patches. Smaller military expended materials could be mistaken for prey items and ingested purposefully or incidentally as the fish is swimming. Prey fishes sometimes dive deeper to avoid an approaching predator (Pitcher 1986). A few of these predatory fishes (e.g., tiger sharks) are known to ingest any type of marine debris that fit into its mouth, even items such as tires.
- **Open-Ocean Planktivores.** Plankton eating fish in the open-ocean portion of the Study Area include anchovies, sardines, flying fishes, ocean sunfish, manta rays, whale sharks, and basking sharks. These fishes feed by either filtering plankton from the water column or by selectively ingesting larger zooplankton. These planktivores could encounter, and incidentally feed on smaller types of military expended materials (e.g., chaff, end caps, pistons) at the surface or in the water column. None of the species listed under the ESA in the Study Area are open ocean

planktivores, but some species in this group of fishes (e.g., anchovies) constitute a major prey base for many important predators.

Military expended materials that could potentially impact these types of fish at or just below the surface or in the water column include those items that float or are suspended in the water column for some period of time (e.g., parachutes and end caps and pistons from chaff cartridges or flares).

Fishes Feeding at the Seafloor

- **Coastal Bottom Dwelling Predators/Scavengers.** Large predatory fishes near the seafloor are represented by rockfishes, groupers, and jacks, which are typical seafloor predators in coastal and deeper nearshore waters of the Study Area (See Table 3.9-7). These species feed opportunistically on or near the bottom, taking fish and invertebrates from the water column and from the bottom (e.g., crabs, octopus). Bottom-dwelling fishes in the nearshore coasts (See Table 3.9-7) may feed by seeking prey and by scavenging on dead fishes and invertebrates (e.g., skates, rays, flatfish, rat fish).

Military expended materials that could be ingested by fish at the seafloor include items that sink (e.g., small-caliber projectiles and casings, fragments from high-explosive munitions).

Potential impacts of ingestion to adults are different than for other lifestages (eggs, larvae, juveniles) because early lifestages are too small to ingest any military expended materials except for chaff, which has been shown to have no impact on fishes. Therefore, no ingestion potential impacts on early lifestages would occur with the exception of later stage larvae and juveniles.

Within the context of fish location in the water column and feeding strategies, the analysis is divided into (1) munitions (small- and medium-caliber projectiles, and small fragments from larger munitions); and (2) military expended material other than munitions (chaff, chaff end caps, pistons, parachutes, flares, and target fragments).

Table 3.9-7: Summary of Ingestion Stressors on Fishes Based on Location

Feeding Guild	Representative Species	ESA-Protected Species	Overall Potential for Impact
Open-ocean Predators	Dorado, most shark species, tuna, billfish	None	These fishes may ingest floating or sinking expended materials, but the encounter rate would be extremely low.
Open-ocean plankton eaters	Basking shark	None	These fishes may ingest floating expended materials incidentally as they feed in the water column, but the encounter rate would be extremely low.
Coastal bottom-dwelling predators	Rockfishes, groupers, jacks	None	These fishes may ingest expended materials on the seafloor, but the encounter rate would be extremely low.
Coastal/estuarine bottom-dwelling predators and scavengers	Skates and rays, flounders	None	These fishes could incidentally ingest some expended materials while foraging, especially in muddy waters with limited visibility. However, encounter frequency would be extremely low.

Note: ESA = Endangered Species Act

3.9.3.5.1 Impacts from Munitions and Military Expended Materials other than Munitions

The potential impacts of ingesting foreign objects on a given fish depend on the species and size of the fish. Fish that normally eat spiny, hard-bodied invertebrates could be expected to have tougher mouths and digestive systems than fish that normally feed on softer prey. Materials that are similar to the normal diet of a fish would be more likely to be ingested and more easily handled once ingested—for example, by fish that feed on invertebrates with sharp appendages. These items could include fragments from high-explosives that a fish could encounter on the seafloor. Relatively small or smooth objects, such as small caliber projectiles or their casings, might pass through the digestive tract without causing harm. A small sharp-edged item could cause a fish immediate physical distress by tearing or cutting the mouth, throat, or stomach. If the object is rigid and large (relative to the fish's mouth and throat), it may block the throat or obstruct the flow of waste through the digestive system. An object may be enclosed by a cyst in the gut lining (Danner et al. 2009; Hoss and Settle 1990). Ingestion of large foreign objects could lead to disruption of a fish's normal feeding behavior, which could be sublethal or lethal.

Munitions are heavy and would sink immediately to the seafloor, so exposure would be limited to those fish identified as bottom-dwelling predators and scavengers. It is possible that expended small caliber projectiles on the seafloor could be colonized by seafloor organisms and mistaken for prey or that expended small caliber projectiles could be accidentally or intentionally eaten during foraging. Over time, the metal may corrode or become covered by sediment in some habitats, reducing the likelihood of a fish encountering the small caliber, non-explosive practice munitions.

Fish feeding on the seafloor in the offshore locations where these items are expended (e.g., gunnery boxes) would be more likely to encounter and ingest them than fish in other locations. A particularly large item (relative to the fish ingesting it) could become permanently encapsulated by the stomach lining, with the rare chance that this could impede the fish's ability to feed or take in nutrients. However, in most cases, a fish would pass a round, smooth item through its digestive tract and expel it, with no long-term measurable reduction in the individual's fitness.

If high-explosive ordnance does not explode, it would sink to the bottom. In the unlikely event that explosive material, high-melting-point explosive (known as HMX) or royal demolition explosive (known as RDX), is exposed on the ocean floor it would break down in a few hours (U.S. Department of the Navy 2001b). HMX or RDX would not accumulate in the tissues of fish (Lotufo et al. 2010; Price et al. 1998). Fish may take up trinitrotoluene (TNT) from the water when it is present at high concentrations but not from sediments (Lotufo et al. 2010). The rapid dispersal and dilution of TNT expected in the marine water column reduces the likelihood of a fish encountering high concentrations of TNT to near zero.

3.9.3.5.1.1 No Action Alternative – Training Activities

Projectiles

Table 3.0-65 lists the number and location of small- and medium-caliber projectiles. As indicated in Section 3.0.5.3.5.1 (Non-explosive Practice Munitions) under the No Action Alternative, small- and medium-caliber projectile use would occur in the Hawaii and SOCAL Range Complexes. Species that occur in these areas would have the potential to be exposed to small- and medium-caliber projectiles.

Table 3.0-66 lists the number and location of activities that expend fragments from high-explosive ordnance and munitions (e.g., demolition charges, grenades, bombs, missiles, and rockets). The number and footprint of high-explosive ordnance and munitions are detailed in Table 3.3-5; however, the fragment size cannot be quantified. As indicated in Section 3.0.5.3.5.2 (Fragments from High-explosive

Munitions), under the No Action Alternative, high-explosive ordnance and munitions use would occur in the Hawaii and SOCAL Range Complexes. Species that occur in these areas would have the potential to be exposed to fragments from high explosive ordnance and munitions. These items are heavy and would sink immediately to the seafloor, so exposure to fishes would be limited to those groups identified as bottom-dwelling predators and scavengers. It is possible that expended small-caliber projectiles on the seafloor could be colonized by seafloor organisms and mistaken for prey or that expended small-caliber projectiles could be accidentally or intentionally eaten during foraging. Over time, the metal corrodes slowly or may become covered by sediment in some habitats, reducing the likelihood of a fish encountering the small-caliber non explosive practice munitions. High explosive munitions are typically fused to detonate within 5 ft. (1.5 m) of the water surface, with steel fragments breaking off in all directions and rapidly decelerating in the water and settling to the seafloor. The analysis generally assumes that most explosive expended materials sink to the seafloor and become incorporated into the seafloor, with no substantial accumulations in any particular area (see Section 3.1, Sediments and Water Quality).

Encounter rates in locations with concentrated small-caliber projectiles would be assumed to be greater than in less concentrated areas. Fishes feeding on the seafloor in the offshore locations where these items are expended (e.g., focused in gunnery boxes) would be more likely to encounter these items and at risk for potential ingestion impacts than in other locations. If ingested, and swallowed, these items could potentially disrupt an individual's feeding behavior or digestive processes. If the item is particularly large for the fish ingesting it, the projectile could become permanently encapsulated by the stomach lining, with the rare chance that this could impede the fish's ability to feed or take in nutrients. However, in most cases a fish would pass the round and smooth item through their digestive tract and expel the item with full recovery expected without impacting the individual's growth, survival, annual reproductive success, or lifetime reproductive success. There are no ESA-listed species that occur at the offshore locations where small-caliber projectile use is concentrated.

Unexploded high-explosive munitions would sink to the bottom. The residual explosive material would not be exposed to the marine environment, as it is encased in a non-buoyant cylindrical package. Should the High Melting point Explosive or Royal Demolition Explosive be exposed on the ocean floor, they would break down within a few hours (Department of the Navy 2001b) and would not accumulate in the tissues of fishes (Lotufo, Gibson, et al. 2010; Price et al. 1998). Trinitrotoluene (TNT) would bioaccumulate in fish tissues if present at high concentrations in the water, but not from fish exposure to TNT in sediments since it is rapidly degraded (Lotufo, Blackburn, et al. 2010). Given the rapid dispersal and dilution expected in the marine water column, the likelihood of a fish encountering high concentrations of TNT is very low. Over time, Royal Demolition Explosive residue would be covered by ocean sediments in most habitats or diluted by ocean water.

It is not possible to predict the size or shape of fragments resulting from high explosives. High explosives used in the Study Area range in size from medium-caliber projectiles to large bombs, rockets, and missiles. When these items explode, they partially break apart or remain largely intact with irregular shaped pieces—some of which may be small enough for a fish to ingest. Fishes would not be expected to ingest most fragments from high explosives because most pieces would be too large to ingest. Also, since fragment size cannot be quantified, it is assumed that fragments from larger munitions are similarly sized as larger munitions, but more fragments would result from larger munitions than smaller munitions. Small-caliber projectiles far outnumber the larger-caliber high explosive projectiles/bombs/missiles/rockets expended as fragments in the Study Area. Although it is possible that the number of fragments resulting from a high explosive could exceed this number, this cannot be quantified. Therefore, small-caliber projectiles would be more prevalent throughout the Study Area, and more likely to be encountered by bottom-dwelling fishes, and potentially ingested than fragments from any type of high explosive munitions.

Chaff and Flares

Tables 3.0-85 and 3.0-86 lists the number and location of expended chaff and flares. As indicated in Section 3.0.5.3.5.3 (Military Expended Materials Other Than Munitions) under the No Action Alternative, activities that expend chaff and flares occur in the open ocean areas of the Hawaii and SOCAL Range Complexes. Species that occur in these areas would have the potential to be exposed to chaff and flares. Under all Alternatives, a total of 20,950 chaff cartridges would be expended from aircraft during training activities. No potential impacts would occur from the chaff itself, as discussed in Section 3.0.5.3.5.3, but there is some potential for the end caps or pistons associated with the chaff cartridges to be ingested. Under all Alternatives, a total of 10,050 flares would be expended during training flare exercises. The flare device consists of a cylindrical cartridge approximately 1.4 in (3.6 cm) in diameter and 5.8 in (14.7 cm) in length. Items that could be potentially ingested from flares include plastic end caps and pistons. An extensive literature review and controlled experiments conducted by the U.S. Air Force revealed that self-protection flare use poses little risk to the environment (U.S. Air Force 1997). The light generated by flares in the air (designed to burn out completely prior to entering the water) would have no impact on fish based on short burn time, relatively high altitudes where they are used, and the wide-spread and infrequent use. The potential exists for large, open-ocean predators (e.g., tunas, billfishes, pelagic sharks) to ingest self-protection flare end caps or pistons as they float on the water column for some time. A variety of plastic and other solid materials have been recovered from the stomachs of billfishes, dorado (South Atlantic Fishery Management Council 2011) and tuna (Hoss and Settle 1990).

End caps and pistons sink in saltwater (Spargo 1999), which reduces the likelihood of ingestion by surface-feeding fishes. However, some of the material could remain at or near the surface, and predatory fishes may incidentally ingest these items. The highest density of chaff and flare end caps/pistons would be expended in the SOCAL Range Complex. Assuming that all end-caps and pistons would be evenly dispersed in the SOCAL Range Complex, the annual relative end-cap and piston concentration would be very low (0.07 nm^2).

Based on the low environmental concentration (Table 3.3-5), it is unlikely that a larger number of fish would ingest an end cap or piston, much less a harmful quantity. Furthermore, a fish might expel the item before swallowing it. The number of fish potentially impacted by ingestion of end caps or pistons would be low based on the low environmental concentration and population-level impacts are not expected to occur.

Summary of Training Activities

Overall, the potential impacts of ingesting small-caliber projectiles, high explosive fragments, parachutes, or end caps/pistons would be limited to individual cases where a fish might suffer a negative response, for example, ingesting an item too large to be digested. While ingestion of ordnance-related materials, or the other military expended materials identified here, could result in sublethal or lethal impacts, the likelihood of ingestion is low based on the dispersed nature of the materials and the limited exposure of those items at the surface/water column or seafloor where certain fishes could be at risk of ingesting those items. Furthermore, a fish might taste an item then expel it before swallowing it (Felix et al. 1995), in the same manner that fish would temporarily take a lure into its mouth, then spit it out. Based on these factors, the number of fish potentially impacted by ingestion of ordnance-related materials would be low and population-level impacts are not likely to occur.

Based on the primarily nearshore distribution of steelhead trout and overlap of munitions use, potential ingestion risk would be greatest in the coastal areas of the SOCAL Range Complex and SSTC. While munitions use could overlap with steelhead trout, the likelihood of ingestion would be extremely low given the low abundance of steelhead trout in the Study Area and the dispersed nature of the activity. However, there would be the potential for effect. The majority of the primary constituent elements required by steelhead trout are applicable to freshwater and estuaries (i.e., spawning sites, rearing sites, and migration corridors), and are outside the Study Area. Therefore, munitions use would not affect steelhead trout critical habitat.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size for training activities under the No Action Alternative may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size for training activities under the No Action Alternative would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5.1.2 No Action Alternative – Testing Activities

Table 3.0-65 lists the number and location of small- and medium-caliber projectiles. As indicated in Section 3.0.5.3.5.1 (Non-explosive Practice Munitions) under the No Action Alternative, only medium caliber projectile use would occur in the SOCAL Range Complex. Species that occur in these areas would have the potential to be exposed to small- and medium-caliber projectiles.

Table 3.0-66 lists the number and location of activities that expend fragments from high-explosive ordnance and munitions (e.g., demolition charges, grenades, bombs, missiles, and rockets). The number and footprint of high-explosive ordnance and munitions are detailed in Table 3.3-5; however, the fragment size cannot be quantified. As indicated in Section 3.0.5.3.5.2 (Fragments from High-explosive Munitions), under the No Action Alternative, high-explosive ordnance and munitions use would occur in the Hawaii and SOCAL Range Complexes. Species that occur in these areas would have the potential to be exposed to fragments from high explosive ordnance and munitions.

Under the No Action Alternative, no testing activities use chaff or flares (Tables 3.0-85 and 3.0-86).

Overall, the potential impacts of ingesting small-caliber projectiles, high-explosive fragments, parachutes, or flare end caps/pistons would be limited to individual cases where a fish might suffer a negative response, for example, ingesting an item too large to be digested. While ingestion of ordnance-related materials, or the other military expended materials identified here, could result in sublethal or lethal impacts, the likelihood of ingestion is low based on the dispersed nature of the materials and the limited exposure of those items at the surface/water column or seafloor where certain fishes could be at risk of ingesting those items. Furthermore, a fish might expel the item before swallowing it. Based on these factors, the number of fish potentially impacted by ingestion of ordnance-related materials would be low and population-level impacts are not likely to occur.

Based on the primarily nearshore distribution of steelhead trout and overlap of munitions use, potential ingestion risk would be greatest in the coastal areas of the SOCAL Range Complex and SSTC. While munitions use could overlap with steelhead trout, the likelihood of ingestion would be extremely low given the low abundance of steelhead trout in the Study Area and the dispersed nature of the activity. However, there would be the potential for effect. The majority of the primary constituent elements required by steelhead trout are applicable to freshwater and estuaries (i.e., spawning sites, rearing sites, and migration corridors), and are outside the Study Area. Therefore, munitions use would not affect steelhead trout critical habitat.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size for testing activities under the No Action Alternative may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size for testing activities under the No Action Alternative would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5.1.3 Alternative 1 – Training Activities

Projectiles

Table 3.0-65 lists the number and location of small- and medium- caliber projectiles. As indicated in Section 3.0.5.3.5.1 (Non-explosive Practice Munitions) under Alternative 1, small- and medium-caliber projectile use would occur in the open ocean portions of the Study Area. Species that occur in these areas would have the potential to be exposed to small- and medium-caliber projectiles.

Table 3.0-66 lists the number and location of activities that expend fragments from high-explosive ordnance and munitions (e.g., demolition charges, grenades, bombs, missiles, and rockets). The number and footprint of high-explosive ordnance and munitions are detailed in Table 3.3-6; however, the fragment size cannot be quantified. As indicated in Section 3.0.5.3.5.2 (Fragments from High-explosive Munitions), under Alternative 1, high-explosive ordnance and munitions use would occur in the open ocean portions of the Study Area. Species that occur in these areas would have the potential to be exposed to fragments from high explosive ordnance and munitions.

Chaff and Flares

Tables 3.0-85 and 3.0-86 lists the number and location of expended chaff and flares. As indicated in Section 3.0.5.3.5.3 (Military Expended Materials Other Than Munitions) under Alternative 1, activities that expend chaff and flares occur in the open ocean areas of the Hawaii and SOCAL Range Complexes. Species that occur in these areas would have the potential to be exposed to chaff and flares. Although the number and location of training activities under Alternative 1 are slightly higher than training activities under the No Action Alternative,. the impacts and comparisons to the No Action Alternative would be similar to those as described in Section 3.9.3.5.1.1 (No Action Alternative – Summary of Training Activities).

The increase in expended materials under Alternative 1 would increase the probability of ingestion risk; however, as discussed under the No Action Alternative, the likelihood of ingestion would still be low based on the dispersed nature of the materials and the limited exposure of those items at the surface/water column or seafloor where certain fishes could be at risk of ingesting those items. Therefore, the number of fish potentially impacted by ingestion of expended materials would be low and population-level impacts are not likely to occur.

Based on the primarily nearshore distribution of steelhead trout and overlap of munitions use, potential ingestion risk would be greatest in the coastal areas of the SOCAL Range Complex and SSTC. While munitions use could overlap with steelhead trout, the likelihood of ingestion would be extremely low given the low abundance of steelhead trout in the Study Area and the dispersed nature of the activity. However, there would be the potential for effect. The majority of the primary constituent elements required by steelhead trout are applicable to freshwater and estuaries (i.e., spawning sites, rearing sites, and migration corridors), and are outside the Study Area. Therefore, munitions use would not affect steelhead trout critical habitat.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size for training activities under Alternative 1 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size for training activities under Alternative 1 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5.1.4 Alternative 1 – Testing Activities

Table 3.0-65 lists the number and location of small- and medium-caliber projectiles. As indicated in Section 3.0.5.3.5.1 (Non-explosive Practice Munitions) under Alternative 1, small- and medium-caliber projectile use would occur in the entre Study Area. Species that occur in these areas would have the potential to be exposed to small- and medium-caliber projectiles.

Table 3.0-66 lists the number and location of activities that expend fragments from high-explosive ordnance and munitions (e.g., demolition charges, grenades, bombs, missiles, and rockets). The number and footprint of high-explosive ordnance and munitions are detailed in Table 3.3-6; however, the fragment size cannot be quantified. As indicated in Section 3.0.5.3.5.2 (Fragments from High-explosive Munitions), under Alternative 1, high-explosive ordnance and munitions use would occur in the open ocean portions of the Study Area. Species that occur in these areas would have the potential to be exposed to fragments from high explosive ordnance and munitions.

Tables 3.0-85 and 3.0-86 lists the number and location of expended chaff and flares. As indicated in Section 3.0.5.3.5.3 (Military Expended Materials Other Than Munitions) under Alternative 1, activities that expend chaff and flares occur in the open ocean areas of the Hawaii and SOCAL Range Complexes. Species that occur in these areas would have the potential to be exposed to chaff and flares. Although the number and location of testing activities under Alternative 1 are slightly higher than testing activities under the No Action Alternative, the impacts and comparisons to the No Action Alternative would be similar to those described in Section 3.9.3.5.1.1 (No Action Alternative).

Given the reasons stated under the training activities, the number of fish potentially impacted by ingestion of ordnance-related materials would be low and population-level impacts are not likely to occur.

Based on the primarily nearshore distribution of steelhead trout and overlap of munitions use, potential ingestion risk would be greatest in the coastal areas of the SOCAL Range Complex and SSTC. While munitions use could overlap with steelhead trout, the likelihood of ingestion would be extremely low given the low abundance of steelhead trout in the Study Area and the dispersed nature of the activity. However, there would be the potential for effect. The majority of the primary constituent elements required by steelhead trout are applicable to freshwater and estuaries (i.e., spawning sites, rearing sites, and migration corridors), and are outside the Study Area. Therefore, munitions use would not affect steelhead trout critical habitat.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size for testing activities under Alternative 1 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size for testing activities under Alternative 1 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5.1.5 Alternative 2 – Training Activities

Under Alternative 2, the number of military expended materials would be the same as under Alternative 1 (Tables 3.0-65 and 3.0-66). Therefore, the impact of military expended materials would be the same as under Alternative 1.

Based on the primarily nearshore distribution of steelhead trout and overlap of munitions use, potential ingestion risk would be greatest in the coastal areas of the SOCAL Range Complex and SSTC. While munitions use could overlap with steelhead trout, the likelihood of ingestion would be extremely low given the low abundance of steelhead trout in the Study Area and the dispersed nature of the activity. However, there would be the potential for effect. The majority of the primary constituent elements required by steelhead trout are applicable to freshwater and estuaries (i.e., spawning sites, rearing sites, and migration corridors), and are outside the Study Area. Therefore, munitions use would not affect steelhead trout critical habitat.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size for training activities under Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size for training activities under Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5.1.6 Alternative 2 – Testing Activities

Under Alternative 2, the number of military expended materials would increase slightly compared to the No Action Alternative (Tables 3.0-65 and 3.0-66). Given the reasons stated under the training activities under Alternative 1 and despite the slight increase, the number of fish potentially impacted by ingestion from munitions use would be low and population-level impacts are not likely to occur.

Based on the primarily nearshore distribution of steelhead trout and overlap of munitions use, potential ingestion risk would be greatest in the coastal areas of the SOCAL Range Complex and SSTC. While munitions use could overlap with steelhead trout, the likelihood of ingestion would be extremely low given the low abundance of steelhead trout in the Study Area and the dispersed nature of the activity. However, there would be the potential for effect. The majority of the primary constituent elements required by steelhead trout are applicable to freshwater and estuaries (i.e., spawning sites, rearing sites, and migration corridors), and are outside the Study Area. Therefore, munitions use would not affect steelhead trout critical habitat.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size for testing activities Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size for testing activities under Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5.2 Summary and Conclusions of Ingestion Impacts

3.9.3.5.2.1 Combined Ingestion Stressors

An individual fish could experience the following consequences of ingestion stressors: stress, behavioral changes, ingestion causing injury, and ingestion causing mortality. Ingestion causing mortality cannot act in combination because mortal injuries occur with the first instance. Therefore, there is no possibility for the occurrence of this consequence to increase if sub-stressors are combined.

Sub-lethal consequences may result in delayed mortality because they cause irrecoverable injury or alter the individual's ability to feed or detect and avoid predation. Normally, for fish large enough to ingest it, most small-caliber projectiles would pass through a fish's digestive system without injury. However, in this scenario it is possible that a fish's digestive system could already be compromised or blocked in such a manner that the small-caliber projectiles can no longer easily pass through without harm. It is conceivable that a fish could first ingest a small bomb fragment that might damage or block its digestive tract, then ingest a small-caliber projectile, with magnified combined impacts. Sub-lethal effects resulting in mortality could be more likely if the activities occurred in essentially the same location and occurred within the individual's recovery time from the first disturbance. This circumstance is likely to arise only during training and testing activities that cause frequent and recurring ingestion stressors to essentially the same location (e.g., chaff cartridge end caps/flares expended at the same location as small-caliber projectiles). In these specific circumstances the potential consequences to fishes from combinations of ingestion stressors may be greater than the sum of their individual consequences.

These specific circumstances that could magnify the consequences of ingestion stressors are highly unlikely to occur because, with the exception of a sinking exercise, it is highly unlikely that chaff cartridge end caps/flares and small-caliber projectiles would impact essentially the same location because most of these sub-stressors are widely dispersed in time and space.

The combined impact of these sub-stressors does not increase the risk in a meaningful way because the risk of injury or mortality is extremely low for each sub-stressor independently. While it is conceivable that interaction between sub-stressors could magnify their combined risks, the necessary circumstances are highly unlikely to overlap. Interaction between ingestion sub-stressors is likely to have neutral consequences for fishes.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size for training activities under the No Action Alternative, Alternative 1, or Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size for training activities under the No Action Alternative, Alternative 1, or Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.5.2.2 Summary and Conclusions of Ingestion Impacts

The Navy identified and analyzed three military expended materials types that have ingestion potential for fishes: non-explosive practice munitions, military expended materials from high explosives, and military expended materials from non-ordnance items (e.g., end caps, canisters, chaff, and accessory materials). The probability of fishes ingesting military expended materials depends on factors such as the size, location, composition, and the buoyancy of the expended material. These factors, combined with the location and feeding behavior of fishes were used to analyze the likelihood the expended material would be mistaken for prey and what the potential impacts would be if ingested. Most expended materials, such as large- and medium-caliber ordnance, would be too large to be ingested by a fish, but other materials, such as small-caliber munitions or some fragments of larger items, may be small enough to be swallowed by some fishes. During normal feeding behavior, many fishes ingest nonfood items and often reject (spit out) nonfood items prior to swallowing. Other fishes may ingest and swallow both food and nonfood items indiscriminately. There are concentrated areas where bombing, missile, and gunnery activities that generate materials that could be ingested. However, even within those areas, the overall impact on fishes would be inconsequential.

The potential impacts of military expended material ingestion would be limited to individual cases where a fish might suffer a negative response, for example, ingesting an item too large, sharp, or pointed to pass through the digestive tract without causing damage. Based on available information, it is not possible to accurately estimate actual ingestion rates or responses of individual fishes. Nonetheless, the number of military expended materials ingested by fishes is expected to be very low and only an extremely small percentage of the total would be potentially encountered by fishes. Certain feeding behavior such as “suction feeding” along the seafloor exhibited by sturgeon may increase the probability of ingesting military expended materials relative to other fishes; however, encounter rates would still remain low.

Pursuant to the ESA, the use of munitions or military expended materials of ingestible size under the No Action Alternative, Alternative 1, or Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The use of munitions or military expended materials of ingestible size under the No Action Alternative, Alternative 1, or Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.3.6 Secondary Stressors

This section analyzes potential impacts on fishes exposed to stressors indirectly through impacts on habitat, sediment, or water quality. These are also primary elements of marine fish habitat and firm distinctions between indirect impacts and habitat impacts are difficult to maintain. For the purposes of this analysis, indirect impacts on fishes via sediment or water which do not require trophic transfer (e.g., bioaccumulation) in order to be observed are considered here. It is important to note that the terms "indirect" and "secondary" do not imply reduced severity of environmental consequences, but instead describe how the impact may occur in an organism or its ecosystem.

Stressors from Navy training and testing activities could pose secondary or indirect impacts on fishes via habitat, sediment, and water quality. These include: (1) explosives and by-products; (2) metals; (3) chemicals; (4) other materials such as targets, chaff, and plastics, and (5) impacts on fish habitat. Activities associated with these stressors are detailed in Tables 2.8-1 to 2.8-5 and analyses of their potential impacts are discussed in Section 3.1 (Sediments and Water Quality) and Section 3.3 (Marine Habitats).

3.9.3.6.1 Explosives

In addition to directly impacting fish and fish habitat, underwater explosions could impact other species in the food web including plankton and other prey species that fish feed upon. The impacts of underwater explosions would differ depending upon the type of prey species in the area of the blast. As discussed in Section 3.9.4.1, fish with swim bladders are more susceptible to blast injuries than fish without swim bladders.

In addition to physical impacts of an underwater blast, prey might have behavioral reactions to underwater sound. For instance, prey species might exhibit a strong startle reaction to detonations that might include swimming to the surface or scattering away from the source. This startle and flight response is the most common secondary defense among animals (Hanlon and Messenger 1996). The sound from underwater explosions might induce startle reactions and temporary dispersal of schooling fishes if they are within close proximity. The abundances of fish and invertebrate prey species near the detonation point could be diminished for a short period of time before being repopulated by animals from adjacent waters. Alternatively, any prey species that would be directly injured or killed by the blast could draw in scavengers from the surrounding waters that would feed on those organisms, and in turn could be susceptible to becoming directly injured or killed by subsequent explosions. Any of these scenarios would be temporary, only occurring during activities involving explosives, and no lasting impact on prey availability or the pelagic food web would be expected. Indirect impacts of underwater detonations and high explosive ordnance use under the Proposed Action would not result in a decrease in the quantity or quality of fish populations or fish habitats in the Study Area.

3.9.3.6.2 Explosion By-Products, and Unexploded Ordnance

Deposition of undetonated explosive materials into the marine environment can be reasonably well estimated by the known failure and low-order detonation rates of high explosives. Undetonated explosives associated with mine neutralization activities are collected after training is complete; therefore, potential impacts are assumed to be inconsequential for these training and testing activities, but other activities could result in unexploded ordnance and unconsumed explosives on the seafloor. Fishes may be exposed by contact with the explosive, contact with contaminants in the sediment or water, and ingestion of contaminated sediments.

High-order explosions consume most of the explosive material, creating typical combustion products. In the case of Royal Demolition Explosive, 98 percent of the products are common seawater constituents and the remainder are rapidly diluted below threshold impact level. Explosion by-products associated with high order detonations present no indirect stressors to fishes through sediment or water. However, low order detonations and unexploded ordnance present elevated likelihood of impacts on fishes.

Indirect impacts of explosives and unexploded ordnance to fishes via sediment is possible in the immediate vicinity of the ordnance. Degradation of explosives proceeds via several pathways discussed in Section 3.1. Degradation products of Royal Demolition Explosive are not toxic to marine organisms at realistic exposure levels (Rosen and Lotufo 2010). TNT and its degradation products impact developmental processes in fishes and are acutely toxic to adults at concentrations similar to real-world exposures (Halpern et al. 2008; Rosen and Lotufo 2010). Relatively low solubility of most explosives and their degradation products means that concentrations of these contaminants in the marine environment are relatively low and readily diluted. Furthermore, while explosives and their degradation products were detectable in marine sediment approximately 6 to 12 in (15.2 to 30.5 m) away from degrading ordnance, the concentrations of these compounds were not statistically distinguishable from background beyond 3 to 6 ft. (0.9 to 1.8 m) from the degrading ordnance (Section 3.1). Taken together, it is likely that various lifestages of fishes could be impacted by the indirect impacts of degrading explosives within a very small radius of the explosive 1 to 6 ft. (0.3 to 1.8 m).

3.9.3.6.3 Metals

Certain metals are harmful to fishes at concentrations above background levels (e.g., cadmium, chromium, lead, mercury, zinc, copper, manganese, and many others) (Wang and Rainbow 2008). Metals are introduced into seawater and sediments as a result of Navy training and testing activities involving vessel hulks, targets, ordnance, munitions, and other military expended materials (Section 3.1). Some metals bioaccumulate and physiological impacts begin to occur only after bioaccumulation concentrate the metals (see Section 3.3, Marine Habitats, and Chapter 4, Cumulative Impacts). Indirect impacts of metals to fishes via sediment and water involve concentrations several orders of magnitude lower than concentrations achieved via bioaccumulation. Fishes may be exposed by contact with the metal, contact with contaminants in the sediment or water, and ingestion of contaminated sediments. Concentrations of metals in sea water are orders of magnitude lower than concentrations in marine sediments. It is extremely unlikely that fishes would be indirectly impacted by toxic metals via the water.

3.9.3.6.4 Chemicals

Several Navy training and testing activities introduce potentially harmful chemicals into the marine environment; principally, flares and propellants for rockets, missiles, and torpedoes. Polychlorinated biphenyls (PCBs) are discussed in Section 3.1. Properly functioning flares missiles, rockets, and torpedoes combust most of their propellants; leaving benign or readily diluted soluble combustion by-products (e.g., hydrogen cyanide). Operational failures allow propellants and their degradation products to be released into the marine environment.

The greatest risk to fishes from flares, missile, and rocket propellants is perchlorate which is highly soluble in water, persistent, and impacts metabolic processes in many plants and animals. Fishes may be exposed by contact with contaminated water or ingestion of contaminated sediments. Since perchlorate is highly soluble, it does not readily absorb to sediments. Therefore, missile and rocket fuel poses no risk of indirect impact on fishes via sediment. In contrast, the principal toxic components of torpedo fuel, propylene glycol dinitrate and nitrodiphenylamine, adsorbs to sediments, has relatively low toxicity, and is readily degraded by biological processes (Section 3.1). It is conceivable that various lifestages of fishes could be indirectly impacted by propellants via sediment in the immediate vicinity of the object (e.g., within a few inches), but these potential impacts would diminish rapidly as the propellant degrades.

3.9.3.6.5 Other Materials

Some military expended materials (e.g., parachutes) could become remobilized after their initial contact with the sea floor (e.g., by waves or currents) and could be reintroduced as an entanglement or ingestion hazard for fishes. In some bottom types (without strong currents, hard-packed sediments, and low biological productivity), items such as projectiles might remain intact for some time before becoming degraded or broken down by natural processes. While these items remain intact sitting on the bottom, they could potentially remain ingestion hazards. These potential impacts may cease only (1) when the military expended materials are too massive to be mobilized by typical oceanographic processes, (2) if the military expended materials become encrusted by natural processes and incorporated into the seafloor, or (3) when the military expended materials become permanently buried. In this scenario, a parachute could initially sink to the seafloor, but then be transported laterally through the water column or along the seafloor, increasing the opportunity for entanglement. In the unlikely event that a fish would become entangled, injury or mortality could result. The entanglement stressor would eventually cease to pose an entanglement risk as it becomes encrusted or buried.

3.9.3.6.6 Impacts on Fish Habitat

The Proposed Action could result in localized and temporary changes to the benthic community during activities that impact fish habitat. Fish habitat could become degraded during activities that would strike the seafloor or introduce military expended materials, bombs, projectiles, missiles, rockets, or fragments to the seafloor. During, or following activities that impact benthic habitats, fish species may experience loss of available benthic prey at locations in the Study Area where these items might be expended on essential fish habitat or habitat areas of particular concern. Additionally, plankton and zooplankton that are eaten by fish may also be negatively impacted by these same expended materials. The spatial area of Essential Fish Habitat and habitat areas of particular concern impacted by the Proposed Action would be relatively small compared to the available habitat in the HSTT Study Area. Potentially a maximum area of 0.3 nm^2 of essential fish habitat and habitat areas of particular concern may have decreased habitat value resulting from the Proposed Action, based on the footprint of expended materials. However, there would still be vast expanses of essential fish habitat and habitat areas of particular concern adjacent to the areas of habitat impact that would remain undisturbed by the Proposed Action.

Impacts of physical disturbance and strikes by small, medium, and large projectiles would be concentrated within designated gunnery box areas, resulting in localized disturbances of hard bottom areas, but could occur anywhere in the range complexes or the Study Area. Hard bottom is important habitat for many different species of fish, including those fishes managed by various fishery management plans.

When a projectile hits a biogenic habitat, the substrate immediately below the projectile is not available at that habitat type on a long-term basis, until the material corrodes. The substrate surrounding the projectile would be disturbed, possibly resulting in short-term localized increased turbidity. Given the large spatial area of the range complexes compared to the small percentage covered by biogenic habitat, it is unlikely that most of the small, medium, and large projectiles expended in the Study Area would fall onto this habitat type. Furthermore, these activities are distributed within discrete locations within the Study Area, and the overall footprint of these areas is quite small with respect to the spatial extent of this biogenic habitat within the Study Area.

Sinking exercises could also provide secondary impacts on deep sea populations. These activities occur in open-ocean areas, outside of the coastal range complexes, with potential direct disturbance or strike impacts on deep sea fishes, covered in Sections 3.9.2.4 through 3.9.2.22. Secondary impacts on these fishes could occur after the ship hulks sink to the seafloor. Over time, the ship hulk would be colonized by marine organisms that attach to hard surfaces. For fishes that feed on these types of organisms, or whose abundances are limited by available hard structural habitat, the ships that are sunk during sinking exercises could provide an incidental beneficial impact on the fish community (Love and York 2005).

Designated critical habitat of steelhead trout includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek, and is outside the Study Area. Therefore, would be no impacts associated with secondary stressors.

Pursuant to the ESA, secondary stressors resulting under the No Action Alternative, Alternative 1, or Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

Secondary stressors under the No Action Alternative, Alternative 1, or Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.4 Summary of Potential Impacts (Combined Impacts from All Stressors) on Fish

As described in Section 3.0.5.5 (Resource-Specific Impacts Analysis for Multiple Stressors), this section evaluates the potential for combined impacts of all the stressors from the Proposed Action. The analysis and conclusions for the potential impacts from each individual stressor are discussed in the analyses of each stressor in the sections above and summarized in Sections 3.9.4.2 (Endangered Species Act Determinations).

There are generally two ways that a fish could be exposed to multiple stressors. The first would be if a fish were exposed to multiple sources of stress from a single activity (e.g., a mine warfare activity may include the use of a sound source and a vessel). The potential for a combination of these impacts from a single activity would depend on the range of effects of each stressor and the response or lack of response to that stressor. Most of the activities as described in the Proposed Action involve multiple stressors; therefore, it is likely that if a fish were within the potential impact range of those activities, they may be impacted by multiple stressors simultaneously. This would be even more likely to occur during large-scale exercises or activities that span a period of days or weeks (such as a sinking exercises or composite training unit exercise).

Fish could be exposed to a combination of stressors from multiple activities over the course of its life. This is most likely to occur in areas where training and testing activities are more concentrated (e.g., near naval ports, testing ranges, and routine activity locations outlined in Table 3.0-3 and in areas that individual fish frequent because it is within the animal's home range, migratory corridor, spawning or feeding area. Except for in the few concentration areas mentioned above, combinations are unlikely to occur because training and testing activities are generally separated in space and time in such a way that it would be very unlikely that any individual fish would be exposed to stressors from multiple activities. However, animals with a home range intersecting an area of concentrated Navy activity have elevated exposure risks relative to animals that simply transit the area through a migratory corridor. The majority of the proposed training and testing activities occur over a small spatial scale relative to the entire Study Area, have few participants, and are of a short duration (the order of a few hours or less).

Multiple stressors may also have synergistic effects. For example, fish that experience temporary hearing loss or injury from acoustic stressors could be more susceptible to physical strike and disturbance stressors via a decreased ability to detect and avoid threats. Fish that experience behavioral and physiological consequences of ingestion stressors could be more susceptible to entanglement and physical strike stressors via malnourishment and disorientation. These interactions are speculative, and without data on the combination of multiple Navy stressors, the synergistic impacts from the combination of Navy stressors are difficult to predict in any meaningful way. Navy research and monitoring efforts include data collection through conducting long-term studies in areas of Navy activity, occurrence surveys over large geographic areas, biopsy of animals occurring in areas of Navy activity, and tagging studies where animals are exposed to Navy stressors. These efforts are intended to contribute to the overall understanding of what impacts may be occurring overall to animals in these areas.

Although potential impacts to certain fish species from the Proposed Action may include injury or mortality, impacts are not expected to decrease the overall fitness of any given population. Mitigation measures designed to reduce the potential impacts are discussed in Chapter 5, Standard Operating Procedures, Mitigation, and Monitoring. The potential impacts anticipated from the Proposed Action are summarized in Sections 3.9.4.2, Endangered Species Act Determinations, with respect to each regulation applicable to fish.

Pursuant to the ESA, the combined impacts of all the stressors under the No Action Alternative, Alternative 1, or Alternative 2 may affect, but is not likely to adversely affect, ESA-listed steelhead trout.

The combined impacts of all the stressors under the No Action Alternative, Alternative 1, or Alternative 2 would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

3.9.5 Endangered Species Act Determinations

Table 3.9-8 summarizes the ESA determinations for each substressor analyzed. For all substressors, training and testing activities would have no effect on steelhead trout critical habitat, which includes the estuarine and freshwater habitat of San Juan Creek, Trabuco Creek, and San Mateo Creek.

Table 3.9-8: Summary of Endangered Species Act Determinations for Training and Testing Activities for the Preferred Alternative

Stressor		Steelhead Trout
Acoustic Stressors		
Non-Impulsive Sources	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Explosives and other non-impulsive sources	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Energy Stressors		
Electromagnetic devices	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Physical Disturbance and Strike Stressors		
Vessels and in-water devices	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Military expended materials	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Seafloor devices	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Entanglement Stressors		
Cables and wires	Training Activities	No effect
	Testing Activities	No effect
Parachutes	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Ingestion Stressors		
Munitions	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Military expended materials other than munitions	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect
Secondary Stressors		
Secondary Stressors	Training Activities	May affect, not likely to adversely affect
	Testing Activities	May affect, not likely to adversely affect

3.10 CULTURAL RESOURCES

CULTURAL RESOURCES SYNOPSIS

The United States Department of the Navy considered all potential stressors, and the following have been analyzed for submerged cultural resources:

- Acoustic (underwater explosives and pile-driving)
- Physical disturbance (in-water devices, military expended materials, sea floor devices)

Preferred Alternative

- Acoustics and Physical Disturbance: Acoustic and physical stressors, as indicated above, would not affect submerged cultural resources within United States (U.S.) territorial waters in accordance with Section 106 of the National Historic Preservation Act because measures were previously implemented to protect these resources. A Finding of No Effects on historic properties within the Area of Potential Effect has been determined by the U.S. Department of the Navy, and the California State Historic Preservation Officer (California State Historic Preservation Office 2012) concurs with this finding.

3.10.1 INTRODUCTION AND METHODS

3.10.1.1 Introduction

Cultural resources are found throughout the Hawaii-Southern California Training and Testing (HSTT) Study Area (Study Area). The approach to assessing cultural resources includes defining the resource; presenting the regulatory requirements for identifying, evaluating, and treating the resource within established jurisdictional parameters; establishing the specific resource subtypes in the Study Area; identifying the data used to define the current conditions; and describing the method of impact analysis.

Cultural resources are defined as districts, landscapes, sites, structures, objects, and ethnographic resources, as well as other physical evidence of human activity, that are considered to be important to a culture, subculture, or community for scientific, traditional, religious, or other reasons. Cultural resources include archaeological resources, historic architectural resources, and traditional cultural properties related to prehistoric/pre-contact (prior to European contact) and historic/post-contact periods.

Archaeological resources include prehistoric and historic sites and artifacts. Archaeological resources can have a surface component, a subsurface component, or both. Prehistoric resources are physical properties resulting from human activities that predate written records, and include village sites, temporary camps, lithic scatters, roasting pits, hearths, milling features, petroglyphs, rock features, and burials. Historic resources postdate the advent of written records in a region, and include building foundations, refuse scatters, wells, cisterns, and privies. Submerged cultural resources include historic shipwrecks and other submerged historic materials, such as sunken airplanes and prehistoric cultural remains. Architectural resources are elements of the built environment consisting of standing buildings or structures from the historic period. These resources include existing buildings, dams, bridges, lighthouses, and forts. Traditional cultural resources are resources associated with beliefs or cultural practices of a living culture, subculture, or community. These beliefs and practices must be rooted in the group's history and must be important in maintaining the cultural identity of the group. Prehistoric archaeological sites and artifacts, historic and contemporary locations of traditional events, sacred places, landscapes, and resource collection areas, including fishing, hunting and gathering areas, may be traditional cultural resources.

3.10.1.2 Identification, Evaluation, and Treatment of Cultural Resources

Procedures for identifying, evaluating, and treating cultural resources within state territorial waters (within 3 nautical miles [nm] of the coast) and United States (U.S.) territorial waters (within 12 nm of the coast) are contained in a series of federal and state laws and regulations, and agency guidelines. Archaeological, historical architectural, and cultural (including Native American and Native Hawaiian) resources are protected by a variety of laws and their implementing regulations: the National Historic Preservation Act of 1966 as amended in 2006, the Archeological and Historic Preservation Act of 1974, the Archaeological Resources Protection Act of 1979, the American Indian Religious Freedom Act of 1978, the Native American Graves Protection and Repatriation Act of 1990, the Submerged Lands Act of 1953, the Abandoned Shipwreck Act of 1987, and the Sunken Military Craft Act of 2004. The Advisory Council on Historic Preservation (Advisory Council) further guides treatment of archaeological and architectural resources through the regulations, *Protection of Historic Properties* (36 Code of Federal Regulations [C.F.R.] Part 800). The category of "historic properties" is a subset of cultural resources that is defined in the National Historic Preservation Act (16 United States Code [U.S.C.] § 470w(5)) as any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places (National Register), including artifacts, records, and material remains related to such a property or resource.

Section 106 of the National Historic Preservation Act requires federal agencies to consider the effects of their actions on cultural resources listed in or eligible for inclusion in the National Register. The regulations implementing Section 106 (36 C.F.R. Part 800) specify a consultation process to assist in satisfying this requirement. Consultation with the appropriate State Historic Preservation Offices, the Advisory Council, Native American tribes and Native Hawaiian organizations, the public, and state and federal agencies is required by Section 106 of the National Historic Preservation Act. Government-to-government consultation required by Executive Order (EO) 13007 will be accomplished concurrently with the preparation of this Environmental Impact Statement (EIS)/Overseas EIS (OEIS) for the portion of the Proposed Action within state territorial waters (within 3 nm). Section 106 consultation letters for the undertaking described under this EIS/OEIS were delivered to California and Hawaii State Historic Preservation Officers and to the appropriate federally recognized Native American tribes or Native Hawaiian organizations. In a letter dated 5 June 2012, the California State Historic Preservation Office concurred that the Area of Potential Effect for the portion of the undertaking under its jurisdiction had been adequately determined, and further concurred with the U.S. Department of the Navy's (Navy's) finding of No Historic Properties Affected (California State Historic Preservation Office 2012). A finding of No Effect on Historic Properties was submitted to the Hawaii State Historic Preservation Office, and no formal response or objection was received within the 30 days required by law. In accordance with 36 C.F.R. 800.4(d)(1)(i), concurrence by the Hawaii State Historic Preservation Office with the finding is assumed. Consultation with State Historic Preservation Offices, tribes, or Native Hawaiian organizations will continue if required, as stipulated by Section 106.

Additional regulations and guidelines for submerged historic resources include 10 U.S.C. 113, note for the Sunken Military Craft Act; the *Abandoned Shipwreck Guidelines* prepared by the National Park Service (National Park Service 2007) and, for the purposes of conducting research or recovering Navy ship and aircraft wrecks, the *Guidelines for Archaeological Research Permit Applications on Ship and Aircraft Wreck*s *under the Jurisdiction of the Department of the Navy* (36 C.F.R. Part 767) overseen by the Naval History and Heritage Command. The Sunken Military Craft Act does not apply to actions taken by, or at the direction of, the United States. In accordance with the Abandoned Shipwreck Act of 1987, abandoned shipwrecks in state waters are considered the property of the U.S. Government if the shipwreck meets the criteria for inclusion in the National Register of Historic Places. However, the federal government may transfer the title of an abandoned shipwreck to the state if the shipwreck falls within the jurisdiction of the state (Barnette 2010). Warships or other vessels used for military purposes at the time of their sinking retain sovereign immunity (e.g., Japanese freighters). According to the principle of sovereign immunity, foreign warships sunk in U.S. territorial waters are protected by the U.S. Government, which acts as custodian of the sites in the best interest of the sovereign nation (Neyland 2001). In addition, the federal archaeological program developed by the National Park Service pursuant to a Presidential Order, includes a collection of historical and archaeological resource protection laws to which federal managers adhere.

The addendum to the National Historic Preservation Act (16 U.S.C. 470a-2: International Federal activities affecting historic properties) requires an assessment by federal agencies of project effects on resources located outside U.S. territorial waters that are identified on the World Heritage List. Papahanaumokuakea is located within the Study Area.

No specific procedures for identifying and protecting cultural resources in the open ocean have been defined by the international community (Zander and Varmer 1996). No treaty offering comprehensive protection of submerged cultural resources has been developed and implemented. However a few international conventions prepared by the United Nations Educational, Scientific, and Cultural Organization apply to submerged cultural resources, including the 1970 Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property, the 1972 Convention Concerning the Protection of the World Cultural and Natural Heritage, the 1982 Convention on the Law of the Sea, and the 2001 Convention on the Protection of the Underwater Cultural Heritage. Only the 1970 and 1972 conventions have been fully ratified by the United States.

3.10.1.3 Methods

3.10.1.3.1 Approach

The approach for establishing current conditions is based on different regulatory parameters defined by geographical location. Within U.S. territorial waters (12 nm), the National Environmental Policy Act (NEPA) is the guiding mandate. Areas beyond 12 nm in the open ocean will not be analyzed, as those areas are beyond the jurisdiction of the National Historic Preservation Act and NEPA.

The implementing regulations of Section 106 of the National Historic Preservation Act require federal agencies to take into account the effects that a proposed action would have on cultural resources included in or eligible for inclusion in the National Register of Historic Places. “Historic properties” is synonymous with National Register-eligible or -listed archaeological, architectural, or traditional resources. Cultural resources that have not been formally evaluated (i.e., a Consensus Determination in consultation with the State Historic Preservation Office) may be considered potentially eligible, and thus are afforded the same regulatory consideration as resources listed in the National Register. Evaluations and determinations of historic properties within the Study Area are the responsibility of the federal agency, in consultation with either the State Historic Preservation Office (California) or the State Historic Preservation Division (Hawaii).

Properties are evaluated for nomination to the National Register and for National Register eligibility using the following criteria (36 C.F.R. § 60.4(a)-(d)):

- Criterion A: Be associated with events that have made a significant contribution to the broad patterns of American history
- Criterion B: Be associated with the lives of persons significant in the American past
- Criterion C: Embody the distinctive characteristics of a type, period, or method of construction, or represent the work of a master, or possess high artistic values, or represent a significant and distinguishable entity whose components may lack individual distinction
- Criterion D: Yield, or may be likely to yield, information important in prehistory or history

A historic property also must possess the following aspects of integrity: location, design, setting, materials, workmanship, feeling, and association to convey its significance and to qualify for the National Register. These seven aspects, in various combinations, define integrity. To retain integrity, a property will always possess several, and usually most, of these aspects.

Cultural resources in U.S. territorial waters (within 12 nm of the coastline) are as follows:

- Resources listed on or eligible for listing on the National Register (Section 106 of the National Historic Preservation Act)
- Resources entitled to sovereign immunity (e.g., Japanese midget submarine)

3.10.1.3.2 Data Sources

Cultural resources information relevant to this EIS/OEIS was derived from a variety of sources, including previous environmental documents, national and international shipwreck databases, the National Register Information System (managed by the National Park Service), information repositories associated with State Historic Preservation Offices, on-line maps and data, and published sources, as cited. Previous environmental documents used for general information include the *Hawaii Range Complex EIS/OEIS* (U.S. Department of the Navy 2008a), *Southern California Range Complex EIS/OEIS* (U.S. Department of the Navy 2008b), and *Silver Strand Training Complex EIS* (U.S. Department of the Navy 2011).

The national and international shipwreck databases researched included the National Oceanic and Atmospheric Administration’s Office of Coast Survey Advanced Wreck and Obstruction Information System, National Oceanic and Atmospheric Administration Aids to Navigation, California State Lands Commission Shipwrecks database, and the General Dynamics Global Maritime Wrecks Database, as well as secondary sources of shipwreck information. Many of the shipwreck databases and secondary sources overlap, generating repetitiveness in data. Many federal agencies “share” data as well as secondary sources. The intent of this analysis is not to provide a definitive number of shipwrecks, obstructions, or hazards within a defined area, however, but rather to provide an overview of the potential resources in an area.

The online National Register Information System was reviewed to identify National Register-listed properties, historic districts, and National Historic Landmarks. Appropriate information repositories associated with the State Historic Preservation Offices were contacted or their online databases were reviewed for information on shipwreck locations, types, and eligibility for listing on the state registers and National Register of Historic Places.

3.10.1.3.3 Cultural Context

Several types of cultural properties may be present in the Study Area, including: submerged prehistoric occupation sites along the continental shelf; wrecks of ships, submarines, aircraft, and barges; sunken navigational equipment, such as buoys; man-made obstructions; and Indian tribe and Native Hawaiian marine resource gathering areas (e.g., Traditional Cultural Properties such as traditional fishing, seaweed, mussel, abalone, clam-gathering grounds, and whaling areas). Research suggests that the sea level rose steadily from about 18,000 years ago to about 7,500 years ago, whereupon it reached present-day levels. In California, PaleoIndian and Archaic period sites were submerged by the rising ocean. Many of these sites would not have been preserved as the encroaching ocean inundated, reworked, and redeposited sediments. In California, locations where PaleoIndian and Archaic period sites may have been preserved include: back barrier deposits or mainland shore deposits located behind large, nearshore islands, estuaries, and portions of coastal floodplains.

3.10.1.3.3.1 Hawaii

Human colonization of the Hawaiian Islands occurred after sea levels stabilized, so no sites are known to exist beyond the current coast lines. Traditional Hawaiian cultural resources, such as stone artifacts, sinkers, and octopus lures, may be located below the water surface; however, because of environmental factors, such as weathering, the location of these resources are not known, and therefore they are not eligible for listing on the National Register of Historic Places (Minerals Management Service 1990, National Oceanic and Atmospheric Adminstration 2012).

Archaeological evidence suggests that the first permanent settlements appeared in the Hawaiian Islands around approximately Anno Domini (A.D.) 300. Because the sea level had already stabilized by the time the Hawaiian Islands were first settled, no pre-contact submerged archaeological sites are found in Hawaii. Any submerged cultural resources are the result of natural erosion or modern/historical development.

European contact with the Hawaiian Islands occurred when Captain James Cook landed in Waimea Harbor in 1778. Kamehameha I united the Hawaiian Islands in 1818. Hawaii assumed importance in the east-west fur trade during this period, and later became the focal point for the Pacific whaling industry. Honolulu and Lahaina became the principal ports for the whaling fleet in Hawaii. By the 1840s, approximately 600 whaling vessels were arriving in Hawaii each year (Kelley 2006). Sunken vessels from this period may be located near the coasts of the Hawaiian Islands. Pearl Harbor became an import harbor in the late 19th century and, in 1887, the U.S. Senate allowed the Navy to lease Pearl Harbor. The harbor was dredged in the early 20th century to accommodate large vessels and, in 1908, Pearl Harbor Naval Shipyard was established.

3.10.1.3.3.2 Southern California

The Late Prehistoric Period along the coast of Southern California was characterized by elaborate artifact inventories and distinctive local cultural complexes that lasted until contact with Europeans (Sutton 2010). Artifacts from this period include circular fishhooks, whalebone markers, asphalt skirt weights, steatite ollas, shell beads, bone gorges, composite fishhooks, Cottonwood series projectile points, and spear points (Noah 1998, Sutton 2010). Evidence from numerous archaeological sites along the coast suggests an exploitation of bay and estuary kelp beds, rocky areas, and offshore environments. Bones from numerous species of fish and marine mammals have been recovered from middens. Coastal Late Prehistoric settlements were located near estuaries, along mouths of sloughs and rivers, and around bays, such as Mission Bay in San Diego. Prehistoric habitation sites are not commonly found outside of the inner continental shelf. During the Late Prehistoric Period, cultural traits associated with Kumeyaay, Luiseño, Cupeño, and Cahuilla peoples of the ethnographic period are found.

The maritime history along the west coast of the United States is a history of exploration, imperial competition, and commercial adventurism. The period of exploration began at least as early as the first Spanish voyages northward from Mexico in the 1530s, and by 1578 the British were encroaching on the Spanish monopoly along the coast of California. Undiscovered sunken vessels from early Spanish and British exploration, colonization, and trade may be present in coastal Southern California.

Prior to World War I, the Navy did not have strong presence in San Diego. By 1921, the Navy acquired a site for the U.S. Destroyer Base, San Diego facility. During the 1930s, San Diego harbor was dredged as a result of Public Works Administration projects, and San Clemente Island was purchased by the Navy as a firing range. The Navy base expanded considerably during World War II, with over 5,100 ships being serviced as a result of the war in the Pacific. Because of the importance of Naval Base San Diego and San Clemente Island Naval Auxiliary Landing Field, the region could contain sunken vessels that were associated with these facilities (Naval Base San Diego 2012).

3.10.2 Affected Environment

The Study Area is divided into three distinct regions for cultural resources evaluation: Southern California, Hawaii, and the open ocean Transit Corridor between them (see Figure 2.1-1). The Study Area covers 335,000 square nautical miles (nm^2); however, only the regions that are located in the offshore waters of Hawaii and Southern California are being evaluated. In the Hawaii Operating Area (OPAREA) (235,000 nm^2), a component of the Hawaii Range Complex (HRC), there are a number of known wrecks, obstructions, and occurrences; however, these sites have not been evaluated as properties eligible for listing in the National Register of Historic Places. In the Southern California (SOCAL) Range Complex within the SOCAL OPAREA (120,000 nm^2), a few hundred such sites have been recorded. The Study Area could contain submerged prehistoric sites on the continental shelf.

3.10.2.1 Hawaii

3.10.2.1.1 Submerged Prehistoric Resources

A few submerged prehistoric resources are located in the waters surrounding the Hawaiian Islands. These resources primarily consist of old shoreline features, such as fishponds. Four extant fishponds lie within the boundaries of the Area of Potential Effects in Pearl Harbor. One fishpond, Pamoku/Puuloa, is filled in with boulders but is intact. The remaining three fish ponds, Paaiau, Okiokilepe, and Laulaunui, become submerged during tidal changes. These fishponds are filled with mangroves and are in waters too shallow for ships to safely navigate, so there would be no effect on these properties. In addition, these fishponds are not located in the loch where sonar testing would occur.

3.10.2.1.2 Known Wrecks, Obstructions, Occurrences, or "Unknowns"

A number of submerged cultural resources lie in the open, deep waters surrounding the Hawaiian Islands. Typical among these resources are wrecks of World War II submarines and ships, commercial fishing vessels and tankers, and aircraft. The most likely types of shipwrecks to occur around the Hawaiian Islands are 19th century cargo ships, submarines, old whaling and merchant ships, fishing boats, 20th century U.S. Warships, and recreational craft. The *Automated Wreck and Obstruction Information System*, Region 16 (2010) records the approximate locations of some deep-water submerged shipwrecks. The majority of these cultural resources, if not all, are likely in poor condition and lack the integrity to qualify as historic properties eligible for listing to the National Register of Historic Places.

A variety of submerged resources are located in the waters surrounding the Hawaiian Islands (U.S. Department of the Navy 2008a). The most common of these submerged resources are shipwrecks. However, junked motor vehicles, harbor features, and old shoreline features are also present. Figure 3.10-1 through Figure 3.10-3 illustrate offshore shipwrecks near the Hawaiian Islands.

Shipwrecks located near the Island of Hawaii are concentrated along the northwestern coastline and within Hilo Bay. The numerous known wrecks in the waters surrounding Oahu include: the largely intact Sea Tiger, a World War II-era Japanese midget submarine; the *Mahi* a Navy minesweeper/cable layer intentionally sunk off the Waianae Coast to create an artificial reef; and the YO-257, a Navy yard oiler built in the 1940s, intentionally sunk off Waikiki to create an artificial reef. The *Mahi* and the YO-257 are both artificial reefs, so they are not eligible for listing in the National Register of Historic Places. Within the Ewa Training Minefield, off of the southern coast of Oahu, there is one known shipwreck (Figure 3.10-3). The wreck is likely the *USS Chittenden County* that was sunk as a target in 1958 by the *Sargo SS-583*; this shipwreck is not eligible for listing in the National Register. Because offshore shipwrecks are in relatively deep water and their locations are not precisely known, a figure illustrating offshore Hawaii shipwrecks is not presented in this document. Submerged resources in Pearl Harbor are discussed in Section 3.10.2.1.3.

3.10.2.1.3 Cultural Resources Eligible for Listing or Listed in the National Register

The data indicate that no shipwrecks in the State of Hawaii are listed in the National Register, excluding those at Naval Station Pearl Harbor. At Pearl Harbor, which is listed in the National Register as a National Historic Landmark, an abundance of submerged cultural resources are associated with World War II. Major shipwrecks include the *USS Arizona* and the *USS Utah*, both of which are listed in the National Register. Training and testing activities would not affect historic properties within Pearl Harbor.

3.10.2.1.4 Cultural Resources Eligible for or Listed on the State Inventory of Historic Places

Outside of Pearl Harbor, the Study Area contains no Hawaii State Register-listed or -eligible sites.

3.10.2.1.5 World Heritage Sites

The Hawaii region of the Study Area contains one World Heritage Site, the Papahanaumokuakea Marine National Monument. This area is protected and encompasses 140,000 square miles of ocean and 10 islands and atolls northwest of Kauai. The Monument contains historic shipwrecks; however, these shipwrecks are not listed as historic properties in the National Register. The Navy would continue its testing and training in existing designated areas, so no activities related to the HSTT would occur within the Papahanaumokuakea Marine National Monument.

3.10.2.1.6 Resources with Sovereign Immunity

The Study Area contains at least one resource with sovereign immunity: a World War II-era Japanese Midget "A" submarine that was sunk by the *USS Ward* (New South Wales 2012). As the midget submarine is a known obstruction, which the Navy avoids, training and testing activities associated with the HSTT would not affect this resource.

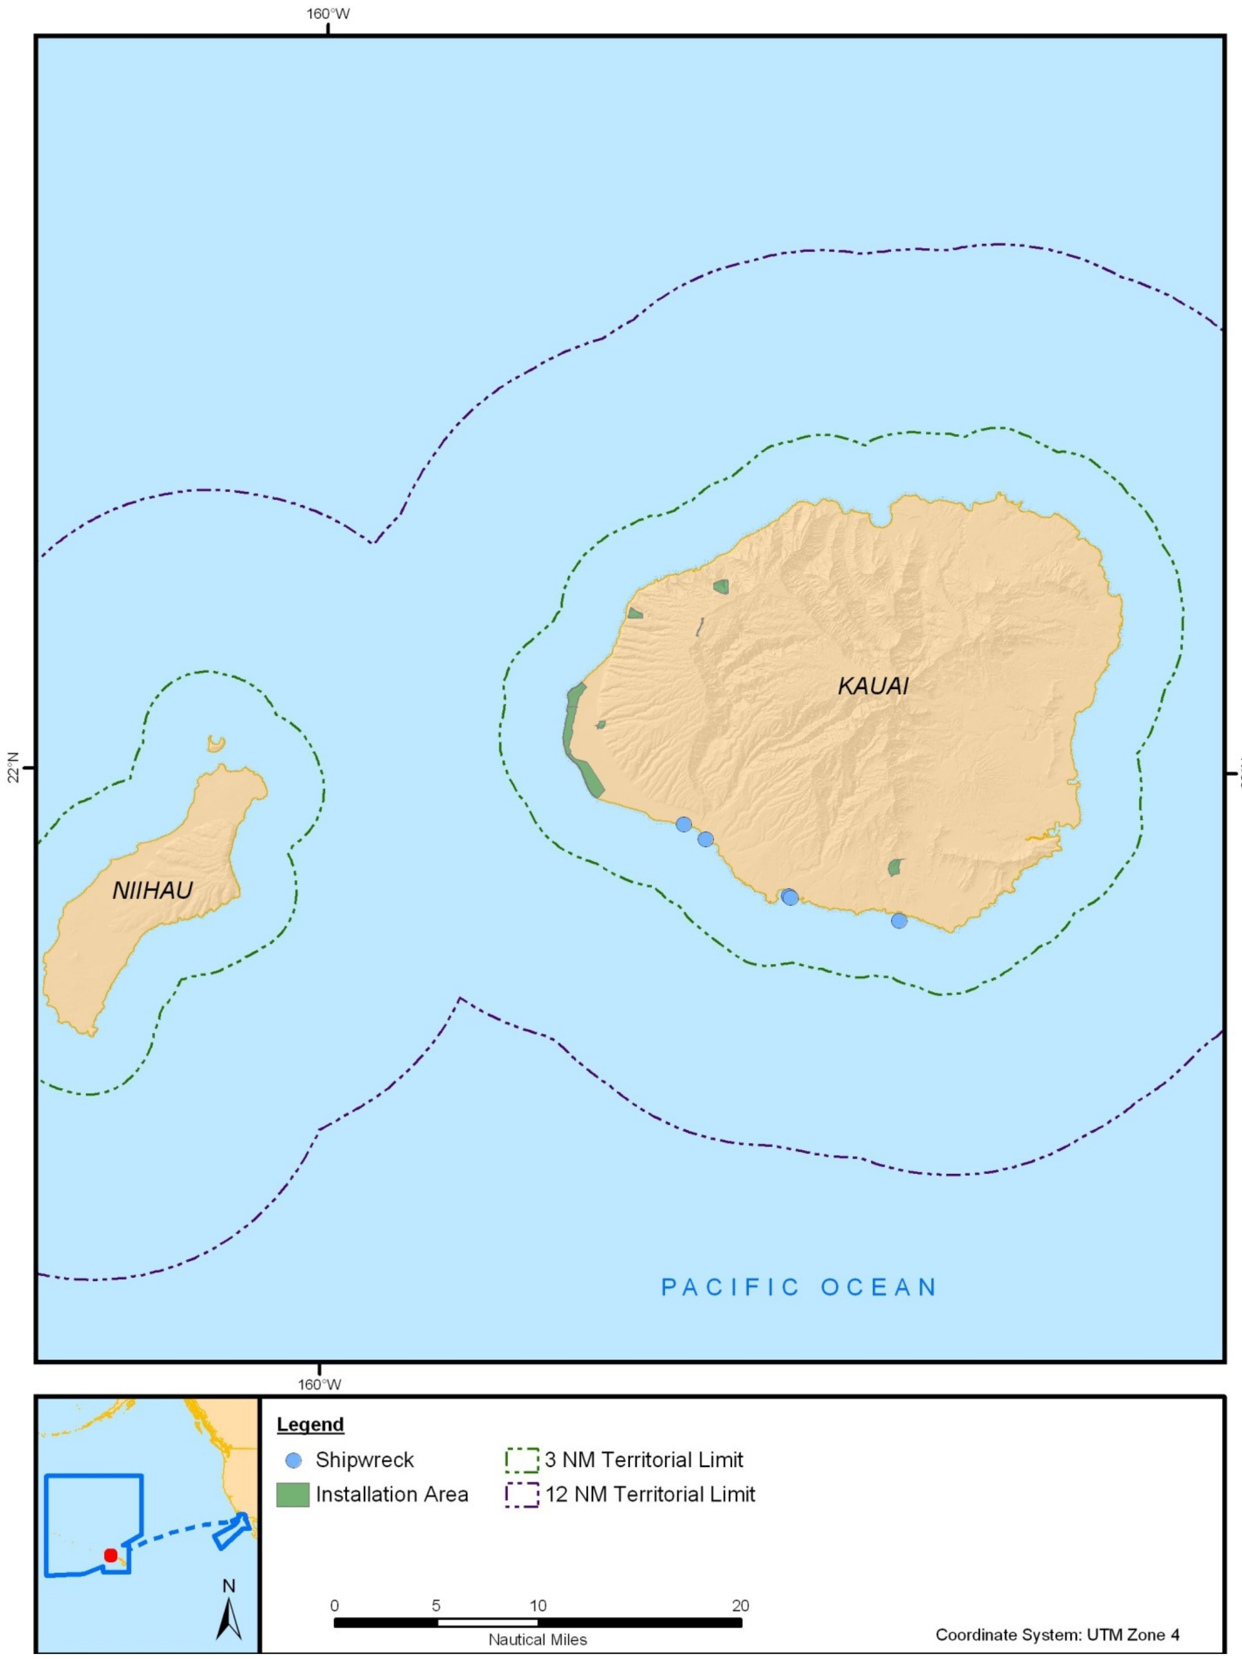

Figure 3.10-1: Kauai Known Shipwrecks

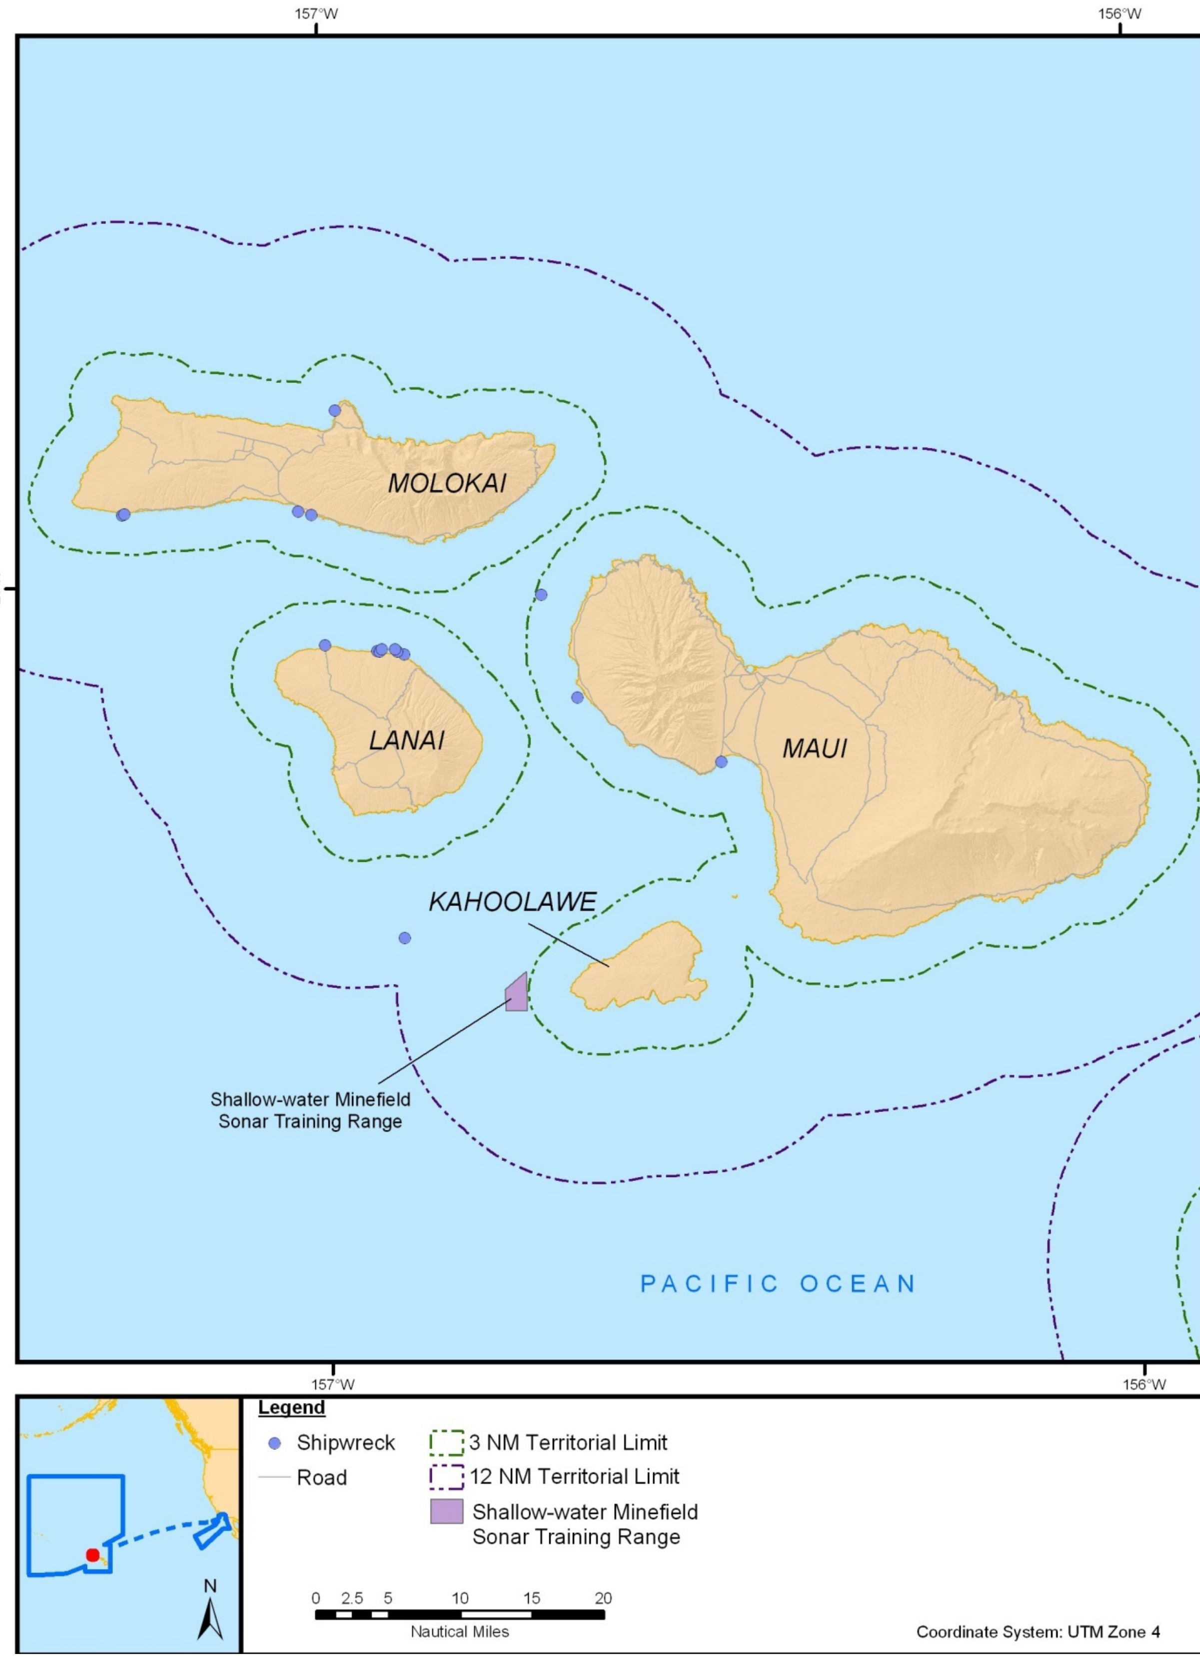

Figure 3.10-2: Molokai, Lanai, Maui, and Kahoolawe Known Shipwrecks

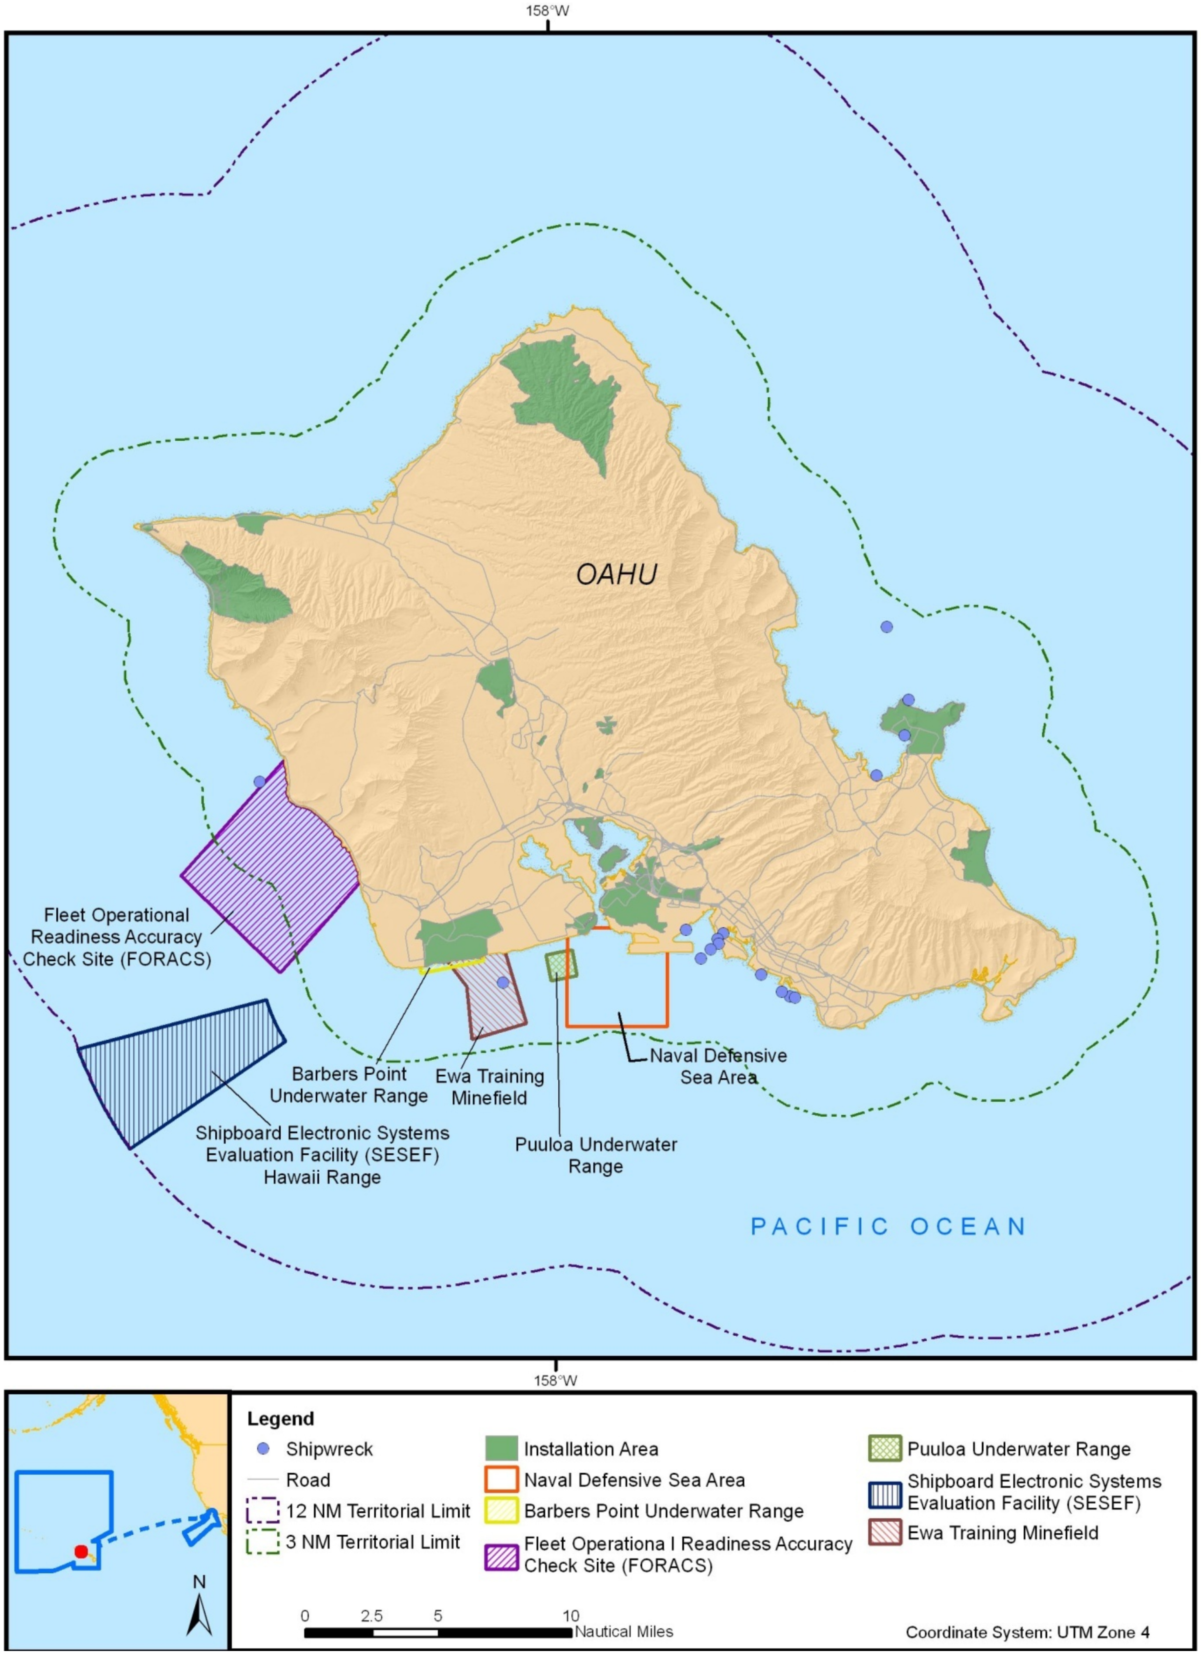

Figure 3.10-3: Oahu Known Shipwrecks

3.10.2.2 Southern California

3.10.2.2.1 Submerged Prehistoric Resources

PaleoIndian and Archaic period sites occur on the continental shelf off the coast of California. Approximately 110 submerged artifacts and sites from the Archaic period have been identified in Southern California (Masters 2003). However, they are located outside of Navy training and testing areas. Prehistoric cultural materials, such as stone bowls and mortars, are also common off the coast of San Diego County (Masters and Schneider 2000, Masters 2003). A concentration of this cultural material is located off La Jolla and Point Loma (Masters 2003).

3.10.2.2.2 Known Wrecks, Obstructions, Occurrences, or "Unknowns"

3.10.2.2.2.1 Offshore

From the early period of Spanish exploration to the intense commercialization of the 19th and 20th centuries, there has been a great variety of shipwrecks in the Pacific Ocean. The earliest known shipwreck was the Manila galleon *San Agustin* that sank off the northern coast of California in 1595. Since that time, thousands of vessels of varying types and descriptions have sunk off the coast of California. Various databases of these shipwrecks have been compiled, including the *Automated Wreck and Obstruction Information System* database (Automated Wreck and Obstruction Information System Database 2010). As part of a Minerals Management Service study (Minerals Management Service 1990), a database was compiled that documents 4,676 shipwrecks off the coast of California, with 876 wrecks in Southern California. The *Automated Wreck and Obstruction Information System* database (Automated Wreck and Obstruction Information System Database 2010) documents 292 wrecks just in San Diego, Orange, Los Angeles, and Ventura Counties.

Submerged cultural resources in the waters around San Clemente Island include pleasure craft, sport and commercial fishers, and cargo and military vessels (Department of the Navy 2008b). Of these 68 submerged cultural resources, 22 are within 12 nm of San Clemente Island and seven are beyond the territorial limit. Submerged aircraft are also reported off San Clemente Island. Figure 3.10-4 illustrates known submerged cultural resources near San Clemente Island.

The potential for long-term preservation of historic properties in the waters surrounding San Clemente Island is considered low, because the intertidal waters in the area create a high-energy environment that accelerates the decay of archaeological resources. Submerged cultural resources identified include 35 shipwrecks, 17 aircraft, an anchor, and the abandoned Sea Lab.

3.10.2.2.2.2 Silver Strand Training Complex

On the bay side of Silver Strand peninsula, three shipwrecks are in or near the training beaches. Unnamed wrecks are recorded in shallow water at the northern end of Delta South beach, in the middle of San Diego Bay, and at the mouth of Fiddler's Cove. The ages and cultural value of these wrecks are not known (U.S. Department of the Navy 2008b).

On the ocean side of the peninsula, three shipwrecks are located near Silver Strand Training Complex (SSTC) training areas: the bark Narwhale (sank in 1934); the submarine S-142: and the Subchaser YC689 (sank in 1943). The destroyer *USS Hogan* (DD178), a military aircraft (S2F Tracker), and a sunken sailboat are located offshore, south of SSTC and west of the City of Imperial Beach (Figure 3.10-5) (U.S. Department of the Navy 2008b).

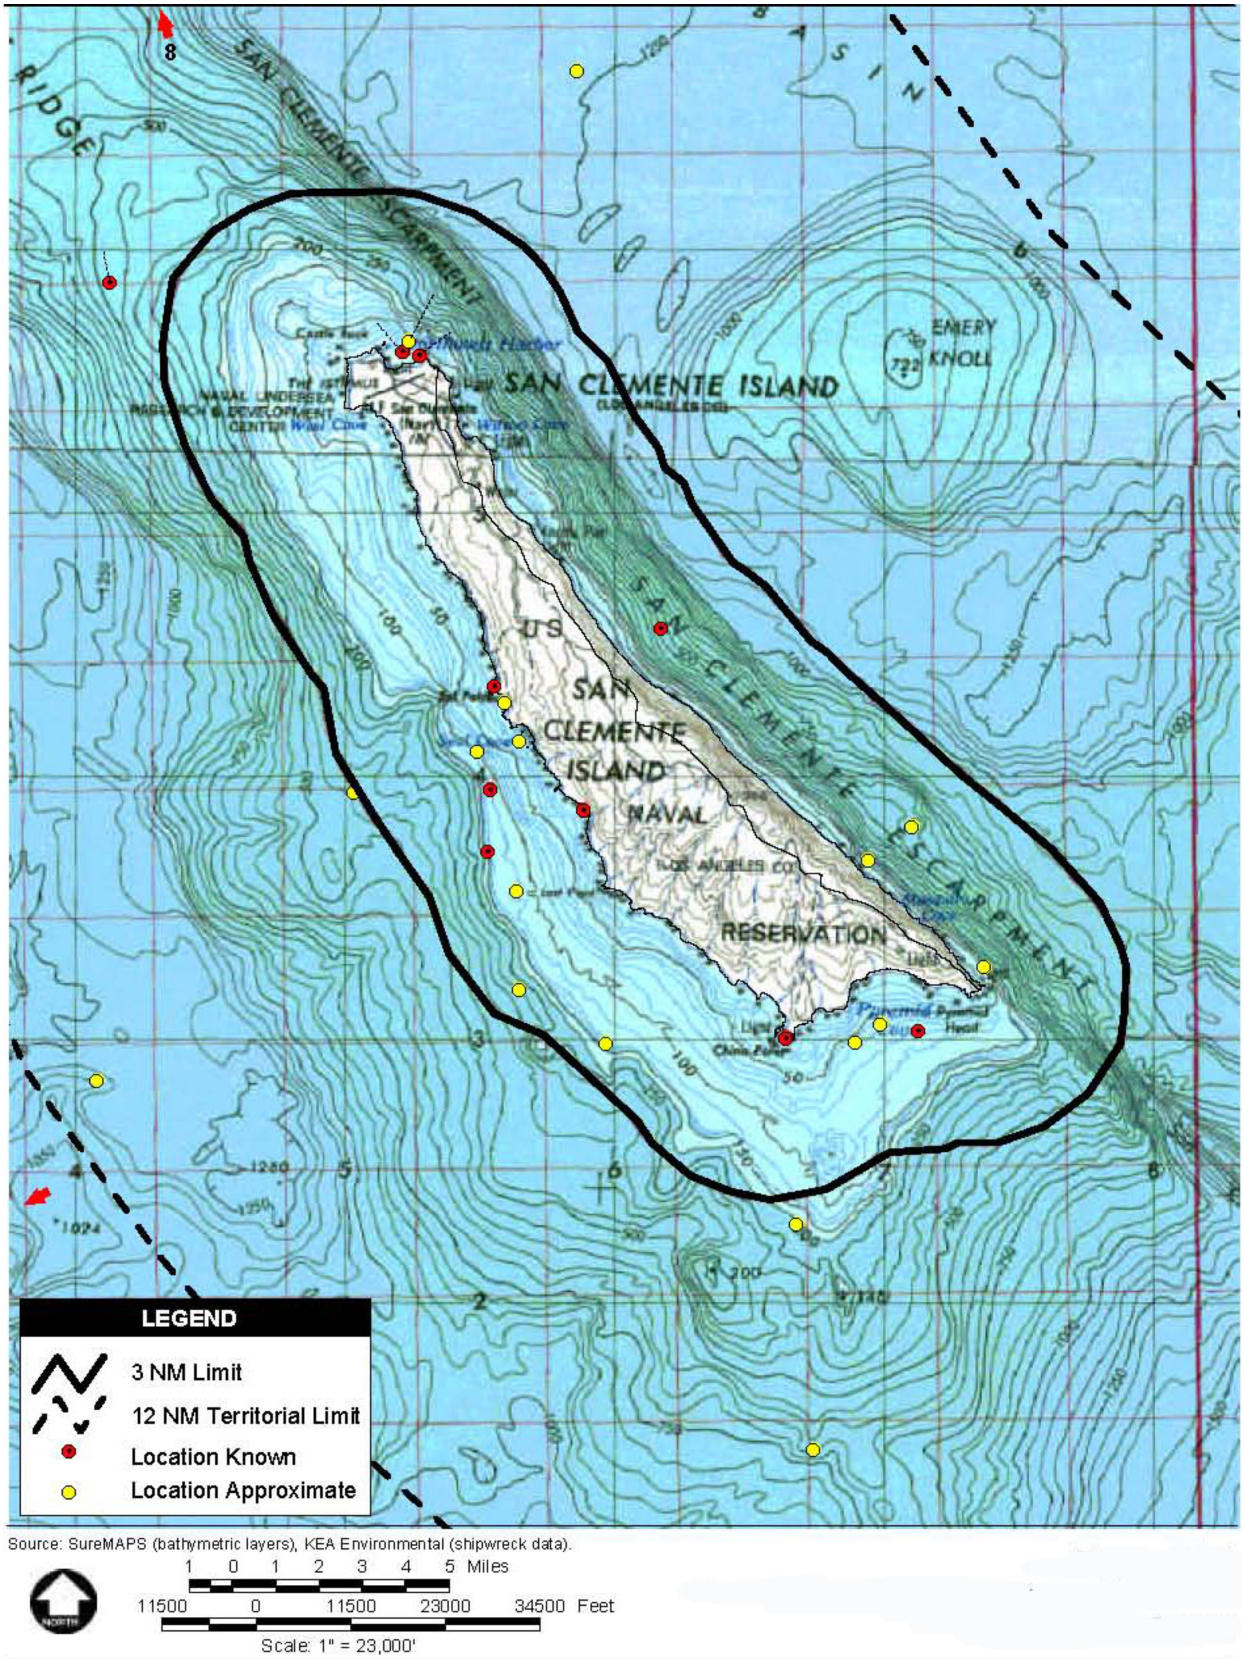

Figure 3.10-4: San Clemente Island Submerged Shipwrecks and Obstructions

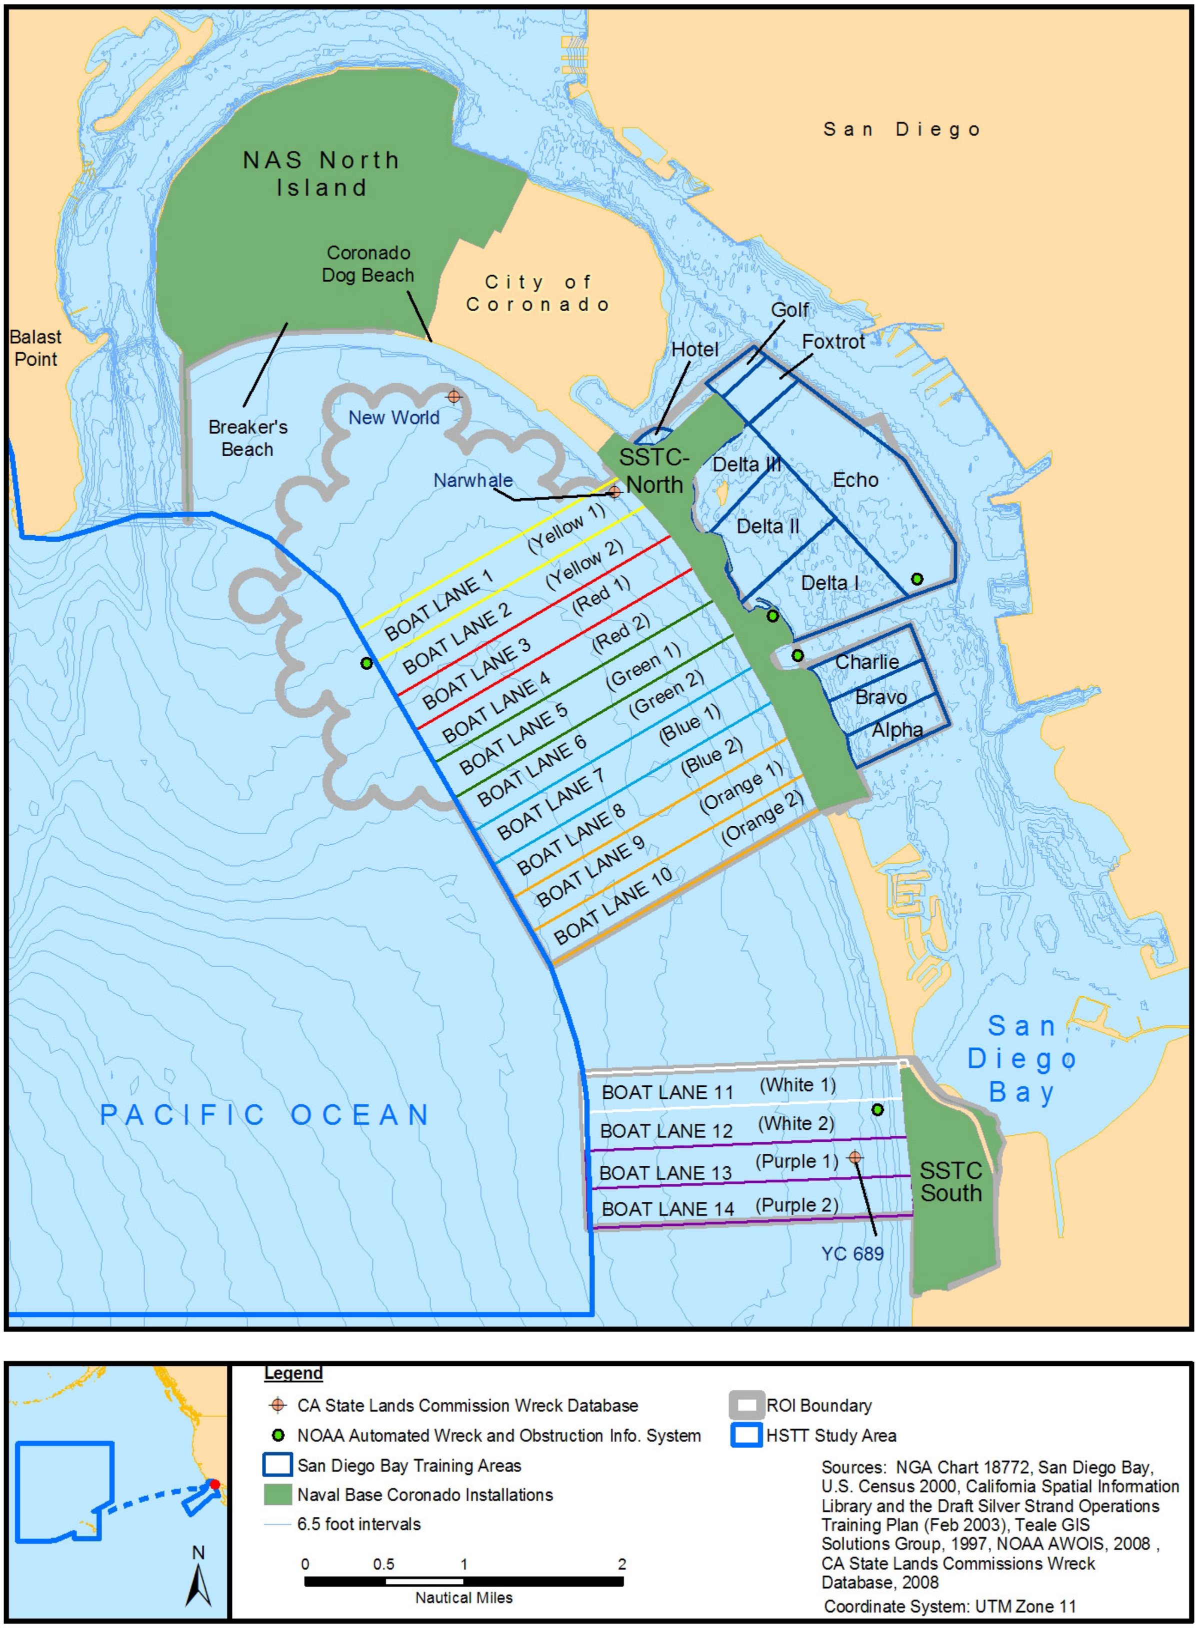

Figure 3.10-5: San Diego Bay and Silver Strand Training Complex Submerged Cultural Resources

3.10.2.2.2.3 San Diego Bay

Known cultural resources in San Diego Bay have not been inventoried. However, cultural resources were reviewed for the San Diego Deepening at Tenth Avenue Marine Terminal project (EDAW 2005). This review identified three known submerged cultural features: a shipwreck (the *Della*), an 1887 marine utility cable, and a sunken Ford Model T. The EDAW study identified 24 cultural resources with unknown location, but known to be lost in the San Diego area, including schooners, barges, a submarine, clippers, gas and oil screws, a yacht, a bark, a ferry, a ship, and a steamer. Figure 3.10-5 illustrates known submerged cultural resources in San Diego Bay.

3.10.2.2.3 Cultural Resources Eligible for or Listed on the National Register

The Study Area contains no National Register-listed or -eligible sites.

3.10.2.2.4 Cultural Resources Eligible for or Listed on the California Register

The Study Area contains no California Register-listed or -eligible sites.

3.10.2.2.5 World Heritage Sites

The Study Area contains no World Heritage Sites.

3.10.2.2.6 Resources with Sovereign Immunity

The Study Area contains no resources with sovereign immunity.

3.10.2.3 Hawaii-Southern California Training and Testing Transit Corridor

The length and variable width of the HSTT transit corridor creates such a vast area that it precludes a systematic survey for submerged historic resources. Waters along the HSTT transit corridor are deep, sometimes over 18,000 feet (ft.) (5,486.4 meters [m]); thus, identifying cultural resources on the ocean floor in the corridor is difficult. However, in accordance with the addendum to the National Historic Preservation Act (16 U.S.C. 470a-2) regarding international federal activities affecting historic properties, the World Heritage List was reviewed and no resources on the list were identified within the HSTT transit corridor.

3.10.2.4 Current Practices

The Navy routinely avoids locations of known obstructions, which include submerged cultural resources such as historic shipwrecks. Known obstructions are avoided to prevent damage to sensitive Navy equipment and vessels, allowing uninterrupted training and testing exercises.

3.10.2.5 Programmatic Agreement on Navy Undertakings in Hawaii

A programmatic agreement was executed for Navy undertakings in Hawaii, including Pearl Harbor Naval Shipyard and Intermediate Maintenance Facility; outlying Oahu installations; and Pacific Missile Range Facility at Barking Sands, Kauai (Hawaii State Historic Preservation Division 2003). The Programmatic Agreement includes stipulations for development of an integrated cultural resources management plan, determinations of areas of potential effects, identification of historic properties, access to historic sites and interpretative activities, review of project effects, monitoring of ground disturbing activities, annual reporting requirements, and consultation with Native Hawaiians and other consulting parties. Submerged resources are specifically identified under Stipulation X.D (Ground Disturbing Activities: Any undertakings in areas known to have a potential for submerged cultural resources will be planned in consultation with the National Park Service, State Historic Preservation Office, and Office of Hawaiian

Affairs as appropriate to develop a work plan and monitoring plan that will ensure avoidance of effects on the resource) and Stipulation XI.A (Discoveries and Emergencies: If during the performance of an undertaking, historic properties, including submerged archaeological sites and traditional cultural properties, are discovered or unanticipated effects are found, or a previously unidentified property which may be eligible for listing on the National Register is discovered, Commander, Navy Region Hawaii would take all reasonable measures to avoid or minimize harm to the property until it concludes consultation with the State Historic Preservation Office and any Native Hawaiian organization, including Oahu Council of Hawaiian Civic Clubs, which has made known to Commander, Navy Region Hawaii that it attaches religious and cultural significance to the historic property).

3.10.2.5.1.1 Programmatic Agreement on Operational and Developmental Undertakings at San Clemente Island, California

Within the SOCAL Range Complex, a programmatic agreement was established to address impacts on cultural resources around San Clemente Island, off-island ranges, and operational training areas within the respective territorial and administrative jurisdictions of the United States and the State of California (California State Historic Preservation Office 2012). The programmatic agreement includes stipulations for the review of both range sustainability and operational training and support activities; determinations of areas of potential effects; identification of historic properties through survey; National Register evaluations through pro-active testing of selected resources; findings of effect; preparation of an integrated cultural resources management plan; treatment of archaeological historic properties including avoidance measures, monitoring, and protective signage; preparation of annual reports; and consultation with Native American Tribes and other consulting parties.

3.10.3 Environmental Consequences

This section evaluates how and to what degree the activities described in Chapter 2 (Description of Proposed Action and Alternatives) could impact cultural resources within U.S. territorial waters and World Heritage sites located in the Study Area. Tables 2.8-1 through 2.8-5 present the baseline and proposed training and testing activity locations for each alternative (including numbers of events and ordnance expended). Appendix F (Training and Testing Activities Matrices) describes the warfare areas and associated stressors that were considered for analysis of cultural resources. The stressors vary in intensity, frequency, duration, and location within the Study Area. The stressors applicable to cultural resources in the Study Area that are analyzed include:

- Acoustic
    - Impacts from explosives- shock (pressure) waves from underwater explosions
    - Impacts from explosives-cratering
    - Impacts from pile-driving
- Physical
    - Impacts from in-water devices
    - Impacts from deposition of military expended materials
    - Impacts from seafloor devices

Sonar and other non impulsive sources do not affect the structural elements of historic shipwrecks and, therefore, an in-depth analysis of sonar impacts will not be included in this section. Archaeologists regularly use multi-beam sonar and side-scan sonar to explore shipwrecks without disturbing them. Based on the physics of underwater sound, the shipwreck would need to be very close (less than 22 ft. [6.7 m]) to the sonar sound source for the shipwreck to experience any slight oscillations from the induced pressure waves. Any oscillations experienced at a depth of less than 22 ft. (6.7 m) would be negligible up to within a few yards from the sonar source. This distance is smaller than the typical safe navigation and operating depth for most sonar sources, and therefore is not expected to impact historic shipwrecks.

3.10.3.1 Acoustic Stressors

Acoustic stressors that could impact cultural resources are vibration and shock waves from underwater explosions. A shock wave and oscillating bubble pulses resulting from any kind of underwater explosion, such as explosive torpedoes, missiles, bombs, projectiles, mines, and certain sonobuoys and explosive sonobuoys, could impact the exposed portions of submerged historic resources if such resources were located nearby. Shock waves (pressure) generated by underwater explosions would be periodic rather than continuous, and could create overall structural instability and eventual collapse of architectural features of submerged historic resources. The amount of damage would depend on factors such as the size of the charge, the distance from the historic shipwreck, the water depth, and the topography of the ocean floor.

3.10.3.1.1 Impacts of Explosive Shock Waves from Underwater Explosions

Anti-surface missiles and projectiles explode at or immediately below the ocean surface (within one meter). Shock waves (pressure) from these types of explosions within the water column would not reach historic resources on the ocean floor. Underwater detonations of improved extended echo ranging sonobuoys and high explosives would occur well below the surface and on or near the ocean bottom. Shock waves from nearby underwater detonations may affect the exposed portions of historic shipwrecks if such resources were located in the area. Underwater explosions generating vibration and shock waves within the Study Area would not impact any cultural resources because (1) known historic shipwrecks, obstructions, and archaeological sites are routinely avoided during training and testing; and (2) most shipwrecks are located at substantial depths and they are distributed over large areas of the sea floor.

3.10.3.1.1.1 No Action Alternative

Training

Under the No Action Alternative, training activities would continue at current levels within existing designated areas within the OPAREAs in the offshore waters of Hawaii and Southern California. Current training activities would continue to be conducted in accordance with programmatic agreements that are already in place for existing training areas. Consequently, no impacts on cultural resources are expected by underwater detonations at depth.

Testing

Under the No Action Alternative, testing activities would continue within existing designated areas within the OPAREA along the offshore waters of Hawaii and Southern California. Current testing activities would continue to be conducted in accordance with programmatic agreements that are already in place for existing testing areas. Consequently, no impacts on cultural resources are expected by underwater detonations at depth.

3.10.3.1.1.2 Alternative 1

Training

Under Alternative 1, the number of explosive round detonations (high explosions) would remain the same as the No Action Alternative. Training would continue in the same localities specified in current HRC, SSTC, and SOCAL EIS documents. Because the Navy routinely avoids locations of known obstructions, which include submerged historic resources, and because of the Navy's compliance with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources by underwater detonations at depth are expected within U.S. territorial waters, and no World Heritage sites would be affected.

Testing

Under Alternative 1, the number of high-explosive rounds detonated during testing activities would increase within the OPAREAs in the offshore waters of Hawaii and Southern California. Testing would continue in the same localities specified in current HRC, SSTC, and SOCAL EIS documents. Because the Navy routinely avoids locations of known obstructions, which include submerged historic resources, and because of the Navy's compliance with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources by underwater detonations at depth are expected within U.S. territorial waters, and no World Heritage sites would be affected.

3.10.3.1.1.3 Alternative 2

Training

Under Alternative 2, the number of high-explosive rounds detonated would remain the same as under the No Action Alternative. Training would continue in the same localities specified in current HRC, SSTC, and SOCAL EIS documents. Because the Navy routinely avoids locations of known obstructions, which include submerged historic resources, and because of the Navy's compliance with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources by underwater detonations at depth are expected within U.S. territorial waters, and no World Heritage sites would be affected.

Testing

Under Alternative 2, the numbers of high-explosive rounds detonated during testing activities would increase within the OPAREA along the offshore waters of Hawaii and Southern California. Testing would continue in the same localities specified in current HRC, SSTC, and SOCAL EIS documents. Because the Navy routinely avoids locations of known obstructions, which include submerged historic resources, and because of the Navy's compliance with the programmatic agreement for Hawaii that includes the protection of cultural resources, no impacts on cultural resources by underwater detonations at depth are expected within U.S. territorial waters, and no World Heritage sites would be affected.

3.10.3.1.2 Impacts from Explosives – Cratering

Underwater explosions at depth or on or near the ocean bottom could displace sediment and leave a crater. Cratering could affect submerged prehistoric sites and previously unidentified historic resources (e.g., shipwrecks) located at or near the point of detonation. Cratering of unconsolidated, soft-bottom habitats would result from Mine Neutralization charges set on or near the bottom. These charges are set on the sea floor by Navy divers in shallow waters. Cratering could potentially disrupt stratigraphic sedimentation and/or affect cultural resources. However, it is unlikely that these resources could be disturbed or destroyed by cratering created by underwater explosions during mine warfare activities because the Navy routinely avoids locations of known obstructions, which include submerged historic resources.

3.10.3.1.2.1 No Action Alternative

Training

Under the No Action Alternative, training activities would continue at current levels within existing designated areas. In Southern California, cratering would be associated with underwater detonations at

San Clemente Island (Northwest Harbor, Horse Beach Cove, Kingfisher), Southern California Anti-Submarine Warfare Range, Shallow Water Training Range, Shallow Water Minefield, Camp Pendleton Amphibious Assault Area, and at SSTC (Boat Lanes 1-14, Breakers Beach, and Delta and Echo training areas). In Hawaii, cratering would be associated with underwater detonations at Puuloa Underwater Range, Marine Corps Base Hawaii, Marine Corps Training Area Bellows, Barbers Point Underwater Range, Naval Inactive Ship Maintenance Facility, Lima Landing, Kingfisher, Shallow Water Minefield, Sonar Training Area, and Ewa Training Minefield. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated within U.S. territorial waters.

Testing

Under the No Action Alternative, testing activities would continue at current levels within existing designated areas within the OPAREAs in the offshore waters of Hawaii and Southern California. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated within U.S. territorial waters.

3.10.3.1.2.2 Alternative 1

Training

Under Alternative 1, the number of high explosive rounds associated with mine warfare training activities would increase within the OPAREA in the offshore waters of Hawaii and Southern California. Cratering created by deep underwater explosions could disturb or damage previously unidentified artifacts on the sea floor and archaeological deposits buried in the ocean sediments if such resources were located nearby. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated.

Testing

Under Alternative 1, the number of high explosive rounds associated with mine warfare activities would increase within the OPAREAs in the offshore waters of Hawaii and Southern California. Cratering created by deep underwater explosions could disturb or damage previously unidentified artifacts on the sea floor and archaeological deposits buried in the ocean sediments if such resources were located nearby. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated.

3.10.3.1.2.3 Alternative 2 (Preferred Alternative)

Training

Under Alternative 2, the number of high explosive rounds associated with mine warfare activities would increase within the OPAREA along the offshore waters of Hawaii and Southern California. Cratering created by deep underwater explosions could disturb or damage previously unidentified artifacts on the sea floor and archaeological deposits buried in the ocean sediments if such resources were located nearby. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated.

Testing

Under Alternative 2, the number of high explosive rounds associated with mine warfare activities would increase within the OPAREA in the offshore waters of Hawaii and Southern California. Cratering created by deep underwater explosions could disturb or damage previously unidentified artifacts on the sea floor and archaeological deposits buried in the ocean sediments if such resources were located nearby. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated.

3.10.3.1.3 Impacts of Pile-Driving

3.10.3.1.3.1 No Action Alternative

Training

Under the No Action Alternative, training activities would continue at current levels within existing designated areas. In Southern California pile-driving for Elevated Causeway training at SSTC, would subject nearshore sediments to vibration, disruption, and compaction. Pile-driving would not occur in Hawaii. Elevated Causeway training at SSTC would occur only in the Oceanside Boat Lanes 110 and in the bayside Bravo training area. A bark (a three- or four-masted sailing vessel) built in 1883, the Narwhal, lies in Boat Lane 1, but the Navy would routinely avoid training near known submerged cultural resources. On the bayside of SSTC, sediments have been periodically dredged and the potential for encountering submerged historic resources that retain their integrity is low.

Testing

Pile-driving is not associated with any testing activities under the No Action Alternative.

3.10.3.1.3.2 Alternative 1

Training

Under Alternative 1, the number of Elevated Causeway training events would not increase relative to the No Action Alternative. Therefore, the potential for affecting submerged historic resources would be the same as described under the No Action Alternative.

Testing

Pile-driving is not associated with any testing activities under Alternative 1.

3.10.3.1.3.3 Alternative 2 (Preferred Alternative)

Training

Under Alternative 2, the number of Elevated Causeway training events would not increase relative to the No Action Alternative. Therefore, the potential for affecting submerged historic resources would be the same as described under the No Action Alternative.

Testing

Pile-driving is not associated with any testing activities under Alternative 2.

3.10.3.1.4 Regulatory Conclusions for Acoustic Stressors

In accordance with Section 106 of the National Historic Preservation Act, acoustic stressors resulting from underwater explosions at depth during training and testing activities would not affect submerged historic resources in U.S. territorial waters, and no World Heritage sites would be affected under the No Action Alternative, Alternative 1, and Alternative 2 because the Navy routinely avoids known submerged obstructions and protective measures are in place as stipulated by a programmatic agreement. Pile-driving for Elevated Causeway training at SSTC is not expected to affect submerged cultural resources.

3.10.3.2 Physical Disturbance and Strike Stressors

Any physical disturbance on the continental shelf and seafloor, such as ship anchoring, targets or mines resting on the seafloor, moored mines, bottom-mounted tripods, unmanned underwater vehicles, or bottom crawlers, could inadvertently damage or destroy submerged prehistoric sites and historic resources. A towed system and attachment cable or vessel strike could inadvertently encounter, snag, damage, or destroy submerged historic resources in shallow water. Expended materials such as chaff, flares, projectiles, casings, target or missile fragments, non-explosive practice munitions, rocket fragments, ballast weights, sonobuoys, torpedo launcher accessories, or mine shapes could be deposited on the ocean bottom on or near submerged prehistoric sites or historic resources. Heavier expended materials could damage intact fragile shipwreck features if they landed with velocity on a resource. However, it is unlikely that these resources could be disturbed or destroyed because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources.

3.10.3.2.1 Impacts from Vessels and In-Water Devices

Use of a towed system and attachment cable could inadvertently encounter, snag, damage, or destroy historic shipwrecks, particularly those situated in relatively shallow water, and especially during low tide. Prior to deploying a towed device, the standard operating procedure is to search the intended path of the device for any floating debris (e.g., driftwood) or other potential surface obstructions, since they could damage the device. Therefore, submerged objects, including cultural resources, if present, would be avoided.

3.10.3.2.1.1 No Action Alternative

<u>**Training**</u>

Under the No Action Alternative, training operations and major range events would continue at current levels within designated areas of the OPAREAs in the offshore waters of Hawaii and Southern California. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no significant impacts on known cultural resources are expected from towed-in-water devices snagging and damaging historic shipwrecks within U.S. territorial waters in the Study Area.

<u>**Testing**</u>

Under the No Action Alternative, testing activities using towed-in-water devices would continue within existing designated areas of the OPAREAs in the offshore waters of Hawaii and Southern California. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated within U.S. territorial waters.

3.10.3.2.1.2 Alternative 1

Training

Under Alternative 1, the number of training activities using towed-in-water devices would increase in the OPAREAs in offshore waters of Hawaii and Southern California. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

Testing

Under Alternative 1, the number of testing activities using towed-in-water devices would increase in the OPAREAs in the offshore waters of Hawaii and Southern California. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

3.10.3.2.1.3 Alternative 2 (Preferred Alternative)

Training

Under Alternative 2, the number of training activities using towed-in-water devices would increase in the OPAREAs in the offshore waters of Hawaii and Southern California. Because the Navy routinely avoids locations of known obstructions, which include submerged historic resources, and because of the Navy's compliance with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

Testing

Under Alternative 2, the number of testing activities using towed-in-water devices would increase in the OPAREAs in the offshore waters of Hawaii and Southern California. Because the Navy routinely avoids locations of known obstructions, which include submerged historic resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

3.10.3.2.2 Impacts from Military Expended Materials

The deposition of non-explosive practice munitions, sonobuoys, and military expended materials other than ordnance could impact submerged cultural resources if such resources are located nearby. Most of the anticipated expended munitions (e.g., large-caliber, non-explosive practice munitions) would be small objects and fragments that would slowly drift to the sea floor after striking the ocean surface. Larger and heavier objects (e.g., ship hulks) could displace sediments and artifacts upon impacting the ocean floor despite a reduction in their descent velocity. Additionally, post deposition and impacts on sites could occur should expended material fall on or near them. However, the likelihood of these materials either impacting or landing on submerged cultural resources is very low because of the sizes of the regions and because the Navy routinely avoids submerged obstructions.

3.10.3.2.2.1 No Action Alternative

Training

Under the No Action Alternative, training activities would continue at current levels within existing designated areas within the OPAREA along the offshore waters of Hawaii and Southern California. Expended materials may be deposited on the ocean bottom on or near submerged prehistoric sites and historic resources. If they sink near either type of cultural resource, the expended materials would not affect the archaeological or historic characteristics of the submerged prehistoric site or the historic resource. Because the Navy routinely avoids known submerged obstructions, these materials likely would not contact a submerged prehistoric site or a historic resource.

Testing

Under the No Action Alternative, testing activities would continue at current levels within existing designated areas within the OPAREA along offshore waters of Hawaii and Southern California. Expended materials may be deposited on the ocean bottom on or near submerged prehistoric sites and historic resources. Because the Navy routinely avoids known submerged obstructions, these materials likely would not contact a submerged prehistoric site or a historic resource.

3.10.3.2.2.2 Alternative 1

Training

Under Alternative 1, the number of expended items from training activities would increase within designated areas of the OPAREA along the offshore waters of Hawaii and Southern California (most of the expended items are small- to medium-sized caliber that are no larger than a roll of quarters). Expended materials could be deposited on the ocean bottom on or near submerged. Because the Navy routinely avoids known submerged obstructions, these materials likely would not contact a submerged prehistoric site or a historic resource.

Testing

Under Alternative 1, the number of expended items from testing activities would increase within designated areas of the OPAREA along the offshore waters of Hawaii and Southern California (most of the expended items are small- to medium-sized caliber that are no larger than a roll of quarters). Expended materials could be deposited on the ocean bottom on or near submerged prehistoric sites and historic resources. Because the Navy routinely avoids known submerged obstructions, these materials likely would not contact a submerged prehistoric site or a historic resource.

3.10.3.2.2.3 Alternative 2 (Preferred Alternative)

Training

Under Alternative 2, the number of expended items from training activities would increase within designated areas of the OPAREA along the offshore waters of Hawaii and Southern California (most of the expended items are small- to medium-sized caliber that are no larger than a roll of quarters). Expended materials could be deposited on the ocean bottom on or near submerged prehistoric sites and historic resources. Because the Navy routinely avoids known submerged obstructions, these materials likely would not contact a submerged prehistoric site or a historic resource.

Testing

Under Alternative 2, the number of expended items from testing activities would increase within designated areas of the OPAREA along the offshore waters of Hawaii and Southern California (most of the expended items are small- to medium-sized caliber that are no larger than a roll of quarters). Expended materials could be deposited on the ocean bottom on or near submerged prehistoric sites and historic resources. Because the Navy routinely avoids known submerged obstructions, these materials likely would not contact a submerged prehistoric site or a historic resource.

3.10.3.2.3 Impacts from Seafloor Devices

Physical disturbances on the continental shelf and seafloor, such as precision anchoring, targets or mines resting on the ocean floor, moored mines, bottom-mounted tripods, bottom crawlers (unmanned underwater vehicles) could damage or destroy submerged prehistoric sites or historic resources if such resources are located nearby. Precision anchoring could crush or snag structural elements of historic resources and damage intact sediments of submerged prehistoric sites; however, this is highly unlikely because divers are used to set bottom and moored mine anchors (blocks of concrete weighing several hundred pounds) in waters less than 150 ft. (45.7 m) deep and routinely avoid known obstructions, which include cultural resources and any unrecorded obstructions they might encounter.

3.10.3.2.3.1 No Action Alternative

Training

Under the No Action Alternative, training activities using seafloor deployed devices would continue at current levels in existing designated areas within the offshore waters of the Hawaii and Southern California OPAREAs. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated within U.S. territorial waters.

Testing

Under the No Action Alternative, testing activities using seafloor deployed devices would continue at current levels in existing designated areas in the offshore waters of the Hawaii and Southern California OPAREAs. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, effects on underwater cultural resources are not anticipated within U.S. territorial waters.

3.10.3.2.3.2 Alternative 1

Training

Under Alternative 1, the number of training activities using seafloor deployed devices would not increase in the offshore waters of the Hawaii and Southern California OPAREAs. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

Testing

Under Alternative 1, testing activities would increase in the offshore waters of the Hawaii and Southern California OPAREAs. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

3.10.3.2.3.3 Alternative 2 (Preferred Alternative)

Training

Under Alternative 2, the number of annual training activities using seafloor deployed devices would not increase within the offshore waters of the Hawaii and Southern California OPAREAs. Because the Navy routinely avoids locations of known obstructions, which include submerged cultural resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

Testing

Under Alternative 2, testing activities would increase in the offshore waters of the Hawaii and Southern California OPAREAs. Because the Navy routinely avoids locations of known obstructions, which include submerged historic resources, and because the Navy complies with a programmatic agreement that includes the protection of cultural resources, no impacts on cultural resources are expected within U.S. territorial waters, and no World Heritage sites would be affected.

3.10.3.2.4 Regulatory Conclusions for Physical Stressors

In accordance with Section 106 of the National Historic Preservation Act, physical stressors resulting from use of marine and seafloor devices during training and testing activities under the No Action Alternative, Alternative 1, and Alternative 2 would not adversely affect submerged cultural resources in U.S. territorial waters, and no World Heritage sites would be affected. Both Alternative 1 and Alternative 2 would increase the number of training and testing activities. However, because the Navy routinely avoids known submerged obstructions and protective measures are in place as stipulated by programmatic agreement, no submerged cultural resources would be affected.

3.10.3.3.1 No Action Alternative

Acoustic and physical stressors associated with training and testing activities would not impact submerged cultural resources. Training and testing activities would continue in existing locations, as specified in the HRC, SSTC, and SOCAL EISs, however, so no impacts on cultural resources are expected within U.S. territorial waters because measures have been previously implemented to protect these resources.

3.10.3.3.2 Alternative 1

An increase in training and testing activities would occur in existing locations, as specified in the HRC, SSTC, and SOCAL EISs, under Alternative 1. Acoustic and physical stressors associated with training and testing activities would not impact cultural resources because measures have been previously implemented to protect them.

3.10.3.3.3 Alternative 2 (Preferred Alternative)

Under Alternative 2, an increase in training and testing activities would occur only in the existing locations, as specified in the HRC, SSTC, and SOCAL EISs. Acoustic and physical stressors associated with training and testing activities would not impact cultural resources because measures have been previously implemented to protect them.

3.10.3.4 Regulatory Determinations

Table 3.10-1 summarizes the potential effects of the Proposed Action on submerged resources under the No Action Alternative, Alternative 1, and Alternative 2. The Proposed Action is not anticipated to affect known cultural resources within the Study Area, and programmatic agreements between the Navy and State Historic Preservation Offices exist to address the protection and management of cultural resources. Accordingly, per Section 106, the Navy will continue, as appropriate, to consult with the California and Hawaii State Historic Preservation Offices.

Table 3.10-1: Summary of Section 106 Effects of Training and Testing Activities on Cultural Resources

Alternative and Stressor	Section 106 Effects of Training and Testing Activities
No Action Alternative	
Acoustic Stressors	Acoustic stressors resulting from underwater explosions creating shock (pressure) waves and cratering of the sea floor would not affect submerged cultural resources. Training and testing would continue only in areas currently utilized for these activities. As a result, effects on cultural resources are not anticipated within United States (U.S.) territorial waters because measures have been previously implemented to protect these resources.
Physical Stressors	Physical stressors resulting from use of towed-in water devices, and use of seafloor devices would not adversely affect submerged cultural resources. Testing and training would continue only in areas currently utilized for these activities. As a result, effects on cultural resources are not anticipated within U.S. territorial waters because measures have been previously implemented to protect these resources. Military expended materials are not expected to affect submerged cultural resources.
Alternative 1	
Acoustic Stressors	Acoustic stressors resulting from underwater explosions creating shock (pressure) waves and cratering of the seafloor would not affect submerged cultural resources. Testing and training would continue only in areas currently utilized for these activities. As a result, effects on cultural resources are not anticipated within U.S. territorial waters because measures have been previously implemented to protect these resources.
Physical Stressors	Physical stressors resulting from use of seafloor devices during training and testing activities could affect submerged cultural resources. Testing and training would continue only in areas currently utilized for these activities. As a result, effects on cultural resources are not anticipated within U.S. territorial waters because measures have been previously implemented to protect these resources. Military expended materials are not expected to affect submerged cultural resources.
Regulatory Determination	Alternative 1 contains increases in the number of training and testing activities compared to the No Action Alternative. No effects on submerged cultural resources would occur because measures were previously implemented to protect these resources. A Finding of No Effects on historic properties within the Area of Potential Effect has been determined by the California State Historic Preservation Officer (Saunders 2012). A Finding of No Effects on historic properties within the Area of Potential Effect has been determined by the Hawaii State Historic Preservation Office, as assumed by their no response or objections under 36 Code of Federal Regulations 800.4(d)(1)(i).

Table 3.10-1: Summary of Section 106 Effects of Training and Testing Activities on Cultural Resources (continued)

Alternative and Stressor	Section 106 Effects of Training and Testing Activities
Alternative 2 (Preferred Alternative)	
Acoustic Stressors	Acoustic stressors resulting from underwater explosions creating shock (pressure) waves and cratering of the seafloor would not affect submerged cultural resources. Testing and training would continue only in areas currently utilized for these activities. As a result, effects on cultural resources are not anticipated within U.S. territorial waters because measures have been previously implemented to protect these resources.
Physical Stressors	Physical stressors resulting from use of towed-in water devices, and use of seafloor devices during training and testing activities would not affect submerged cultural resources. Testing and training would continue only in areas currently identified for these activities. As a result, effects on cultural resources are not anticipated within U.S. territorial waters because measures have been previously implemented to protect these resources. Military expended materials are not expected to affect submerged cultural resources.
Regulatory Determination	Alternative 2 contains increases in the number of training and testing activities compared to the No Action Alternative. Depending on the location, an increase in the number of activities could increase the probability of disturbing submerged cultural resources. Submerged cultural resources would not be affected, however, because testing and training would only occur within areas now used for these activities. As a result, effects on cultural resources are not anticipated within U.S. territorial waters because measures have been previously implemented to protect these resources.

3.11 Socioeconomic Resources

SOCIOECONOMIC RESOURCES SYNOPSIS

The United States Department of the Navy considered all potential stressors, and the following have been analyzed for socioeconomic resources:

- Accessibility (limiting access to the ocean and the air)
- Physical disturbance and strike (aircraft, vessels and in-water devices, military expended materials)
- Airborne acoustics (weapons firing, aircraft and vessel noise)
- Secondary

Preferred Alternative (Alternative 2)

- Accessibility: Accessibility stressors are not expected to result in impacts on commercial transportation and shipping, commercial and recreational fishing, subsistence use, or tourism because inaccessibility to areas of co-use would be temporary and of short duration (hours).
- Physical disturbance and strike: Physical disturbance and strikes are not expected to result in impacts on commercial and recreational fishing, subsistence use, or tourism because of the large size of the Study Area, the limited areas of operations, and implementation of the Navy's standard operating procedures.
- Airborne acoustics: Airborne acoustic stressors are not expected to result in impacts to tourism or recreational activity because the Navy's training and testing would occur well out to sea, far from tourism and recreation locations.
- Secondary: Secondary stressors are not expected to result in impacts to fishing, subsistence use, or tourism, based on the level of impacts described in other resources sections.

3.11.1 Introduction and Methods

This section provides an overview of the characteristics of socioeconomic resources in the Hawaii-Southern California Training and Testing (HSTT) Study Area (Study Area) and describes in general terms the methods used to analyze potential impacts on these resources from the Proposed Action.

The Council on Environmental Quality regulations implementing the National Environmental Policy Act (NEPA) state that when economic or social effects and natural or physical environmental effects are interrelated, the Environmental Impact Statement (EIS) will discuss these effects on the human environment (40 Code of Federal Regulations [C.F.R.] 1508.14). The Council on Environmental Quality regulations state that the "human environment shall be interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment." To the extent that the ongoing and proposed United States (U.S.) Department of the Navy (Navy) training and testing activities in the Study Area could affect the natural or physical environment, the socioeconomic analysis evaluates how elements of the human environment might be affected. The Navy identified four broad socioeconomic topics based on their association with human activities and livelihoods in the Study Area. Each of these socioeconomic resources is an aspect of the human environment that involves economics (i.e., employment, income, or revenue) and social conditions (i.e., enjoyment and quality of life) associated with the marine environment of the Study Area. Therefore, this evaluation considered potential impacts on four topics:

- Commercial transportation and shipping
- Commercial and recreational fishing
- Subsistence use
- Tourism

The baseline for identifying the socioeconomic conditions in the Study Area was derived using relevant published information from sources that included federal, state, regional and local government agencies and databases, academic institutions, conservation organizations, technical and professional organizations, and private groups. Previous environmental studies were also reviewed for relevant information.

The alternatives were evaluated based upon the potential for and the degree to which training and testing activities could impact socioeconomics. The potential for impacts depends on the likelihood that the testing and training activities would interface with public activities or infrastructure. Factors considered in the analysis include whether there would be temporal or spatial interfaces between the public or infrastructure and Navy testing and training. If there is potential for this interface, factors considered to estimate the degree to which an exposure could impact socioeconomics include whether there could be an impact on livelihood, quality of experience, resource availability, income, or employment. If there is no expected potential for the public to interface with an activity, the impacts would be considered negligible.

3.11.2 Affected Environment

The area of interest for assessing potential impacts on socioeconomic resources is the U.S. Territorial Waters of Hawaii and Southern California coasts (seaward of the mean high water line to 12 nautical miles [nm]). This section describes the four socioeconomic resources associated with human activities and livelihoods in the Study Area from shore to 12 nm from shore consistent with NEPA.

3.11.2.1 Transportation and Shipping

Current military and civilian use of the offshore sea and air areas is compatible, with Navy ships accounting for six percent of the total ship presence out to 200 nm (Mintz and Filadelfo 2011). The Navy conducts training and testing activities in operating areas (OPAREAs) away from commercially used waterways and within special use airspace (Mintz and Filadelfo 2011). Notifications of potentially hazardous operations are communicated to all vessels and operators by use of Notices to Mariners, issued by the U.S. Coast Guard and Notices to Airmen, issued by the Federal Aviation Administration. The Department of Defense (DoD) also publishes separate Notices to Airmen about runway closures, missile launches, special traffic management procedures, and malfunction of navigational aids.

3.11.2.1.1 Ocean Traffic

Ocean traffic is the transit of commercial, private, or military vessels at sea, including submarines. The ocean traffic flow in congested waters, especially near coastlines, is controlled by the use of directional shipping lanes for large vessels, including cargo, container ships, and tankers. Traffic flow controls are also implemented to ensure that harbors and ports-of-entry remain as uncongested as possible. There is less control on open-ocean traffic involving recreational boating, sport fishing, commercial fishing, and activity by naval vessels. In most cases, the factors that govern shipping or boating traffic include the following: adequate depth of water, weather conditions (primarily affecting recreational vessels), availability of fish, and temperature. Higher air and water temperatures increase recreational boat traffic (e.g., sailing, power boating, windsurfing, kayaking, and using jet skis) as well as diving activities. Recreational activities also fluctuate seasonally, with increased activity in summer when, along with warmer weather, there are more daylight hours and greater opportunity for recreational activities.

Areas of surface water within the Study Area are designated as danger zones and restricted areas as described in the C.F.R., Title 33 (Navigation and Navigable Waters), Part 334 (Danger Zone and Restricted Area Regulations) and established by the U.S. Army Corps of Engineers. Danger zones are areas used for target practice, bombing, rocket firing, or other especially hazardous training operations. A danger zone may be closed to the public full-time or on an intermittent basis, as stated in the regulations. A restricted area is designated for the purpose of prohibiting or limiting public access to an area. Restricted areas generally provide security for government property and protection to the public from risks of damage or injury arising from government activities occurring in the area (33 C.F.R. 334.2). Danger zones and restricted areas located within 12 nm from shore in the Study Area have the potential to impact the four socioeconomic resources identified above.

3.11.2.1.1.1 Hawaii Range Complex

Ocean shipping is a significant component to Hawaii's economy. Major inter-island ports include Honolulu, Barbers Point, Hilo, Kawaihae, and Kahului. The U.S. Army Corps of Engineers ranked 149 U.S. ports by cargo volume in 2009. Based on those rankings, Barbers Point (Oahu) ranked 48th in total trade (domestic and foreign) with over 9.6 million tons of imports and exports. Other ranked cities in Hawaii were Honolulu at 49th, Kahului at 96th, Kawaihae at 125th, Hilo at 126th, and Nawiliwili (Kauai) at 130 (Table 3.11-1)

Shipping routes around the Hawaiian Islands are shown in Figure 3.11-1.

Table 3.11-1: United States Port Rankings by Cargo Volume for Hawaii Ports in 2009

Port Name	Total Trade Rank (Domestic and Foreign)	Total Foreign Trade	Total Domestic Trade
Barbers Point, Oahu	48th	35th	101st
Honolulu, Oahu	49th	81st	31st
Kahului, Maui	96th	113th	74th
Kawaihae Harbor, Hawaii	125th	130th	105th
Hilo, Hawaii	126th	116th	106th
Nawiliwili, Kauai	130th	118th	108th

Source: Association of Port Authorities 2009

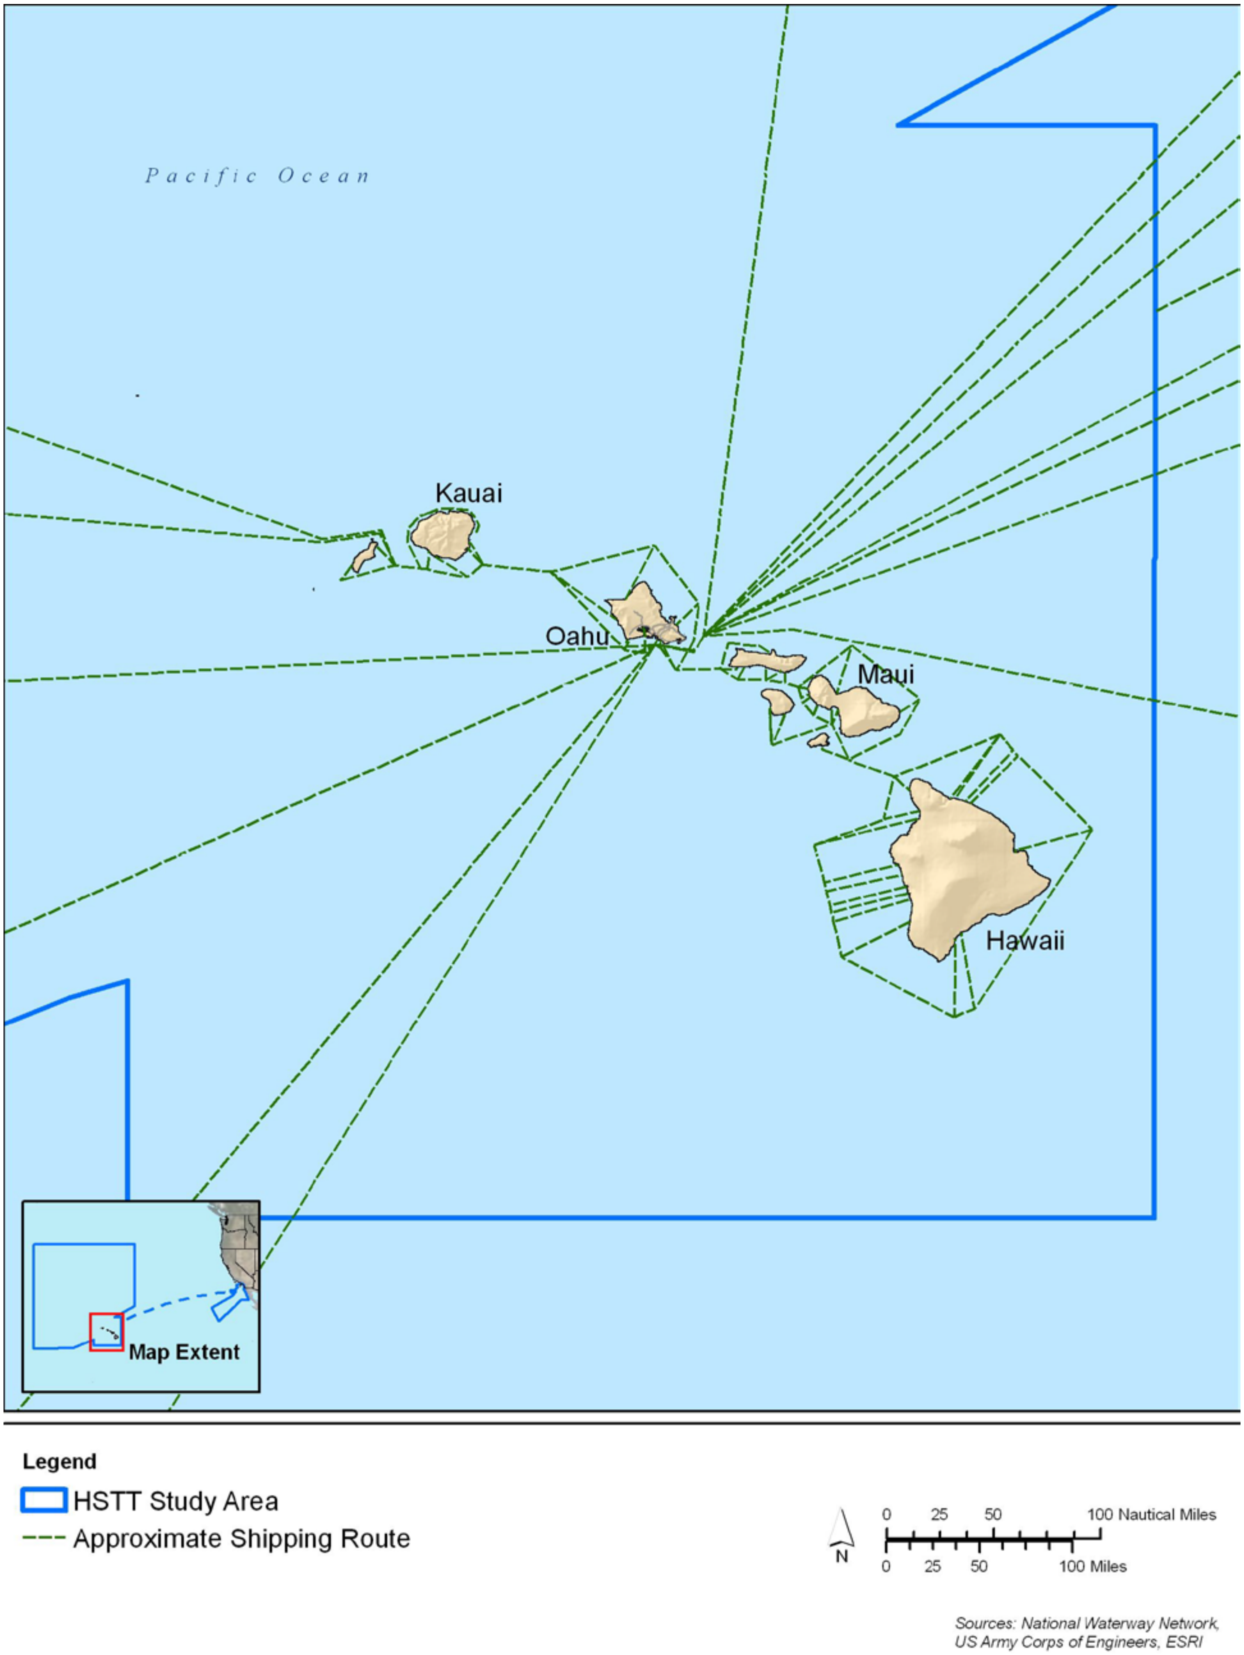

Figure 3.11-1: Hawaiian Islands Shipping Routes

3.11.2.1.1.2 Southern California Range Complex and Silver Strand Training Complex

Ocean shipping is a significant component of the Southern California regional economy. Key ports in Southern California include Los Angeles, Long Beach, and, to a lesser degree, Port Hueneme and San Diego. Of 149 U.S. ports evaluated by the U.S. Army Corps of Engineers, Los Angeles and Long Beach ranked fourth and ninth, respectively, in total trade (measured in tons) in 2009 (the most recent year data are available); Port Hueneme ranked 118th and San Diego ranked 123rd (Intermodal Association of North America 2008; Association of Port Authorities 2009) (Table 3.11-2). Total trade at Long Beach exceeded 72 million tons of foreign and domestic imports and exports. Total trade at Los Angles was over 58 million tons.

Table 3.11-2: United States Port Rankings by Cargo Volume for Southern California Ports in 2009

Port Name	Total Trade Rank (Domestic and Foreign)	Total Foreign Trade	Total Domestic Trade
Long Beach	4th	4th	20th
Los Angeles	9th	5th	38th
Port Hueneme	118th	71st	142nd
San Diego	123rd	76th	139th

Source: Association of Port Authorities 2009

A significant amount of ocean traffic, consisting of both large and small vessels, transits through the Southern California (SOCAL) Range Complex. For instance, there was an annual average of over 1,200 commercial ship transits into and out of the Port of San Diego between 2007 and 2010 (San Diego Unified Port District 2011). For commercial vessels, the major transoceanic routes to the southwest pass north and south of San Clemente Island (Figure 3.11-2).

The approach and departure routes into San Diego and the ports of Los Angeles-Long Beach Harbor pass to the east of San Clemente Island and Santa Catalina Island. Naval vessels operate within and transit through the SOCAL Range Complex. The location of San Clemente Island creates a separation zone within the SOCAL Range Complex. Most vessels entering or leaving the ports of Los Angeles or Long Beach travel northwest through the Santa Barbara Channel, west just south of the northern Channel Islands, or south along the coast to San Diego, the Panama Canal, or South America.

Shipping to and from the south includes an inshore route to the east of San Clemente Island within the SOCAL Range Complex. Ships traveling between Los Angeles/Long Beach and Hawaii via the most direct route pass to the north of the SOCAL Range Complex. Vessels coming or going from the Port of San Diego generally travel along shipping routes north or south near the coast, which includes inshore waters of the SOCAL Range Complex but bypass San Clemente Island to the east. Another commercial shipping route extends from the Port of San Diego to Japan and the eastern Pacific crossing the SOCAL Range Complex just south of San Clemente Island.

Recreational traffic is typically found within a mile from shore and rarely found in the outer waters, shipping lanes, or near San Clemente Island, with the exception of recreational fishing (i.e., charter) vessels traveling to deeper water. Within the SOCAL Range Complex, fishing is centered primarily around San Clemente Island and secondarily in the shallower waters over the Tanner and Cortes Banks. Because those banks are inherently more hazardous, the nearshore waters of San Clemente Island are a more popular destination than the more remote banks.

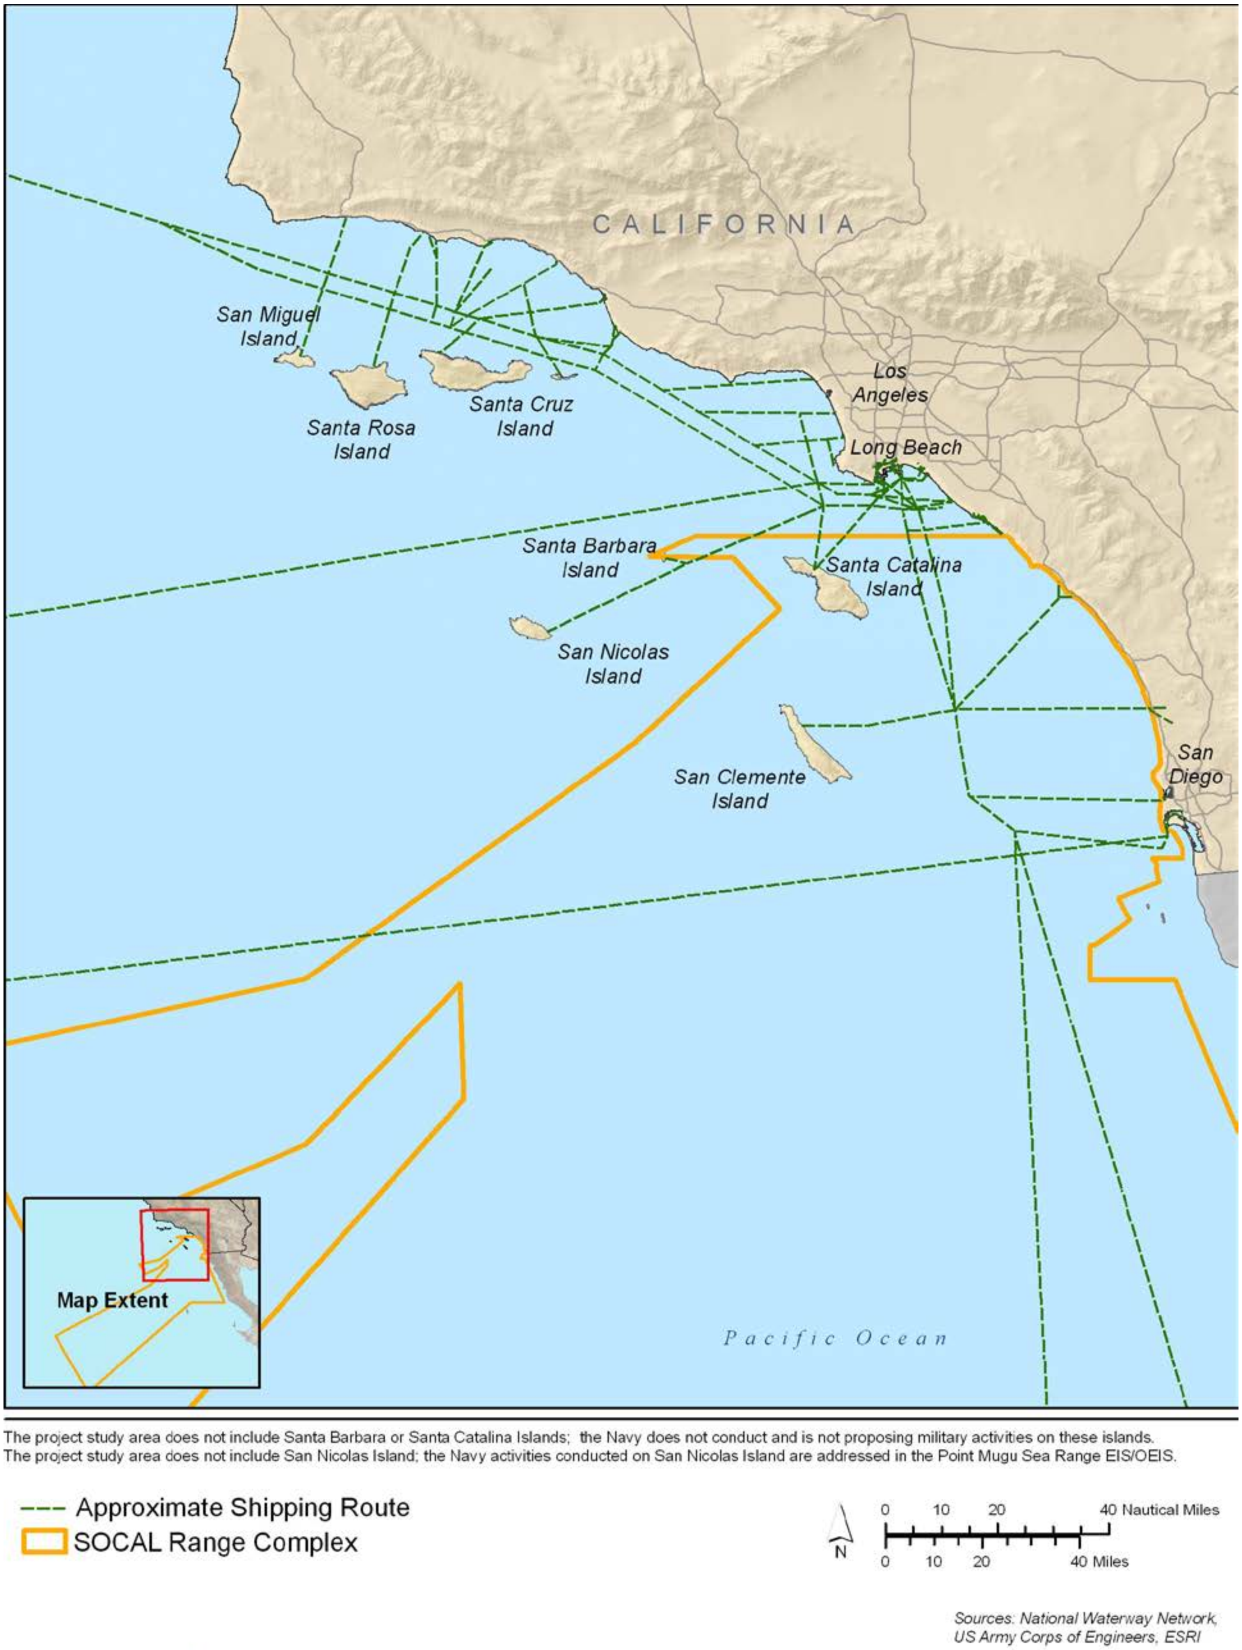

Figure 3.11-2: Southern California Range Complex Shipping Routes

Marine traffic in the Silver Strand Training Complex (SSTC) region consists of vessels transiting to multiple marinas, mooring locations, commercial ports, fishing harbors, and military installations. San Diego Bay is bordered by the cities of San Diego, National City, Chula Vista, Imperial Beach, and Coronado. The SSTC Boat Lanes located on the ocean side of the SSTC are commonly used by sportfishing charters, baitfishing to support sportfishing, lobster fishing, and competition sailing regattas. Access to San Diego Bay by incoming vessels is through the mouth of the harbor to the north, or through the many marinas and boat launch facilities located along the perimeter of the Bay.

3.11.2.1.1.3 Transit Corridor

Major commercial shipping vessels use the transit corridor for shipping goods between Southern California and Hawaii because it is the shortest distance between these two points (Figure 2.1-1). Vessels using this corridor are outside of military training areas and typically follow all U.S. Coast Guard maritime regulations. The Navy also uses this corridor for training and testing activities while en route between Southern California and Hawaii.

3.11.2.1.2 Air Traffic

Air traffic refers to movements of aircraft through airspace (Figure 3.11-3). Safety and security factors dictate that use of airspace and control of air traffic be closely regulated. Accordingly, regulations applicable to all aircraft are promulgated by the Federal Aviation Administration to define permissible uses of designated airspace, and to control that use. These regulations are intended to accommodate the various categories of aviation, whether military, commercial, or general aviation.

The system of airspace designation uses various definitions and classifications of airspace in order to facilitate control. Airspace is categorized generally as either “controlled” airspace or “uncontrolled” airspace. Controlled airspace is further organized into several difference classes of airspace distinguished by altitude range, use (e.g., commercial or military), and proximity to a major airport. Controlled airspace means that services supporting aircraft flying under Instrument Flight Rules are available. Such services include air-to-ground radio communication, navigational aids, and air traffic control services for maintaining separation between aircraft. Controlled airspace does not mean that all flights are controlled by air traffic control.

Special use airspace consists of both controlled and uncontrolled airspace and has defined dimensions where flight and other activities are confined because of their nature and the need to restrict or prohibit non-participating aircraft for safety reasons. Special use airspace are established under procedures outlined in 14 C.F.R. Part 73.1. The majority of special use airspace is established for military flight activities and, with the exception of prohibited areas (e.g., over the White House) may be used for commercial or general aviation when not reserved for military activities. There are multiple types of special use airspace, including prohibited, restricted, warning, alert, and military operations areas (Federal Aviation Administration 2009). One type of special use airspace, of particular relevance to the Study Area, is a warning area, which is defined in 14 C.F.R. Part 1 as follows:

> “A warning area is airspace of defined dimensions, extending from 3 nm outward from the coast of the United States that contains activity that may be hazardous to nonparticipating aircraft. The purpose of such warning areas is to warn nonparticipating pilots of the potential danger. A warning area may be located over domestic or international waters or both.”

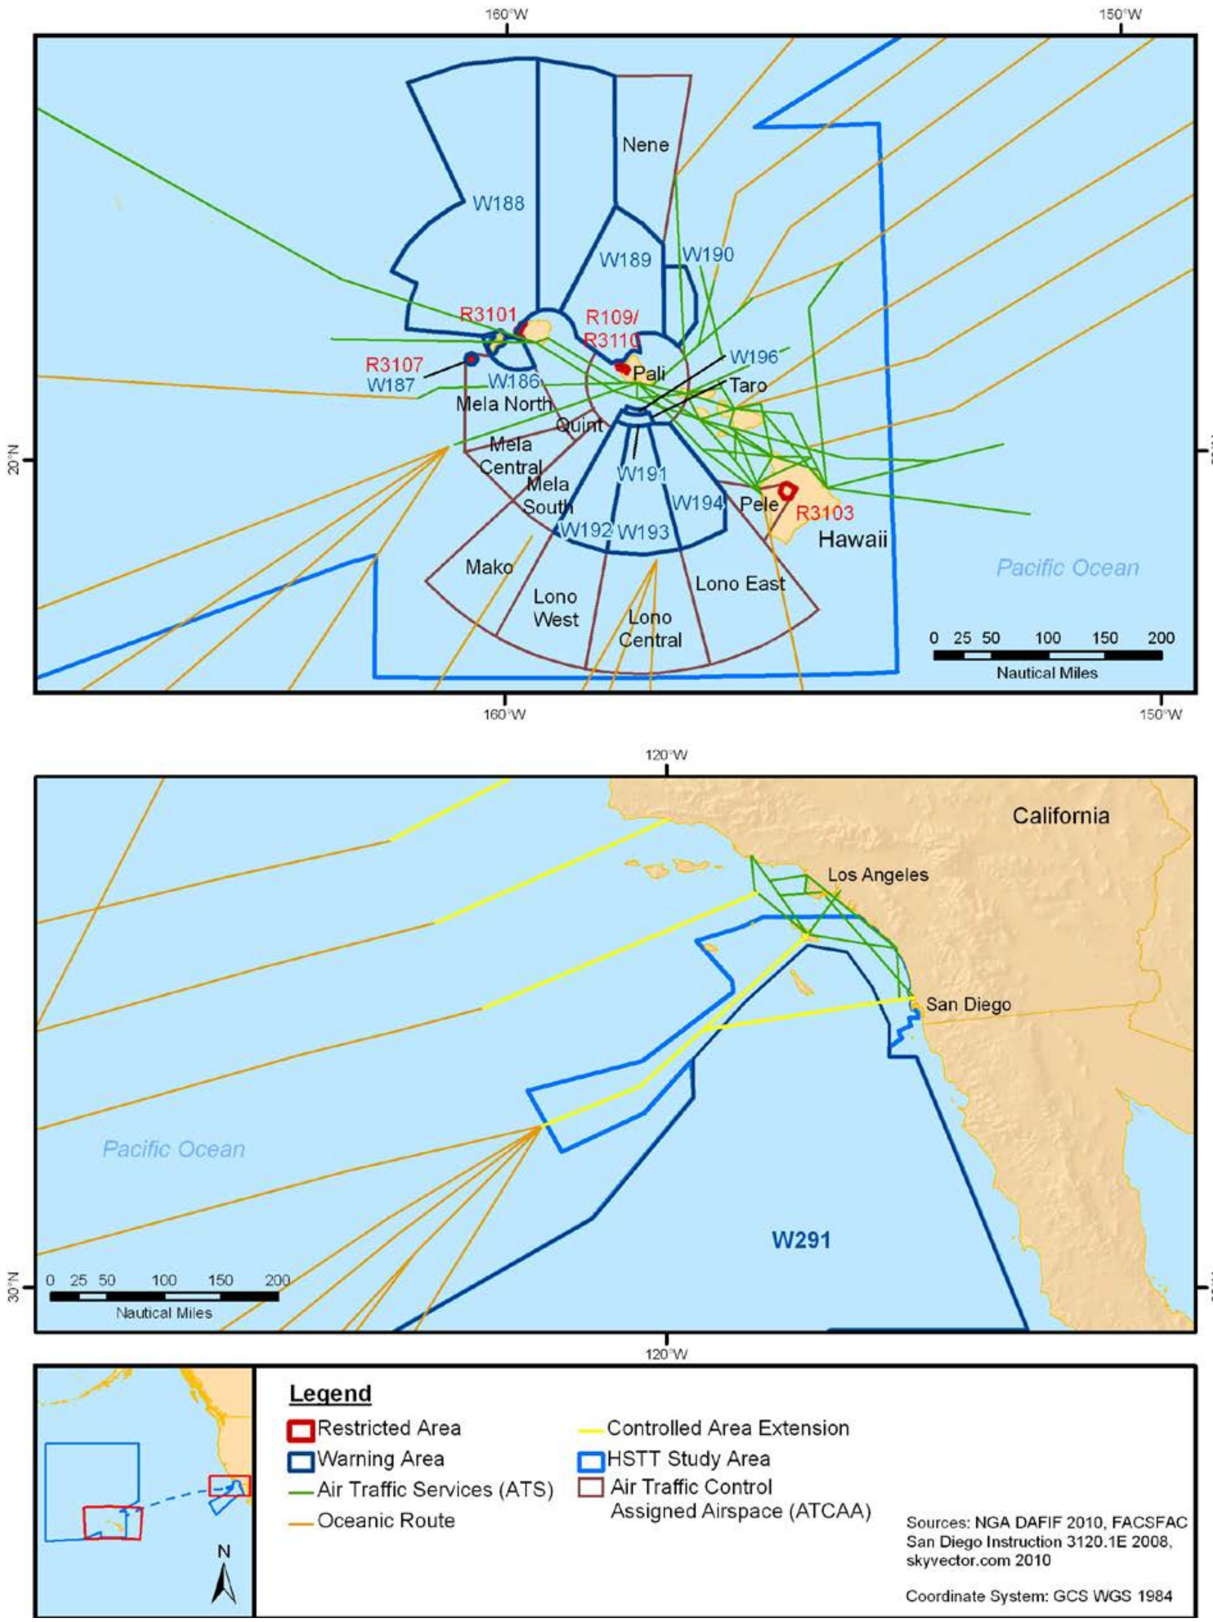

Figure 3.11-3: Air Traffic Routes in the Study Area, Hawaii Range Complex (top) and Southern California Range Complex (bottom)

Warning areas are established to contain a variety of hazardous aircraft and non-aircraft activities, such as aerial gunnery, air and surface missile firings, bombing, aircraft carrier operations, surface and subsurface operations, and naval gunfire. When these activities are conducted in international airspace, the Federal Aviation Administration regulations may warn against, but do not have the authority to prohibit, flight by nonparticipating aircraft. A restricted area, such as Restricted Area 3107 (R-3107), is a type of special use airspace within which nonmilitary flight activities are closely restricted.

3.11.2.1.2.1 Hawaii Range Complex

Military Air Transit

The special use airspace in the region of influence (Figure 3.11-3) consists of W-188 and R-3101 north and west of Kauai, and W-186 southwest of Kauai, controlled by Pacific Missile Range Facility. Warning Areas 188 Rainbow, W-189 and W-190 north of Oahu, W-187 and R-3107 surrounding Kaula Island, and W-191, W-192, W-193, W-194, and W-196 south of Oahu are scheduled through the Navy Fleet Area Control and Surveillance Facility Pearl Harbor, which then coordinates with the Honolulu Combined Facility. There are also 12 Air Traffic Control Assigned Airspace areas within the Hawaii Range Complex (HRC). These Air Traffic Control Assigned Airspace areas provide additional controlled airspace adjacent to and between the warning areas.

Commercial and General Aviation

Most of the airspace within the region of influence is in international airspace, and air traffic is managed by the Honolulu Control Facility. The Honolulu Control Facility includes the Air Route Traffic Control Center, the Honolulu Control Tower, and the Combined Radar Approach Control collocated in a single facility. Airspace outside that managed by the Hawaii Combined Facility is managed by the Oakland Air Route Traffic Control Center.

The airspace within the HRC has several en route high-altitude jet routes, as shown on Figure 3.11-3. Most of the oceanic routes enter the HRC from the northeast and southwest and are generally outside the special use airspace warning areas described above. The Air Traffic Services routes are concentrated along the Hawaiian islands chain. Most of the open-ocean area region of influence is well removed from the jet routes that crisscross the north Pacific Ocean.

3.11.2.1.2.2 Southern California Range Complex

Military Air Transit

The SOCAL Range Complex contains three warning areas (W): W-290, W-291, and a small portion of W-289. Each extends from the surface to 80,000 feet (ft.) (24,384 meters [m]) above mean sea level (Figure 3.11-4). All three warning areas can be activated by the Federal Aviation Administration at the Navy's request when operations that would pose a hazard to nonparticipating aircraft are being conducted. Other special use airspace within W-291 includes nine Tactical Maneuvering Areas and two Missile Ranges.

Military pilots travel under Instrument Flight Rules from local air bases until they reach W-291 and proceed under a Visual Flight Rules to their instructed tactical maneuvering areas or missile range OPAREA. Activation by the Federal Aviation Administration is performed by notifying the controlling air traffic agency of the change in status in the area. This allows the agency to issue notices to pilots to alter their courses to avoid military activities.

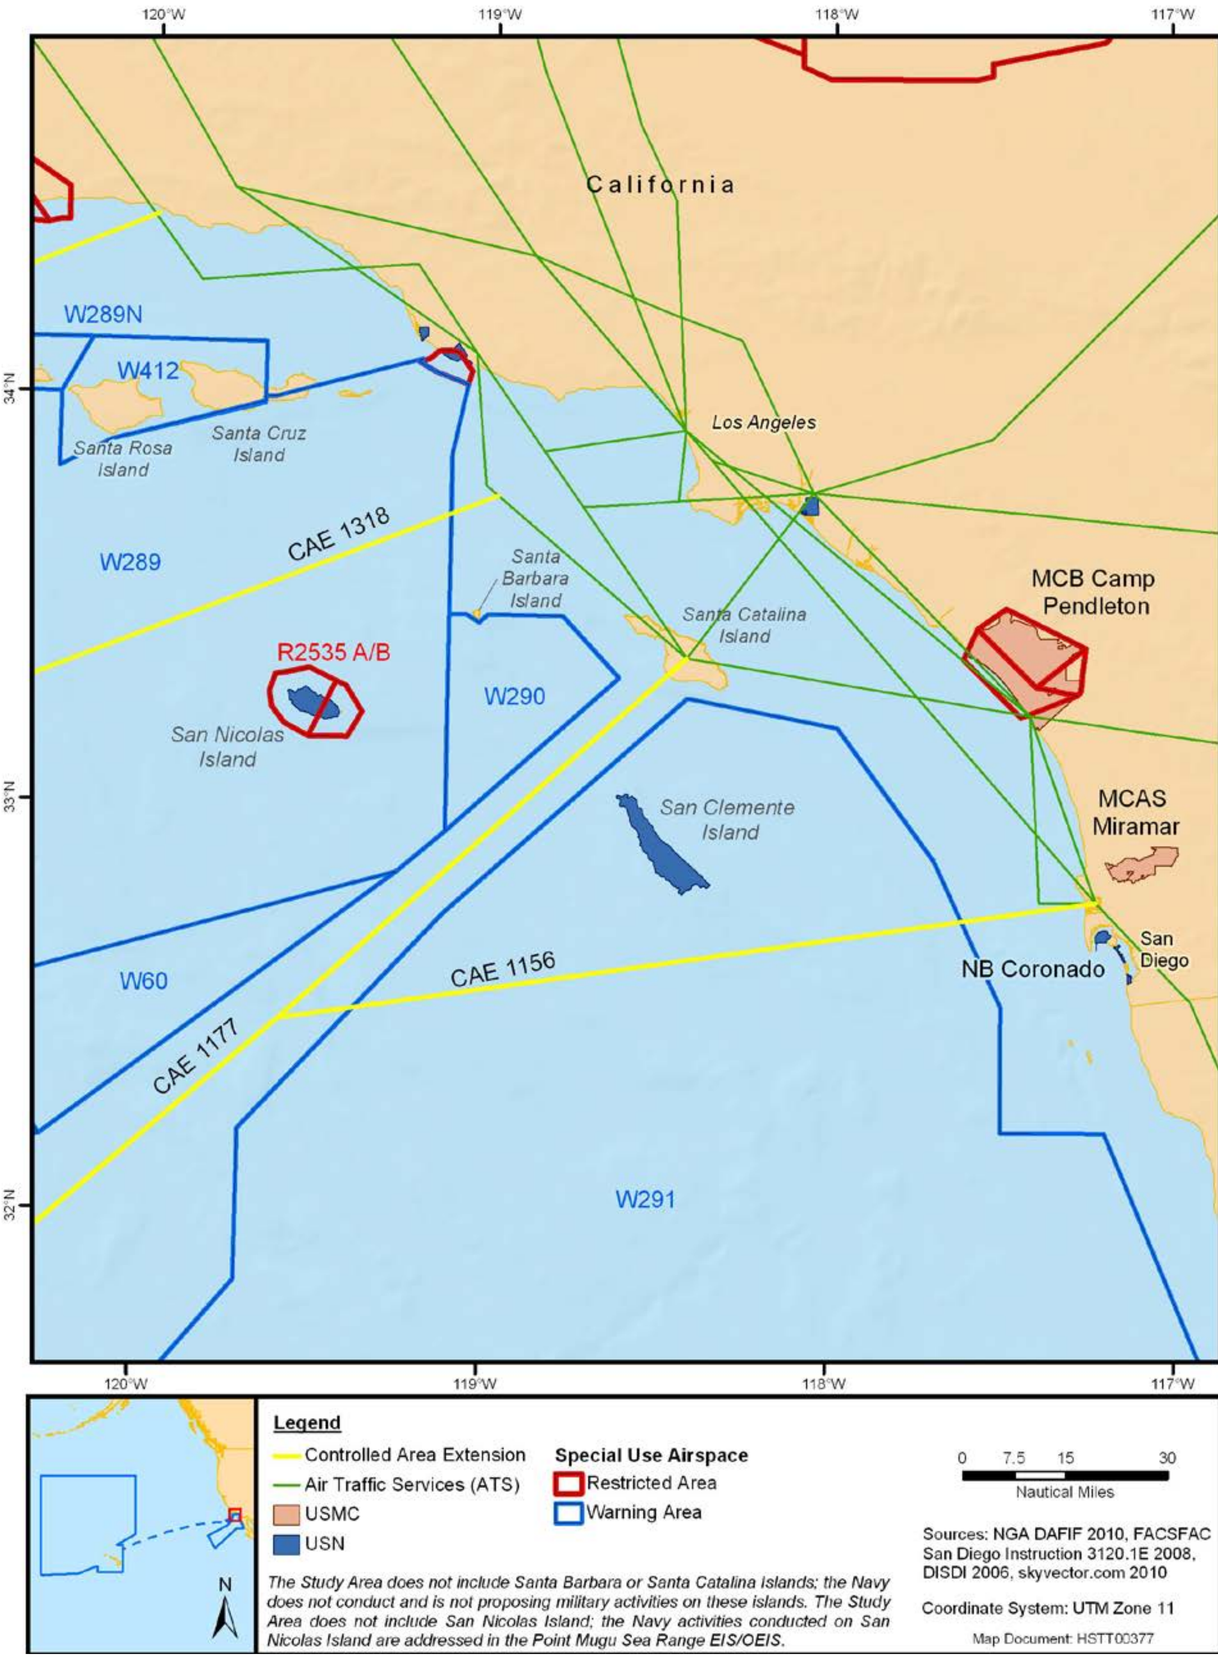

Figure 3.11-4: Southern California Offshore Airspace

In the Fleet Area Control and Surveillance Facility San Diego annual utilization report for fiscal year 2010, (1 October 2009 through 30 September 2010) there were 36,194 air operations in W-291, exclusive of air operations that utilize the Naval Auxiliary Landing Field at San Clemente Island (see below). During fiscal year 2010, W-291 airspace was released to the controlling agency, Los Angeles Air Route Traffic Control Center, for 619 hours of public use.

The Study Area off the coast of Southern California contains a restricted area over San Nicolas Island, R-2535 A/B, which is located within the Pt. Mugu Sea Range. Other types of special use airspace are found within the SOCAL Range Complex OPAREAs including missile ranges and tactical maneuvering areas.

The Naval Auxiliary Landing Field at San Clemente Island is located within W-291 airspace. To support the safe and efficient air traffic movement to/from Naval Auxiliary Landing Field San Clemente Island, Class D airspace has been established. Class D airspace is airspace tailored to the specific needs of the airport to ensure separation between aircraft. The airspace above San Clemente Island consists of a 5 nm radius circle centered on Fleet Area Control and Surveillance Facility San Clemente Island and includes the airspace from the surface to 2,700 ft. (823 m) mean sea level. All aircraft entering this airspace, or operating within it, must maintain radio contact with the Fleet Area Control and Surveillance Facility San Clemente Island control tower. An aircraft operation at Fleet Area Control and Surveillance Facility San Clemente Island is defined as an aircraft event that involves a takeoff, landing, low approach to the airfield, or touch-and-go landing. Thus, a single sortie from the airfield could generate several reportable “operations.” The baseline level of airfield operations at Fleet Area Control and Surveillance Facility is 25,120 operations.

Commercial and General Aviation

Aircraft operating under Visual Flight Rules can fly along the coast between San Diego and Orange County and out to Santa Catalina Island largely unconstrained, except by safety requirements and mandated traffic flow requirements. Aircraft operating under Instrument Flight Rules clearances, authorized by the Federal Aviation Administration, normally fly on the airway route structures. In Southern California, these routes include both high and low altitude routes between San Diego and Los Angeles and to Santa Catalina Island. There are two control area extensions from Southern California through nearby W-291 to facilitate easier access to air routes out to Hawaii and other transpacific locations. These routes allow general aviation and commercial air travel to coexist with military operations. Control area extension 1177 extends from Santa Catalina Island southwest between W-291 and the Pt. Mugu Sea Range. Control area extension 1156 extends west from San Diego through the northern portion of W-291. When W-291 is active, control area extension 1156 is normally closed. Control area extension 1177, the more important route through the coastal warning areas, is closed only when weapons hazard patterns extend into the area, and this closure is fully coordinated with the Federal Aviation Administration. When W-291 is active, aircraft on Instrument Flight Rules clearances are precluded from entering W-291 by the Federal Aviation Administration. However, since W-291 is located entirely over international waters, nonparticipating aircraft operating under Visual Flight Rules are not prohibited from entering the area. Examples of aircraft flights of this nature include light aircraft, fish spotters, and whale watchers, which occur under Visual Flight Rules throughout W-291 on a variable basis.

3.11.2.1.2.3 Silver Strand Training Complex

Military Air Transit

Military overflights generated for SSTC activities are based out of Naval Air Station North Island and Navy Outlying Landing Field Imperial Beach. The airspace over both facilities is classified as Class D airspace defined by a five nautical miles (nine kilometers) radius and extending to 2,800 ft. (853 m) over Naval Air Station North Island and to 1,500 ft. (457 m) over Navy Outlying Landing Field Imperial Beach. The two airspace extend over the SSTC and much of San Diego Bay and the surrounding area. These airspace are under Navy control, and air operations in support of SSTC training, including helicopter insertions and extractions, and parachute drops into designated drop zones must comply with the Air Operations Manual. Flight paths servicing nearby San Diego Airport are geographically separate from helicopter sorties bound for SSTC training areas and approach and departure patterns for fixed wing aircraft into Naval Air Station North Island.

Commercial and General Aviation

Commercial and general aviation air traffic is controlled by the San Diego Air Route Traffic Control Center. Flight paths servicing San Diego Airport located to the North of Naval Air Station North Island are geographically separate from helicopter sorties traveling to SSTC training areas and approach and departure patterns for fixed wing aircraft into Naval Air Station North Island.

3.11.2.1.2.4 Transit Corridor

There are numerous commercial air routes over the transit corridor between Southern California and Hawaii. Commercial aircraft typically fly above 30,000 ft. (9,144 m) in this area. These air routes are controlled by the Federal Aviation Administration.

3.11.2.2 Commercial and Recreational Fishing

Commercial fishing takes place throughout the Study Area from nearshore waters adjacent to the mainland and offshore islands, to the offshore banks and waters within the transit area. Many different types of fishing gear are used by commercial and recreational fishermen in the Study Area, such as gillnets, longline gear, troll gear, trawls, seines, traps or pots, harpoons, and hook and line.

3.11.2.2.1.1 Hawaii Range Complex

The data that individual fishermen report on commercial fishing reports are confidential, protected by Hawaii state law (189-3, Hawaii Revised Statutes), and can only be released to the public in summarized form. Table 3.11-3 shows that commercial landings for all fisheries from 2006 to 2010 in Hawaiian waters totaled 140,142,310 pounds (lb.) (63,567,480 kilograms [kg]). Based on the catch data presented in Table 3.11-3, the total value of reported commercial landings for all accounted species in Hawaii from 2006-2010 was $381,742,062 (National Marine Fisheries Service 2011).

Hawaii does not collect data on non-commercial marine fishing consistently, although occasional surveys have been conducted. In 2001, NMFS and the Hawaii Division of Aquatic Resources began collecting data on recreational fishing in Hawaii using the Marine Recreational Fishing Survey. Results of the survey are reported through the Marine Recreational Fishery Statistics Survey website, which has been reporting similar data for other coastal states since 1979. Hawaii does not have a mandatory recreational marine fishing license as many other coastal states do, and does not have mandatory reporting of recreational catches (National Marine Fisheries Service and Hawaii Division of Aquatic Resources 2010). Fishing destinations vary in response to changing fishing conditions, and many charter boats fish HRC waters on a routine basis. Sport fishermen pursue various fish species with hook and line; some divers also spearfish or take invertebrates by hand within the Hawaii nearshore waters.

Table 3.11-3: Total Commercial Landings (Pounds) and Total Value (Dollars) within the Hawaii Range Complex (2006–2010)

Major Species and Species Group		Total Catch 2006–2010 (pounds)
Fish	Tuna (yellowfin, skipjack, bluefin, albacore, etc.)	81,749,277
	Billfish (blue marlin, striped marlin, swordfish)	25,616,726
	Bottomfish (opakapaka, onaga, uku)	1,522,474
	Other Pelagic Fish (mahimahi and wahoo)	10,433,429
	All Other Fish	20,774,305
	Total Fish	**140,096,211**
Invertebrates	Spiny Lobster	45,046
	Saltwater Shrimp	1,053
Totals	**Total Invertebrates**	**46,099**
	Combined Total	**140,142,310**
	Value of Combined Total	**$381,742,062**

Source: National Marine Fisheries Service 2011, Pacific Islands Fisheries Science Center 2011, National Marine Fisheries Service 2012

Nearshore target fish species include akule, opelu, ta'ape, snapper, moana, weke, ulua, menpachi, o'ie, and bonefish. Longer charters target species typically found father offshore, such as mahi mahi, ono, ahi, swordfish, tuna, and marlin (blue, black, striped). Although, many of these species are caught relatively close to shore (within 3 nm), because water depth increases dramatically only a short distance from shore creating habitat attract to many pelagic species. In many areas, such as off Kona, fishing takes place year round. Tournaments held off of Oahu, Maui, and Kona occur from February through early November; however, most tournaments are scheduled between June and August (Sportfish Hawaii 2008).

The U.S. Fish and Wildlife Service conducts a telephone survey every 5 years to estimate the total numbers of fishermen and hunters in each state. On average, in 1995, about 260,000 people fished recreationally in Hawaii, of which about half were residents. The estimated 130,000 Hawaii residents who fish recreationally far outnumber the 3,500-plus licensed commercial fishermen in Hawaii (National Marine Fisheries Service and Hawaii Division of Aquatic Resources 2010).

State and federal agencies protect a variety of marine areas in Hawaii; fisheries have improved as a result. These areas include Marine Life Conservation Districts, Fisheries Management Areas, Fisheries Replenishment Areas, Bottomfish Restricted Fishing Areas, Hawaii Marine Laboratory Refuge-Coconut Island, Kahoolawe Island Reserve, Paiko Lagoon Wildlife Sanctuary, Ahihi-Kinau Natural Area Reserve, South Kona Opelu Fishing Area, the Hawaiian Islands Humpback Whale National Marine Sanctuary, and the Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve (Friedlander, Aeby et al. 2004).

3.11.2.2.1.2 Southern California Range Complex and Silver Strand Training Complex

The California Department of Fish and Game maintains commercial catch block data for waters in the northern part of W-291 (Section 3.9, Fish), and all statements referring to catch are for that part of the Study Area for which data are available. For 2011, the most commonly harvested commercial species in the SOCAL Range Complex were tuna, Pacific sardine, swordfish, spiny lobster, crab, sea urchin, squid, and other invertebrates (Table 3.11-4). During 2011, Southern California accounted for 39 percent of all California fish and invertebrate landings. In 2009, Southern California accounted for 10 percent of all fish and invertebrate landings, for California waters.

Table 3.11-4: Annual Commercial Landing of Fish and Invertebrates and Value within the Southern California Range Complex and Silver Strand Training Complex (2011)

Major Species and Species Group		Annual 2011 Catch (pounds)	Value ($)
Fish	Tuna (yellowfin, bluefin, and albacore)	455,630	$508,914
	Pacific Sardine	38,804,579	$3,378,952
	Swordfish	88,511	$468,963
	All Other Fish	5,724,708	$3,564,549
	Total Fish	**45,073,428**	**$7,921,378**
Invertebrates	Spiny Lobster	503,492	$8,636,545
	Crab	294,392	$344,609
	Other Crustaceans (shrimp and prawn)	176,892	$1,536,512
	Sea Urchins	1,683,458	$1,622,037
	Squid	112,390,626	$30,391,039
	Other Invertebrates	308,146	$1,121,981
Totals	**Total Invertebrates**	**115,357,006**	**$43,652,723**
	Combined Total	**160,430,434**	**$51,574,101**

Source: California Department of Fish and Game 2012

In the SOCAL Range Complex, groundfishes (e.g., flatfishes, skates, sharks, chimeras, rockfishes) are important recreational and commercial species. Highly migratory species (e.g., tuna, billfish, sharks, dolphinfish, and swordfish) and coastal pelagic species such as anchovies, mackerel, sardines, and squid also support extensive fisheries in the area. The harvest of coastal pelagic species is one of the largest fisheries in the SOCAL Range Complex in terms of landed biomass and volume, as well as revenue (California Department of Fish and Game 2012). In 2010, California ranked fourth in the nation for commercial fisheries landings (measured in pounds) (National Marine Fisheries Service 2011). For recreational fisheries, California ranked 14th in the nation in landings of finfish (bony and cartilaginous fish that use fins for locomotion).

Pelagic, flatfish, demersal fish, and other fish associated with the ocean bottom account for about 50 percent of the average annual catch of fish within the Study Area OPAREAs (Table 3.11-4). Pelagic species encompass the majority of the commercial portion of the average annual pound of catch. The average annual catch of pelagic, flatfish, demersal, and all other fish amounts to 36,951,285 lb. (16,760,818 kg) and $8,152,845. The Pacific sardine fishery is one of the most valuable fisheries among the coastal pelagic finfish in California, with the majority of the fish landed in SOCAL and Ensenada (California Department of Fish and Game 2005).

The average annual catch of crustaceans is comprised of approximately half spiny lobster (377,607 lb. [171,279.6 kg] per year) and half crab and shrimp (average 340,845 lb. [154,604.7 kg] per year). The catch of crustaceans in the SOCAL Range Complex OPAREAs was worth $10,517,666 in 2011. In comparison, total commercial landings of market squid in 2011 were worth $30,391,039 and urchins were worth $1,622,037. Red sea urchins are the most commonly harvested invertebrate species within the SOCAL OPAREA. Other invertebrates (e.g., snails, sea cucumbers, sea stars, whelks) were worth $1,121,981 in 2009 (Table 3.11-4) (California Department of Fish and Game 2009).

Fishing activities occur at varying degrees of intensity and duration throughout the year within the SOCAL Range Complex. Fishermen often fish for more than one species and land their catch in various ports depending on the season in order to maximize their economic return. Key commercial fishing ports in Southern California include Los Angeles and San Diego, with numerous smaller ports and harbors located between these major port complexes. A wide range of commercial fishing methods are used in this region that are fishery-specific such as drift gillnets, longline gear, troll gear, trawls, seining, and traps or pots (Naval Undersea Warfare Center 2009).

The SOCAL Range Complex marine environments are popular locations for recreational fishing. Charter and privately operated boats enter the SOCAL Range Complex and San Clemente Island waters for salt-water sport fishing, recreational diving, and other boating activities. Commercial passenger fishing vessels, more commonly target fish further offshore compared to private boats, due to the high cost of private large boat ownership, the capability of the larger vessels to go farther, and the greater experience of professional captains. Recreational fishing and diving are centered primarily around San Clemente Island and secondarily in the shallower waters over Tanner and Cortes banks. These banks are inherently more hazardous due to their distance from shore and open-ocean diving conditions. Therefore, the near shore waters off San Clemente Island are a more popular destination than the more remote banks. Commercial passenger fishing vessels usually perform full-day trips; however, some charter boats occasionally may spend nights at sea (Naval Undersea Warfare Center 2009). More than 200 commercial passenger fishing vessels operate between Point Conception and the U.S./Mexican border (California Marine Life Protection Act Initiative 2009). These vessels operate from ports including San Diego, Oceanside, Dana Point, Newport Beach, Long Beach, Los Angeles, and from other locations all along the coast.

Major sport fish species include albacore and yellowfin tuna, shallow water rockfish (*Sebastes* spp.), yellowtail rockfish (*Sebastes flavidus*), kelp bass (*Paralabrax clathratus*), yellowtail (*Seriola lalandi*), California sheephead (*Semicossyphus pulcher*), ocean whitefish (*Caulolatilus princeps*), dolphin (*Coryphaena hippurus*), marlin (*Tetrapturus audax*), barracuda (*Sphyraena argentea*), swordfish (*Xiphias gladius*) and lingcod (*Opiodon elongatus*) (Fletcher 1999, Helgren 1999). Sport fishermen fish for bluefin tuna, yellowfin tuna, yellowtail rockfish, and rock cod (*Sebastes* spp.) in the vicinity of the offshore islands and on Tanner and Cortes banks (Fletcher 1999, Helgren 1999). Halibut (*Paralichthys californicus*) and white seabass (*Atractoscion nobilis*) are fished in sand channels and kelp beds around San Clemente Island.

Fishing destinations are generally fluid, in response to changing fishing conditions, but a number of charter boats fish waters of the SOCAL Range Complex on a routine basis. Sport fishermen pursue various fish species with almost exclusively rod and reel gear (hook and line); some divers also spearfish or take invertebrates (mainly lobster) by hand within the SOCAL Range Complex. The recreational fishing season is dependent on oceanographic conditions and generally occurs in late spring through the fall (Pacific Fishery Management Council 2007).

3.11.2.2.1.3 Transit Corridor

There are no data on commercial or recreational fishing within the transit corridor area because of the distance from land.

3.11.2.3 Subsistence Use

The U.S. Environmental Protection Agency considers subsistence fishers to be people who rely on noncommercial fish as a major source of protein. Subsistence fishers tend to consume noncommercial fish and/or shellfish at higher rates than other fishing populations, and for a greater percentage of the year, because of cultural and/or economic factors. There are very few studies in the United States that have focused specifically on subsistence fishers. The United States has issued no regulations to determine what or who would be considered a subsistence fisher. In addition, in the United States, there are no particular criteria or thresholds (such as income level or frequency of fishing) that definitively describe subsistence fishers. The U.S. Environmental Protection Agency issued guidance to state that at least 10 percent of licensed fishers in any area will be subsistence fishers (U.S. Environmental Protection Agency 2011). Because the 10 percent estimate is not based on actual subsistence fishing data, the number may overestimate or underestimate the number.
The U.S. Environmental Protection Agency (2011) suggests that Native Americans, lower income urban populations, and Asian-Americans are often subsistence fishers (Gassel et al. 1997). Therefore, an increased number of individuals below the poverty rate or an increased percentage of population classified as Native American or Asian may indicate an area with a higher amount of subsistence fishers.

Low-income populations would have limited means and opportunity to travel offshore to federal waters (i.e., beyond 3 nm from shore) for fishing. Nearshore waters surrounding the city of Coronado and the Silver Strand Training Complex provide fishing opportunities in San Diego Bay and along the Pacific coast of the peninsula. A variety of fish are caught mainly by hook and line from beaches, piers, and small boats (USA Today 2012). Thus, it is assumed that the majority of subsistence fishing would occur in waters close to the coastline. Inshore fishing usually occurs within sight of the shoreline in bays, flats, and marshes or under piers, bridges, or near the jetties where water is generally less than 100 ft. (30 m) deep. Boats used by subsistence fishers are generally smaller and more affordable.

3.11.2.3.1.1 Hawaii Range Complex

There have been no comprehensive surveys of subsistence-fishing activities in Hawaii and economic surveys have been episodic. Therefore, there is limited information from which to fully assess the subsistence fishing contribution to island economies, but the value of fishing for subsistence by contemporary Native Hawaiians is known to be an important component of some communities, particularly rural communities (Pooley 1993). However, it is believed that combined offshore recreational and subsistence catch is likely equal to or greater than the offshore commercial fisheries catch, with more species taken using a wider range of fishing gear (Friedlander et al. 2004).

3.11.2.3.1.2 Southern California Range Complex and Silver Strand Training Complex

In Southern California, people fish off piers and in local bays, harbors, and waterways for regular subsistence rather than for recreation. In Los Angeles County, where a high cost of living and low incomes have produced food insecurity among certain populations, subsistence fishing is more and more common. Although the economic value of subsistence fisheries may often be low, they may be critical for the livelihoods of many communities.

3.11.2.3.1.3 Transit Corridor

It is assumed that there is limited to no subsistence fishing activity within the Transit Corridor because of the distance from land to the Transit Corridor and because the majority of subsistence use occurs nearshore.

3.11.2.4 Tourism

Coastal tourism and recreation can be defined as the full range of tourism, leisure, and recreationally oriented activities that take place in the coastal zone and the offshore coastal waters. These activities include coastal tourism development (hotels, resorts, restaurants, food industry, vacation homes, second homes, etc.), and the infrastructure supporting coastal development (retail businesses, marinas, fishing tackle stores, dive shops, fishing piers, recreational boating harbors, beaches, recreational fishing facilities, etc.). Also included is ecotourism (e.g., whale watching) and recreational activities such as recreational boating, cruises, swimming, recreational fishing, surfing, snorkeling, and diving (National Oceanic Atmospheric Administration 1998).

3.11.2.4.1.1 Hawaii Range Complex

Navy vessels present on the waters of the HRC represent a small fraction of the overall commercial and recreational boat traffic and, correspondingly, account for only a small fraction of the potentially restrictive circumstances present in the open-ocean area around Hawaii.

The waters surrounding the main Hawaiian Islands are used for a variety of recreational, commercial, scientific, transportation, cultural, and institutional purposes. The intensity of use generally declines with increasing distance from shore, although specific resources in the open-ocean area may result in a concentration of use (e.g., seamounts are preferred fishing and diving locations). Offshore areas that are shielded by landmasses from the full force of wind and waves, such as the channels between Maui and adjacent islands, are preferred areas for recreational boating and diving. In addition, there are numerous beaches and parks throughout the islands (Figure 3.11-5 through Figure 3.11-7).

Recreational fishing in Hawaii is very important economically with anglers spending over $755 million on trip and durable expenditures in 2006. This level of expenditures generated $253.6 million in income, supported 7,000 jobs, and generated $105.0 million in government revenue in 2006 (Gentner 2009). Tourism, and by extension recreational fishing by tourists, varies seasonally. Additionally, the country or region of origin (e.g., U.S. west coast, U.S. east coast, Japan, etc.) of the tourists varies seasonally, influencing the types of activities in which tourists participate (Hawai'i Tourism Authority 2010). Surfing can also be found in the nearshore areas of all the Hawaiian Islands depending on the seasonal swell direction. Swells typically approach from the north in the winter months and from the south in the summer.

Humpback whale watching around the Hawaiian Islands peaks from late February through early April (Mobley, Spitz et al. 2001; Carretta, Forney et al. 2005). Direct revenues attributed to whale watching were $11–$16 million in Hawaii during the 1999 whale season (National Oceanic and Atmospheric Administration 2000; Pendleton 2006). Marine mammal sightings are expected to occur from the coast to 50 nm offshore, including the areas off Pacific Missile Range Facility, close to shore at Pyramid Rock Beach on Oahu, or areas within the 100-fathom contours such as the Molokai–Lanai–Maui–Kahoolawe channels and Penguin Bank. However, tourist day trips typically stay closer to shore or from beach vantage points, these activities can occur throughout the HRC. Additional information on humpback whales, including description, habitat, abundance, and distribution, is provided in Section 3.4 (Marine Mammals).

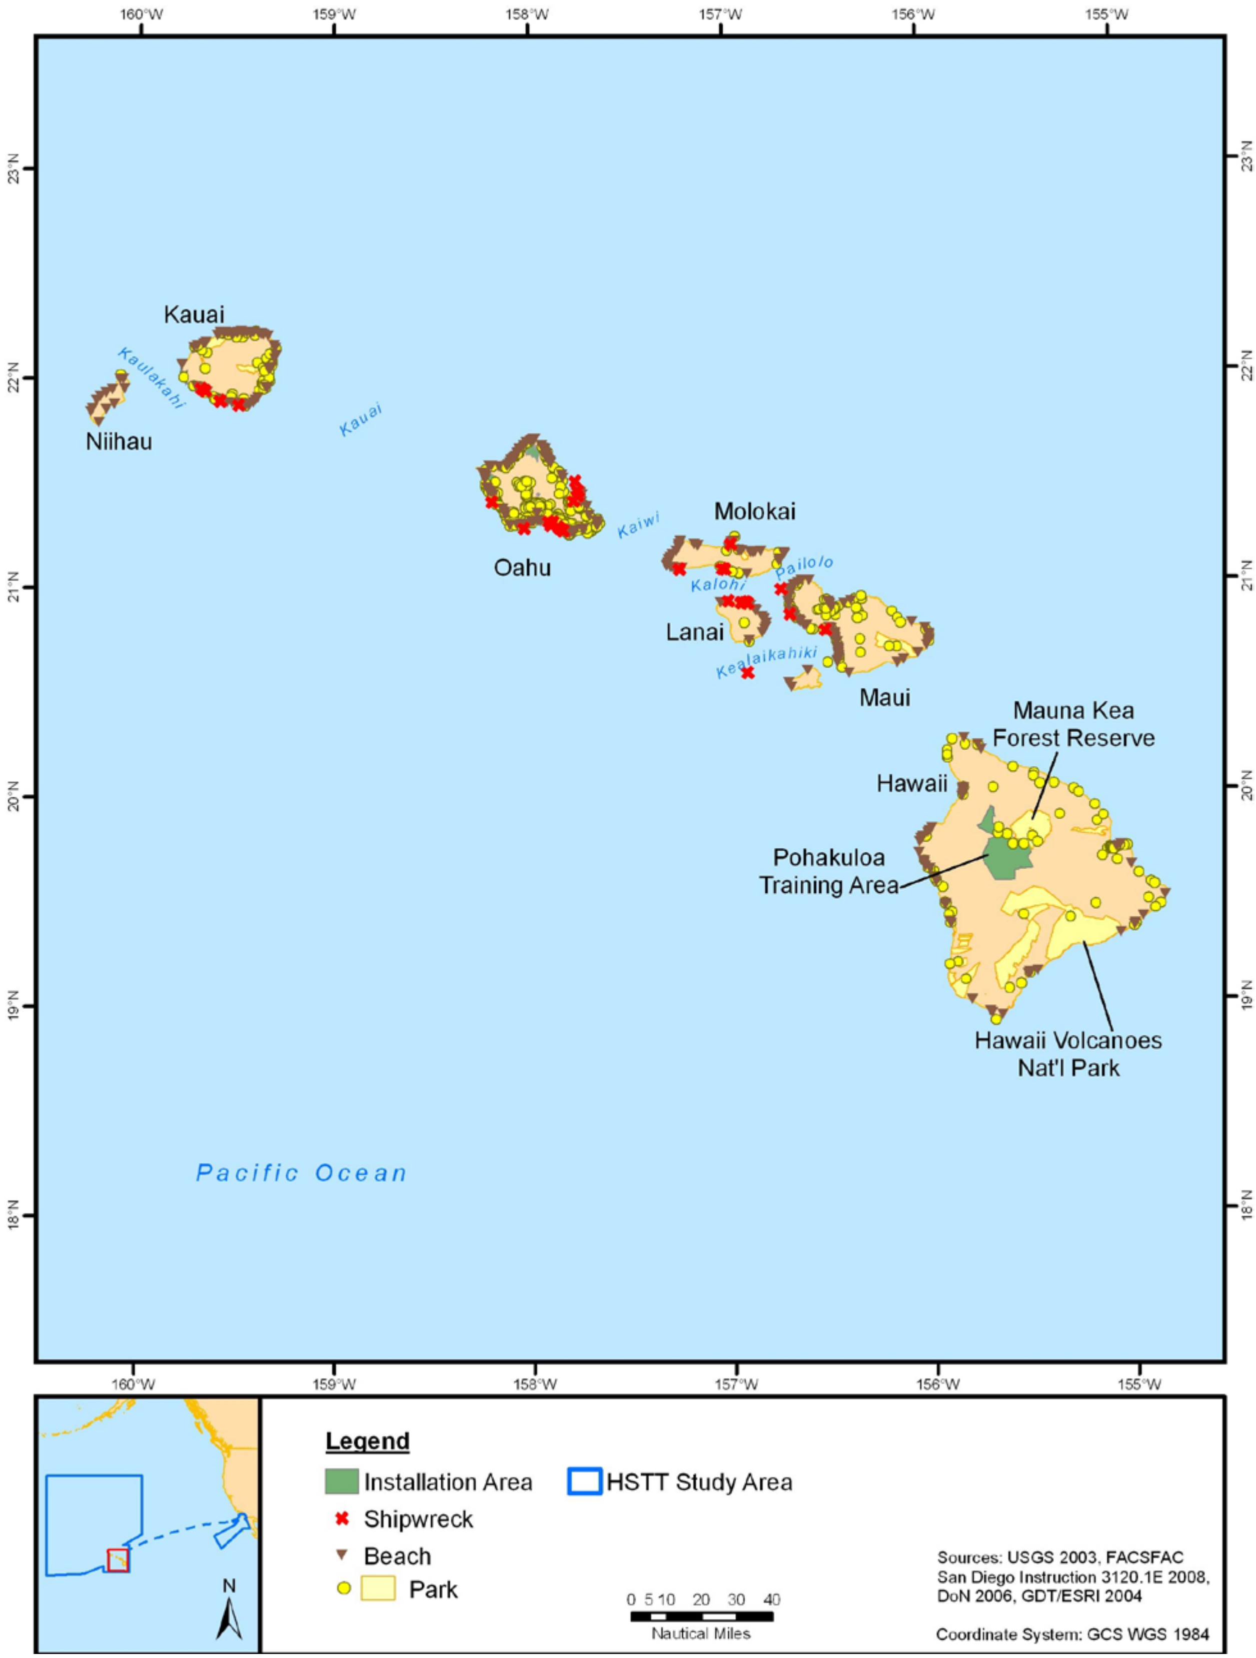

Figure 3.11-5: Hawaiian Island Recreational Areas

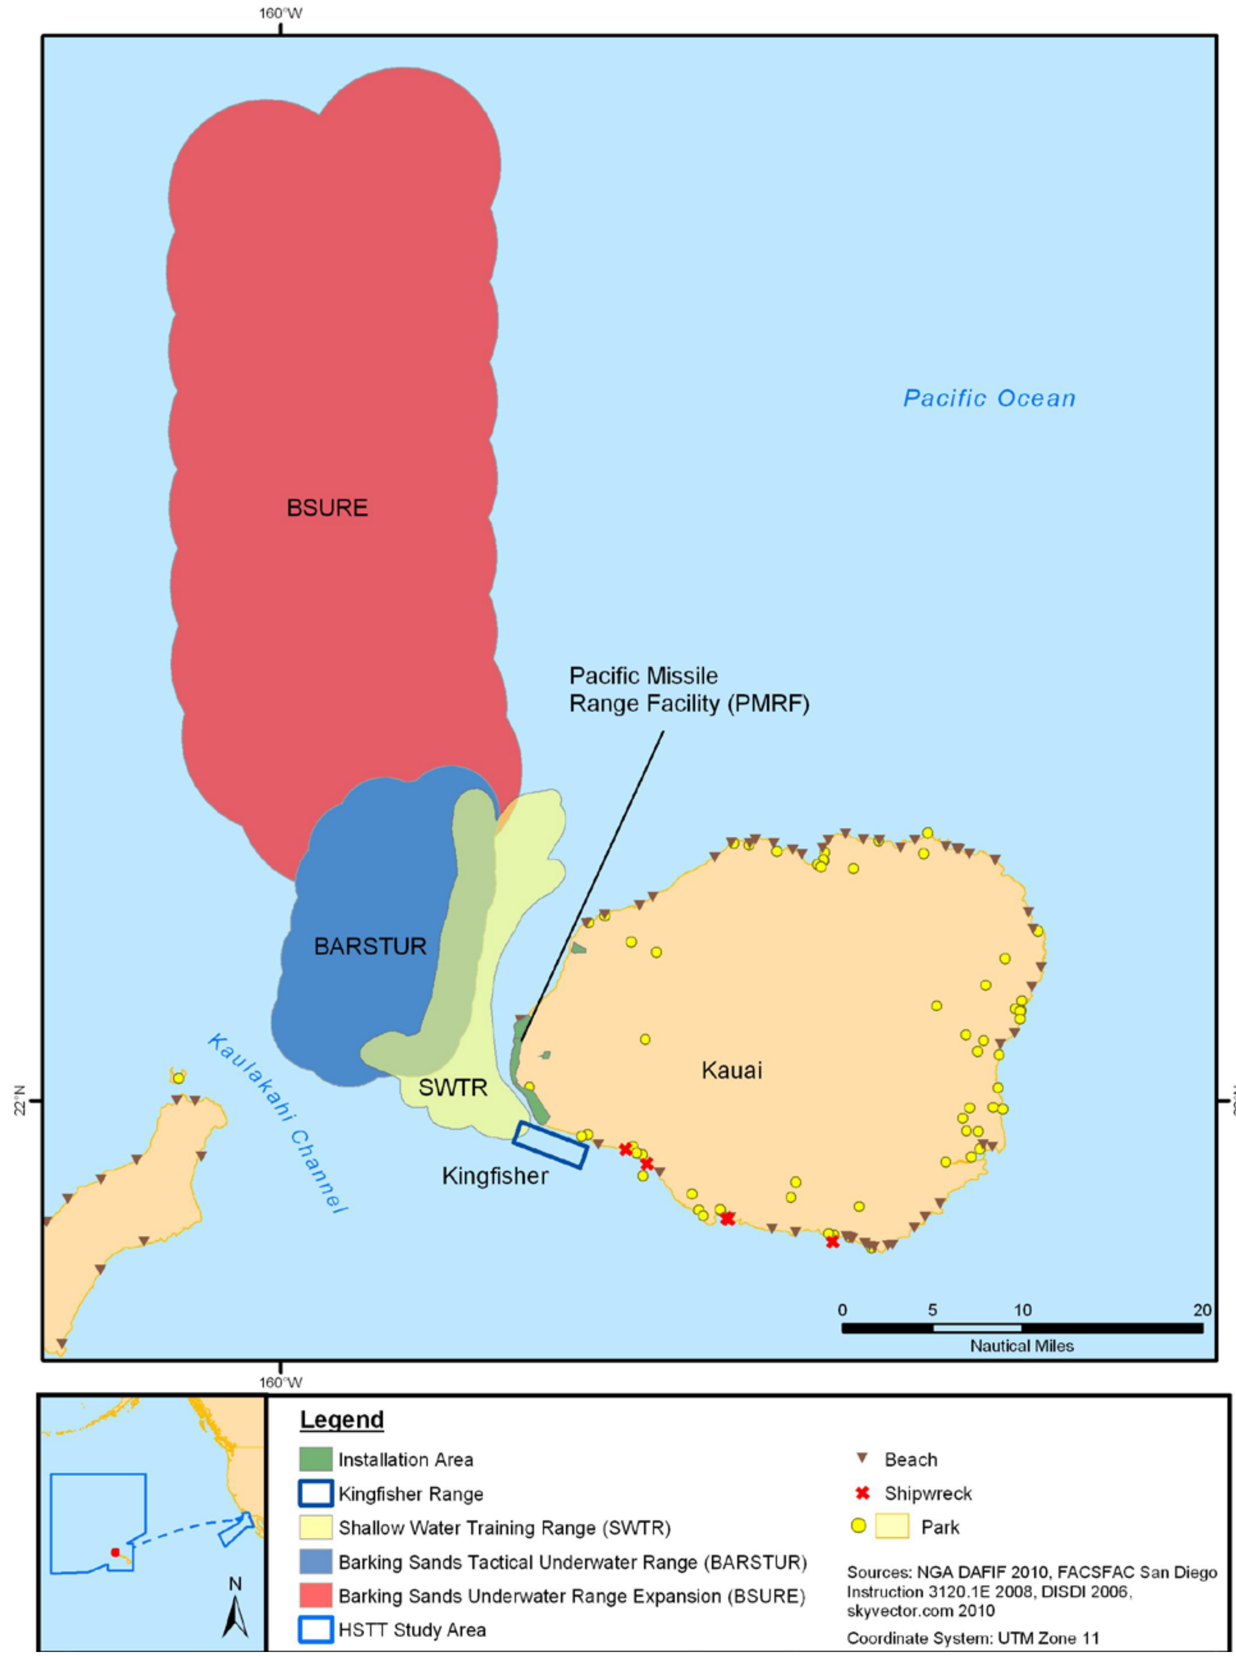

Figure 3.11-6: Kauai–Niihau Island Recreation Areas

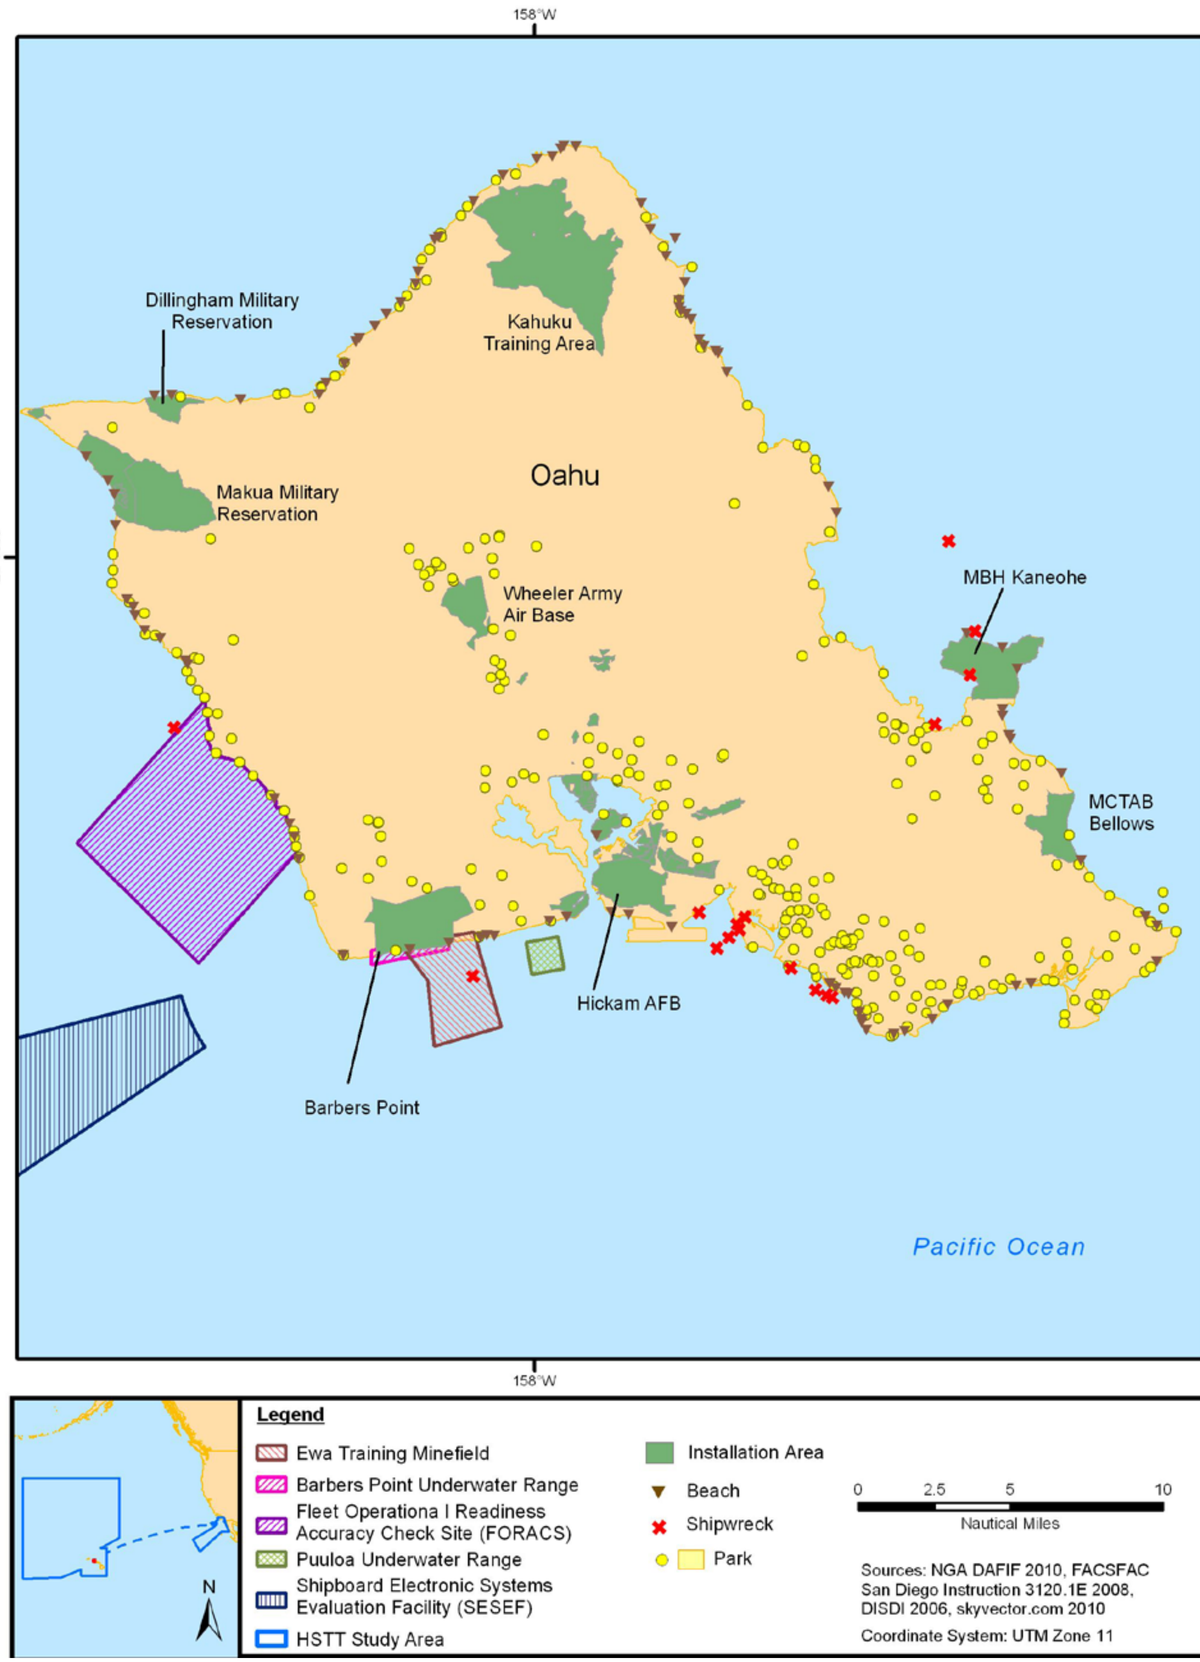

Figure 3.11-7: Oahu Island Recreation Areas

3.11.2.4.1.2 Southern California Range Complex

The SOCAL Range Complex marine environments are popular locations for recreational activities including sightseeing, whale watching, sport fishing, boating, diving, and surfing. Most recreation and tourism activities occur close to the mainland coast of Southern California or between the mainland and the Channel Islands. The shallower waters near the Channel Islands and some offshore banks, such as Tanner and Cortes Banks, are especially popular areas for self-contained underwater breathing apparatus (SCUBA) diving, fishing, and occasionally surfing. There is very little recreational activity in the southwestern portion of the SOCAL Range Complex due to its distance from land and its water depth.

Santa Catalina and Santa Barbara Islands are within the Study Area and visited by tourists. While Navy activities are conducted offshore of these islands, there is little interaction between the public and Navy activities.

Whale watching takes place primarily from December through March, for the annual gray whale southward migration and the northward migration. Though tourist day trips typically stay closer to the mainland, these activities can occur throughout the SOCAL Range Complex.

During the fall-winter period, primarily charter and privately operated boats enter the SOCAL Range Complex OPAREAs and San Clemente Island waters for salt-water sport fishing (Figure 3.11-8), recreational diving, surfing, and other boating activities. Salt-water sport fishing and recreational diving take place primarily around San Clemente Island, and to a lesser extent in the shallower waters over the Tanner and Cortes Banks. Some limited, seasonal surfing can occur near the Tanner and Cortes Banks. Due to distance from shore, Tanner and Cortes Banks are inherently more hazardous due to their open ocean diving conditions. Therefore, the nearshore waters off San Clemente Island are a more popular destination than the more remote banks. This makes them suitable primarily for skilled divers, a more limited market for charter operators.

San Clemente Island's relatively warm waters, good underwater visibility, and largely pristine diving conditions make it a popular destination. Charter dive trips to specific sites are often published and booked as many as six months in advance. Diving occurs year-round, though the number of trips to San Clemente Island and the banks appear to peak during lobster season (October–March).

Fishing destinations are generally more fluid, in response to changing fishing conditions, but a number of charter boats operate in SOCAL Range Complex waters on a routine basis. Sport fishermen pursue various fish species with hook and line; some divers also spearfish or take invertebrates (mainly lobster) by hand within the SOCAL Range Complex OPAREAs. Surfing can also be found in the offshore OPAREAs and nearshore San Clemente Island areas.

In the winter months, when large northern Pacific ocean swell is generated, some charter and private vessels travel out to Cortes Bank to surf the waves created by the rapidly rising seamounts. In addition, surfers can venture year-round to the breaks off of San Clemente Island to surf the island's south points (China and Pyramid Points) and up the west shore of the island depending on the swell direction of the season (Figure 3.11-8). Although both areas within the SOCAL Range Complex OPAREAs are accessed throughout the year, due to the difficulty in access and a rare culmination of conditions necessary for surfing these spots, these areas are rarely accessed.

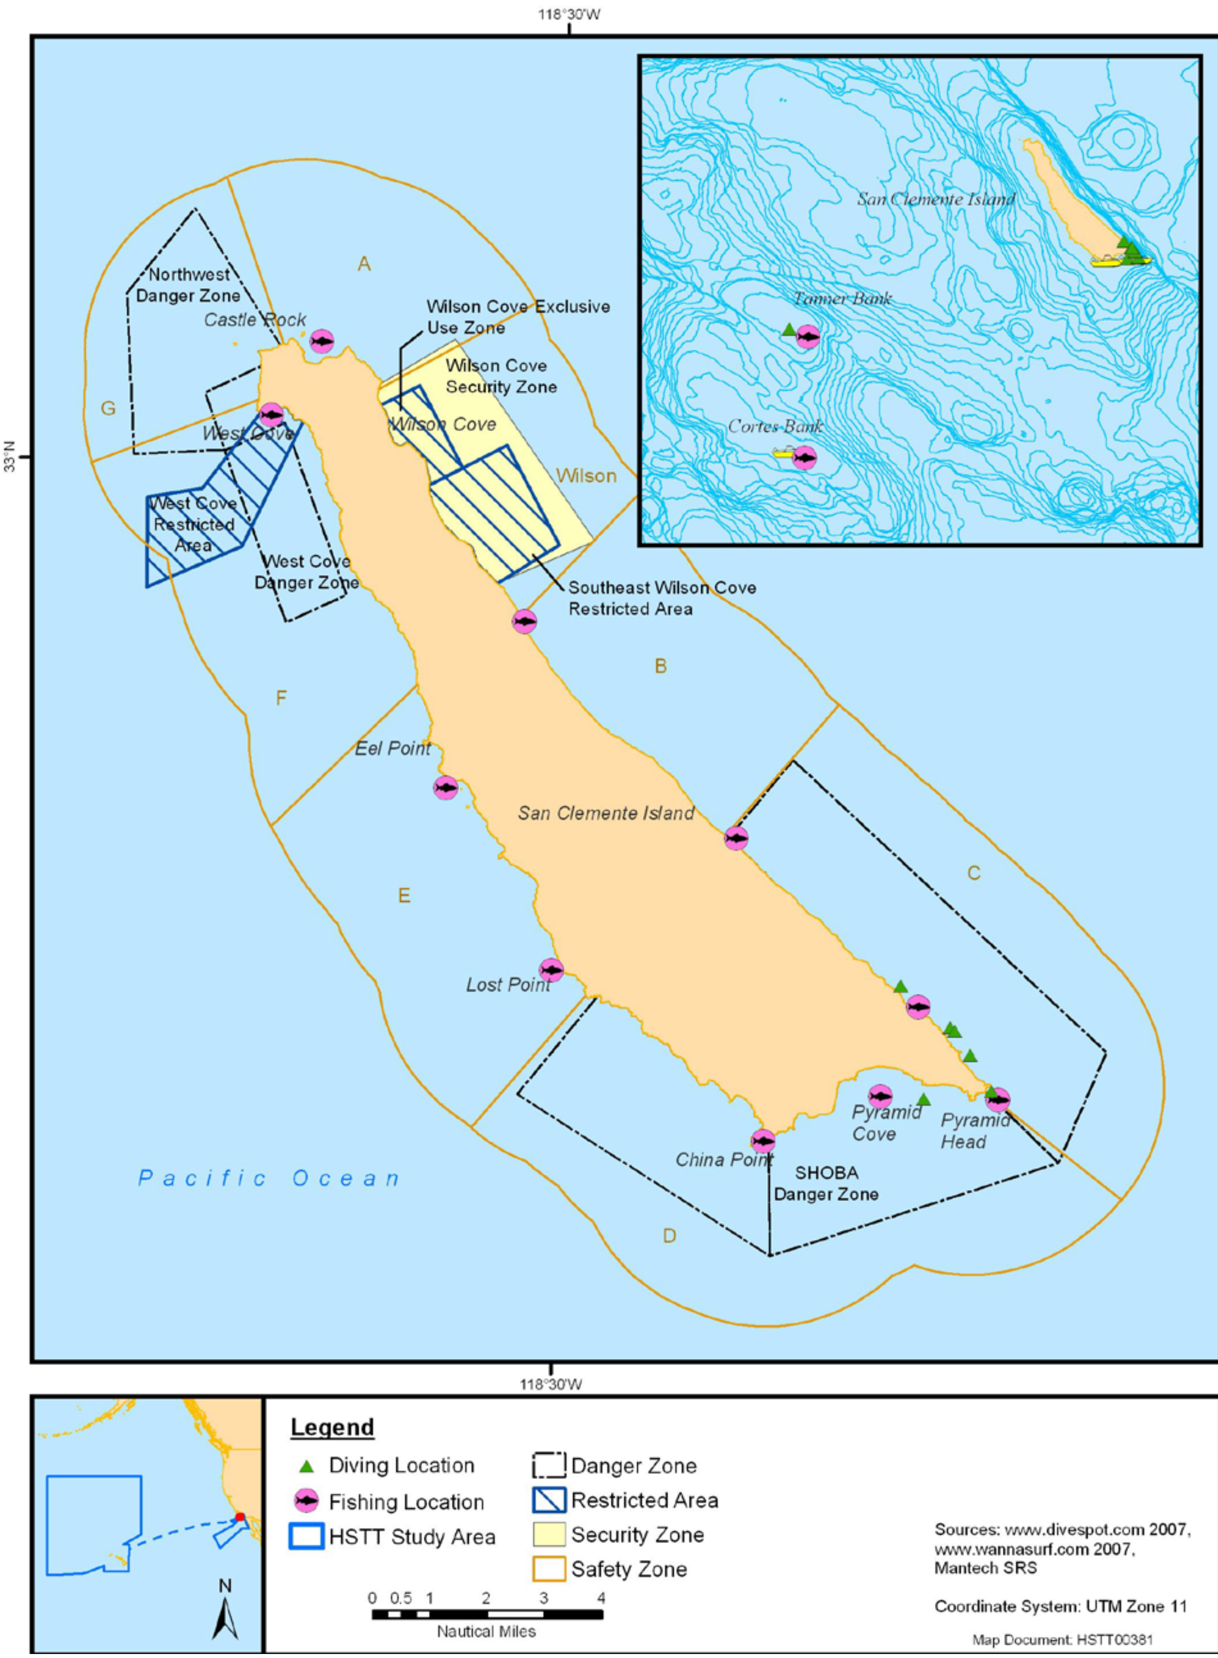

Figure 3.11-8: Recreation Areas around San Clemente Island

Other limited surf spots and dive sites occur throughout the nearshore areas, for diving, at various shipwrecks and reefs and, for surfing, off of Point Loma and around Santa Catalina Island. In addition, “big wave” surfers are known to travel farther offshore to Tanner and Cortez banks when ocean conditions produce large swells that form into giant waves in excess of 60 ft. (18 m) in height when they reach the shallow banks (Casey 2010).

3.11.2.4.1.3 Silver Strand Training Complex

The San Diego Bay is a natural harbor adjacent to downtown San Diego. The San Diego Bay is frequently used by recreational boaters from surrounding marinas and mooring areas. The City of San Diego, City of Coronado, City of Imperial Beach, City of Chula Vista, and National City all surround, and have an interest in activities within San Diego Bay. The Sweetwater Canal, located in south San Diego Bay is the site of the National City Marina and Pepper Park. Further south in San Diego Bay is the Chula Vista Marina. Both marinas are recreational boating access points that contribute to the amount of vessels within San Diego Bay (Figure 3.11-9).

Fiddler’s Cove Marina, operated by the Navy, is located to the south of SSTC-North on the bayside along Silver Strand State Highway/SR-75, just north of Loews Coronado Resort. The marina has approximately 150 moorings and approximately 130 dock slips; the recreational vehicle park offers year-round camping. Both facilities are open to active duty, retirees, DoD civilians, and sponsored civilian guests.

Glorietta Bay is located to the north of SSTC-North on the bayside and is used by the public for recreation and pleasure boating (Figure 3.11-9). Navy piers at the Naval Amphibious Base Coronado extend into Glorietta Bay from its southern shore and support small boat training activities at the SSTC.

In San Diego Bay, there is a designated restricted area from the northern and eastern boundary of Naval Amphibious Base Coronado (33 C.F.R. 334.860) (Figure 3.11-9); activities such as swimming, fishing, waterskiing, and mooring are not allowed within this area. All vessels entering the restricted area must proceed across the area by the most direct route and without unnecessary delay. For vessels under sail, necessary tacking constitutes a direct route. A portion of the restricted area extending 120 ft. from pierheads and from the low water mark on shore where piers do not exist is closed to all persons and vessels except those owned by, under hire to, or performing work for, the Naval Amphibious Base.

Recreational activities offshore of SSTC and the Naval Amphibious Base Coronado are permitted outside of the restricted areas and include sportfishing, bait fishing for the sport fishermen, lobster fishing, and sailboat regattas. Organized activities (such as sail races and regattas) within the restricted area may be allowed providing that a request has been made to the Commanding Officer, Naval Amphibious Base, Coronado. Silver Strand State Beach offers ocean side camping, kite surfing, and surfing. The City of Coronado beach, which lies between Naval Air Station North Island and Naval Amphibious Base Coronado, is a major public beach. The YMCA Surf Camp at SSTC-S is a major recreational facility for military and civilian families with surfing and beach activities.

3.11.2.4.1.4 Transit Corridor

It is assumed that there is limited to no tourism activity within the transit corridor because of the distance from land to the transit corridor and because the majority of tourism activity occurs nearshore.

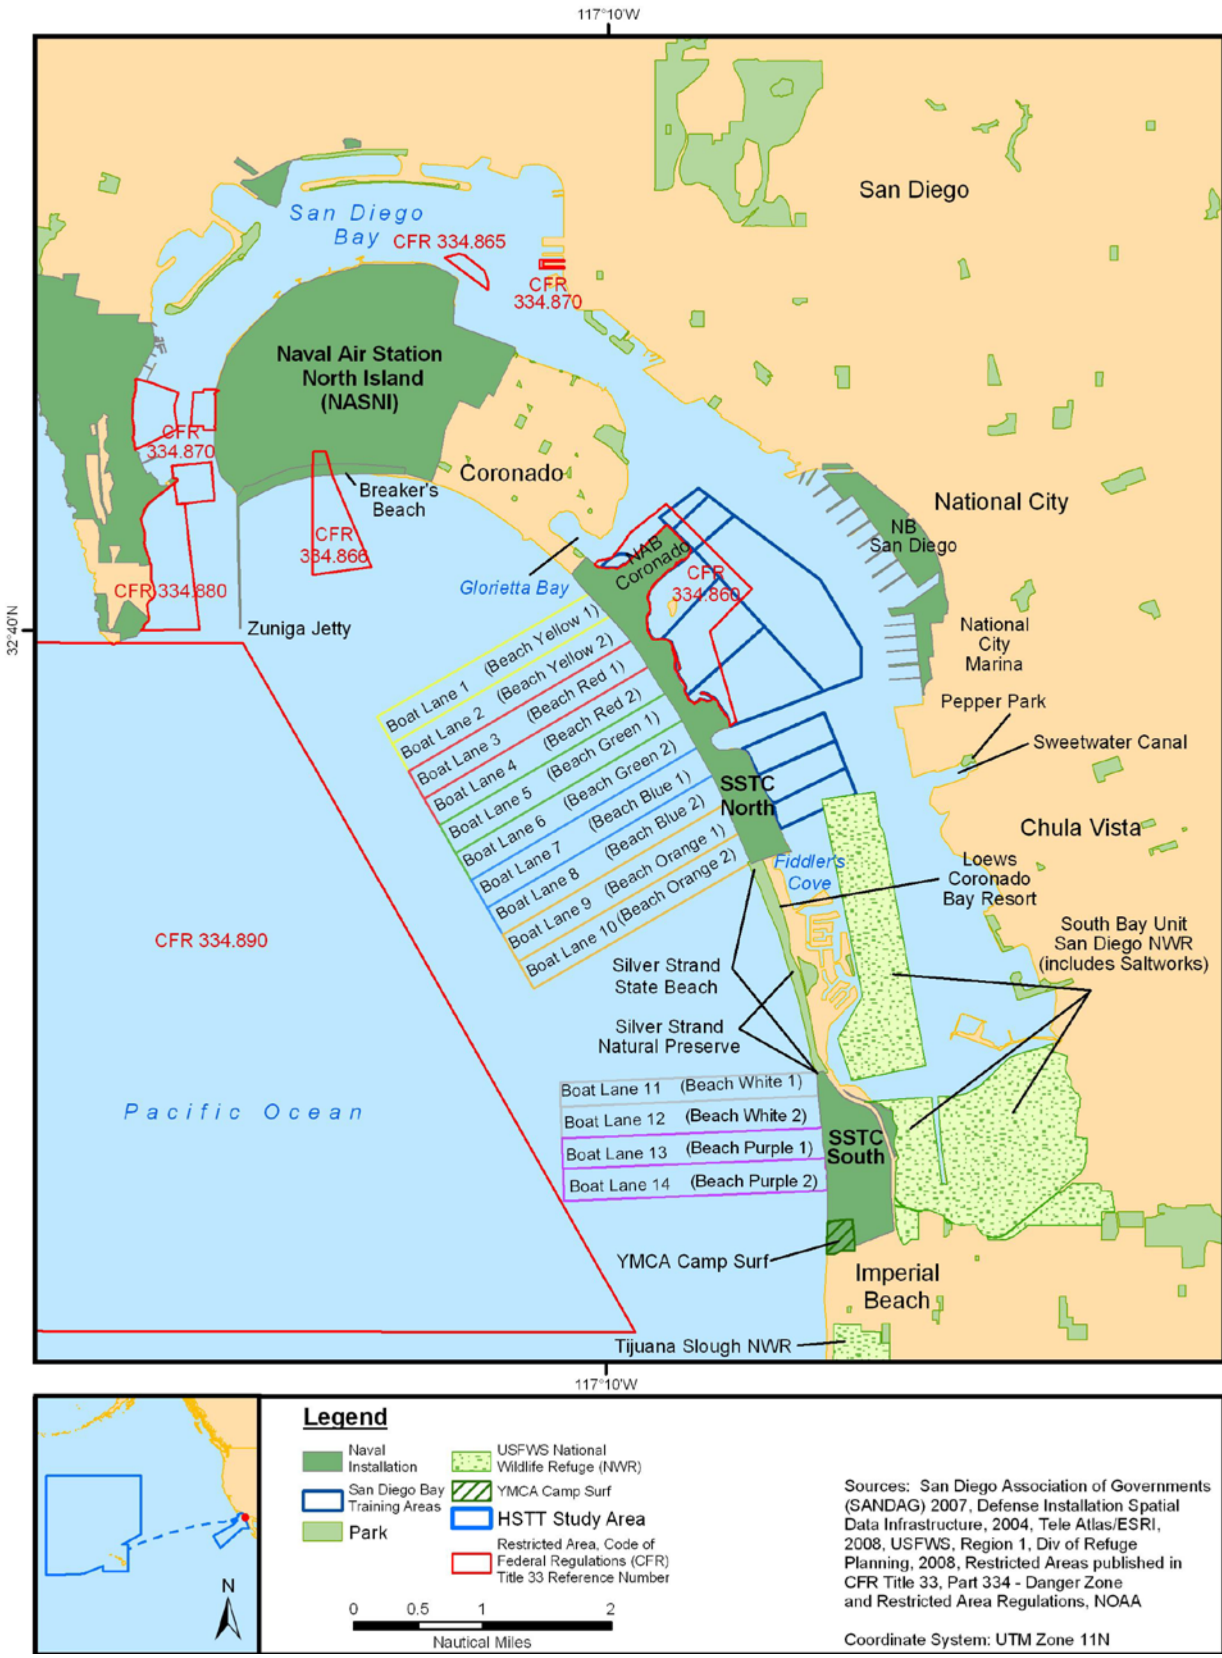

Figure 3.11-9: Recreational Map of the Silver Strand Training Complex

3.11.3 Environmental Consequences

This section evaluates how and to what degree the activities described in Chapter 2 (Description of Proposed Action and Alternatives) could impact socioeconomic resources of the Study Area. Tables 2.8-1 through 2.8-5 present the baseline and proposed training and testing activity locations for each alternative (including number of events and ordnance expended). Each socioeconomic resource stressor is introduced, analyzed by alternative, analyzed for training and testing activities, and then a NEPA determination is made by stressor. Table H-3 in Appendix H shows the warfare areas and associated stressors that were considered for analysis of socioeconomic resources. The stressors vary in intensity, frequency, duration, and location within the Study Area. The primary stressors applicable to socioeconomic resources in the Study Area and that are analyzed include the following:

- Accessibility
- Physical disturbance and strikes
- Airborne acoustics
- Secondary

Secondary stressors resulting in indirect impacts to socioeconomic resources are discussed in Section 3.11.4. Analysis of economic impacts evaluates the impacts of the alternatives on the economy of the region of influence while analysis of social impacts considers the change to human populations and how the action alters the way individuals live, work, play, relate to one another, and function as members of society. Because proposed HSTT activities are predominantly offshore, socioeconomic impacts would be associated with economic activity, employment, income, and social conditions (i.e., livelihoods) of industries or operations that use the ocean resources within the Study Area. Although there are no permanent population centers in the region of influence and the typical socioeconomic considerations such as population, housing, and employment are not applicable, this section will analyze the potential for fiscal impacts on marine-based activities and coastal communities. When considering impacts on recreational activities such as fishing, boating, and tourism, both the economic impact associated with revenue from recreational tourism and public enjoyment of recreational activities are considered.

The proposed HSTT training and testing activities were evaluated to identify specific components that could act as stressors by having direct or indirect effects on sources of commercial transportation and shipping, commercial and recreational fishing, subsistence use, and tourism. For each stressor, a discussion of impacts on these sources is included for each alternative.

The evaluation indicated that the relative potential for socioeconomic impacts would be similar across various areas and marine ecosystems in the Study Area. Therefore, the analysis of environmental consequences was not broken down by large marine ecosystem. Based on an initial screening of potential impacts of sonar maintenance and testing, pierside locations have been eliminated from detailed consideration in the analysis of impacts on energy, mineral extraction, and transportation and shipping. Elimination of these resources was based on the extremely limited potential for active sonar to damage infrastructure or interfere with transportation operations.

3.11.3.1 Accessibility

Navy training and testing activities have the potential to temporarily limit access to areas of the ocean for a variety of human activities associated with commercial transportation and shipping, commercial recreation and fishing, subsistence use, and tourism in the Study Area.

When training or testing activities are scheduled that require specific areas to be free of nonparticipating vessels due to public safety concerns, the Navy requests that the U.S. Coast Guard issue Notices to Mariners to warn the public of upcoming Navy activities. Training and testing activities occur in established restricted or danger areas as published on navigation charts.

The changes in accessibility to human activities in the ocean would be an impact if it directly contributed to loss of income, revenue, or employment. Disturbance to human activities that result in impacts on payrolls, revenue, or employment is quantified by the amount of time the activity may be halted or rerouted or the ability to move to another location.

Accessibility, or restrictions to the availability of ocean space, would be a temporary condition. While mariners have a responsibility to be aware of conditions on the ocean, it is not expected that direct conflicts in accessibility would occur. The locations of restricted areas are published and available to mariners, who typically review such information before boating in any area. Restricted areas are typically avoided by experienced mariners. Prior to initiating a training activity, the Navy would follow standard operating procedures to visually scan an area to ensure that nonparticipants are not present. If nonparticipants are present, the Navy delays, moves, or cancels its activity. Public accessibility is no longer restricted once the activity concludes.

3.11.3.1.1 Socioeconomic Activities

3.11.3.1.1.1 Commercial Transportation and Shipping

The offshore and nearshore areas of the Study Areas include established Navy OPAREAs used for military training and testing activities. Commercial vessels entering OPAREAs, including established restricted areas and danger zones, within the Study Area operate under maritime regulations and are not limited by Navy activities. Potential disruptions to commercial shipping are limited or avoided by the Navy issuing Notices to Mariners through the U.S. Coast Guard. Notices to Mariners advise commercial ship operators, commercial fishermen, recreational boaters, and other users of the area that the military will be operating in a specific area, allowing them to plan their activities accordingly. These temporary clearance procedures are established and implemented for the safety of the public and have been employed regularly over time without significant socioeconomic impacts on commercial shipping activities.

3.11.3.1.1.2 Commercial and Recreational Fishing

Commercial and recreational fishing activities make an appreciable contribution to the overall economy within the Study Area. The Navy has performed military activities within this region in the past with limited interruption to fishing or recreational activities. Commercial and recreational interests such as fishing, boating, and beach use are only restricted temporarily. Temporary closing of areas within the Study Area (typically offshore areas of the Pacific Missile Range Facility and areas in the vicinity of San Clemente Island) for security and safety does not limit public access to surrounding areas. These areas that are temporarily closed are only closed for the duration of the activity and are re-opened at the completion of the activity.

These temporary range clearance procedures for safety purposes do not adversely affect commercial and recreational fishing activities because displacement is of short duration (less than 24 hours). When range clearance is required, the public is notified via Notices to Mariners. These measures provide mariners with advance notice of areas being used by the Navy for training and testing activities. This allows the public to select an alternate destination without appreciable effect to their activities.

Scheduled closures to Navy training and testing areas are also posted on several publicly accessible Navy websites. Online searches for San Clemente Island or the Southern California Offshore Range (SCORE) should provide links with information on closures around San Clemente Island. The public website for the Naval Base Coronado provides advance notice of training activities originating from the base.

The Notices to Mariners and postings on Navy websites are intended to prevent fishermen from expending time and fuel resources transiting to a closed location. In 2009, the Navy completed a study to assess the effects of Navy activities on commercial and recreational fishing near San Clemente Island in the SOCAL Range Complex (Naval Undersea Warfare Center 2009). The SOCAL Fisheries Study reported the results of a survey of local fishermen and resulted in several recommendations to improve communications between the Navy and commercial and recreational fishermen. Improved communications would enable fishermen to be better informed of range closures, and would reduce the number of times fishermen traveled to temporarily closed areas. To enhance communications with fishermen and the local community, the Navy (1) issues regular and up-to-date broadcasts of scheduled closures on very high frequency (VHF) radio, (2) provides frequent updates to the San Clemente Island website, (3) has established a single Navy point of contact with the most up-to-date information on closures for fishermen without website access, and (4) specifies if a scheduled Navy activity requires a complete closure or if fishing can occur simultaneously with the Navy activity. During the course of the study, some of the recommendations have been addressed by the Southern California Offshore Range, which has operational authority over the San Clemente Island ranges. In particular, the Southern California Offshore Range initiated development of more robust range operations control, which allows fishermen to contact the San Clemente Island range in real-time using marine band VHF radio or cellular phones to obtain the status of OPAREA availability. In addition, a list of acronyms and codes was generated and posted as a link on the main page of the San Clemente Island website, which, along with other user-friendly website implementations (e.g., Twitter link for updates to safety zone scheduling), have been added to the San Clemente Island website.

Upon completion of training, the range would be reopened and fishermen would be able to return to fish in the previously closed area. To help manage competing demands and maintain public access in the Study Area, the Navy conducts its offshore operations in a manner that minimizes restrictions to commercial fisherman. Navy ships, fishermen, and recreational users operate within the area together, and keep a safe distance between each other, and the Navy exercise participants relocate as necessary to avoid conflicts with nonparticipants. Only specific areas within the HRC, SSTC, and SOCAL Range Complex have been designated as danger zones or restricted areas. In addition to these areas, the Navy may temporarily establish an exclusion zone for the duration of a specific activity (e.g., an activity involving the detonation of explosives) to prevent non-participating vessels and aircraft from entering and unsafe area. Exclusion zones typically have a radius of only a couple of miles (this varies depending on the activity), are surveyed before during, and after the activity takes place, and end after the activity is completed (see Section 3.12, Public Health and Safety).

The Navy does not exclude fishing activities from occurring in areas of the HRC, SOCAL Range Complex, and SSTC that are not being used by the Navy during training and testing activities. The Navy has been conducting training and testing activities within the Study Area for decades, and has taken and will continue to take measures to prevent interruption of commercial and recreational fishing activities. To minimize potential military/civilian interactions, the Navy will continue to publish scheduled operation times and locations on publicly accessible Navy websites and through U.S. Coast Guard issued Notices to Mariners up to 6 months in advance. These efforts are intended to ensure that commercial and recreational users are aware of the Navy's plans and allow users to plan their activities to avoid scheduled Navy activities. Therefore, decreases in the frequency of fishing trips or in the availability of desirable fishing locations due to Navy activities is not expected. For safety reasons, the Navy may restrict access to a specific surface water area through the establishment of an exclusion zone, which would temporarily limit commercial and recreational fishing in that specific area; however, other areas in the Study Area would remain open to commercial and recreational fishing. A Navy activity involving the use of explosive ordnance is one example of an activity that could require establishment of a temporary exclusion zone. Typically, an exclusion zone is established only for a few hours and extends over a circular area with a radius of a couple of miles (depending on the activity). Commercial and recreational fishing activities could occur in the area before and after the temporary restriction. Should the Navy find nonparticipants present in an exclusion zone, the Navy would halt or delay (and reschedule, if necessary) all potentially hazardous activity until the nonparticipants have exited the exclusion zone.

3.11.3.1.1.3 Subsistence Use

Subsistence uses typically occur from the shore or from small vessels within state waters (3 nm or closer to shore). Navy training and testing activities occur farther from shore in offshore waters where subsistence fishing typically does not occur. Therefore, there would be no foreseeable impact on subsistence uses from conducting proposed training and testing activities in the Study Area.

3.11.3.1.1.4 Tourism

Tourism activities make an appreciable contribution to the overall economy within the Study Area. Temporary range clearance procedures in the area, mainly around the Pacific Missile Range Facility and San Clemente Island, for safety purposes, do not adversely affect tourism activities because displacement is of short duration (typically less than 24 hours) and are in areas where tourism activities are not as prevalent. The Navy temporarily limits public access only to areas where there is a risk of injury or property damage and publishes scheduled activities through the use of Notices to Mariners and publically accessible websites. The Navy strives to conduct its operations in a manner that is compatible with recreational ocean users by minimizing temporary access restrictions. Published notices allow recreational users to adjust their routes to avoid temporary restricted areas. If civilian vessels are within a testing or training area at the time of a scheduled operation, Navy personnel would continue operations only where and when it is safe and possible to avoid the civilian vessels. If avoidance is not safe or possible, the operation would be halted and may relocate or be delayed. In some instances where safety requires exclusive use of a specific area, nonparticipants in the area are asked to relocate to a safer area for the duration of the operation.

3.11.3.1.2 No Action Alternatives

<u>Training</u>

Under the No Action Alternative, potential accessibility impacts would be associated primarily with anti-air warfare, anti-surface warfare, anti-submarine warfare, mine warfare, amphibious warfare, and naval special warfare. Training activities would continue at current levels and within established ranges and training locations. There would be no anticipated impacts on commercial transportation and shipping, commercial and recreational fishing, subsistence use, or tourism because inaccessibility to areas of co-use would be temporary and of short duration (hours). In addition, the Navy has implemented recommendations from the SOCAL Fisheries Study, which should improve communications between the Navy and fishermen, both recreational and commercial, and reduce the number of instances when fishermen must leave a temporarily closed area (Naval Undersea Warfare Center 2009). Based on the Navy’s standard operating procedures and the large expanse of the Study Area that would be available to the public, accessibility impacts would remain negligible.

Testing

Under the No Action Alternative, the impact on accessibility would be negligible for the same reasons stated for training activities above.

3.11.3.1.3 Alternative 1

Alternative 1 consists of the No Action Alternative plus the expansion of the Study Area boundaries, adjustments to the tempo of training and testing activities, and the addition of new weapons, platforms, and systems. The changes in the tempo of training and testing activities would result in an increase in sonar activities, underwater detonations, aircraft transits, and weapons firing throughout the Study Area.

Training

Training activities as described under the No Action Alternative would continue but with an approximate 5 percent increase in tempo within the Study Area. There would be no changes to the Navy's current standard operating procedures defining safety precautions and actions taken by the Navy to protect the public during hazardous training activities on the ocean. Under Alternative 1, potential impacts affecting accessibility to areas of the Study Area would be the same as those associated with the No Action Alternative. Despite the increase in tempo of training activities and the expansion of the Study Area, no impacts from Alternative 1 activities on commercial transportation and shipping, commercial and recreational fishing, subsistence use, or tourism are anticipated, because training activities would place only temporary and short duration (hours) restrictions on public use of scheduled training areas. In addition, the Navy is implementing recommendations from the SOCAL Fisheries Study, which should improve communications between the Navy and fishermen, both recreational and commercial, and reduce the number of instances when fishermen must leave a temporarily closed area (Naval Undersea Warfare Center 2009). Based on the Navy's standard operating procedures and the large expanse of the Study Area that would be available to the public, accessibility impacts would remain negligible.

Testing

Under the Alternative 1, the impact on accessibility from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.1.4 Alternative 2

Alternative 2 consists of Alternative 1 plus an increase in tempo. Changes in testing tempo under Alternative 2 would result in an increase in sonar activities, underwater detonations, aircraft transiting, and weapons firing throughout the Study Area.

Training

Training activities as described under Alternative 1 would continue at the same tempo within the Study Area. There would be no changes to the Navy's current standard operating procedures defining safety precautions and actions taken by the Navy to protect the public during hazardous training activities on the ocean. Despite the increase in tempo of training activities, no impacts from Alternative 2 activities on commercial transportation and shipping, commercial and recreational fishing, subsistence use, or tourism are anticipated, because training activities would place only temporary and short duration (hours) restrictions on public use of scheduled training areas. In addition, the Navy is implementing recommendations from the SOCAL Fisheries Study which should improve communications between the Navy and recreational fishermen and reduce the number of instances when fishermen must leave a temporarily closed area (Naval Undersea Warfare Center 2009). Based on the Navy's standard operating procedures and the large expanse of the Study Area that would be available to the public, accessibility impacts would remain negligible.

Testing

Under the Alternative 2, the impact on accessibility from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.2 Physical Disturbances and Strikes

The evaluation of impacts on socioeconomic resources from physical disturbance and strike stressors focuses on direct physical encounters or collisions with objects moving through the water or air (e.g., vessels, aircraft, unmanned devices, and towed devices), dropped or fired into the water (non-explosive practice munitions, other military expended materials, and ocean bottom deployed devices), or resting on the ocean floor (anchors, mines, targets) that may damage or encounter civilian equipment. Physical disturbances that damage equipment and infrastructure could disrupt the collection and transport of products, which may impact industry revenue or operating costs.

Navy training and testing equipment and vessels moving through the water could collide with non-Navy vessels and equipment. Most of the training and testing activities involve vessel movement and use of towed devices. However, the likelihood that a Navy vessel would collide with a non-Navy vessel is remote because of the prevalent use of navigational aids or buoys separating vessel traffic, shipboard lookouts, radar, and marine band radio communications by both Navy and civilians. Therefore, the potential to impact commercial transportation and shipping by physical disturbance or strike is negligible and requires no further analysis.

Aircraft conducting training or testing activities in the Study Area operate in designated military special use airspace (e.g., warning areas). All aircraft, military and civilian, are subject to Federal Aviation Administration regulations, which define permissible uses of designated airspace, and are implemented to control those uses. These regulations are intended to accommodate the various categories of aviation, whether military, commercial, or general aviation. By adhering to these regulations, the likelihood of civilian aircraft coming into contact with military aircraft or ordnance is remote. In addition, Navy aircraft follow procedures outlined in Navy air operations manuals, which are specific to a warning area or other special use airspace, and which describe procedures for operating safely when civilian aircraft are in the vicinity.

Military expended materials can physically interact with civilian equipment and infrastructure. Almost all training and testing activities produce military expended materials such as chaff, flares, projectiles, casings, target fragments, missile fragments, rocket fragments, and ballast weights.

3.11.3.2.1 Socioeconomic Activities

3.11.3.2.1.1 Commercial and Recreational Fishing/Subsistence Use

The majority of commercial and recreational fishing in the Study Area takes place in state waters, where the Navy conducts very limited training and testing activities. Less than 10 percent of recreational fishing takes place in federal waters, which are located beyond 3 nm from shore. Therefore, most recreational fishing would occur away from physical disturbances and strikes associated with training and testing activities. Some commercial fishing may occur beyond 3 nm in Navy training and testing areas and could be affected by the proposed activities if those activities were to alter fish population levels in those areas to such an extent that commercial fishers would no longer be able to find their target species. As described in Section 3.9.3 (Fish, Environmental Consequences), the behavioral responses that could occur from various types of physical stressors associated with training and testing activities would not compromise the general health or condition of fish and, as such, commercial or recreational fishing resources.

Commercial fishing activities have the potential to interact with equipment placed in the ocean or on the ocean floor for use during proposed Navy training and testing activities. This equipment could include ship anchors, moored or bottom mounted targets, mines and mine shapes, tripods, and use of towed system and attachment cables. Many different types of commercial fishing gear are used in the Study Area, including gillnets, longline gear, troll gear, trawls, seines, and traps or pots. Commercial bottom fishing activities that use these types of gear have a greater potential to be affected by interaction with Navy training and testing equipment, resulting in the loss of or damage to both the Navy equipment and the commercial fishing gear. The Navy recovers many of the targets (e.g., mines and mine shapes) and target fragments used in training and testing activities, and would continue to do so to minimize the potential for interaction with fishing gear and fishing vessels. Unrecoverable items are typically small, constructed of soft materials (such as target cardboard boxes or tethered target balloons), or are intentionally designed to sink to the bottom after serving their purpose (such as expended 55-gallon steel drums), so that they would not represent a collision risk to vessels, including commercial fishing vessels. Although larger expended items, such as 55-gallon drums, may pose a risk to certain types of fishing gear used for bottom fishing, the probability of encountering such an item is remote given the large area over which expended materials would be distributed; the depth of the water where most activities using expended materials would occur; and the tendency for larger, heavier materials to become embedded in soft sediments, making them less likely to be snagged by fishing gear.

3.11.3.2.1.2 Tourism

While Navy training and testing activities can occur throughout the Study Area, most (especially hazardous) activities occur well out to sea. Most civilian recreational activities engaged in by both tourists and residents take place within a few miles of land.

Snorkeling and diving take place primarily at known recreational sites, including shipwrecks and reefs. Temporary range clearance procedures in the areas, mainly around the Pacific Missile Range Facility and San Clemente Island, for safety purposes, do not adversely affect tourism activities because displacement is of short duration (typically less than 24 hours) and are in areas where tourism activities are not as prevalent. The Navy temporarily limits public access to areas where there is a risk of injury or property damage through the use of Notices to Mariners. The Navy also maintains a website which provides information on scheduled closures around San Clemente Island. Published notices allow recreational users to adjust their routes to avoid temporary restricted areas. If civilian vessels are within a testing or training area at the time of a scheduled operation, Navy personnel continue operations and avoid them if it is safe and possible to do so. If avoidance is not safe or possible, the operation may relocate or be delayed. In some instances where safety requires exclusive use of a specific area, nonparticipants in the area are asked to relocate to a safer area for the duration of the operation. Because Navy training and testing activities vary in location and are primarily short-term in duration, impacts on tourism activities from rerouting or postponing activities would be negligible.

Other tourism activities such as whale watching, boating, or use of other watercraft occur farther out at sea and are conducted by boat, aircraft, or from land. These activities would be conducted with boats that are typically well marked and visible to Navy ships conducting training and testing activities. Individual boaters engaged in tourism activities, such as whale watching, plan and monitor navigational information to avoid Navy training and testing areas. Vessels are responsible for being aware of designated danger areas in surface waters and any Notices to Mariners that are in effect. Operators of recreational or commercial vessels have a duty to abide by maritime requirements as administered by the U.S. Coast Guard. At the same time, Navy vessels ensure that an area is clear of nonparticipants prior to testing and training exercises. As a result, conflicts between Navy training and testing activities in offshore areas and whale watching or other offshore recreational use would not occur. Changes to current offshore tourism activities in the Study Area would not be expected from the proposed training and testing activities. Therefore, loss of revenue or employment associated with tourism would not occur.

The Navy would continue to recover many of the targets (e.g., mines and mine shapes) and target fragments used in training and testing activities so that they would not pose a collision risk to vessels. Unrecoverable items are typically small, constructed of soft materials (such as target cardboard boxes or tethered target balloons), or are intentionally designed to sink to the bottom after serving their purpose (such as expended 55-gallon steel drums), so that they would not represent a collision risk to vessels.

3.11.3.2.2 No Action Alternative

Training

Under the No Action Alternative, potential physical disturbance and strike impacts would be associated primarily with anti-air warfare, anti-surface warfare, anti-submarine warfare, mine warfare, and amphibious warfare. Training activities would continue at current levels and within established ranges and training locations.

There would be no anticipated impacts on commercial and recreational fishing, subsistence use, or tourism because of the large size of the Study Area, the limited areas of operations, and implementation of the Navy's standard operating procedures, which includes ensuring that an area is clear of all nonparticipating vessels before training activities take place. In addition, the Navy provides advance notification of training activities to the public through Notices to Mariners and postings on Navy websites (e.g., the San Clemente Island website). Damage to or loss of commercial fishing gear from interaction with Navy equipment or other expended materials is unlikely. The Navy recovers many practice munitions (e.g., mines and mine shapes) for reuse following the activity. The Navy also recovers larger floating objects or materials, such as targets or target fragments, to avoid having them become hazards to navigation. Smaller objects that remain in the water column would be unlikely to pose a risk to fishing gear. Considering the expansive size of the Navy's OPAREAs, the disbursement of military expended materials over these large areas, and the Navy's standard operation procedures and mitigation measures (see Chapter 5), impacts from physical disturbances and strikes on commercial and recreational fishing, subsistence use, or tourism would be negligible.

Testing

Under the No Action Alternative, the impact associated with physical disturbances and strikes from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.2.3 Alternative 1

Alternative 1 consists of the No Action Alternative plus the expansion of the Study Area boundaries, adjustments to the tempo of training and testing activities, and the addition of new weapons, platforms and systems. The changes in training tempo would result in an increase in sonar activities, underwater detonations, aircraft transiting, and weapons firing throughout the Study Area.

Training

Under Alternative 1, potential physical disturbance and strike impacts would be the same as those associated with the No Action Alternative. Training activities would continue but with an approximate 5 percent increase in tempo and associated increase in the quantity of military expended materials released within the Study Area. There would be no changes to the Navy's standard operating procedures for hazardous training activities performed in the Study Area. The expansive size of the Navy's OPAREAs, the disbursement of military expended materials over these large areas, and implementation of the Navy's standard operating procedures and mitigation measures (see Chapter 5) ensure that impacts from physical disturbances and strikes would be negligible. The advance public release of Notices to Mariners and postings of upcoming activities on Navy websites (e.g., the San Clemente Island website) would inform the public of upcoming activities, and enable them to plan to avoid the area. Therefore, impacts from physical disturbance and strike on commercial and recreational fishing, subsistence use, and tourism would be negligible.

Testing

Under Alternative 1, the impact associated with physical disturbances and strikes from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.2.4 Alternative 2

Alternative 2 consists of Alternative 1 plus an increase in tempo. Changes in testing tempo under Alternative 2 would result in an increase in sonar activities, underwater detonations, aircraft transiting, and weapons firing throughout the Study Area.

Training

Under Alternative 2, potential physical disturbance and strike impacts would be the same as those associated with the No Action Alternative. Training activities would continue at the same tempo as Alternative 1. There would be no changes to the Navy's standard operating procedures for hazardous training activities performed in the Study Area. The expansive size of the Navy's OPAREAs, the disbursement of military expended materials over these large areas, and implementation of the Navy's standard operating procedures and mitigation measures (see Chapter 5) ensure that impacts from physical disturbances and strikes would be negligible. The advance public release of Notices to Mariners and postings of upcoming activities on Navy websites (e.g., the San Clemente Island website) would inform the public of upcoming activities, and enable them to plan to avoid the area. Therefore, impacts from physical disturbance and strike on commercial and recreational fishing, subsistence use, or tourism would be negligible.

Testing

Under Alternative 2, the impact associated with physical disturbances and strikes from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.3 Airborne Acoustics

As an environmental stressor, loud noises, sonic booms, and vibrations generated from Navy training and testing activities such as weapons firing, in-air explosions, and aircraft transiting have the potential to disrupt wildlife and humans in the Study Area.

3.11.3.3.1 Socioeconomic Activities

3.11.3.3.1.1 Tourism

Noise interference could decrease public enjoyment of recreational activities. These effects would occur on a temporary basis, only when weapons firing, in-air explosions, and aircraft transiting occur. Of these activities, Navy training and testing activities involving weapons firing and in-air explosions would only occur when the Navy can confirm the area is clear of nonparticipants, reducing the likelihood that noise from these activities would disturb tourists. Most naval training would occur well out to sea, while tourism and civilian recreational activities are largely conducted within a few miles of shore. Tourism and recreational activity revenue is not expected to be impacted by airborne noise.

3.11.3.3.2 No Action Alternative

Training

Under the No Action Alternative, potential airborne noise impacts would be associated primarily with anti-air warfare, anti-surface warfare, anti-submarine warfare, mine warfare, and amphibious warfare. Training activities would continue at current levels and within established ranges and training locations. There would be no anticipated impacts on tourism because (1) most Navy training occurs well out to sea, while most tourism and recreational activities occur near shore; and (2) Navy training activities producing airborne noise are normally short term and temporary. Therefore, airborne noise impacts on tourism would be negligible.

Testing

Under the No Action Alternative, impacts associated with airborne acoustics from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.3.3 Alternative 1

Alternative 1 consists of the No Action Alternative plus the expansion of the Study Area boundaries, adjustments to the tempo of training and testing activities, and the addition of new weapons, platforms and systems. The changes in training tempo would result in an approximate 5 percent increase in noise-generating activities such as sonar activities, underwater detonations, aircraft transiting, and weapons firing throughout the Study Area.

Training

Under Alternative 1, potential airborne noise would be the same as that associated with the No Action Alternative. Training activities would continue but with an increase in tempo within the Study Area. Similar to the No Action Alternative and despite the increase in tempo, there would be no anticipated impacts on tourism because (1) most Navy training occurs well out to sea, while most tourism and recreational activities occur near shore and (2) Navy training activities producing airborne noise are normally short term and temporary. Therefore, airborne noise impacts on tourism would be negligible.

Testing

Under Alternative 1, impacts associated with airborne acoustics from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.3.4 Alternative 2

Alternative 2 consists of Alternative 1 plus an increase in tempo. Changes in testing tempo under Alternative 2 would result in an increase in sonar activities, underwater detonations, aircraft transiting, and weapons firing throughout the Study Area.

Training

Under Alternative 2, potential airborne noise would be the same as that associated with the No Action Alternative. Training activities would continue at the same tempo as Alternative 1 within the Study Area. Similar to Alternative 1, there would be no anticipated impacts on tourism because (1) most Navy training occurs well out to sea, while most tourism and recreational activities occur near shore and (2) Navy training activities producing airborne noise are normally short term and temporary. Therefore, airborne noise impacts on tourism would be negligible.

Testing

Under Alternative 2, impacts associated with airborne acoustics from testing activities would be negligible for the same reasons stated for training activities above.

3.11.3.4 Analysis of Secondary Stressors

Socioeconomics could be impacted if the proposed activities led to changes to physical and biological resources to the extent that they would alter the way industries can utilize those resources. The secondary stressor of resource availability pertains to the potential for loss of fisheries resources within the Study Area.

Fishing, subsistence use, and tourism could be impacted if the proposed activities altered fish population levels to such an extent that these activities would no longer be able to find their target species. Similarly, disturbances to marine mammal populations could impact the whale watching industry. Analyses in Sections 3.4 (Marine Mammals), 3.8 (Marine Invertebrates), and 3.9 (Fish) concluded that impacts to marine species from training and testing activities are not anticipated. Based on these conclusions, secondary impacts on commercial or recreational fishing, subsistence use, or tourism are not anticipated.

3.11.4 Summary of Potential Impacts (Combined Impacts of All Stressors) on Socioeconomics

Stressors described in this EIS/OEIS that could result in potential impacts on socioeconomic resources include accessibility to areas within the Study Area, physical disturbance and strikes, airborne acoustics, and secondary stressors resulting from Impacts to marine species populations. Under the No Action Alternative, Alternative 1, and Alternative 2, these activities would be widely dispersed throughout the Study Area. These activities are also dispersed temporally (i.e., few stressors would occur in the same location at the same time). Therefore, no greater impacts from the combined operation of more than one stressor are expected. The aggregate impact on socioeconomics would not observably differ from existing conditions.

3.12 PUBLIC HEALTH AND SAFETY

PUBLIC HEALTH AND SAFETY SYNOPSIS

The United States Department of the Navy considered all potential stressors, and the following stressors have been analyzed for public health and safety:

- Underwater energy
- In-air energy
- Physical interactions
- Secondary

Alternative 2 (Preferred Alternative)

Because of the Navy's standard operating procedures, impacts on public health and safety would be unlikely.

3.12.1 INTRODUCTION AND METHODS

3.12.1.1 Introduction

This section analyzes potential impacts on public health and safety within the Hawaii-Southern California Training and Testing (HSTT) Study Area (Study Area). Unlike military training and testing activities conducted within the boundaries of a fenced-land installation, public access to ocean areas or to the overlying airspace cannot be physically controlled. The United States (U.S.) Department of the Navy (Navy) coordinates use of these areas through the scheduling of activities, and issues warnings and notices to the public prior to conducting potentially hazardous activities (Section 3.12.2.2). Sensitivity to public health and safety concerns within the Study Area is heightened in areas where the public may be close to certain activities (e.g., pierside testing or littoral training).

Generally, the greatest potential for a proposed activity to affect the public is near the coast because that is where public activities are concentrated. These coastal areas could include dive sites or other recreational areas where the collective health and safety of groups of individuals that could be exposed to the hazards of training and testing would be of concern. Most commercial and recreational marine activities are close to the shore, and are usually limited by the capabilities of the boat used. Commercial and recreational fishing may extend as far as 100 nautical miles (nm) from shore, but are concentrated near the coast.

3.12.1.2 Methods

Baseline public health and safety conditions were derived from the current training and testing activities in the Southern California (SOCAL) Range Complex and the Hawaii Range Complex (HRC). The No Action Alternative does not include the Transit Corridor of the Study Area (Chapter 2, Description of Proposed Action and Alternatives). Existing procedures for assuring public health and safety and other elements of the baseline (e.g., restricted areas) were derived from federal regulations, Department of Defense (DoD) directives, and Navy instructions for training and testing. The directives and instructions provide specifications for mission planning and execution that describe criteria for public health and safety considerations. These directives and instructions include criteria for public health and safety considerations for training and testing planning and execution.

The alternatives were evaluated based on two factors: the potential for a training or testing activity to impact public health and safety and the degree to which those activities could have an impact. The likelihood that the public would be near a training or testing activity determines the potential for exposure to the activity. If the potential for exposure exists, the degree of the potential impacts on public health and safety, including increased risk of injury or loss of life, is determined. If the potential for exposure were zero, then public health and safety would not be affected. Isolated incidents and other conditions that affect single individuals, although important for safety awareness, may not rise to the level of a public health or safety issue, and are not considered in this assessment (i.e., airborne noise effects are not addressed in this section).

3.12.2 Affected Environment

3.12.2.1 Overview

Military, commercial, institutional, and recreational activities take place simultaneously in the Study Area (Figure 3.12-1), and have coexisted safely for decades. These activities coexist because established rules and practices lead to safe use of the waterway and airspace. The following paragraphs briefly discuss the rules and practices for recreational, commercial, and military use in sea surface areas and airspace.

Figure 3.12-1: Simultaneous Activities within the Hawaii-Southern California Training and Testing Study Area

3.12.2.1.1 Sea Space

Most of the sea space in the Study Area is accessible to recreational and commercial activities. However, some activities are prohibited or restricted in certain areas (e.g., danger zones and restricted areas) in accordance with Title 33 Code of Federal Regulations, Part 334 (Danger Zone and Restricted Area Regulations). These restrictions can be permanent or temporary. Nautical charts issued by the National Oceanic and Atmospheric Administration include these federally designated zones and areas. Operators of recreational and commercial vessels have a duty to abide by maritime regulations administered by the U.S. Coast Guard.

In accordance with Title 33 Code of Federal Regulations 72 (Aids to Navigation), the U.S. Coast Guard and the Department of Homeland Security inform private and commercial vessels about temporary closures via Notices to Mariners. These Notices provide information about durations and locations of closures because of activities that are hazardous to surface vessels. Broadcast notices on maritime frequency radio, weekly publications by the appropriate U.S. Coast Guard Navigation Center, and global positioning system navigation charts disseminate these navigational warnings.

3.12.2.1.2 Airspace

Most of the airspace in the Study Area is accessible to general aviation (recreational, private, corporate) and commercial aircraft. Like waterways, however, some areas are temporarily off limits to civilian and commercial use. The Federal Aviation Administration has established Special Use Airspace—airspace of defined dimensions wherein activities must be confined because of their nature or wherein limitations may be imposed upon aircraft operations that are not part of those activities (Federal Aviation Administration 2013). Special Use Airspace in the Study Area includes:

- **Restricted Airspace:** Areas where aircraft are restricted because of unusual (often invisible) hazards to aircraft (e.g., release of ordnance). Some areas are under strict control of the DoD, and some are shared with nonmilitary agencies.
- **Military Operations Areas:** Areas typically below 18,000 feet (ft.) used to separate certain nonhazardous military flight activities from instrument flight rules traffic and to identify visual flight rules traffic where these activities are conducted.
- **Warning Areas:** Areas of defined dimensions, beyond three nm from the coast of the United States, which warn nonparticipating aircraft of potential danger.
- **Air Traffic Controlled Assigned Airspace:** Airspace that is Federal Aviation Administration-defined and is not over an existing operating area. This airspace is used to contain specified activities, such as military flight training, that are segregated from other instrument flight rules air traffic.

Notices to Airmen are created and transmitted by government agencies and airport operators to alert aircraft pilots of any hazards en route to or at a specific location. The Federal Aviation Administration issues Notices to Airmen to disseminate information on upcoming or ongoing military exercises with airspace restrictions. Civilian aircraft are responsible for being aware of restricted airspace and any Notices to Airmen that are in effect. Pilots have a duty to abide by aviation rules as administered by the Federal Aviation Administration.

Weather conditions dictate whether aircraft (general aviation, commercial, or military) can fly under visual flight rules, or whether instrument flight rules are required. Under visual flight rules, the weather is favorable and the pilot is required to remain clear of clouds by specified distances to ensure separation from other aircraft under the concept of see and avoid. Pilots flying under visual flight rules must be able to see outside of the cockpit, control the aircraft’s attitude, navigate, and avoid obstacles and other aircraft based on visual cues. Pilots flying under visual flight rules assume responsibility for their separation from all other aircraft, and are generally not assigned routes or altitudes by air traffic control.

During unfavorable weather, pilots must follow instrument flight rules. Factors such as visibility, cloud distance, cloud ceilings, and weather phenomena cause visual conditions to drop below the minimums required to operate by visual flight referencing. Instrument flight rules are the regulations and restrictions a pilot must comply with when flying in weather conditions that restrict visibility. Pilots can fly under instrument flight rules in visual flight rules weather conditions; however, pilots cannot fly under visual flight rules in instrument flight rules weather conditions.

3.12.2.2 Safety and Inspection Procedures

During training and testing, Navy policy is to ensure the safety and health of personnel and the general public (U.S. Department of the Navy 2011c). The Navy achieves these conditions by considering a location when planning activities, scheduling and notifying potential users of an area, and ensuring that an area is clear of nonparticipants. The Navy also has a proactive and comprehensive program of compliance with applicable standards and implementation of safety management systems.

As previously stated, the greatest potential for a training or testing activity to affect the public is in coastal areas because of the concentration of public activities. When planning a training or testing event, the Navy considers proximity of the activity to public areas in choosing a location. Important factors considered include the ability to control access to an area; schedule (time of day, day of week); frequency, duration, and intensity of activities; range safety procedures; operational control of activities or events; and safety history.

The Navy's Fleet Area Control and Surveillance Facilities actively manage assigned airspace, operating areas, ranges, and training and testing resources to enhance combat readiness of U.S. Pacific Fleet units. The Navy schedules activities through the Fleet Area Control and Surveillance Facilities, which coordinate air and surface use of the operating areas (OPAREAs) with the Federal Aviation Administration and the U.S. Coast Guard, which issue Notices to Airmen and Notices to Mariners, respectively.

During training and testing activities in the Study Area, the Navy ensures that the appropriate safety zone is clear of non-participants before engaging in certain activities, such as firing weapons. Inability to obtain a "clear range" could cause an event to be delayed, cancelled, or relocated. Navy procedures ensure public safety during Navy activities that otherwise could harm nonparticipants. Navy practices employ the use of sensors and other devices (e.g., radar) to ensure public health and safety while conducting training and testing activities. The following subsections outline the current requirements and practices for human safety as they pertain to range safety procedures, range inspection procedures, exercise planning, and scheduling and coordinating procedures for the Navy.

Training activities comply with Fleet Area Control and Surveillance Facility procedures. Fleet Area Control and Surveillance Facilities San Diego and Hawaii have published safety procedures for activities on the offshore and nearshore areas (U.S. Department of the Navy 2011a, b). These guidelines (and others) apply to range users as follows:

- Navy personnel are responsible for ensuring that impact areas and targets are clear before commencing hazardous activities.
- The use of underwater ordnance must be coordinated with submarine operational authorities. The coordination also applies to towed sound navigation and ranging (sonar) arrays and torpedo decoys.
- Aircraft or vessels expending ordnance shall not commence firing without permission of the Range Safety Officer for their specific range area.
- Firing units and targets must remain in their assigned areas, and units must fire in accordance with current safety instructions.

- Aircraft carrying ordnance to or from ranges shall avoid populated areas to the maximum extent possible.
- Strict on-scene procedures include the use of ship sensors, visual surveillance of the range from aircraft and range safety boats, and radar and acoustic data to confirm the firing range and target area are clear of civilian vessels, aircraft, or other nonparticipants.

Testing activities have their own comprehensive safety planning instructions (U.S. Department of the Navy 2008b, 2009). These instructions provide guidance on how to identify the hazards, assess the potential risk, analyze risk control measures, implement risk controls, and review safety procedures. They apply to all testing activities including ground, waterborne, and airborne testing activities involving personnel, aircraft, inert minefields, equipment, and airspace. The guidance applies to system program managers, program engineers, test engineers, test directors, and aircrews that are responsible for incorporating safety planning and review when conducting test programs.

The following safety and inspection procedures are implemented for training activities. Each commanding officer is responsible for implementing safety and inspection procedures for activities inside and outside established ranges. In the absence of specific guidance on matters of safety, the Navy follows the most prudent course of action. The following section contains information on the Navy's program of compliance with applicable standards and implementation of safety management systems.

3.12.2.2.1 Aviation Safety

Navy procedures on planning and managing Special Use Airspace are provided in Chief of Naval Operations Instruction 3770.2K, *Airspace Procedures and Planning Manual* (U.S. Department of the Navy 2007). Scheduling and planning procedures for air operations on range complexes are issued through the Navy's Fleet Area Control and Surveillance Facilities San Diego and Hawaii (U.S. Department of the Navy 2011b). Testing ranges have their own procedures for aviation safety, like the Naval Surface Warfare Center Instruction (U.S. Department of the Navy 2008b) and Naval Undersea Warfare Center Division Instruction (U.S. Department of the Navy 2009).

Aircrews involved in a training or testing exercise must be aware that nonparticipating aircraft and ships are not precluded from entering the area and may not comply with Notices to Airmen or Notices to Mariners. Aircrews are required to maintain a continuous lookout for nonparticipating aircraft while operating in warning areas under visual flight rules. In general, aircraft carrying ordnance are not allowed to fly over surface vessels.

3.12.2.2.2 Submarine Navigation Safety

Submarine crews use various methods to avoid collisions while they are surfaced, including visual and radar scanning, acoustic depth finders, and state-of-the-art satellite navigational systems. When transiting submerged, submarines use all available ocean navigation tools, including inertial navigation charts that calculate position based on the submerged movements of the submarine. Areas with surface vessels can then be avoided to protect both the submarines and surface vessels.

3.12.2.2.3 Surface Vessel Navigational Safety

The Navy practices the fundamentals of safe navigation. While in transit, Navy surface vessel operators are alert at all times, use extreme caution, use state-of-the-art satellite navigational systems, and are trained to take proper action if there is a risk. Surface vessels are also equipped with trained and qualified Navy Lookouts. Individuals trained as lookouts have the necessary skills to detect objects or activity in the water that could be a risk for the vessel.

For specific testing activities, like unmanned surface vehicle testing, a support boat would be used near the testing to ensure safe navigation. Before firing or launching a weapon or radiating a non-eyesafe laser, Navy surface vessels are required to determine that all safety criteria have been satisfied. When applicable, the surface vessel would use aircraft and other boats to aid in navigation. In accordance with Navy instructions presented in this chapter, safety and inspection procedures ensure public health and safety.

3.12.2.2.4 Sound Navigation and Sounding (Sonar) Safety

Surface vessels and submarines may use active sonar in the pierside locations listed in Chapter 2 (Description of Proposed Action and Alternatives) and during transit to the training or testing exercise location. To ensure safe and effective sonar use, the Navy applies the same safety procedures for pierside sonar use as described in Section 3.12.2.2 (Safety and Inspection Procedures).

Naval Sea Systems Command Instruction 3150.2, Appendix 1A, *Safe Diving Distances from Transmitting Sonar*, is the Navy's governing document for protecting divers during active sonar use (U.S. Department of the Navy 2011d). This instruction provides procedures for calculating safe distances from active sonar. These procedures are derived from experimental and theoretical research conducted at the Naval Submarine Medical Research Laboratory and the Navy Experimental Diving Unit. Safety distances vary based on conditions that include diver attire, type of sonar, and duration of time in the water. Some safety procedures include on-site measurements during testing activities to identify an exclusion area for nonparticipating swimmers and divers.

3.12.2.2.5 Electromagnetic Energy Safety

All frequencies (or wavelengths) of electromagnetic energy are referred to as the electromagnetic spectrum, and include electromagnetic radiation and radio frequency radiation. Communications and electronic devices such as radar, electronic warfare devices, navigational aids, two-way radios, cell phones, and other radio transmitters produce electromagnetic radiation. While such equipment emits electromagnetic energy, some of these systems are the same as, or similar to, civilian navigational aids and radars at local airports and television weather stations. Radio waves and microwaves emitted by transmitting antennas are a form of electromagnetic energy collectively referred to as radio frequency radiation. Radio frequency energy includes frequencies ranging from 0 to 3,000 gigahertz. Exposure to radio frequency energy of sufficient intensity at frequencies between 3 kilohertz and 300 gigahertz can adversely affect people, ordnance, and fuel.

To avoid excessive exposures to electromagnetic energy, military aircraft are operated in accordance with standard operating procedures that establish minimum separation distances between electromagnetic energy emitters and people, ordnance, and fuels (U.S. Department of Defense 2009). Thresholds for determining hazardous levels of electromagnetic energy to humans, ordnance, and fuel have been determined for electromagnetic energy sources based on frequency and power output, and current practices are in place to protect the public from electromagnetic radiation hazards (U.S. Department of Defense 2002, 2009). These procedures include setting the heights and angles of electromagnetic energy transmissions to avoid direct exposure, posting warning signs, establishing safe operating levels, activating warning lights when radar systems are operational, and not operating some platforms that emit electromagnetic energy within 15 nm of shore. Safety planning instructions provide clearance procedures for nonparticipants in operational areas prior to conducting training

(U.S. Department of the Navy 2011a, b) and testing (U.S. Department of the Navy 2008b, 2009) activities that involve underwater electromagnetic energy (e.g., mine warfare).

Mine warfare devices are analyzed under other resource topics in this Environmental Impact Statement (EIS)/Overseas EIS (OEIS) because they emit electromagnetic energy. The electromagnetic effects of mine warfare devices are very local, however, unlike radars and radios. Measures to avoid public interaction with mine warfare devices are effective in protecting the public from these effects.

3.12.2.2.6 Laser Safety

Lasers produce light energy. The Navy uses tactical lasers for precision range finding, as target designation and illumination devices for engagement with laser-guided weapons, and for mine detection and mine countermeasures. Laser safety procedures for aircraft require an initial pass over the target prior to laser activation to ensure that target areas are clear. The Navy observes strict precautions, and has written instructions in place for laser users to ensure that nonparticipants are not exposed to intense light energy. During actual laser use, aircraft run-in headings are restricted to avoid unintentional contact with personnel or nonparticipants. Personnel participating in laser training activities are required to complete a laser safety course (U.S. Department of the Navy 2008a).

3.12.2.2.7 High-Explosive Ordnance Detonation Safety

Pressure waves from underwater detonations can pose a physical hazard in surrounding waters. Before conducting an underwater training or testing activity, Navy personnel establish an appropriately sized exclusion zone to avoid exposure of nonparticipants to the harmful intensities of pressure. Naval Sea Systems Command Instruction 3150.2, Chapter 2, *Safe Diving Distances from Transmitting Sonar*, provides procedures for determining safe distances from underwater explosions (U.S. Department of the Navy 2011d). In accordance with training and testing procedures for safety planning related to detonations (see Section 3.12.2.2.8, Weapons Firing and Ordnance Expenditure Safety), the Navy uses the following general and underwater detonation procedures:

- Navy personnel are responsible for ensuring that impact areas and targets are clear before commencing hazardous activities.
- The use of underwater ordnance must be coordinated with submarine operational authorities.
- Aircraft or vessels expending ordnance shall not commence firing without permission of the Range Safety Officer or Test Safety Officer for their specific range area.
- Firing units and targets must remain in their assigned areas, and units must fire in accordance with current safety instructions.
- Detonation activities will be conducted during daylight hours.

3.12.2.2.8 Weapons Firing and Ordnance Expenditure Safety

In accordance with safety and inspection procedures (U.S. Department of the Navy 2011b), any unit firing or expending ordnance shall ensure that all possible safety precautions are taken to prevent accidental injury or property damage. The Officer Conducting the Exercise shall permit firing or jettisoning of aerial targets only when the area is confirmed to be clear of nonparticipating units, both civilian and military.

Safety is a primary consideration for all training and testing activities. The range must be able to safely contain the hazard area of the weapons and equipment employed. The hazard area is based on the size and net explosive weight of the weapon. The type of activity determines the size of the buffer zone. For activities with a large hazard area, special sea and air surveillance measures are implemented to ensure that the area is clear before activities commence. Before aircraft can drop ordnance, they are required to make a preliminary pass over the intended target area to ensure that it is clear of boats, divers, or other nonparticipants. Aircraft carrying ordnance are not allowed to fly over surface vessels.

Training and testing activities are delayed, moved, or cancelled if there is a question about the safety of the public. Target areas must be clear of nonparticipants before conducting training and testing. When using ordnance with flight termination systems (which terminate the flight of airborne missiles or launch vehicles when they veer from their targeted path), the Navy is required to follow standard operating procedures to ensure public health and safety. In those cases where a weapons system does not have a flight termination system, the size of the target area that needs to be clear of nonparticipants is based on the flight distance of the weapon plus an additional distance beyond the system's performance capability.

3.12.3 Environmental Consequences

This section evaluates how and to what degree the activities described in Chapter 2 (Description of Proposed Action and Alternatives) could impact public health and safety. In this section, each public health and safety stressor is introduced, analyzed by alternative, and analyzed for training activities and testing activities. Tables 2.8-1 through 2.8-5 present the baseline and proposed training and testing activity locations for each alternative (including the number of events and ordnance expended). Tables F-1 and F-2 in Appendix F describe all of the warfare areas and associated stressors that were considered for analysis of public health and safety. The stressors vary in intensity, frequency, duration, and location within the Study Area. The stressors applicable to public health and safety are:

- underwater energy
- in-air energy
- physical interactions
- secondary

Alternatives 1 and 2 include an expansion of the Study Area and pierside training areas, as described in Chapter 2 (Description of the Proposed Action and Alternatives). Alternatives 1 and 2 would adjust locations and tempo of training and testing activities, but existing safety procedures and standard operating procedures would be employed such that no new or additional impacts to public health and safety would occur. Therefore, the Study Area expansion will not be addressed in the analysis below.

Potential public health and safety impacts were evaluated assuming continued implementation of the Navy's current safety procedures for each training and testing activity or group of similar activities. Generally, the greatest potential for the proposed activities to be co-located with public activities would be in coastal areas because most commercial and recreational activities occur close to the shore.

Training and testing activities in the Study Area are conducted in accordance with guidance provided in Fleet Area Control and Surveillance Facility Instructions (U.S. Department of the Navy 2011a, b) and Test and Safety Planning Instructions (U.S. Department of the Navy 2008b, 2009). These instructions provide operational and safety procedures for all normal range events. They also provide information to range users that is necessary to operate safely and avoid affecting nonmilitary activities such as shipping, recreational boating, diving, and commercial or recreational fishing. Ranges are managed in accordance with standard operating procedures that ensure public health and safety. Current requirements and practices (e.g., standard operating procedures) designed to prevent public health and safety impacts are identified in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring).

3.12.3.1 Underwater Energy

Underwater energy can come from acoustic sources or from electromagnetic devices. Active sonar, underwater explosions, airguns, and vessel movements all produce underwater acoustic energy. Sound will travel from air to water during aircraft overflights. Electromagnetic energy can enter the water from mine warfare training devices and from unmanned underwater systems. The potential for the public to be exposed to these stressors would be limited to individuals, such as recreational swimmers or self-contained underwater breathing apparatus (SCUBA) divers, that are underwater and within unsafe proximity of a training or testing event.

Many of the proposed activities generate underwater acoustic energy; however, not all sources rise to the level of consideration in this EIS/OEIS. Swimmers or divers might intermittently hear ship noise or underwater acoustic energy from aircraft overflights if they are near a training or testing event, but public health and safety would not be affected because these events would be infrequent and short in duration. Pierside integrated swimmer defenses are tested with underwater airguns during swimmer defense and diver deterrent training and testing activities; public health and safety would be ensured for these local activities because access to pierside locations by nonparticipants is controlled for safety and security reasons. Because of the infrequency and short duration of the events, underwater acoustic energy from vessel movements, aircraft overflights, and airguns is not analyzed in further detail. Active sonar and underwater explosions are the only sources of underwater acoustic energy evaluated for potential impacts on public health and safety.

The proposed activities that would result in underwater acoustic energy include anti-surface warfare, anti-submarine warfare, mine warfare, surface warfare testing, littoral combat ship testing, sonar maintenance, pierside sonar testing, and unmanned vehicle testing. A limited amount of active sonar would be used during transit between range complexes and training and testing locations.

The effect of active sonar on humans varies with the sonar frequency. Of the four types of sonar (very high-, high-, mid-, and low-frequency), mid-frequency and low-frequency sonar have the greatest potential to impact humans because of the range of human hearing. Underwater explosives cause a physical shock front that compresses the explosive material, and the pressure wave then passes into the surrounding water. Generally, the pressure wave would be the primary cause of injury. The effects of an underwater explosion depend on several factors, including the size, type, and depth of the explosive charge and where it is in the water column.

Systems like the Organic Airborne and Surface Influence Sweep emit an electromagnetic field and sound to simulate the presence of a ship. Unmanned underwater vehicles, some unmanned surface vehicles, and towed devices use electromagnetic energy. Electronic warfare activities involve aircraft, surface ship, and submarine crews attempting to control portions of the electromagnetic spectrum to degrade or deny the enemy’s ability to take defensive actions. An electromagnetic signal dissipates quickly with increasing distance from its source. The literature lacks evidence to conclude that any adverse health effects result from exposure to electromagnetic energy, which is why no federal standards have been set for occupational exposures to this type of energy. Because standard operating procedures require an exercise area to be clear of participants, the public would not be exposed to electromagnetic energy the way a worker could experience long-term, occupational exposures. In the unlikely event that the public was exposed, the level of electromagnetic energy associated with the Proposed Action would not be enough to pose a health or safety risk.

As previously stated, the potential for the public to be exposed to these stressors would be limited to divers within unsafe proximity of an event. SCUBA diving is a popular recreational activity that is typically concentrated around known dive attractions such as reefs and shipwrecks. In general, recreational divers should not exceed 130 ft. (39.6 m) (Professional Association of Diving Instructors 2012). This depth limit typically limits this activity's distance from shore. Therefore, training and testing activities closest to shore have the greatest potential to co-occur with the public.

Swimmers and recreational SCUBA divers are not expected to be near Navy pierside locations (which include shipyards) because access to these areas is controlled for safety and security reasons. Locations of popular offshore diving spots are well documented, and dive boats (typically well marked) and diver-down flags would be visible from the ships conducting the training and testing. Therefore, co-occurrence of recreational divers and Navy activities is unlikely. Swimmers and recreational divers are not expected to be near training and testing locations where active sonar, underwater explosions, and electromagnetic activities would occur because of the strict procedures for clearance of nonparticipants before conducting activities.

The U.S. Navy Dive Manual (U.S. Department of the Navy 2011d) prescribes safe distances for divers from active sonar sources and underwater explosions. Safety precautions for use of electromagnetic energy are specified in DoD Instruction 6055.11 (U.S. Department of Defense 2002, 2009) and Military Standard 464A (U.S. Department of Defense 2002). These distances would be used as the standard safety buffers for underwater energy to protect public health and safety. If unauthorized personnel were detected within the exercise area, the activity would be temporarily halted until the area was again cleared and secured. Therefore, the public is unlikely to be exposed to underwater energy at Navy pierside locations, in training or testing areas, or in ports.

3.12.3.1.1 No Action Alternative

3.12.3.1.1.1 Training

Under the No Action Alternative, active sonar training activities such as anti-submarine warfare, mine warfare, and sonar maintenance would continue at current levels and within established ranges and training locations, including the Hawaii Range Complex and the SOCAL Range Complex, and other HSTT areas. Most of the sonar training events would be in the SOCAL and HRC range complexes.

Activities involving underwater explosions, such as anti-surface warfare and mine warfare, also would continue at current levels and within established ranges and training locations. Current locations for underwater explosions include specific training areas in the HRC, in the SOCAL Range Complex, and in Silver Strand Training Complex (SSTC).

The analysis indicates that no impact on public health and safety would result from training activities using underwater energy, based on the Navy's implementation of strict operating procedures that protect public health and safety. These operating procedures include ensuring clearance of the area before commencing training activities involving underwater energy. Because of the Navy's safety procedures, the potential for training activities using underwater energy to impact public health and safety under the No Action Alternative would be low.

3.12.3.1.1.2 Testing

Under the No Action Alternative, active sonar testing activities such as anti-submarine warfare, mine warfare, pierside sonar testing, unmanned vehicle testing, and sonar maintenance would continue at current levels and in current locations, including areas such as the Hawaii and SOCAL OPAREAs. Pierside testing of active sonar would continue in Pearl Harbor and in San Diego Bay. Most of these activities would occur in the SOCAL Range Complex.

Testing activities involving underwater explosions, such as anti-air warfare, anti-surface warfare, anti-submarine warfare, mine warfare, and surface combatant sea trials also would continue at current levels and within established ranges and locations. Current locations for underwater explosions include specific training areas in HRC (Puuloa Underwater Range, Marine Corps Base Hawaii, Marine Corps Training Area Bellows, Barbers Point Underwater Range, Ewa Training Minefield, and Lima Landing) and in the SOCAL Range Complex (San Clemente Island's Northwest Harbor and Horse Beach Cove, Shallow Water Training Range), and SSTC's Boat Lanes 1–14.

The analysis indicates that no impact on public health and safety would result from testing activities using underwater energy, based on the Navy's implementation of strict operating procedures that protect public health and safety. These operating procedures include ensuring clearance of the area before commencing testing activities involving underwater energy. Because of the Navy's safety procedures, the potential for testing activities to impact public health and safety under the No Action Alternative would be low.

3.12.3.1.2 Alternative 1

Alternative 1 consists of the activities in the No Action Alternative plus the expansion of the Study Area and adjustments in the locations and tempos of training and testing activities. Alternative 1 includes changes in force structure (personnel, weapons and assets), new or upgraded weapons and platforms, and the training and testing required for proficiency with these systems. Alternative 1 includes the expansion of the Study Area to include the Transit Corridor and pierside activities in San Diego Bay and Pearl Harbor. This expansion would not increase the potential for public exposure over the No Action Alternative because the same safety procedures would be in place to assure that these areas were clear of nonparticipants.

3.12.3.1.2.1 Training

Active sonar training would continue at current locations under Alternative 1. In many instances, however, the potential activity areas would be expanded (see tables in Chapter 2). Locations for active sonar training include the same areas as described under the No Action Alternative, as well as the Transit Corridor and pierside areas in San Diego Bay and Pearl Harbor. While Alternative 1 would expand the locations and increase the tempos of active sonar training activities, the Navy would continue to implement standard operating and safety procedures; therefore, the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely to increase.

Activities involving underwater explosions, such as anti-surface warfare, mine warfare, and civilian port defense, would also continue within established ranges and training locations, as described under the No Action Alternative. While Alternative 1 would adjust locations and tempos of underwater explosives training activities, the Navy would continue to implement standard operating and safety procedures; therefore, an increased potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely. The Navy's safety procedures would ensure that the potential for training activities to impact public health and safety under Alternative 1 would be low.

3.12.3.1.2.2 Testing

The locations and tempo of active sonar testing activities would increase over the No Action Alternative. Alternative 1 also includes the expansion of the Study Area, plus changes in force structure (personnel, weapons, and assets), new or upgraded weapons and platforms, and the testing required for these systems.

Under Alternative 1, active sonar testing activities such as anti-submarine warfare, mine warfare, pierside sonar testing, unmanned vehicle testing, and sonar maintenance would increase. These activities would occur in established locations and ranges, as described under the No Action Alternative. Pierside testing of active sonar would continue to occur in San Diego Bay and Pearl Harbor. While Alternative 1 would increase the locations and tempo of active sonar testing activities, the Navy would continue to implement standard operating and safety procedures, so the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely to increase.

Testing activities involving underwater explosions, such as anti-air warfare, anti-surface warfare, anti-submarine warfare, mine warfare, surface combatant sea trials, littoral combat ship testing, combat ship qualifications, and at-sea explosive testing would occur within established ranges and locations. Proposed locations for underwater explosions are the same as described under the No Action Alternative. While Alternative 1 would increase the tempo of underwater explosives testing activities, the Navy would continue to implement standard operating and safety procedures; therefore, the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely to increase. Because of the Navy’s safety procedures, the potential for testing activities to impact public health and safety under Alternative 1 would be negligible.

3.12.3.1.3 Alternative 2 (Preferred Alternative)

Alternative 2 consists of the activities in the No Action Alternative, plus adjustments to locations and tempo of training and testing activities. Alternative 2 includes changes in force structure (personnel, weapons, and assets), new or upgraded weapons and platforms, and the training and testing required for proficiency with these systems. Alternative 2 includes the expansion of the Study Area and pierside areas of San Diego Bay and Pearl Harbor. This expansion would not increase the potential for public exposure over the No Action Alternative because the same safety procedures would be in place to make sure these areas are clear of nonparticipants.

3.12.3.1.3.1 Training

Alternative 2 is similar to Alternative 1 in the increase in active sonar, underwater explosions, and electromagnetic activities over the No Action Alternative. Alternative 2 is identical to Alternative 1 in the proposed locations for these activities. As concluded under Alternative 1, because of the Navy’s safety procedures, the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely to increase.

3.12.3.1.3.2 Testing

Similar to Alternative 1, Alternative 2 would increase active sonar testing activities such as anti-submarine warfare, mine warfare, pierside sonar testing, unmanned vehicle testing, and sonar maintenance. These activities would continue in established locations and ranges, as described under the No Action Alternative. Pierside testing of active sonar would continue in Pearl Harbor and in San Diego Bay. Changes in the locations and tempo of active sonar testing activities would not impact public health or safety because the safety procedures used under the No Action Alternative would still be in place.

Testing activities involving underwater explosions, such as anti-air warfare, anti-surface warfare, anti-submarine warfare, mine warfare, surface combatant sea trials, littoral combat ship testing, combat ship qualifications, and at-sea explosive testing would occur within established ranges and locations, as described under the No Action Alternative. Changes in the locations and tempo of underwater explosion testing activities could not impact public health or safety because the safety procedures used under the No Action Alternative would still be in place. Because of the Navy's safety procedures, the potential for underwater testing activities to impact public health and safety under Alternative 2 would be negligible.

3.12.3.2 In-Air Energy

In-air energy stressors include sources of electromagnetic energy and lasers. The sources of electromagnetic energy include radar, navigational aids, and electronic warfare systems. These systems operate similarly to other navigational aids and radars at local airports and television weather stations throughout the United States. Electronic warfare systems emit electromagnetic energy similar to that from cell phones, hand-held radios, commercial radio stations, and television stations. Current practices protect Navy personnel and the public from electromagnetic energy hazards. These procedures include setting the heights and angles of electromagnetic energy transmissions to avoid direct human exposure, posting warning signs, establishing safe operating levels, and activating warning lights when radar systems are operational. Procedures also are in place to limit public and participant exposure from electromagnetic energy emitted by military aircraft. As stated in Section 3.12.3.1 (Underwater Energy), the level of electromagnetic energy associated with the Proposed Action would not be enough to pose a health or safety risk to the public.

A comprehensive safety program exists for the use of lasers. Current Navy practices protect individuals from the hazard of severe eye injury caused by laser energy. Laser safety requires pilots to verify that target areas are clear prior to commencement of an exercise. In addition, during actual laser use, the aircraft run-in headings are restricted to preclude inadvertent lasing of areas where the public may be present.

Training and testing activities involving electromagnetic energy include electronic warfare activities that use airborne and surface electronic jamming devices to defeat tracking and communications systems. Training activities involving low-energy lasers include anti-surface warfare, mine warfare, and Homeland Security/Anti-Terrorism Force Protection with Unmanned Vehicles. Testing activities involving low-energy lasers include surface warfare, air exercises at the test range, and mine warfare testing.

3.12.3.2.1 No Action Alternative

3.12.3.2.1.1 Training

Under the No Action Alternative, electronic warfare training activities involving electromagnetic energy sources would continue at current levels and locations, including the Hawaii OPAREA and the SOCAL Range Complex's Electronic Warfare Range. Laser targeting activities and mine detection activities using lasers also would continue at current levels and within established ranges and training locations, including the HRC's Warning Area 188 and the SOCAL Range Complex's Southern California Anti-Submarine Warfare Range and San Clemente Island Shore Bombardment Range.

The public would not likely be exposed to electromagnetic energy sources or lasers under the No Action Alternative. Based on the Navy's strict safety procedures for use of lasers and electronic warfare, these activities would not likely be conducted close enough to the public to pose an increased risk. Because of the Navy's safety procedures, the potential for these training activities to impact public health and safety under the No Action Alternative would be negligible.

3.12.3.2.1.2 Testing

Under the No Action Alternative, electronic warfare testing activities involving electromagnetic energy sources would continue at current levels and within established ranges and testing locations. Laser targeting activities and mine detection activities using lasers would continue at current levels and within established ranges and locations.

The public would not likely be exposed to electromagnetic energy sources or lasers from testing activities under the No Action Alternative. Based on the Navy's strict safety procedures for use of lasers and electronic warfare, these activities would not likely be conducted close enough to the public to pose an increased risk. Because of the Navy's safety procedures, the potential for these testing activities to impact public health and safety under the No Action Alternative would be negligible.

3.12.3.2.2 Alternative 1

Alternative 1 consists of the activities in the No Action Alternative plus adjustments to locations and tempos of training and testing activities. Alternative 2 includes changes in force structure (personnel, weapons, and assets), new or upgraded weapons and platforms, and the training and testing required for proficiency with these systems. Alternative 1 includes the expansion of the Study Area to include the Transit Corridor, and Navy piers in San Diego Bay and Pearl Harbor. This expansion would not increase the potential for public exposure over the No Action Alternative because the same safety procedures would be in place to ensure that these areas are clear of nonparticipants.

3.12.3.2.2.1 Training

Under Alternative 1, the number of training activities that use electromagnetic energy would increase, and would continue to occur within established ranges and training locations, as described under the No Action Alternative. Laser targeting activities and mine detection activities using lasers would increase but also would occur within established ranges and training locations.

While Alternative 1 would increase locations and tempos of training activities involving electromagnetic energy and lasers, the Navy would continue to implement standard operating and safety procedures. Therefore, the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely to increase.

3.12.3.2.2.2 Testing

Under Alternative 1, the number of testing activities that use electromagnetic energy would increase, and would continue to occur within established ranges and testing locations. Testing activities that use electromagnetic energy would take place in the same areas as described under the No Action Alternative. Additional locations proposed under this alternative include pierside locations in San Diego and in Pearl Harbor.

While Alternative 1 would increase locations and tempos of testing activities involving electromagnetic energy and lasers, the Navy would continue to implement standard operating and safety procedures. Therefore, an increased potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely.

3.12.3.2.3 Alternative 2 (Preferred Alternative)

Alternative 2 consists of the activities in the No Action Alternative plus adjustments to locations and tempo of training and testing activities. This alternative includes changes in force structure (personnel, weapons, and assets), new or upgraded weapons and platforms, and the training and testing required for proficiency with these systems. Alternative 2 includes the expansion of the Study Area to include the Transit Corridor and Navy piers in San Diego Bay and Pearl Harbor. This expansion would not increase the potential for public exposure over the No Action Alternative because the same safety procedures would be in place to make sure these areas are clear of nonparticipants.

3.12.3.2.3.1 Training

Alternative 2 is similar to Alternative 1 in the increase in electromagnetic energy and laser training activities over the No Action Alternative. Alternative 2 is identical to Alternative 1 in the proposed locations for these activities. As concluded under Alternative 1, impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely.

While Alternative 2 would adjust locations and tempo of training activities involving electromagnetic energy and lasers, the Navy would continue to implement standard operating and safety procedures; therefore, the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely to increase.

3.12.3.2.3.2 Testing

Similar to Alternative 1, Alternative 2 would increase electromagnetic energy and laser testing activities. Electromagnetic energy activities would continue to occur in established location and ranges, as described under the No Action Alternative, and at pierside locations in San Diego and Pearl Harbor. Laser targeting activities would occur in the HRC's Warning Area 188 and the SOCAL Range Complex's Southern California Anti-Submarine Warfare Range and San Clemente Island's Shore Bombardment Range. Changes in the locations and tempo of in-air testing activities and the addition of new activities would not impact public health or safety because safety procedures would be in place.

While Alternative 2 would adjust locations and tempos of testing activities involving electromagnetic energy and lasers, the Navy would continue to implement standard operating and safety procedures; therefore, the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be unlikely to increase.

3.12.3.3 Physical Interactions

Public health and safety could be impacted by direct physical interactions with Navy activities. Navy aircraft, vessels, targets, munitions, towed devices, seafloor devices, and other training and testing expended materials could have a direct physical encounter with recreational, commercial, institutional, and governmental aircraft, vessels, and users such as swimmers, divers, and anglers.

Both Navy and public aircraft operate under visual flight rules requiring them to observe and avoid other aircraft. In addition, Notices to Airmen advise pilots about when and where Navy training and testing activities are scheduled. Finally, Navy personnel are required to verify that the range is clear of nonparticipants before initiating any potentially hazardous activity. Together, these procedures would minimize the potential for adverse interactions between Navy and nonparticipant aircraft. The Navy's standard operating procedures assure that private and commercial aircraft traversing the Study Area during training or testing activities do not interact with Navy aircraft, ordnance, or aerial targets.

Both Navy and public vessels operate under maritime navigational rules requiring them to observe and avoid other vessels. In addition, Notices to Mariners advise vessel operators about when and where Navy training and testing activities are scheduled. Finally, Navy personnel are required to verify that the range is clear of nonparticipants before initiating any potentially hazardous activity. Together, these procedures minimize the potential for adverse interactions between Navy and nonparticipant vessels. The Navy's standard operating procedures assure that private and commercial vessels traversing the Study Area during training or testing activities do not interact with Navy vessels, ordnance, or surface targets.

Recreational diving within the Study Area takes place primarily at known diving sites such as shipwrecks and reefs. The locations of these popular dive sites are well documented, dive boats are typically well-marked, and diver-down flags are visible from a distance. As a result, ships conducting training or testing activities would easily avoid dive sites. Interactions between training and testing activities and recreational divers thus would be minimized, reducing the potential for collisions or ship strikes. Similar knowledge and avoidance of popular fishing areas would minimize interactions between training and testing activities and recreational fishing.

Commercial and recreational fishers could encounter military expended materials that could entangle fishing gear and could pose a safety risk. The Navy would continue to recover targets at or near the surface that were used during training or testing to ensure that they would not pose a collision risk. Unrecoverable pieces of military expended materials are typically small (such as sonobuoys), constructed of soft materials (such as target cardboard boxes or tethered target balloons), or intended to sink to the bottom after their useful function was completed, so they would not be a collision risk to civilian vessels or equipment. Thus, these targets do not pose a safety risk to individuals using the area for recreation because the public would not likely be exposed to these items before they sank to the seafloor.

As discussed in Sediments and Water Quality (Section 3.1), a west coast study categorized types of marine debris collected by a trawler during a groundfish survey. Military expended materials were categorized as plastic, metal, fabric and fiber, and rubber comprising 7.4, 6.2, 13.2, and 4.7 percent of the total count of items collected, respectively. The footprint of military expended materials in the Study Area is discussed in Marine Habitats (Section 3.3), which concluded that if all military expended materials were located side by side in the Study Area, the footprint would be approximately 0.05 square nautical miles. Because the footprint of military expended materials in the Study Area is small, recreational and commercial fishers probably would not encounter military expended materials.

Section 3.1 (Sediments and Water Quality) also discussed the low failure rates of munitions, which indicate that most munitions function as intended. While fish trawls may encounter undetonated ordnance lying on the ocean floor, such an encounter would be unlikely because the density of munitions in the Study Area is low. The Army Corps of Engineers prescribes the following procedure if military munitions are encountered: recognize when you may have encountered a munition, retreat from the area without touching or disturbing the item, and report the item to local law enforcement by calling 911 or the U.S. Coast Guard.

The analysis focuses on the potential for a direct physical interaction with an aircraft, vessel, target, or expended training item. All proposed activities have some potential for a direct physical interaction that could pose a risk to public health or safety, so the following analysis is not activity-specific. While some of the activities may not pose a potential for a direct physical interaction (like pierside testing) the platforms used in the activity (aircraft, vessel, towed device) could have a direct physical interaction that could pose a risk. The greatest potential for a physical interaction would be along the coast because of the high concentration there of public activities.

3.12.3.3.1 No Action Alternative

3.12.3.3.1.1 Training

Under the No Action Alternative, training activities would continue at current levels and within established locations. The potential for a direct physical interaction between the public and aircraft, vessels, targets, or expended materials would not change from the baseline. The Navy implements strict operating procedures that protect public health and safety. These operating procedures include ensuring clearance of the area prior to commencing training activities.

The analysis indicates that public health and safety would not be affected by physical interactions with training activities, based on the Navy's implementation of strict operating procedures that protect public health and safety. These operating procedures include ensuring clearance of the area before commencing training activities involving physical interactions. Because of the Navy's safety procedures, the potential for training activities to impact public health and safety under the No Action Alternative would be negligible.

3.12.3.3.1.2 Testing

Because the potential for a physical interaction is not activity-specific or location-specific, the analysis of the training activities above applies to testing activities under the No Action Alternative. As concluded above, because of the Navy's safety procedures, the potential for testing activities to impact public health and safety under the No Action Alternative would be negligible.

3.12.3.3.2 Alternative 1

Alternative 1 consists of the activities included in the No Action Alternative, plus adjustments in the locations and tempos of training and testing activities. This alternative includes changes in force structure (personnel, weapons, and assets), new or upgraded weapons and platforms, and the training and testing required for proficiency with these systems. Alternative 1 includes the expansion of the Study Area to include the Transit Corridor, and Navy piers in San Diego Bay and Pearl Harbor. This expansion would not increase the potential for public exposure over the No Action Alternative because the same safety procedures would be in place to make sure these areas are clear of nonparticipants.

3.12.3.3.2.1 Training

Under Alternative 1, the number of training activities would increase, but would continue within established locations. However, the increased number of aircraft and vessel movements or use of targets and expended materials would be conducted under the same safety and inspection procedures as under the No Action Alternative. While Alternative 1 would adjust locations and tempos of training activities, the Navy would continue to implement standard operating and safety procedures. Therefore, the potential for impacts on public health and safety, beyond those identified under the No Action Alternative, would be negligible.

3.12.3.3.2.2 Testing

Because the potential for a physical interaction is not activity-specific or location-specific, the analysis of the training activities presented above also applies to testing activities under Alternative 1. As concluded above, because of the Navy's safety procedures, the potential for testing activities to impact public health and safety under Alternative 1 would be negligible.

3.12.3.3.3 Alternative 2 (Preferred Alternative)

Alternative 2 consists of the activities included in the No Action Alternative plus adjustments to locations and tempos of training and testing activities. This alternative includes changes in force structure (personnel, weapons, and assets), new or upgraded weapons and platforms, and the training and testing required for proficiency with these systems. Alternative 2 includes the expansion of the Study Area to include the Transit Corridor and Navy piers in San Diego Bay and Pearl Harbor. This expansion would not increase the potential for public exposure over the No Action Alternative because the same safety procedures would be in place to make sure these areas are clear of nonparticipants.

3.12.3.3.3.1 Training

Under Alternative 2, the number of training activities would increase. The potential for a direct physical interaction between the public and aircraft, vessels, targets, or expended materials would also increase. While Alternative 2 would adjust locations and tempos of training activities, the Navy would continue to implement standard operating and safety procedures. Therefore, the potential for impacts on public health and safety beyond those identified under the No Action Alternative would be negligible.

3.12.3.3.3.2 Testing

The potential for a physical interaction is not activity-specific or location-specific, so the analysis of the training activities presented above also applies to testing activities under Alternative 2. As concluded above, because of the Navy's safety procedures, the potential for testing activities to impact public health and safety under Alternative 1 would be negligible.

3.12.3.4 Secondary Impacts

Public health and safety could be impacted if sediment or water quality were degraded. Section 3.1 (Sediments and Water Quality) considered the impacts on marine sediments and water quality of explosives and explosive byproducts, metals, chemicals other than explosives, and other materials (marine markers, flares, chaff, targets, and miscellaneous components of other materials). The analysis determined that neither state nor federal standards or guidelines would be violated by the No Action Alternative, Alternative 1, or Alternative 2. Because these standards and guidelines are structured to protect human health, and the proposed activities do not violate them, no secondary impacts on public health and safety would result from the training and testing activities proposed by the No Action Alternative, Alternative 1, or Alternative 2.

3.12.4 Summary of Potential Impacts (Combined Impacts of All Stressors) on Public Health and Safety

Activities described in this EIS/OEIS that could affect public health or safety include those that release underwater energy, in-air energy, or physical interactions, or that have secondary impacts from changes in sediment or water quality. Under the No Action Alternative, Alternative 1, or Alternative 2, these activities would be widely dispersed throughout the Study Area. Such activities also are dispersed temporally (i.e., few stressors would be present at the same time). For these reasons, no greater impacts from the combined operation of more than one stressor are expected. The aggregate impact on public health and safety would not observably differ.

There are no figures in this section.

4 CUMULATIVE IMPACTS

4.1 INTRODUCTION

The analysis of cumulative impacts (or cumulative effects)[1] presented in this section follows the requirements of the National Environmental Policy Act (NEPA) and Council on Environmental Quality guidance (Council on Environmental Quality 1997). The Council on Environmental Quality regulations (40 Code of Federal Regulations [C.F.R.] §§ 1500-1508) provide the implementing regulations for NEPA. The regulations define cumulative impacts as

> "…the impact on the environment which results from the incremental impact of the action when added to the other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 C.F.R. § 1508.7)."

While a single project may have minor impacts, overall impacts may be collectively significant when the project is considered together with other projects on a regional scale. A cumulative impact is the additive effect of all projects in the geographic area. The Council on Environmental Quality provides guidance on cumulative impact analysis in *Considering Cumulative Impacts under the National Environmental Policy Act* (Council on Environmental Quality 1997). This guidance further identifies cumulative impacts as those environmental impacts resulting "from spatial and temporal crowding of environmental perturbations. The impacts of human activities will accumulate when a second perturbation occurs at a site before the ecosystem can fully rebound from the impacts of the first perturbation." This guidance observes that "no universally accepted framework for cumulative impacts analysis exists…" while noting that certain general principles have gained acceptance. The Council on Environmental Quality provides guidance on the extent to which agencies of the federal government are required to analyze the environmental impacts of past actions when they describe the cumulative environmental effect of an action. This guidance provides that an analysis of cumulative impacts might encompass geographic boundaries beyond the immediate area of an action and a timeframe that includes past actions and foreseeable future actions. Thus, the Council on Environmental Quality guidelines observe, "[it] is not practical to analyze cumulative impacts of an action on the universe; the list of environmental impacts must focus on those that are truly meaningful."

4.2 APPROACH TO ANALYSIS

4.2.1 OVERVIEW

Cumulative impacts were analyzed for each resource addressed in Chapter 3 (Affected Environment and Environmental Consequences) for the No Action Alternative, Alternative 1, and Alternative 2 (the alternatives) in combination with past, present, and reasonably foreseeable future actions. The cumulative impacts analysis included the following steps, described in more detail below:

1. Identify appropriate level of analysis for each resource.
2. Define the geographic boundaries and timeframe for the cumulative impacts analysis.
3. Describe current resource conditions and trends.

[1] Council on Environmental Quality Regulations provide that the terms "cumulative effects" and "cumulative impacts" are synonymous (40 C.F.R. § 1508.8[b]); the terms are used interchangeably by various sources, but the term "cumulative impacts" will be used in this document except for quotations, for continuity.

4. Identify potential impacts of each alternative that might contribute to cumulative impacts.
5. Identify past, present, and other reasonably foreseeable future actions that affect each resource.
6. Analyze potential cumulative impacts.

4.2.2 IDENTIFY APPROPRIATE LEVEL OF ANALYSIS FOR EACH RESOURCE

In accordance with Council on Environmental Quality guidance (Council on Environmental Quality 1997), the cumulative impacts analysis focused on impacts that are "truly meaningful." The level of analysis for each resource was commensurate with the intensity of the impacts identified in Chapter 3 (Affected Environment and Environmental Consequences). The rationale for the level of analysis applied to each resource is described in Section 4.4 (Resource-Specific Cumulative Impacts).

4.2.3 DEFINE THE GEOGRAPHIC BOUNDARIES AND TIMEFRAME FOR ANALYSIS

The geographic boundaries for the cumulative impacts analysis included the entire Hawaii-Southern California (SOCAL) Training and Testing (HSTT) Study Area (Study Area) (Figure 2.1-1). The geographic boundaries for cumulative impacts analysis for marine mammals and sea turtles were expanded to include activities outside the Study Area that might impact migratory marine mammals and sea turtles. Primary considerations from outside the Study Area include impacts associated with maritime traffic (e.g., vessel strikes and underwater noise) and commercial fishing (e.g., bycatch and entanglement).

Determining the timeframe for the cumulative impacts analysis requires estimating the length of time the impacts of the Proposed Action would last (Council on Environmental Quality 1997) and considering the specific resource in terms of its history of degradation. The Proposed Action includes ongoing and anticipated future training and testing activities. While Navy training and testing requirements change over time in response to world events and several other factors, the general types of activities addressed by this Environmental Impact Statement (EIS)/Overseas EIS (OEIS) are expected to continue indefinitely, and the associated impacts would occur indefinitely. Likewise, some reasonably foreseeable future actions and other environmental considerations addressed in the cumulative impacts analysis are expected to continue indefinitely (e.g., oil and gas production, maritime traffic, commercial fishing). Therefore, the cumulative impacts analysis is not bounded by a specific future timeframe. For past actions, the cumulative impacts analysis only considers those actions or activities that have ongoing impacts.

While the cumulative impacts analysis is not limited by a specific timeframe, it should be recognized that available information, uncertainties, and other practical constraints limit the ability to analyze cumulative impacts for the indefinite future. Navy environmental planning and compliance for training and testing activities is an ongoing process. The Navy intends to submit applications to the National Marine Fisheries Service (NMFS) for Marine Mammal Protection Act (MMPA) authorizations supported by this EIS/OEIS. The anticipated effective dates for these MMPA authorizations would be a 5-year period from January 2014 through December 2018. Future environmental planning documents will include cumulative impacts analysis based on information available at that time.

4.2.4 DESCRIBE CURRENT RESOURCE CONDITIONS AND TRENDS

The Affected Environment sections of Chapter 3 (Affected Environment and Environmental Consequences) describe current resource conditions and trends, and they discuss how past and present human activities influence each resource. The current aggregate impacts of past and present actions are reflected in the baseline information presented in Chapter 3 (Affected Environment and Environmental

Consequences). This information is used in the cumulative impacts analysis to understand how past and present actions are currently impacting each resource and to provide the context for the cumulative impacts analysis.

4.2.5 Identify Potential Impacts of The Alternatives That Might Contribute to Cumulative Impacts

Direct and indirect impacts of the alternatives, presented in Chapter 3 (Affected Environment and Environmental Consequences), were reviewed to identify impacts relevant to the cumulative impacts analysis. Key factors considered included the current status and sensitivity of the resource and the intensity, duration, and spatial extent of the impacts for each stressor. In general, long-term rather than short-term impacts and widespread rather than localized impacts were considered more likely to contribute to cumulative impacts. For example, for biological resources, population-level impacts were considered more likely to contribute to cumulative impacts than were individual-level impacts. Negligible impacts were not considered further in the cumulative impacts analysis. For marine mammals, any stressor that is expected to result in Level A harassment or Level B harassment, as defined by MMPA, was considered in the cumulative impacts analysis. For Endangered Species Act (ESA)-listed species, any stressor that may affect and is likely to adversely affect the species was considered in the cumulative impacts analysis. Stressors that were determined by the Navy to have no effect or that may affect but are not likely to adversely affect ESA-listed species were not analyzed in detail in the cumulative impacts analysis. A determination of "may affect, not likely to adversely affect" indicates that the impacts would be discountable (extremely unlikely) or insignificant.

4.2.6 Identify Other Actions and Other Environmental Considerations That Affect Each Resource

A list of other actions was compiled for the Study Area and surrounding areas based on information obtained during the scoping process (Appendix E [Public Participation]), communications with other agencies, a review of other military activities, literature review, previous NEPA analyses for some of the other actions, and other available information. Identified future actions were reviewed to determine if they should be considered further in the cumulative impacts analysis. Factors considered when identifying other actions to be included in the cumulative impacts analysis included the following:

- Whether the other action is likely or probable (i.e., reasonably foreseeable), rather than merely possible or speculative.
- The timing and location of the other action in relationship to proposed training and testing activities.
- Whether the other action and each alternative would affect the same resources.
- The current conditions, trends, and vulnerability of resources affected by the other action.
- The duration and intensity of the impacts of the other action.
- Whether the impacts have been truly meaningful, historically significant, or identified previously as a cumulative impact concern.

In addition to identifying reasonably foreseeable future actions, other environmental considerations for the cumulative impacts analysis were identified and described. These other considerations include major environmental stressors or issues (e.g., ocean pollution, ocean noise, coastal development, etc.) that tend to be widespread and arise from routine human activities and multiple past, present, and future actions. Including these other environmental considerations allows an analysis of the current aggregate impacts of past and present actions, as well as reasonably foreseeable actions.

4.2.7 Analyze Potential Cumulative Impacts

The current impacts of past and present actions and the anticipated impacts of reasonably foreseeable future actions were characterized and summarized. The incremental impacts of each alternative were then added to the combined impacts of all other actions to describe the cumulative impacts that would result if the No Action Alternative, Alternative 1, or Alternative 2 were implemented. The cumulative impacts analysis considered additive, synergistic, and antagonistic impacts. A qualitative analysis was conducted in most cases based on the available information. The analysis in Chapter 3 (Affected Environment and Environmental Consequences) indicates that the direct and indirect impacts of the No Action Alternative, Alternative 1, and Alternative 2 would be similar for many of the stressors. Therefore, much of the cumulative impacts discussion applies to all three alternatives. Specific differences between the alternatives are discussed when appropriate.

4.3 Other Actions Analyzed in the Cumulative Impacts Analysis

4.3.1 Overview

Table 4.3-1 lists the other actions and other environmental considerations identified for the cumulative impacts analysis. Descriptions of each action and environmental consideration carried forward for analysis are provided in the following sections.

4.3.2 Oil and Natural Gas Exploration, Extraction, and Production

4.3.2.1 Proposed Outer Continental Shelf Oil and Gas Leasing Program 2012–2017

Military activities and oil and gas operations have been conducted concurrently offshore in southern and south-central California for more than 50 years. During that period there have been no major incidents or accidents involving military and outer continental shelf oil and gas operations. Oil and gas resources of the Outer Continental Shelf are governed by the Outer Continental Shelf Lands Act which requires a 5-year leasing program. Areas off the Pacific coast are not included in the 2012–2017 Outer Continental Shelf Oil and Gas Leasing Program finalized by the U.S. Department of the Interior Bureau of Ocean Energy Management.

4.3.2.2 Liquefied Natural Gas Terminals

Liquefied natural gas facilities have been proposed at several locations throughout North America in recent years in response to the quickly escalating domestic demand for this fuel. Currently the only existing terminal near the Study Area is in Baja California, Mexico and only one additional terminal is proposed for the area immediately north of the Study Area (Federal Energy Regulatory Commission 2011).

Potential environmental impacts include those associated with additional ship traffic, underwater noise from construction and operation, and potential releases of liquefied natural gas. Releases of liquefied natural gas can result from equipment leaks or spills during operations. Releases can be accidental (e.g., ship collision) or intentional (e.g., sabotage or terrorist acts).

Table 4.3-1: Other Actions and Other Environmental Considerations Identified for the Cumulative Impacts Analysis

#	Name of Action	Lead Agency or Proponent	Location in the Study Area/LME	Timeframe	Retained for Further Analysis?
Oil and Natural Gas Exploration, Extraction, and Production					
1	Outer Continental Shelf Oil and Gas Leasing Program 2012–2017	Bureau of Ocean Energy Management	All LMEs	Past, present, and foreseeable future	Dismissed, as this leasing program does not include any Pacific Region areas and it therefore poses no potential impact within the Study Area.
2	Liquefied Natural Gas Terminals	Bureau of Ocean Energy Management, Regulation and Enforcement	California Current LME	Past, present, and foreseeable future	Retained.
Offshore Power Generation					
3	Marine Hydrokinetic Projects	Federal Energy Regulatory Commission	All LMEs	Foreseeable future	Retained.
Dredge Disposal, Beach Nourishment, and Mining					
4	Offshore Dredge Disposal Program	U.S. Army Corps of Engineers	All LMEs	Past, present, and future	Dismissed because action involves programs related to dredging and beach nourishment projects. These activities (if applicable) would be analyzed on an individual basis for cumulative impacts.
5	Beach Nourishment Programs	U.S. Army Corps of Engineers	All LMEs	Past, present, and future	Dismissed because of negligible to minor impacts on resources in the area affected by this activity and the Proposed Action.
Other Military Activities					
6	Scripps Pier Replacement at Point Loma	U.S. Department of the Navy	California Current LME	Present and future	Retained.
7	Naval Base Point Loma Fuel Pier	U.S. Department of the Navy	California Current LME	Past, present, and future	Retained.
9	Submarine Drive-In Magnetic Silencing Facility Beckoning Point, Oahu, Hawaii	U.S. Department of the Navy	Insular Pacific-Hawaiian LME	Past, present, and future	Retained.

Table 4.3-1: Other Actions and Other Environmental Considerations Identified for the Cumulative Impacts Analysis (continued)

#	Name of Action	Lead Agency or Proponent	Location in the Study Area/LME	Timeframe	Retained for Further Analysis?
Other Military Activities (continued)					
10	Establishment and Realignment of Navy Helicopter Squadrons on the West Coast	U.S. Department of the Navy	California Current LME	Future	Retained.
11	San Clemente Island Fuel Storage and Distribution System	U.S. Department of the Navy	California Current LME	Past, present, and future	Retained.
12	Wave Energy Test Site	U.S. Department of the Navy University of Hawaii U.S. Department of Energy	Insular Pacific-Hawaiian LME	Future	Retained.
13	Pier 12 Replacement and Dredging Naval Base San Diego	U.S. Department of the Navy	California Current LME	Future	Retained.
14	Homeporting Littoral Combat Ships on the West Coast	U.S. Department of the Navy	California Current LME	Future	Retained for activities associated with homeporting. While NEPA has not been completed and a decision has not been made, the Navy's envisaged homeporting location for the west coast Littoral Combat Ships is Naval Base San Diego. Impacts from Littoral Combat Ship training are considered under Alternatives 1 and 2 and are not considered in cumulative impacts.
15	Surveillance Towed Array Sensor System Low Frequency Active Sonar	U.S. Department of the Navy	All LMEs	Future	Retained
16	Space and Naval Warfare Systems Command Electronic Harbor Security System	U.S. Department of the Navy	California Current LME	Current	Retained.

Table 4.3-1: Other Actions and Other Environmental Considerations Identified for the Cumulative Impacts Analysis (continued)

#	Name of Action	Lead Agency or Proponent	Location in the Study Area/LME	Timeframe	Retained for Further Analysis?
Other Military Activities (continued)					
17	Construction of SEAL Delivery Vehicle Team One Waterfront Operations Facility	U.S. Department of the Navy	Insular Pacific-Hawaiian LME	Current	Retained.
18	Basing of MV-22 and H-1 Aircraft in Support of III Marine Expeditionary Force Elements in Hawaii	U.S. Department of the Navy	Insular Pacific-Hawaiian LME	Future	Retained.
19	Marine Corps Base Hawaii Pyramid Beach Cottage Construction	U.S. Department of the Navy	Insular Pacific-Hawaiian LME	Future	Retained.
20	U.S. Marine Corps Joint Strike Fighter	U.S. Marine Corps	All LMEs	Future	Dismissed. Homebasing activities such as new construction and personnel relocation are not expected to impact marine resources. Joint Strike Fighter training activities are addressed under Alternatives 1 and 2.
21	U.S. Navy Climate Change Roadmap	U.S. Department of the Navy	All LMEs	Present and future	Retained.
22	Hawaii Air National Guard F-22 Beddown	U.S. Air Force	All LMEs	Future	Retained.
23	U.S. Coast Guard Training Activities in Southern California and Hawaii	U.S. Coast Guard	California Current LME Insular Pacific-Hawaiian LME	Past, present, and future	Retained.
24	Joint Logistics Over-the-Shore Training	U.S. Department of the Navy, Marine Corps	California Current LME	Future	Retained.

Table 4.3-1: Other Actions and Other Environmental Considerations Identified for the Cumulative Impacts Analysis (continued)

#	Name of Action	Lead Agency or Proponent	Location in the Study Area/LME	Timeframe	Retained for Further Analysis?
Other Military Activities (continued)					
	Environmental Regulations and Planning				
23	Coastal and Marine Spatial Planning	Regional Ocean Commissions	All LMEs	Future	Dismissed because action involves only planning and policy-related activities (discussed in Chapter 6 [Additional Regulatory Considerations]).
24	Marine Mammal Protection Act Incidental Take Authorizations	National Marine Fisheries Service	All LMEs	Past, present, and future	Retained.
	Other Environmental Considerations				
25	Commercial and Recreational Fishing	National Marine Fisheries Service and private industry	All LMEs and open ocean areas	Past, present, and future	Retained.
26	Maritime Traffic	Not applicable	All LMEs and open ocean areas	Past, present, and future	Retained.
27	Development of Coastal Lands	Local regulatory agencies	All LMEs	Past, present, and future	Retained.
28	Oceanographic Research	Numerous	All LMEs and open ocean areas	Past, present, and future	Retained.
29	Ocean Noise	Not applicable	All LMEs and open ocean areas	Past, present, and future	Retained.
30	Ocean Pollution	U.S. Environmental Protection Agency Applicable State Agencies	All LMEs and open ocean areas	Past, present, and future	Retained.
31	Marine Tourism	Numerous	All LMEs	Past, present, and future	Retained.
32	Commercial and General Aviation	Not applicable	All LMEs and open ocean areas	Past, present, and future	Retained.

Notes: LME = large marine ecosystem, U.S. = United States, EA = Environmental Assessment, MDA = Missile Defense Agency

4.3.3 OFFSHORE POWER GENERATION

4.3.3.1 Outer Continental Shelf Renewable Energy Program

The Outer Continental Shelf (OCS) Renewable Energy Program was finalized in 2009. These regulations provide a framework for leases, easements, and rights-of-way for activities on the OCS that support production and transmission of energy from sources other than oil and natural gas.

4.3.3.2 Offshore Wind Energy

Despite tremendous offshore wind capacity, the United States has no offshore wind energy production to date.

4.3.3.3 Marine Hydrokinetic Projects

Emerging water power technologies offer the potential to capture energy from waves, thermal gradients, tides, and ocean currents. These new technologies once developed will offer alternatives to fossil fuels. At the present time, there is significant research into the performance and economic viability of hydropower technologies. Because no fully developed marine hydrokinetic projects exist in the North American or Polynesia region, the impact on marine species and ecosystems in the region remains largely speculative. Concerns raised include the potential for collisions, noise, physical disturbance, disruption of marine species' behavioral patterns, impacts to local community and fishing industry, ability to monitor projects, cumulative impacts of multiple hydrokinetic projects along the coasts, habitat alteration due to anchors and cables, and release of toxins and chemicals by the projects or by vessels servicing the project. Other considerations include habitat disturbance and the displacement of benthic organisms. These concerns provide the potential for habitat loss and changes to the ecology of a region (Pacific Fishery Management Council 2011); however, initial studies have indicated that with appropriate protocols for siting and design indicates that these impacts are likely to be minimal (Union of Concerned Scientists 2008).

As of June 2011, the Federal Energy Regulatory Commission has issued 70 preliminary permits for hydrokinetic projects and 147 preliminary permits are pending. In California there are four wave preliminary permits and one tidal preliminary permit. In Hawaii there is one wave preliminary permit that has been issued (Center for Climate and Energy Solutions 2012).

4.3.4 DREDGE DISPOSAL, BEACH NOURISHMENT, AND MINING

4.3.4.1 Offshore Dredge Disposal Program

The offshore dredge disposal program is dismissed from analysis because the action involves programs related to dredging and beach nourishment projects. These activities (if applicable) would be analyzed on an individual basis for cumulative impacts.

4.3.4.2 Beach Nourishment Programs

Beach nourishment programs are dismissed from analysis because they result in negligible to minor impacts on resources in the area affected by this activity and the Proposed Action.

4.3.5 OTHER MILITARY ACTIVITIES

4.3.5.1 Scripps Pier Replacement at Point Loma

The proposed project is a joint project between the Navy and University of California San Diego that involves the replacement of the existing Scripps Pier. The project is proposed to begin in the fall of 2013.

4.3.5.2 Naval Base Point Loma Fuel Pier

The proposed project involves the replacement of the existing fuel pier at Point Loma, which will likely require the temporary relocation of the marine mammals from the Space and Naval Warfare Systems Command mammal program and dredging approximately 87,000 cubic yards of sediment to facilitate navigation in the vicinity of the fuel pier.

4.3.5.3 Submarine Drive-In Magnetic Silencing Facility Beckoning Point, Oahu, Hawaii

Construction of a new drive-in submarine magnetic silencing facility was completed on 31 December 2010, at Joint Base Pearl Harbor-Hickam's Beckoning Point. The project was a 2-year effort that replaced existing submarine deperming piers and structures and construction of land-based facilities to include a new rectifier building, back-up generator building, and renovations to the existing control building. Deperming (also known as degaussing) is accomplished by wrapping heavy gauge copper cables around the hull and superstructure of the vessel; very high electrical currents are pulsed through the cables in order to erase the permanent magnetism from ships and submarines to camouflage them against magnetic detection vessels and interference with communications and navigation equipment (U.S. Department of the Navy 2008a, b).

4.3.5.4 Establishment and Realignment of Navy Helicopter Squadrons on the West Coast

The Navy will add four helicopter squadrons on the west coast: establishing three new squadrons and relocating one squadron from the east coast. The realignment will increase the number of helicopters homebased at North Island by 52, from the current number of 151, to 203 helicopters by 2016. Most helicopter squadrons homebased at North Island will transition to the MH-60R and MH-60S helicopters to gradually replace older model H-60 helicopters. A new organizational maintenance hangar and supporting facilities will be constructed and 800 personnel (738 military and 62 civilian) will be added at North Island to support the additional squadrons (U.S. Department of the Navy 2011c).

4.3.5.5 San Clemente Island Fuel Storage and Distribution System

An Environmental Assessment has been implemented to replace the aging underground JP-5 jet fuel tanks and improve the receipt, storage, and delivery capabilities at San Clemente Island.

4.3.5.6 Navy, University of Hawaii, and United States Department of Energy Wave Energy Test Site

Naval Facilities Engineering Command Engineering Services Center proposes to construct and operate a deep-water wave energy test site for offshore wave energy conversion devices at a water depth of up to 328 feet (ft.) (100 meters [m]), roughly 8,200 ft. (2,500 m) offshore from North Beach of MCBH. Upon completion of deep-water test site construction, two additional wave energy conversion devices would be installed and operated at the deep test site, and the existing site (one) operating at about 98 ft. (30 m) depth (known as the medium depth site would remain. Therefore, the existing and expanded test sites would accommodate a maximum of three wave energy conversion devices (U.S. Department of the Navy 2012a).

4.3.5.7 Pier 12 Replacement and Dredging Naval Base San Diego

An Environmental Assessment has been implemented to evaluate the potential environmental consequences for a project at Naval Base San Diego, California that would involve demolition of Pier 12, dredging in berthing and approach for a new pier, dredged material disposal at an approved ocean disposal site and permitted upland landfill, construction of a new pier and associated pier utilities, including upgrades to the electrical infrastructure at the adjacent Pier 13, and re-use of demolition concrete to create fish enhancement structures (artificial reefs) (U.S. Department of the Navy 2011d).

4.3.5.8 Homeporting Littoral Combat Ships on the West Coast

An Environmental Assessment has been implemented to evaluate the potential environmental effects of a naval proposal to homeport up to 16 Littoral Combat Ships and unmanned aerial systems at Naval Base Ventura County Point Mugu and Naval Base San Diego. No in-water construction is proposed and the homeporting would take place between Fiscal Year (FY) 2013 and FY 2020 (U.S. Department of the Navy 2012b).

4.3.5.9 Surveillance Towed Array Sensor System Low Frequency Active Sonar

In August 2011, the Navy released a Draft Supplemental EIS/Supplemental OEIS that evaluated the potential environmental impacts of employing the Surveillance Towed Array Sensor System Low Frequency Active Sonar (U.S. Department of the Navy 2011b). The Navy currently plans to operate up to four Surveillance Towed Array Sensor System Low Frequency Active Sonar systems for routine training, testing, and military operations. Based on current Navy national security and operational requirements, routine training, testing, and military operations using these sonar systems could occur in the Pacific Ocean (including the Study Area), Atlantic Ocean, Indian Ocean, and Mediterranean Sea.

4.3.5.10 Space and Naval Warfare Systems Command – Electronic Harbor Security System Environmental Assessment

A swimmer detection system is to be installed near Naval Base Point Loma and Naval Base San Diego.

4.3.5.11 Construction of Sea, Air, Land Delivery Vehicle Team One Waterfront Operations Facility

This project will construct a 20,000-square-foot addition to Building 987 for Sea, Air, Land (SEAL) Delivery Vehicle Team One platoon operators, divers, and support technicians. Work is expected to begin in 2013.

4.3.5.12 Basing of MV-22 and H-1 Aircraft in Support of III Marine Expeditionary Force Elements in Hawaii

An EIS is currently being prepared for the proposed basing and operation of MV-22 Osprey tiltrotor aircraft and H-1 helicopters in Hawaii. The Proposed Action includes basing and operating up to two Marine Medium Tiltrotor squadrons with a total of 24 MV-22 Osprey aircraft and one Marine Light Attack Helicopter squadron with 15 AH-1 Cobra and 12 UH-1 Huey attack and utility helicopters and conducting aviation training, readiness, and special exercise operations at training facilities statewide. Demolition, new construction, and renovation are proposed to develop basing facilities at Marine Corps Base Hawaii, Kaneohe Bay for the squadrons. Personnel increases would occur from 2012 through 2018 (U.S. Department of the Navy 2011e). The EIS analyzes the impacts of developing basing facilities at Marine Corps Base Hawaii Kaneohe Bay; conducting aviation operations at training areas on the islands of Kauai, Oahu, Molokai, Maui, and Hawaii; and constructing improvements at three existing training facilities.

4.3.5.13 Marine Corps Base Hawaii Pyramid Beach Cottage Construction

Construction of 10 new beach cottages is expected to begin in FY 2015.

4.3.5.14 United States Marine Corps Joint Strike Fighter

This project has been dismissed from further analysis as the homebasing activities included new construction and personnel relocation which are not expected to impact marine resources. Joint Strike Fighter training activities are addressed under Alternatives 1 and 2.

4.3.5.15 United States Department of the Navy Climate Change Roadmap

The Navy Climate Change Roadmap outlines the Navy's approach to observing, predicting, and adapting to climate change by providing a chronological list of Navy-associated action items, objectives and desired effects for FY 2010–2014 (U.S. Department of the Navy 2010).

4.3.5.16 Hawaii Air National Guard F-22 Beddown

The Hawaii Air National Guard and the U.S. Air Force will be conducting "joint" training with the F-22 aircraft which will be a replacement of the existing F-15 aircraft. Training in the F-22 aircraft will be similar to the training currently conducted with the F-15 aircraft (U.S. Department of the Navy 2011a).

4.3.5.17 United States Coast Guard Training Activities in Southern California and Hawaii

Coast Guard Sector San Diego, a shore command within the Coast Guard 11th District, carries out its mission to serve, protect, and defend the American public, maritime infrastructure, and the environment. The Sector San Diego Area of Responsibility extends southward from the Dana Point harbor to the border with Mexico. Equipment utilized by the Coast Guard includes 25 ft. (8 m) response boats, 41 ft. (12 m) utility boats, and 87 ft. (27 m) patrol boats, as well as HH-60 helicopters. Training events include search and rescue, maritime patrol training, boat handling, and helicopter and surface vessel live-fire training with small arms.

Similarly, the Coast Guard's 14th District carries out its mission and conducts unit training in and around Hawaii. U.S. Coast Guard training in Hawaii includes surface vessel live-fire training with small- and medium-caliber weapons, primarily conducted in Warning Areas 189, 193, and 194 within the Hawaii Range Complex.

4.3.5.18 Joint Logistics Over-the-Shore Training

Joint Logistics Over-The-Shore training consists of loading/unloading ships without fixed port facilities. This training may be conducted jointly by the Navy, Marine Corps, and Army at Marine Corps Base Camp Pendleton, California, and includes in-water and land-based activities. Training activities associated with elevated causeway set up and break down in the Camp Pendleton Amphibious Assault Area are addressed under Alternatives 1 and 2 of this EIS/OEIS. Land-based training will be addressed in a separate NEPA document.

4.3.6 Environmental Regulations and Planning

4.3.6.1 Coastal and Marine Spatial Planning

Dismissed because action involves only planning and policy-related activities.

4.3.6.2 Marine Mammal Protection Act Incidental Take Authorizations

The MMPA generally prohibits "take" of marine mammals in U.S. waters by any person and by U.S. citizens in international waters. The National Oceanic and Atmospheric Administration can authorize "take" for specific activities (National Oceanic and Atmospheric Administration 2012).

4.3.7 Other Environmental Considerations

4.3.7.1 Commercial and Recreational Fishing

Commercial and recreational fishing constitutes an important and widespread use of the ocean resources throughout the Study Area. Fishing can adversely affect fish populations, other species, and habitats. Potential impacts of fishing include overfishing of targeted species and bycatch, both of which negatively affect fish stocks and other marine resources. Bycatch is the capture of fish, marine mammals, sea turtles, seabirds, and other nontargeted species that occur incidental to normal fishing operations. Use of mobile fishing gear such as bottom trawls disturbs the seafloor and reduces habitat structural complexity. Indirect impacts of trawls include increased turbidity, alteration of surface sediment, removal of prey (leading to declines in predator abundance), removal of predators, ghost fishing (i.e., lost fishing gear continuing to ensnare fish and other marine animals), and generation of marine debris. Lost gill nets, purse seines, and long-lines may foul and disrupt bottom habitats and have the potential to entangle or be ingested by marine animals.

Fishing can have a profound influence on individual targeted species populations. In a study of retrospective data, Jackson et al. (2001) analyzed paleoecological records of marine sediments from 125,000 years ago to present, archaeological records from 10,000 years before the present, historical documents, and ecological records from scientific literature sources over the past century. Examining this longer-term data and information, they concluded that ecological extinction caused by overfishing precedes all other pervasive human disturbance of coastal ecosystems, including pollution and anthropogenic climatic change. Fisheries bycatch has been identified as a primary driver of population declines in several marine species, including sharks, mammals, seabirds, and sea turtles (Wallace et al. 2010).

4.3.7.2 Maritime Traffic

Portions of the Study Area are heavily traveled by commercial, recreational, and government marine vessels, with several commercial ports occurring in or near the Study Area. The United States has grown increasingly dependent on international trade over the past 50 years. Section 3.11 (Socioeconomic Resources) provides additional information for marine vessel traffic in the Study Area. Primary concerns for the cumulative impacts analysis include vessels striking marine mammals and sea turtles, introduction of non-native species through ballast water, and underwater sound from ships and other vessels.

4.3.7.3 Development of Coastal Lands

Coastal land development adjacent to the Study Area is both intensive and extensive. Development has impacted and continues to impact coastal resources through point and nonpoint source pollution; concentrated recreational use; and intensive ship traffic using major port facilities. The Study Area coastline also includes extensive coastal tourism development (hotels, resorts, restaurants, food industry, residential homes, etc.) and the infrastructure supporting coastal development (retail businesses, marinas, fishing tackle stores, dive shops, fishing piers, recreational boating harbors, beaches, recreational fishing facilities, etc.).

Coastal development intensifies use of coastal resources, resulting in potential impacts on water quality, marine habitat, and air quality. Coastal development is therefore closely regulated by California and Hawaii through the Coastal Zone Management Act. New development in the coastal zone requires a permit from the state or local government to which permitting authority has been delegated (Chapter 6, Additional Regulatory Considerations) provides additional information on coastal zone management in each state).

4.3.7.4 Oceanographic Research

The Auxiliary General Purpose Oceanographic Research (AGOR) 28 research vessel is entering a final design and construction phase and is anticipated to be launched in 2015. The vessel is owned by the U.S. Office of Naval Research for the U.S. Department of the Navy and operated by Scripps. The AGOR 28 is designed to operate globally and support both U.S. Department of the Navy and national oceanographic research objectives to include exploring science and technology in the areas of oceanographic and meteorological observations, modeling and prediction in the battlespace environment, submarine detection and classification and mine warfare application for detecting and neutralizing mines in the ocean and littoral environment. The vessel will be based in the Scripps Nimitz Marine Facility in San Diego Port Loma (Scripps Institution of Oceanography 2012a, c).

Projects are under development to deploy seismometers, pressure gauges, and temperature sensors to measure the size and direction of tsunamis. Future use of the cables could include installation of climate instruments to measure acoustic tomography and water column temperature and conductivity to measure ocean warming. The initial project will focus along a cable route spanning 12,950 kilometers (8,105 miles) from Sydney to Auckland and across the Pacific Ocean to Los Angeles (Scripps Institution of Oceanography 2012b).

The Ocean Conservation Society has three ongoing projects in the Study Area. The Los Angeles Dolphin Project 1 (Ocean Conservation Society 2012a) studies the ecology, social structure and contaminant load comparison of inshore/offshore bottlenose dolphins in the Southern California Bight; the Los Angeles Dolphin Project 2 (Ocean Conservation Society 2012b) studies dolphin, sea lion and seabird aggregations during foraging and feeding activities in the Santa Monica Bay; and the Los Angeles Dolphin Project 3 (Ocean Conservation Society 2012c) studies the effects of coastal pollution and importance of oceanographic features for marine mammals in the waters off Los Angeles, California.

The National Oceanic and Atmospheric Administration has ongoing projects involving such projects as integrated ocean mapping, laser line scanning for habitat assessment, locating and mapping deep-sea coral habitats, species inventory, growth and reproductive studies and food web and species interaction studies, studies designed to understand the use of specific deep-sea species of corals as indicators of climatic change, and the effects on the oceans of deep-sea volcanoes and hydrothermal systems (National Oceanic and Atmospheric Administration 2011b).

4.3.7.5 Ocean Noise

Noise is generally described as unwanted sound—sound that clutters and masks other sounds of interest (Richardson et al. 1995). Anthropogenic sources of noise that are most likely to contribute to increases in ocean noise are vessel noise from commercial shipping and general vessel traffic, oceanographic research, oil and gas exploration, underwater construction, and naval and other use of sound navigation and ranging (sonar).

Any potential for cumulative impact should be put into the context of recent changes to ambient sound levels in the world's oceans as a result of anthropogenic activities. However, there is a large and variable natural component to the ambient noise level as a result of events such as earthquakes, rainfall, waves breaking, and lightning hitting the ocean as well as biological noises such as those from snapping shrimp and the vocalizations of marine mammals.

Andrew et al. (2002) compared ocean ambient sound from the 1960s to the 1990s from a receiver off the California coast. The data showed an increase in ambient noise of approximately 10 decibels (dB) in the frequency ranges of 20 to 80 hertz (Hz) and 200 to 300 Hz, and about 3 dB at 100 Hz over a 33-year period. Each 3 dB increase is noticeable to the human ear and a doubling in sound level. A possible explanation for the rise in ambient noise is the increase in shipping noise. There are approximately 11,000 supertankers worldwide, each operating 300 days per year, producing constant broadband noise at source levels of 198 dB (Hildebrand 2004). Generally the most energetic regularly operated sound sources are seismic airgun arrays from approximately 90 vessels with typically 12 to 48 individual guns per array, firing about every 10 seconds (Hildebrand 2004).

Section 3.0.4 (Acoustic and Explosives Primer), provides additional information about sources of anthropogenic sound in the ocean and other background information about underwater noise. This section describes the different types of effects that are possible and the potential relationships between sound stimuli and long-term consequences for individual animals and populations. A variety of impacts may result from exposure to sound-producing activities. The severity of these impacts can vary greatly between minor impacts that have no real cost to the animal, to more severe impacts that may have lasting consequences. The major categories of potential impacts are: behavioral reactions, physiological stress, auditory fatigue, auditory masking, and direct trauma.

4.3.7.6 Ocean Pollution

Pollution is the introduction of harmful contaminants that are outside the norm for a given ecosystem. Ocean pollution has and will continue to have serious impacts on the marine ecosystems. Common ocean pollutants include toxic compounds such as metals, pesticides, and other organic chemicals; excess nutrients from fertilizers and sewage; detergents; oil; plastics; and other solids. Pollutants enter oceans from non-point sources (i.e., stormwater runoff from watersheds), point sources (i.e., wastewater treatment plant discharges), other land-based sources (i.e., windblown debris), spills, dumping, vessels, and atmospheric deposition.

4.3.7.6.1 Non-Point Sources, Point Sources, and Atmospheric Deposition

Polluted runoff, or nonpoint source pollution, is considered the major cause of impairment of ocean waters. Stormwater runoff from coastal urban areas and beaches carries waste such as plastics and Styrofoam into coastal waters. Sewer outfalls also are a source of ocean pollution. Sewage can be treated to eliminate potentially harmful releases of contaminants; however, releases of untreated sewage occur due to malfunctions or overloads to the infrastructure, resulting in releases of bacteria usually associated with feces, such as *Escherichia coli* and *Enterococci spp*. Bacteria levels are used routinely to determine the quality of water at recreational beaches and as indicators of the possible presence of other harmful microorganisms. In the past, toxic chemicals have been released into sewer systems. While such dumping has long been forbidden by law, the practice left ocean outflow sites contaminated. Sewage treatment facilities generally do not treat or remove persistent organic pollutants, such as polychlorinated biphenyl (PCB) and dichlorodiphenyltrichloroethane (DDT), or other toxins.

Hypoxia (low dissolved oxygen concentration) is a major impact associated with point and non-point sources of pollution. Hypoxia occurs when waters become overloaded with nutrients such as nitrogen and phosphorus, which enter oceans from non-point source runoff, wastewater treatment plants, and atmospheric deposition. Too many nutrients can stimulate algal blooms—the rapid expansion of microscopic algae (phytoplankton). When excess nutrients are consumed, the algae population dies off and the remains are consumed by bacteria. Bacterial consumption causes dissolved oxygen in the water to decline to the point where marine life that depend on oxygen can no longer survive (Boesch et al. 1997).

Harmful algal blooms are proliferations of marine and freshwater algae (including cyanobacteria and non-photosynthetic algae-like organisms) that can produce toxins, causing human illness and massive animal mortalities. They also can accumulate in sufficient numbers to alter ecosystems in detrimental ways.

Non-point sources, point sources, and atmospheric deposition also contribute toxic pollutants such as metals, pesticides, and other organic compounds to the marine environment. Toxic pollutants may cause lethal or sublethal effects if present in high concentrations, and can build up in tissues over time and suppress immune system function, resulting in disease and death.

4.3.7.6.2 Marine Debris

Marine debris is any anthropogenic object intentionally or unintentionally discarded, disposed of, or abandoned that enters the marine environment. Common types of marine debris include various forms of plastic and abandoned fishing gear. Marine debris degrades marine habitat quality and poses ingestion and entanglement risks to marine life and bird (National Marine Fisheries Service 2006).

Plastic marine debris is a major concern because it degrades slowly and many plastics float, allowing the debris to be transported by currents throughout the oceans. Currents in the oceanic convergence zone in the North Pacific Subtropical Gyre act to accumulate the floating plastic marine debris. Additionally, plastic waste in the ocean chemically attracts hydrocarbon pollutants such as PCB and DDT, which accumulate up to one million times more in plastic than in ocean water (Mato et al. 2001). Fish, marine animals, and birds can mistakenly consume these wastes containing elevated levels of toxins instead of their prey. In the North Pacific Subtropical Gyre it is estimated that the fishes in this area are ingesting 12,000 to 24,000 U.S. tons (10,886,216 to 21,772,433 kilograms [kg]) of plastic debris a year (Davison and Asch 2011).

Marine debris has been discovered to be accumulating in gyres throughout the oceans. Law et al. (2010) presented a time series of plastic content at the surface of the western North Atlantic Ocean and Caribbean Sea from 1986 to 2008. More than 60 percent of 6,136 surface plankton net tows collected small, buoyant plastic pieces. The data identified an accumulation zone east of Bermuda that is similar in size to the accumulation zone in the eastern Pacific Ocean.

4.3.7.7 Marine Tourism

Between 1990 and 2000, the ocean-related gross state product for California grew by 10.64 percent, with one of the largest growth trends experienced in coastal recreation and tourism. California's trend reflects the international trend of coastal tourism and recreation growth which has continued in past decades while other industries have declined. Additionally, the growth is seen in the development of "services" rather than "goods-related" activities (Kildow and Colgan 2005). Stakeholders in tourism services have economical motivation to ensure positive management of marine resources on which their industries are based therefore the impacts of marine tourism are generally localized and of small magnitude; however, rapid expansion of tourism could increase pressure for additional coastal and urban development which would result in potential indirect and cumulative effects on marine resources (Harriott 2002). The Marine Institute found that the issues relating to tourism included visitor pressures on coastal ecology; carrying capacity; information gap (i.e., insufficient data to assess impacts of tourism); anthropogenic impacts (i.e., displacement of seabirds, habitat and roosting opportunities, conflicts with users and wildlife, altering food sources); threats to ecology; development pressure; infrastructural support; user conflicts; and motorized crafts (Connolly et al. 2001).

4.3.7.8 Commercial and General Aviation

Commercial and general aviation are retained for analysis and discussion in Section 4.4.4.1 (Greenhouse Gases).

4.4 Resource-Specific Cumulative Impacts

4.4.1 Resource Areas Dismissed from Current Impacts Analysis

In accordance with Council on Environmental Quality guidance (Council on Environmental Quality 2010), the cumulative impacts analysis focused on impacts that are "truly meaningful." The level of analysis for each resource was commensurate with the intensity of the impacts identified in Chapter 3 (Affected Environment and Environmental Consequences). The analysis focused on marine mammals, sea turtles, and cultural resources. While each of the following resources is discussed in the following section, detailed analysis of cumulative impacts was not necessary for the following resources as the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be low. Further analysis of cumulative impacts is not warranted on the following resources:

- Sediments and water quality
- Marine habitats
- Seabirds
- Marine vegetation
- Marine invertebrates
- Fish
- Socioeconomic resources
- Public health and safety

4.4.2 Sediments and Water Quality

The analysis in Section 3.1 (Sediments and Water Quality) indicates that the alternatives could result in local, short- and long-term changes in sediment and water quality. However, chemical, physical, or biological changes to sediments or water quality would be below applicable standards, regulations, and guidelines and would be within existing conditions or designated uses (Section 3.1.1.2, Methods, lists applicable standards, regulations, and guidelines). The short-term impacts would arise from explosions and the byproducts of explosions and combusted propellants. It is unlikely these short-term impacts would overlap in time and space with other future actions that produce similar constituents. For example, training and testing with explosives would not be expected to occur near an oil rig structure-removal operation that could use explosives. Therefore, the short-term impacts described in Section 3.1 (Sediments and Water Quality) are not expected to contribute to cumulative impacts.

The long-term impacts would arise from unexploded ordnance, noncombusted propellant, metals, and other materials. Long-term impacts of each alternative would be cumulative with other actions that cause increases in similar constituents. However, the incremental contribution of the No Action Alternative, Alternative 1, or Alternative 2 to long-term cumulative impacts would be negligible because

- Most training and testing activities are widely dispersed in space and time;
- Most components of expended materials are inert or corrode slowly;

- Numerically, most of the metals expended are small- and medium-caliber projectiles, metals of concern comprise a small portion of the alloys used in expended materials, and metal corrosion is a slow process that allows for dilution;
- Most of the components are subject to a variety of physical, chemical, and biological processes that render them benign; and
- Potential areas of impacts would be limited to small zones immediately adjacent to the explosive, metals, or chemicals other than explosives.

Furthermore, none of the alternatives would result in long-term and widespread changes in environmental conditions, such as nutrient loading, turbidity, salinity, or pH (a measure of the degree to which a solution is either acidic [pH less than 7.0] or basic [pH greater than 7.0]). Based on the analysis presented in Section 3.1 (Sediments and Water Quality) and the reasons summarized above, the changes in sediment or water quality would be measurable, but would still be below applicable standards and guidelines; therefore the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be low and further analysis of cumulative impacts is not warranted.

4.4.3 Air Quality

As detailed in Section 3.2 (Air Quality), increased training and testing activities conducted under Alternatives 1 and 2 would result in increased criteria pollutant emissions and hazardous air pollutant emissions throughout the Study Area. Sources of the increased emissions would include vessels and aircraft, and to a lesser extent munitions. Potential impacts include localized and temporarily elevated pollutant concentrations. Recovery would occur quickly as emissions disperse, and there would be no significant impact on air quality. The impacts of Alternatives 1 or 2 would be cumulative with other actions that involve criteria air pollutant and hazardous air pollutant emissions. However, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be low for the following reasons:

- Prevailing winds along the Pacific coast generally trend east to west, thus reducing the likelihood that offshore emissions would impact air quality control regions ashore.
- For those proposed activities occurring at latitudes consistent with air quality control region nonattainment or maintenance areas in the Southern California region, most training and testing-related emissions are projected to occur at distances greater than 12 nautical miles (nm) from shore.
- Few stationary offshore air pollutant emission sources exist within the Study Area and few are expected in the foreseeable future.
- International regulations by the International Maritime Organization require commercial shipping vessels to switch to lower-sulfur fuel near U.S. and international coasts beginning in 2012 (National Oceanic and Atmospheric Administration 2011a). The Department of Defense has released the Operational Energy Strategy: Implementation Plan which will reduce demand, diversify energy sources, and integrate energy consideration into planning (Department of Defense 2012). The U.S. Department of the Navy policy commits to a reduction of oil consumption by 50 percent by 2015, 40 percent of the Navy's total energy will come from fossil fuel alternatives and 50 percent of its onshore energy will come from renewable sources by 2020 (Environmental and Energy Study Institute 2009, Paige 2009). Similar low-sulfur fuel regulations in California, including a voluntary state slowdown policy, were found to reduce several pollutants, including sulfur dioxide and particulate matter by as much as 90 percent (Lack et al. 2011).

Based on the analysis presented in Section 3.2 (Air Quality) and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be low. Further analysis of cumulative impacts on air quality is not warranted.

4.4.4 CLIMATE CHANGE

This section provides background information and an analysis of the cumulative impacts of climate change and greenhouse gas emissions for the Proposed Action. Climate change is also considered in the overall cumulative impacts analysis as another environmental consideration. The Intergovernmental Panel on Climate Change (2007) reports that physical and biological systems on all continents and in most oceans are already being affected by recent climate changes. Global-scale assessment of observed changes shows that it is likely that anthropogenic warming over the last three decades has had a discernible influence on many physical and biological systems. Some of the major potential concerns for the marine environment include

- Sea temperature rise
- Melting of polar ice
- Rising sea levels
- Changes to major ocean current systems
- Ocean acidification

4.4.4.1 Greenhouse Gases

Greenhouse gases are compounds that contribute to the greenhouse effect. The greenhouse effect is a natural phenomenon in which these gases trap heat within the surface-troposphere (lowest portion of the earth's atmosphere) system, causing heating (radiative forcing) at the surface of the earth. Scientific evidence indicates a trend of increasing global temperature over the past century due to an increase in greenhouse gas emissions from human activities (U.S. Environmental Protection Agency 2012). Without greenhouse gases the planet's surface would be about 60 degrees Fahrenheit (°F) cooler than present, according to the National Oceanic and Atmospheric Administration and National Aeronautics and Space Administration data the average surface temperature has increase by about 1.2 to 1.4°F since 1900. If greenhouse gases continue to increase, models predict that the average temperature at the earth's surface could increase from 2.0 to 11.5°F above the 1990 levels by the end of this century (Le Treut et al. 2007).

Predictions of long-term negative environmental impacts due to global warming include sea level rise, changing weather patterns with increases in the severity of storms and droughts, changes to local and regional ecosystems (including the potential loss of species), shrinking glaciers and sea ice, thawing permafrost, a longer growing season, and shifts in plant and animal ranges.

Over the next several decades, temperatures are projected to rise. The projected warming and more extensive climate-related changes could dramatically alter the region's economy, landscape, character, and quality of life (Le Treut et al. 2007).

In 2009, the United States generated about 6,633.2 teragrams (Tg) (or million metric tons) of carbon dioxide (CO_2) equivalents (U.S. Environmental Protection Agency 2012). The 2009 inventory data (U.S. Environmental Protection Agency 2012) show that CO_2, methane (CH_4), and nitrous oxide (N_2O) contributed from fossil fuel combustion processes from mobile and stationary sources (all sectors) include approximately:

- 5,505.2 Tg of CO_2
- 686.3 Tg CH_4
- 295.6 Tg N_2O

The 6,633.2 Tg CO_2 equivalent (CO_2e) generated in 2009 is a decrease from the 7,263.4 Tg CO_2e generated in 2007 (U.S. Environmental Protection Agency 2011). Among domestic transportation sources, light-duty vehicles (including passenger cars and light-duty trucks) represented 64 percent of CO_2 emissions, medium- and heavy-duty trucks 20 percent, commercial aircraft 6 percent, and other sources 9 percent. Across all categories of aviation, CO_2 emissions decreased by 21.6 percent (38.7 Tg) between 1990 and 2009. This includes a 59 percent (20.3 Tg) decrease in emission from domestic military operations. To place military aircraft in context with other aircraft CO_2 emissions, in 2009, commercial aircraft generated 111.4 Tg CO_2e, military aircraft generated 14.1 Tg CO_2e, and general aviation aircraft generated 13.3 Tg CO_2e. Military aircraft represent roughly 10 percent of emissions from the overall jet fuel combustion category (U.S. Environmental Protection Agency 2012).

This section begins by providing the background and regulatory framework for greenhouse gases. It then provides a quantitative evaluation of changes in greenhouse gas emissions that would occur under the Proposed Action and analyzes the cumulative impacts of greenhouse gas emissions.

4.4.4.1.1 Regulatory Framework

Federal agencies address emissions of greenhouse gases by reporting and meeting reductions mandated in laws, executive orders and policies. The most recent of these are Executive Order (EO) 13514 *Federal Leadership in Environmental, Energy, and Economic Performance* of 5 October 2009 and EO 13423 *Strengthening Federal Environmental, Energy, and Transportation Management* of 26 January 2007.

Executive Order 13514 shifts the way the government operates by (1) establishing greenhouse gases as the integrating metric for tracking progress in federal sustainability; (2) requiring a deliberative planning process; and (3) linking to budget allocations and Office of Management and Budget scorecards to ensure goal achievement.

The targets for reducing greenhouse gas emissions discussed in EO 13514 for Scope 1 (direct greenhouse gas emissions from sources that are owned or controlled by a federal agency) and Scope 2 (direct greenhouse gas emissions resulting from the generation of electricity, heat, or steam purchased by a federal agency) have been set for the Department of Defense at a 34 percent reduction of greenhouse gas from the 2008 baseline by 2020. Scope 3 targets (greenhouse gas emissions from sources not owned or directly controlled by a federal agency but related to agency activities such as vendor supply chains, delivery services, and employee travel and commuting) were set at a 13.5 percent reduction. Executive Order 13514 *Strategic Sustainability Performance Plan* submitted to the Council on Environmental Quality on 2 June 2010 contains a guide for meeting these goals.

Executive Order 13423 established a policy that federal agencies conduct their environmental, transportation, and energy-related activities in support of their respective missions in an environmentally economic way. It included a goal of improving energy efficiency and reducing greenhouse gas emissions of the agency through reduction of energy intensity by 3 percent annually through the end of FY 2015, or 30 percent by the end of FY 2015, relative to the baseline of the agency's energy use in FY 2003.

The *Draft NEPA Guidance on Consideration of the Impacts of Climate Change and Greenhouse Gas Emissions* (Council on Environmental Quality 2010) states that "if a proposed action would be reasonably anticipated to cause direct emissions of 25,000 metric tons or more of CO_2e greenhouse gas emissions on an annual basis, agencies should consider this an indicator that a quantitative and qualitative assessment may be meaningful to decision makers and the public." Because the impact of the Navy's Proposed Action exceeds 25,000 metric tons, a quantitative and quantitative assessment follows.

The Navy is committed to improving energy security and environmental stewardship by reducing reliance on fossil fuels. The Navy is actively developing and participating in energy, environmental, and climate change initiatives that will increase use of alternative energy and help conserve the world's resources for future generations. The Navy Climate Change Roadmap identifies actions the Environmental Readiness Division is taking to implement EO 13514 (U.S. Department of the Navy 2010). The Navy's Task Force Energy is responding to the Secretary of the Navy Energy Goals through energy security initiatives that reduce the Navy's carbon footprint. The Climate Change Roadmap (5-year roadmap) action items, objectives, and desired impacts are organized to focus on strategies, policies and plans; operations and training; investments; strategic communications and outreach; and environmental assessment and prediction.

4.4.4.1.2 Cumulative Greenhouse Gas Impacts

Climate change is a global issue, and greenhouse gas emissions are a concern from a cumulative perspective because individual sources of greenhouse gas emissions are not large enough to have an appreciable impact on climate change. This greenhouse gas analysis considers the incremental contribution of Alternatives 1 and 2 to total estimated U.S. greenhouse emissions and their significance on climate change as compared to the No Action Alternative.

To estimate total greenhouse gas emissions, each greenhouse gas was assigned a global warming potential; that is, the ability of a gas or aerosol to trap heat in the atmosphere. The global warming potential rating system is standardized to CO_2, which has a value of one. For example, CH_4 (methane) has a global warming potential of 21, which means that it has a global warming effect 21 times greater than CO_2 on an equal-mass basis (Intergovernmental Panel on Climate Change 2007). To simplify greenhouse gas analyses, total greenhouse gas emissions from a source are often expressed as CO_2e. The CO_2e is calculated by multiplying the emissions of each greenhouse gas by its global warming potential and adding the results together to produce a single, combined emission rate representing all greenhouse gases. While CH_4 and N_2O (nitrous oxide) have much higher global warming potentials than CO_2, CO_2 is emitted in much higher quantities, so it is the overwhelming contributor to CO_2e from both natural processes and human activities. Global warming potential-weighted emissions are presented in terms of equivalent emissions of CO_2, using units of Tg (1 million metric tons, or 1 billion kilograms) of carbon dioxide equivalents (Tg CO_2e).

Greenhouse gas emissions were calculated (Appendix D Air Quality Calculations) for ships and aircraft, which contribute the majority of emissions associated with training and testing in the Study Area. Greenhouse gas emissions from minor sources such as munitions, weapons platforms, and auxiliary equipment are considered negligible and were not calculated. Ship greenhouse gas emissions were estimated by determining annual ship fuel (typically diesel) use based on proposed activities and multiplying total annual ship fuel consumption by the corresponding emission factors for CO_2, CH_4, and N_2O. Aircraft greenhouse gas emissions were calculated by multiplying jet fuel use rates by the total operating hours, by the corresponding jet fuel emission factors for CO_2, CH_4, and N_2O, and by the total annual sorties. Ship and aircraft greenhouse gas emissions are compared to U.S. 2009 greenhouse gas emissions in Table 4.4-1. The estimated CO_2e emissions from the No Action Alternative and Alternative 1 are 0.030 percent of the total CO_2e emissions generated by the United States in 2009. The estimated CO_2e emissions from Alternative 2 would increase as a result of increased training and testing activities to about 0.031 percent of the total CO_2e emissions generated by the United States in 2009.

Based on the analysis presented in Section 3.2 (Air Quality) and the reasons summarized above, the changes in air quality would be measurable, but would still be below applicable standards and guidelines; therefore the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be low and further analysis of cumulative impacts is not warranted.

Table 4.4-1: Comparison of Ship and Aircraft Greenhouse Gas Emissions to United States 2009 Greenhouse Gas Emissions

Alternative	Annual Greenhouse Gas Emissions (teragrams CO_2e)	Increase over the No Action Alternative	Percentage of U.S. 2009 Greenhouse Gas Emissions
No Action Alternative	1.89	N/A	0.030%
Alternative 1	1.94	2.6%	0.031%
Alternative 2	1.93	2.1%	0.031%
U.S. 2009 Greenhouse Gas Emissions	6,633.2		

Notes: CO_2e = carbon dioxide equivalent, N/A = Not Applicable, U.S. = United States
Source: U.S. Environmental Protection Agency 2011

4.4.5 Marine Habitats

The analysis presented in Section 3.3 (Marine Habitats) indicates that marine habitats could be affected by acoustic stressors (underwater detonations) and physical disturbance or strikes (interactions with vessels and in-water devices, military expended materials, or seafloor devices). Potential impacts include localized disturbance of the seafloor, cratering of soft bottom sediments, and structural damage to hard bottom habitats. Impacts on soft bottom habitats would be short-term, and impacts on hard bottom would be long-term. The impacts of Alternatives 1 and 2 would be cumulative with other actions that cause similar disturbances. However, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be low for the following reasons:

- Most of the proposed activities that might affect marine habitats would occur in areas where hard bottom does not occur.
- Impacts on soft bottom habitats would be confined to a limited area, and recovery would occur quickly.

Based on the analysis presented in Section 3.3 (Marine Habitats) and the reasons summarized above, the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be low. Further analysis of cumulative impacts on marine habitats is not warranted.

4.4.6 Marine Mammals

4.4.6.1 Impacts of Alternatives 1 and 2 That May Contribute to Cumulative Impacts

Based on the analysis presented in Section 3.4 (Marine Mammals) impacts of Alternatives 1 and 2 that might contribute to cumulative impacts on marine mammals include mortality, injury (Level A harassment under the MMPA), and disturbance or behavioral modification (MMPA Level B harassment). Mortality or injury could be caused by underwater explosions or vessel strikes. Injury, in the form of permanent threshold shift (PTS), could also be caused by sonar use. Underwater explosions, pile driving, swimmer defense airguns, and sonar use would result in disturbance that meets the definition of MMPA Level A and B harassment. The remaining stressors analyzed in Section 3.4 (Marine Mammals) are not expected to result in mortality or Level A or B harassment. The incremental contribution of these remaining stressors to cumulative impacts on marine mammals would be negligible. These stressors are discussed in Section 3.4.3.1 through 3.4.3.7. The impacts of Alternatives 1 and 2 considered in the cumulative impacts analysis are summarized in Chapter 3, Section 3.4 (Marine Mammals).

4.4.6.2 Impacts of Other Actions

4.4.6.2.1 Overview

The potential impacts of other actions that are relevant to the cumulative impact analysis for marine mammals include the following:

- Mortality associated with vessel strikes, bycatch in fisheries, and entanglement in fishing and other gear
- Injury associated with vessel strikes, bycatch, entanglement, and underwater sound
- Disturbance, behavioral modifications, and reduced animal fitness associated with underwater noise
- Reduced animal fitness associated with water pollution

Most of the other actions and considerations retained for analysis in Table 4.3-1 would include operation of marine vessels. Exceptions include the actions listed under environmental regulations and permitting. Stressors associated with marine vessel operations that are of primary concern for the cumulative impacts analysis includes vessel strikes and underwater noise. Many of the actions would also result in underwater noise from sources other than vessels, including use of explosives for oil rig removal, seismic surveys, and construction activities. Rather than discussing these stressors for individual actions, their aggregate impacts are considered below as “other environmental considerations” in the maritime traffic and ocean noise subsections. Similarly, many of the actions would result in water pollution. The aggregate impacts of water pollution are addressed below in the ocean pollution section (Section 4.4.6.2.5). Bycatch is associated with commercial fishing, and the primary cause of entanglement is commercial fishing. Therefore, these stressors are discussed below in the commercial fishing section (Section 4.4.6.2.6).

4.4.6.2.2 Surveillance Towed Array Sensor System Low Frequency Active Sonar

Potential impacts on marine mammals from Surveillance Towed Array Sensor System Low Frequency Active Sonar operations include (1) nonauditory injury,[2] (2) permanent loss of hearing, (3) temporary loss of hearing, (4) behavioral change, and (5) masking. The potential effects from Surveillance Towed

[2] Nonauditory injury can be defined as not relating to or functioning in hearing (Merriam-Webster 2012); this includes mortality, strike, and lung injury.

Array Sensor System Low Frequency Active Sonar operations on any stock of marine mammals from injury (nonauditory or permanent loss of hearing) are considered negligible, and the potential effects on the stock of any marine mammal from temporary loss of hearing or behavioral change (significant change in a biologically important behavior) are considered minimal. Any auditory masking in marine mammals due to low-frequency active sonar signal transmissions is not expected to be severe and would be temporary. The operation of Surveillance Towed Array Sensor System Low Frequency Active Sonar with monitoring and mitigation would result in no mortality. The likelihood of low-frequency active sonar transmissions causing marine mammals to strand is negligible (U.S. Department of the Navy 2011b).

4.4.6.2.3 Maritime Traffic and Vessel Strikes

Vessel strikes have been and will continue to be a cause of marine mammal mortality and injury throughout the Study Area. A review of the impacts of vessel strikes on marine mammals is presented in Section 3.4.3.4.1 (Impacts from Vessels). In particular, certain large whales, such as the blue whale, are more prone to vessel strikes (Berman-Kowalewski et al. 2010; Betz et al. 2011). The most vulnerable marine mammals are thought to be those that spend extended periods at the surface or species whose unresponsiveness to vessel sound makes them more susceptible to vessel collisions (Gerstein 2002; Laist and Shaw 2006; Nowacek et al. 2004). Marine mammals such as dolphins, porpoises, and pinnipeds that can move quickly throughout the water column are not as susceptible to vessel strikes. Most vessel strikes of marine mammals reported involve commercial vessels and occur over or near the continental shelf (Laist et al. 2001). The literature review by Laist et al. (2001) concluded that vessel strikes likely have a negligible impact on the status of most whale populations, but that for small populations, vessel strikes may have considerable population-level impacts. The conservation status and abundance of the species struck would determine in large part whether the injury would have population-level impacts on that species (Laist et al. 2001; Vanderlaan and Taggart 2009).

In August 2011, the NMFS Southwest Regional Office provided the Navy with a data summary of all known or suspected ship strikes to marine mammals within California for the period 1988 to June 2011 (National Marine Fisheries Service 2011a). In order to look at a standardized period for the California data, a 20-year subset of the Southwest Regional Office stranding data from 1991 to 2010 was used for this analysis. Similar data for Hawaii was provided by the NMFS' Pacific Island Regional Office in the fall of 2011, and subsequently updated by the Pacific Island Regional Office in March 2012 to cover the period from 2003 to 2010.

In California, there were 86 large whale ship strikes over the 20-year period of the Southwest Regional Office data set analyzed (1991–2010). In looking at the 15-year interval from 1991 to 2005, however, average ship strikes were reported at the rate of three per year. Since 2006, and for the 5-year period from 2006 to 2010, there was an average of eight strikes reported per year.

It is unclear if the differences in pre and post 2006 averages are the result of increasing commercial ship traffic, increasing animal populations, changes in reporting, a statistical anomaly, or any combination of these factors. Some of this pattern of increase must be cautiously viewed in terms of how ship strike data is reported to the NMFS in California. NMFS stranding data is all reported via either self-reporting or from the California stranding network. Vessel-based reporting provides information about the type of ship and exact location where a strike occurred, but may potentially be lacking biological information on the whale struck (species, sex, length/age class, etc.). Stranding network reporting may provide more detailed biological information about the whale struck with determination of ship strike made based on injuries noted during necropsy, but not much may be known about the strike event itself (vessel type, location, ship speed, etc.). Additional temporal variation may arise from increased necropsies over the 20-year interval as more research is conducted to determine large whale mortality from stranded carcasses and from increased interest in the impacts of ship strike as a mortality source.

The California stranding network is composed of up to 17 regional partners throughout the state each with its own area of response and availability of resources. For instance, due to personnel staffing and resources on-hand, necropsies to determine ship strike may be more likely in one geographic region over another. In general, NMFS Southwest Regional Office believes that the state of interest is such that now most if not all of the California stranding network responders will attempt a large whale necropsy. But again over the 20-year time frame of the strike dataset, the percentages of ship strike reporting may have changed (i.e., increased) in some locations (Ms. Sarah Wilkin, Southwest Regional Office stranding coordinator; personal communication February 2012).

The most common species reported struck in the Southwest Regional Office data for all of California include gray whales (35 percent), blue whales (16 percent), fin whales (13 percent), humpback whales (9 percent), and sperm whales (1 percent). However, 25 percent of strikes were to species not identified (either unknown species or unidentified Balaenopterid) and these strikes could have been any of the above species including other large whale species (Bryde’s whale, minke whale, sei whale).

Within the portion of California containing the Navy’s SOCAL Range Complex and for the most part equivalent to Southwest Regional Office’s county listing for San Diego County, there were 23 whale strikes in the period from 1993 to 2010. There were no reported whale strikes from 1991 to 1992. Unknown whale species was the largest percentage of strikes (43 percent or n=10). Gray whales were the second most common (39 percent or n=9). Two fin whales were struck in 2009 by a Navy ship, but there have been no Navy ship strikes in the SOCAL Range Complex since 2009. Of the two blue whale strikes, one was struck by a research vessel in 2003 and the other by a Navy ship in 2004. The number and percentage of ship strikes to large whales in all of California by vessel category were: unknown type (43 percent or n= 37); Navy ship (19 percent or n=16); commercial ship (10 percent or n=9); recreational boat (7 percent or n=6); Coast Guard boat (6 percent or n=5); research vessel or tug (5 percent or n=4); ferry (3 percent or n=3); cruise ship (2 percent or n=2); whale watching boat (2 percent or n=2); and fishing boat (2 percent or n=2). It should be noted that U.S. Navy reports 100 percent of all Navy ship strikes to the NMFS. Only the Navy and the U.S. Coast Guard report vessel strike in this manner.

Therefore, these statistics are skewed by a lack of comprehensive reporting from all non-Navy vessels that may experience vessel strike. For instance, many of the unknown strikes (n=37 or 43 percent of total) may have been from commercial vessels or other non-Navy vessel types. Of the 16 reported Navy ship strikes, 15 occurred within the SOCAL Range Complex (San Diego County).

The Navy stratified the Southwest Regional Office 20-year data set to reflect the relative sub-region along the California coast where a given whale ship strike was reported. Four strata were used and strikes assigned to the most appropriate strata: SOCAL (area only containing SOCAL Range Complex which was mostly equivalent to San Diego County); SOCAL NORTH (area from SOCAL Range Complex northern boundary, including Orange County, Los Angeles County, and Ventura County to Point Conception—areas still within the Southern California Bight, but north and outside of the Study Area); Central California (area from Point Conception to San Francisco); and Northern California (from Marin County to the California-Oregon boundary).

Approximately 74 percent of all reported whale ship strikes occurred north and outside of the Study Area. By geographic sub-strata, the highest percentage of strikes (37 percent) was reported off the northern portion of Southern California (SOCAL NORTH), an area north of the HSTT boundary to Point Conception. This region includes the high volume commercial ship traffic ports of Los Angeles/Long Beach. The second highest percentage of ship strikes (31 percent) was off of central California which includes the commercial ship traffic ports of San Francisco/Oakland.

For the period from 2003 to 2010, there were 53 reported whale ship strikes in Hawaii. Approximately 94 percent of the 2003–2010 Hawaii ship strikes were to humpback whales (n=50), 4 percent to unknown species (n=2), and 2 percent to sperm whale (n=1). The number and percentage of ship strikes to large whales in Hawaii by vessel category were: unknown (34 percent or n=18); tour boat (26 percent or n=14); whale watching boat (9 percent or n=5); Navy ship (8 percent or n=4); research boat (6 percent or n=3); ferry (4 percent or n=2), fishing boat (4 percent or n=2); other non-specified boat (4 percent or n=2); recreational boat (2 percent or n=1); commercial ship (2 percent or n=1); and U.S. Coast Guard boat (2 percent or n=1). Island-specific ship strikes in Hawaii for the years 2003–2010 were: Maui (55 percent or n=29); Hawaii (13 percent or n=7); Kauai (9 percent or n=5); Lanai (9 percent or n=5); Oahu (8 percent or n=4) and at-sea within 300 nm of Hawaii (6 percent or n=3).

4.4.6.2.4 Ocean Noise

As summarized by the National Academies of Science, the possibility that anthropogenic sound could harm marine mammals or significantly interfere with their normal activities is an issue of concern (National Research Council of the National Academies 2005). Noise is of particular concern to marine mammals because many species use sound as a primary sense for navigating, finding prey, and communicating with other individuals. Noise can cause behavioral disturbances, mask other sounds (including their own vocalizations), result in injury, and in some cases, even lead to death (Tyack 2009a; Tyack 2009b, Würsig and Richardson 2008). Human-caused noises in the marine environment come from shipping, seismic and geologic exploration, military training, and other types of pulses produced by government, commercial, industry, and private sources. In addition, noise from whale-watching vessels near marine mammals has received a great deal of attention (Wartzok 2009).

Assessing whether a sound may disturb or injure a marine mammal involves understanding the characteristics of the acoustic sources, the marine mammals that may be present near the sound, and the effects that sound may have on the physiology and behavior of those marine mammals. Although it is known that sound is important for marine mammal communication, navigation, and foraging (National Research Council of the National Academies 2003, 2005), there are many unknowns in assessing the specific effects and significance of responses by marine mammals to sound exposures such as what activity the animal is engaged in at the time of the exposure (Nowacek et al. 2007, Southall et al. 2007). Potential impacts on marine mammals from ocean noise include behavioral reactions, hearing loss in the form of temporary threshold shift (TTS) or PTS, auditory masking, injury, and mortality. Section 3.4.3.1 (Acoustic Stressors) discusses these and other possible impacts of ocean noise on marine mammals.

4.4.6.2.5 Ocean Pollution

As discussed in Section 3.4.3 (Environmental Consequences), pollutants from multiple sources are present in, and continue to be released into, the oceans. Elevated concentrations of certain compounds have been measured in tissue samples from marine mammals. Long-term exposure to pollutants poses potential risks to the health of marine mammals, although for the most part, the impacts are just starting to be understood (Reijnders et al. 2008). Section 3.4.3 (Environmental Consequences) provides an overview of these potential impacts, which include organ anomalies and impaired reproduction and immune function (Reijnders et al. 2008).

If the health of an individual marine mammal were compromised by long-term exposure to pollutants, it is possible that this condition could alter the animal's expected response to stressors associated with Alternatives 1 and 2. The behavioral and physiological responses of any marine mammal to a potential stressor, such as underwater sound, could be influenced by a number of other factors, including disease, dietary stress, body burden of toxic chemicals, energetic stress, percentage body fat, age, reproductive state, size, and social position. Synergistic impacts are also possible. For example, animals exposed to some chemicals may be more susceptible to noise-induced loss of hearing sensitivity (Fechter 2005). While the response of a previously stressed animal might be different than the response of an unstressed animal, there are no data available at this time to accurately predict how stress caused by various ocean pollutants would alter a marine mammal's response to stressors associated with Alternatives 1 and 2.

4.4.6.2.6 Commercial Fishing

Several commercial fisheries operate in the Study Area. Potential impacts from these activities include marine mammal injury and mortality from bycatch and entanglement. Fisheries have also resulted in profound changes to the structure and function of marine ecosystems that adversely affect marine mammals.

Eleven ports in Southern California contain both commercial and commercial passenger fishing vessel (commercial passenger fishing vessel; i.e., recreational) fishing fleets that use the ocean areas within the SOCAL Range Complex portion of the Study Area (U.S. Department of the Navy 2009). Commercial fishing occurs throughout the SOCAL Range Complex from near shore waters adjacent to the mainland and offshore islands, to offshore banks (e.g., Tanner and Cortes Banks), and waters in between. In recent years, the overall number of commercial fishing vessels has decreased which has been attributed to changes in environmental conditions, fishing regulations, and market forces (California Department of Fish and Game 2008a, b).

Between 1990 and 1999, the annual mean bycatch of marine mammals in U.S. fisheries was more than 6,000 animals, and most of these were killed in gill-net fisheries (Read et al. 2006). The impacts of bycatch on marine mammal populations vary based on removal rates, population size, and reproductive rates. Small populations with relatively low reproductive rates are most susceptible. Bycatch rates for about 12 percent of U.S. marine mammal stocks (almost all cetaceans) exceed their potential biological removal levels (Read 2008). The potential biological removal level is the number of animals that can be removed each year without preventing a stock from reaching or maintaining its optimal sustainable population level.

As discussed in Section 3.4.3.5 (Entanglement Stressors), entanglement in fishing gear is another major threat to marine mammals in the Study Area. In addition, overfishing of many fish stocks has resulted in significant changes in trophic structure, species assemblages, and pathways of energy flow in marine ecosystems (Jackson et al. 2001; Myers and Worm 2003; Pauly et al. 1998). These ecological changes may have important and likely adverse consequences for populations of marine mammals (DeMaster et al. 2001).

In summary, future commercial fishing activities in the Study Area are expected to result in significant impacts on some marine mammal species based on the relatively high injury and mortality rates associated with bycatch and entanglement. This mortality could result in or contribute to population declines for some species. Ecological changes brought about by commercial fishing are also expected to adversely impact marine mammals in the Study Area.

Along the U.S. west coast from 1982 to 2010 there have been 272 reported entangled whales (Saez et al. 2012). Entanglements were seen throughout the coast with concentrations near areas where there is higher human population. Identified entangling gear types have included: trap/pot, bottom set longline, and gillnets. Gillnets were the entangling gear type in the majority of reports pre-2000 (64 percent) and trap/pot are the majority post-2000 (45 percent). In the late 1990s, California gillnet regulations changed resulting in a shift and reduction of gillnet fishing effort. Gray and humpback whales are the most frequently reported entangled large whale species along the U.S. West. In California, there were a reported 150 gray whales, 47 humpback whales, 27 unidentified whales, 14 sperm whales, 6 minke whales, and 3 fin whales entangled in fishing gear (Saez et al. 2012). National Marine Fisheries Service provided the Navy with a further breakdown of 16 reported whale fishing gear entanglements within parts of Southern California overlapped by the Navy's SOCAL Range Complex from 2000 to 2011: 8 gray whales (50.0 percent), 3 humpback whales (18.8 percent), 2 unidentified whales (12.5 percent), 2 sperm whales (12.5 percent), and 1 fin whale (6.3 percent) (Saez 2012). National Marine Fisheries Service cautioned that these data represent locations where whales were sighted entangled and may or may not be near the actual location where the entanglement first occurred.

4.4.6.3 Cumulative Impacts on Marine Mammals

The current aggregate impacts of past, present actions and reasonably foreseeable future actions are expected to result in significant impacts on some marine mammal species in the Study Area. The impacts are considered significant because vessel strikes, bycatch, and entanglement associated with other actions are expected to result in relatively high rates of injury and mortality that could cause population declines in some species. Alternatives 1 and 2 could also result in injury and mortality to individuals of some marine mammal species from underwater explosions, sonar, and vessel strikes. Injury and mortality that might occur under Alternatives 1 and 2 would be additive to injury and mortality associated with other actions. However, the relative contribution of the Proposed Action to the overall injury and mortality would be low compared to other actions. While quantitative estimates of marine mammal mortality from other actions are not available, bycatch for cetaceans and pinnipeds in the United States accounted for 4,146 mortalities in 1999 (Read et al. 2006). Some of these mortalities likely occurred in the Study Area or affected individuals that used the Study Area seasonally.

Ocean noise associated with other actions (see Section 4.4.6.2.4, Ocean Noise) and acoustic stressors (underwater explosions and sonar) associated with Alternatives 1 and 2 could also result in additive behavioral impacts on marine mammals. Other future actions such as construction and operation of liquefied natural gas terminals, and wave and tidal energy facilities would be expected to result in MMPA Level B harassment. However, it is unlikely that these actions and underwater explosions or sonar use would overlap in time and space because these activities are dispersed and the sound sources are intermittent. Furthermore, most of these other actions are not compatible with or could interfere with training and testing activities that involve underwater explosions and sonar use. The Navy takes appropriate coordination and scheduling steps (described in Section 3.11, Socioeconomic Resources) to avoid activities that interfere with or are not compatible with training and testing.

It is likely that distant shipping noise, which is more universal and continuous, and sound associated with underwater explosions and sonar would overlap in time and space. However, there is no evidence indicating that the co-occurrence of shipping noise and sounds associated with underwater explosions and sonar use would result in harmful additive impacts on marine mammals.

As discussed in Section 4.4.6.2.5 (Ocean Pollution), the potential also exists for the impacts of ocean pollution and acoustic stressors associated with Alternatives 1 and 2 to be additive or synergistic. It is possible that the response of a previously stressed animal would be more severe than the response of an unstressed animal.

In summary, based on the analysis presented in Section 3.4 (Marine Mammals) the current aggregate impacts of past and present actions and reasonably foreseeable future actions are expected to result in significant impacts on some marine mammal species in the Study Area. Therefore, cumulative impacts on marine mammals would be significant without consideration of the impacts of Alternatives 1 or 2. Alternatives 1 and 2 would contribute to and increase cumulative impacts, but the relative contribution would be low compared to other actions. Further analysis of cumulative impacts on marine mammals is not warranted.

4.4.7 Sea Turtles

4.4.7.1 Impacts of Alternatives 1 and 2 That May Contribute to Cumulative Impacts

Impacts of Alternatives 1 and 2 that might contribute to cumulative impacts on sea turtles include mortality, injury, and short-term disturbance or behavioral modification. Mortality or injury could be caused by underwater explosions or vessel strikes. Injury, in the form of PTS, could also be caused by sonar use. Noninjurious impacts of underwater explosions and sonar use would include short-term disturbance or behavioral modification. The Navy's Endangered Species Act (ESA) determinations presented in Table 3.5-14 are "no effect" or "may affect, not likely to adversely affect" for the remaining stressors analyzed in Section 3.5 (Sea Turtles). The incremental contribution of these remaining stressors to cumulative impacts on sea turtles would be negligible. Therefore, these stressors are not considered further in the cumulative impacts analysis. The impacts of Alternatives 1 and 2 considered in the cumulative impacts analysis are summarized in Table 3.5-14 (Summary of Effects and Impact Conclusions: Sea Turtles).

4.4.7.2 Impacts of Other Actions

The potential impacts of other actions that are relevant to the cumulative impact analysis for sea turtles include the following:

- Mortality associated with vessel strikes, bycatch in fisheries, entanglement, and stressors associated with coastal development and human use of coastal environments (e.g., beach vehicular driving, power plant entrainment [sea turtles being caught in power plant outflow water], etc.)
- Injury associated with vessel strikes, bycatch, entanglement, and underwater sound
- Disturbance, behavioral modifications, and reduced animal fitness associated with underwater noise
- Reduced animal fitness associated with ocean pollution
- Habitat loss related to coastal development

Most of the other actions and considerations retained for analysis in Chapter 3, Section 3.5 (Sea Turtles) would include operation of marine vessels. Exceptions include the actions listed under environmental regulations and planning. Stressors associated with marine vessel operations that are of primary concern for the cumulative impacts analysis includes vessel strikes and underwater noise. Many of the actions would also result in underwater noise from sources other than vessels. Rather than discussing these stressors for individual actions, their aggregate impacts are considered below as "other environmental considerations" in maritime traffic (Section 4.4.6.2.3, Maritime Traffic and Vessel Strikes) and ocean noise (Section 4.4.6.2.4, Ocean Noise). Similarly, many of the actions would result in ocean pollution. The aggregate impacts of water pollution are addressed below in the ocean pollution section (see Section 4.4.6.2.5, Ocean Pollution). Bycatch is associated with commercial fishing, and the primary cause of entanglement is commercial fishing. Therefore, these stressors are discussed below in the commercial fishing section (Section 4.4.6.2.6, Commercial Fishing).

4.4.7.2.1 Surveillance Towed Array Sensor System Low Frequency Active Sonar

Sea turtles could be affected if they are inside the mitigation zone (180 dB sound field) during a Surveillance Towed Array Sensor System Low Frequency Active Sonar transmission. However, because received levels from Surveillance Towed Array Sensor System Low Frequency Active Sonar operations would be below 180 dB sound pressure level within 12 nm or greater distance of any coastlines and offshore biologically important areas, effects on a sea turtle stock could occur only if a significant portion of the stock encountered the Surveillance Towed Array Sensor System Low Frequency Active Sonar vessel in the open ocean. The potential for Surveillance Towed Array Sensor System Low Frequency Active Sonar operations to expose sea turtle stocks to injurious (nonauditory or PTS) sound levels or to cause TTS or behavioral changes is considered negligible because (U.S. Department of the Navy 2011b):

- Most sea turtle species inhabit the earth's oceanic temperate zones, where sound propagation is predominantly characterized by downward refraction (higher transmission loss, shorter range), rather than ducting (lower transmission loss, longer range), which is usually found in cold-water regimes.
- Sea turtle distribution and density are generally low at ranges greater than 12 nm from the coast.
- The Surveillance Towed Array Sensor System Low Frequency Active Sonar signal has a narrow bandwidth (approximately 30 Hz).
- The ship is always moving, and the system has a low duty cycle (estimated 7.5 percent), which means sea turtles would have less opportunity to be in the mitigation zone during a transmission.
- Visual monitoring mitigation is incorporated into the alternatives.

4.4.7.2.2 Maritime Traffic and Vessel Strikes

Maritime traffic has increased over the past 50 years, and continued increases are expected in the future. Vessel strikes have been and will continue to be a cause of sea turtle mortality and injury throughout portions of the Study Area where sea turtles regularly occur. Because of the wide dispersal of large vessels in open ocean areas and the widespread, scattered distribution of turtles at sea, strikes during open-ocean transits are unlikely.

Some vessel strikes would cause temporary reversible impacts, such as diverting the turtle from its previous activity or causing minor injury. A National Research Council report qualitatively ranked the relative importance of various mortality factors for sea turtles. Vessel strikes were ranked 10th, behind leading factors of shrimp trawling and other fisheries (National Research Council 1990). Major strikes would cause permanent injury or death from bleeding, infection, or inability to feed. Apart from the severity of the physical strike, the likelihood and rate of a turtle's recovery from a strike may be influenced by its age, reproductive state, and general condition. Much of what is written about recovery from vessel strikes is inferred from observing individuals some time after a strike. Numerous living sea turtles bear scars that appear to have been caused by propeller cuts or collisions with vessel hulls (Hazel et al. 2007, Lutcavage et al. 1997), suggesting that not all vessel strikes are lethal. Conversely, fresh wounds on some stranded animals may strongly suggest a vessel strike as the cause of death. The actual incidence of recovery versus death is not known, given available data.

4.4.7.2.3 Ocean Noise

Potential impacts on sea turtles from ocean noise include behavioral reactions, hearing loss in the form of TTS or PTS, auditory masking, injury, and mortality. Section 3.4.3.1 (Acoustic Stressors) discusses these and other possible impacts of ocean noise on marine mammals.

4.4.7.2.4 Ocean Pollution

Marine debris can also be a problem for sea turtles through entanglement or ingestion. Sea turtles can mistake debris for prey; one study found 37 percent of dead leatherbacks to have ingested various types of plastic (Mrosovsky et al. 2009). Other marine debris, including abandoned fishing gear and cargo nets, can entangle and drown turtles in all life stages.

4.4.7.2.5 Commercial Fishing

Bycatch is one of the most serious threats to the recovery and conservation of sea turtle populations (National Research Council 1990, Wallace et al. 2010). Among fisheries that incidentally capture sea turtles, certain types of trawl, gillnet, and longline fisheries generally pose the greatest threat. One comprehensive study estimated that worldwide, 447,000 turtles are killed each year from bycatch in commercial fisheries (Wallace et al. 2010).

Other fisheries that result in sea turtle bycatch in the Study Area include pelagic fisheries for swordfish, tuna, shark, and billfish; purse seine fisheries for tuna; commercial and recreational rod and reel fisheries; gillnet fisheries for shark; driftnet fisheries; and bottom longline fisheries (National Marine Fisheries Service 2009).

4.4.7.2.6 Coastal Development

Coastal development and increased human populations in coastal areas will continue to have impacts on sea turtles such as nesting beach habitat degradation, beach vehicular driving, beach lighting, power plant entrainment, and degradation of nearshore water quality and seagrass beds (see Section 3.5, Sea Turtles, for more information on impacts on sea turtles).

4.4.7.2.7 Cumulative Impacts on Sea Turtles

The current aggregate impacts of past, present and reasonably foreseeable future actions are expected to result in impacts on sea turtles. These aggregate impacts include those from bycatch, vessel strikes, entanglement and other stressors associated with other actions, which are expected to result in high rates of injury and mortality that could cause population declines to ESA-listed species or inhibit species recovery. Alternatives 1 and 2 could also result in injury and mortality to individual sea turtles from underwater explosions, sonar, and vessel strikes. Injury and mortality that might occur under Alternatives 1 and 2 would be additive to injury and mortality associated with other actions. However, the relative contribution of Alternatives 1 and 2 to the overall injury and mortality would be low compared to other actions. A total of four potential sea turtle mortalities per year are estimated for the No Action Alternative and five for Alternatives 1 and 2 (see Tables 3.5-9 through 3.5-13).

Ocean noise associated with other actions and acoustic stressors (underwater explosions and sonar) associated with Alternatives 1 and 2 could also result in additive behavioral impacts on sea turtles. Other future actions such as construction and operation of liquefied natural gas terminals, and wave and tidal energy facilities would be expected to result in similar impacts. However, it is unlikely that these actions and underwater explosions or sonar use would overlap in time and space because all of these activities are widespread and the sound sources are intermittent. Furthermore, most of these other actions are not compatible with or could interfere with training and testing activities that involve underwater explosions and sonar use. The Navy takes appropriate steps to avoid activities that interfere with or are not compatible with training and testing.

It is likely that distant shipping noise (which is more pervasive and continuous) and sound associated with underwater explosions and sonar would overlap in time and space. However, there is no evidence indicating that the co-occurrence of shipping noise and sounds associated with underwater explosions and sonar use would result in harmful additive impacts on sea turtles.

The potential also exists for the impacts of ocean pollution and acoustic stressors associated with Alternatives 1 and 2 to be additive or synergistic. It is possible that the response of a previously stressed animal would be more severe than the response of an unstressed animal. However, there are no data indicating that a sea turtle affected by ocean pollution would be more susceptible to stressors associated with Alternatives 1 and 2.

In summary, based upon the analysis in Section 3.5 (Sea Turtles) past and present actions and reasonably foreseeable future actions are expected to result in impacts on sea turtles. Therefore, impacts on sea turtles would occur without consideration of the impacts of Alternatives 1 and 2. Alternatives 1 and 2 would contribute to and increase cumulative impacts, but the relative contribution would be low compared to other actions. Further analysis of cumulative impacts on sea turtles is not warranted.

4.4.8 SEABIRDS

The analysis in Section 3.6 (Seabirds) indicates that birds could be affected by acoustic stressors (tactical acoustic sonar, other acoustic devices, pile driving, underwater explosions, weapons firing noise, aircraft noise, vessel noise), energy stressors (electromagnetic, lasers), physical disturbance and strikes (aircraft, vessels and in-water devices, military expended materials), and ingestion (military expended materials). Potential responses would include a startle response, which includes short-term behavioral (i.e., movement) and physiological components (i.e., increased heart rate). Recovery from the impacts of most stressor exposures would occur quickly, and impacts would be localized. Some stressors, including underwater explosions, physical strikes, and ingestion of military expended materials, could result in mortality. However, the number of individual birds affected would be low, and no population-level impacts are expected. The impacts of Alternatives 1 and 2 would be cumulative with other actions that cause short-term behavioral and physiological impacts and mortality to birds, such as ingestion and entanglement in marine debris. However, the incremental contribution of Alternatives 1 or 2 to cumulative impacts on birds would be low for the following reasons:

- Most of the proposed activities would be widely dispersed in offshore areas where bird distribution is patchy and concentrations of individuals are low. Therefore, the potential for interactions between birds and training and testing activities is low. It is unlikely that training and testing activities would influence nesting because most activities take place in water and away from nesting habitats on land. Alternatives 1 and 2 would not result in destruction or loss of nesting habitat.

- For most stressors, impacts would be short term and localized, and recovery would occur quickly.
- While a limited amount of mortality could occur, no population level impacts would be expected.
- Alternatives 1 and 2 are not likely to adversely affect ESA-listed bird species.

Based on the analysis in Section 3.6 (Seabirds) and the reasons summarized above, the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be negligible. Further analysis of cumulative impacts on birds is not warranted.

4.4.9 Marine Vegetation

The analysis presented in Section 3.7 (Marine Vegetation) indicates that marine vegetation could be affected by acoustic stressors (underwater explosions) and physical stressors (interactions with vessels and in-water devices, military expended materials, or seafloor devices). Potential impacts include localized disturbance and mortality. Recovery would occur quickly, and population level impacts are not anticipated. The impacts of Alternatives 1 or 2 would be cumulative with other actions that cause disturbance and mortality of marine vegetation. However, the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be low for the following reasons:

- Most of the proposed activities would occur in areas where seagrasses and other attached marine vegetation do not grow.
- Impacts would be localized, recovery would occur quickly, and no population level impacts would be expected.
- Alternatives 1 and 2 would not result in impacts that have been historically significant to marine vegetation. For example, Alternatives 1 and 2 would not increase nutrient loading, which can cause algal blooms, decrease light penetration, and impact photosynthesis of seagrasses. Furthermore, Alternatives 1 and 2 would not result in long-term or widespread changes in environmental conditions, such as turbidity, salinity, pH, or water temperature that could impact marine vegetation.
- The Proposed Action would have no effect on ESA-listed species of marine vegetation and would not result in the destruction or adverse modification of critical habitat.

Based on the analysis presented in Section 3.7 (Marine Vegetation) and the reasons summarized above, the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be low. Further analysis of cumulative impacts on marine vegetation is not warranted.

4.4.10 Marine Invertebrates

The analysis presented in Section 3.8 (Marine Invertebrates), indicates that marine invertebrates could be affected by acoustic stressors (tactical acoustic sonar, other acoustic devices, pile driving, underwater explosions, weapons firing noise, aircraft noise, vessel noise), electromagnetic stressors, physical disturbance or strikes (vessels and in-water devices, military expended materials, seafloor devices), entanglement (fiber-optic cables and guidance wires, parachutes), and ingestion (military expended materials). Potential impacts include short-term behavioral and physiological responses. Some stressors could also result in injury or mortality to a relatively small number of individuals, but not to ESA-listed corals. No population-level impacts are anticipated. Stressors from Alternatives 1 and 2 would have no effect or would be not likely to adversely affect ESA-listed corals.

Based upon the analysis in Section 3.8 (Marine Invertebrates) the invertebrate mortality impacts of Alternatives 1 and 2 would be cumulative with other actions that cause mortality (e.g., commercial fishing). However, the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be negligible. Therefore, further analysis of cumulative impacts on marine invertebrates is not warranted.

4.4.11 FISH

The analysis presented in Section 3.9 (Fish) indicates that fishes could be affected by acoustic stressors (tactical acoustic sonar, other acoustic devices, pile driving, underwater explosions, weapons firing noise, aircraft noise, vessel noise), electromagnetic stressors, physical disturbance or strikes (vessels and in-water devices, military expended materials, seafloor devices), entanglement (fiber-optic cables and guidance wires, parachutes), and ingestion (military expended materials). Potential impacts include short-term behavioral and physiological responses. Some stressors could also result in injury or mortality to a relatively small number of individuals, but not to ESA-listed fishes. No population level impacts are anticipated. Stressors from Alternatives 1 and 2 would have no effect or would be not likely to adversely affect ESA-listed fishes.

Based upon the analysis presented in Section 3.9 (Fish), the fish mortality impacts of Alternatives 1 and 2 would be cumulative with other actions that cause mortality (e.g., commercial fishing). However, the incremental contribution of Alternatives 1 and 2 to cumulative impacts would be negligible. Therefore, further detailed analysis of cumulative impacts on fishes is not warranted.

4.4.12 CULTURAL RESOURCES

4.4.12.1 Impacts of Alternatives 1 and 2 That May Contribute to Cumulative Impacts

As discussed in Section 3.10 (Cultural Resources), no impacts on submerged prehistoric sites or previously unidentified submerged historic resources are expected. Testing and training would continue only in areas currently utilized for these activities. As a result, effects on cultural resources are not anticipated within U.S. territorial waters because measures have been previously implemented to protect these resources.

The Navy routinely avoids locations of known obstructions to prevent damage to sensitive Navy equipment and vessels and to ensure the accuracy of training and testing exercises. Known obstructions include some historic shipwrecks.

4.4.12.2 Impacts of Other Actions

With a few exceptions, most of the other actions retained for cumulative impacts analysis (see Table 4.3-1) would involve some form of disturbance to the ocean bottom. Exceptions include environmental regulations and planning actions, ocean pollution, and most forms of ocean noise. Actions that would disturb the ocean bottom could impact submerged cultural resources. For example, ocean bottom disturbance would occur from construction related activities such as installation of offshore natural gas terminals and pipelines, ship anchoring, and installation of wind turbine piers and excavation of cable trenches. Any physical disturbance on the continental shelf and ocean floor could inadvertently damage or destroy submerged prehistoric sites and submerged historic resources. Excavation such as pipeline installation for liquefied natural gas terminals could disrupt the horizontal patterning and vertical stratigraphy of submerged prehistoric sites and submerged historic resources.

The other actions that result in ocean bottom disturbance require some form of federal authorization or permitting. Therefore, requirements of the National Historic Preservation Act apply to actions in territorial waters. Federal agency procedures have been implemented to identify cultural resources, avoid impacts, and mitigate if impacts cannot be avoided. For example, the Bureau of Ocean Energy Management, Regulation and Enforcement has procedures in place to identify the probability for the presence of submerged historic resources and the locations submerged prehistoric sites shoreward from the 148 ft. (45.1 m) isobath, and for project redesign and relocation to avoid identified resources (Minerals Management Service 2007).

4.4.12.3 Cumulative Impacts on Cultural Resources

Impacts on submerged cultural resources from other actions would typically be avoided or mitigated through implementing federal agency programs. Disturbance or destruction of submerged prehistoric sites would diminish the overall archaeological record and decrease the potential for meaningful research on Paleoindian (late Pleistocene) and Early Archaic (early Holocene) occupations. Disturbance or destruction of submerged historic sites, including shipwrecks, would diminish the overall record for these resources and decrease the potential for meaningful research on these resources. Based upon the analysis in Section 3.10 (Cultural Resources), when considered with other actions, Alternatives 1 and 2 would contribute to and increase the cumulative impacts on submerged prehistoric and historic resources. Further analysis of cumulative impacts on cultural resources is not warranted.

4.4.13 Socioeconomics

The analysis in Section 3.11 (Socioeconomic Resources) indicates that the impacts of Alternatives 1 and 2 on socioeconomic resources would be negligible. Alternatives 1 and 2 are not expected to contribute incrementally to cumulative socioeconomic impacts. Therefore, further analysis of cumulative impacts on socioeconomic resources is not warranted.

4.4.14 Public Health and Safety

The analysis presented in Section 3.12 (Public Health and Safety) indicates that the impacts of Alternatives 1 and 2 on public health and safety would be negligible. Alternatives 1 and 2 are not expected to contribute incrementally to cumulative health and safety impacts. Therefore, further analysis of cumulative impacts on public health and safety is not warranted.

4.5 Summary of Cumulative Impacts

Marine mammals and sea turtles are the primary resources of concern for cumulative impacts analysis:

- Past human activities have impacted these resources to the extent that several marine mammal species and all sea turtles species occurring in the Study Area are ESA-listed.
- These resources would be impacted by multiple ongoing and future actions.
- Explosive detonations and vessel strikes under the No Action Alternative, Alternative 1, and Alternative 2 have the potential to disturb, injure, or kill marine mammals and sea turtles.

The aggregate impacts of past, present, and other reasonably foreseeable future actions are expected to result in significant impacts on some marine mammal and all sea turtle species in the Study Area. The No Action Alternative, Alternative 1, or Alternative 2 would contribute to cumulative impacts, but the relative contribution would be low compared to other actions. Compared to potential mortality, strandings, or injury resulting from Navy training and testing activities, marine mammal and sea turtle mortality and injury from bycatch, commercial vessel ship strikes, entanglement, ocean pollution, and other human causes are estimated to be orders of magnitude greater (hundreds of thousands of animals versus tens of animals) (Culik 2004, International Council for the Exploration of the Sea 2005, Read et al. 2006).

The analyses presented in this chapter and Chapter 3 (Affected Environment and Environmental Consequences) indicate that the incremental contribution of the No Action Alternative, Alternative 1, or Alternative 2 to cumulative impacts on sediments and water quality, air quality, marine habitats, birds, marine vegetation, marine invertebrates, fish, socioeconomic resources, and public health and safety would be negligible. When considered with other actions, the No Action Alternative, Alternative 1, or Alternative 2 might contribute to cumulative impacts on submerged prehistoric and historic resources, if such resources are present in areas where bottom-disturbing training and testing activities take place. The No Action Alternative, Alternative 1, or Alternative 2 would also make an incremental contribution to greenhouse gas emissions, representing approximately 0.030 percent, 0.031 percent, and 0.031 percent of U.S. 2009 greenhouse gas emissions, respectively.

LIST OF FIGURES

5 STANDARD OPERATING PROCEDURES, MITIGATION, AND MONITORING

This chapter describes the United States (U.S.) Department of the Navy (Navy) standard operating procedures, mitigation measures, and marine species monitoring and reporting efforts. Standard operating procedures are essential to maintaining safety and mission success, and in many cases have the added benefit of reducing potential environmental impacts. Mitigation measures are designed to help reduce or avoid potential impacts on marine resources. Marine species monitoring efforts are designed to track compliance with take authorizations, evaluate the effectiveness of mitigation measures, and improve understanding of the impacts of training and testing activities on marine resources within the Hawaii-Southern California Training and Testing (HSTT) Study Area (Study Area).

5.1 STANDARD OPERATING PROCEDURES

Effective training, maintenance, research, development, testing, and evaluation (hereafter referred to collectively as the Proposed Action) require that participants utilize their sensors and weapon systems to their optimum capabilities as required by the activity objectives. The Navy currently employs standard practices to provide for the safety of personnel and equipment, including vessels and aircraft, as well as the success of the training and testing activities. For the purpose of this document, the Navy will refer to standard practices as standard operating procedures. Because of their importance for maintaining safety and mission success, standard operating procedures have been considered as part of the Proposed Action under each alternative, and therefore are included in the Chapter 3 (Affected Environment and Environmental Consequences) environmental analyses for each resource.

Navy standard operating procedures have been developed and refined over years of experience, and are broadcast via numerous naval instructions and manuals, including the following sources:

- Ship, submarine and aircraft safety manuals
- Ship, submarine and aircraft standard operating manuals
- Fleet Area Control and Surveillance Facility range operating instructions
- Fleet exercise publications and instructions
- Naval Sea Systems Command test range safety and standard operating instructions
- Navy instrumented range operating procedures
- Naval shipyard sea trial agendas
- Research, development, test and evaluation plans
- Naval gunfire safety instructions
- Navy planned maintenance system instructions and requirements
- Federal Aviation Administration regulations

In many cases there are incidental environmental, socioeconomic, and cultural benefits resulting from standard operating procedures. Standard operating procedures serve the primary purpose of providing for safety and mission success, and are implemented regardless of their secondary benefits. This is what distinguishes standard operating procedures, which are a component of the Proposed Action, from mitigation measures, which are designed entirely for the purpose of reducing environmental impacts resulting from the Proposed Action. Because standard operating procedures are crucial to safety and mission success, the Navy will not modify them as a way to further reduce impacts on environmental resources. Rather, mitigation measures will be used as the tool for avoiding and reducing potential environmental impacts. Standard operating procedures that are recognized as providing a potential secondary benefit are provided below.

5.1.1 VESSEL SAFETY

For the purposes of this chapter, the term 'ship' is inclusive of surface ships and surfaced submarines. The term 'vessel' is inclusive of ships and small boats (e.g., rigid-hull inflatable boats).

Ships operated by or for the Navy have personnel assigned to stand watch at all times, day and night, when moving through the water (underway). Watch personnel undertake extensive training in accordance with the U.S. Navy Lookout Training Handbook or civilian equivalent, including on-the-job instruction and a formal Personal Qualification Standard program (or equivalent program for supporting contractors or civilians), to certify that they have demonstrated all necessary skills (such as detection and reporting of floating or partially submerged objects). Watch personnel are composed of officers, enlisted men and women, and civilian equivalents. Their duties may be performed in conjunction with other job responsibilities, such as navigating the ship or supervising other personnel. While on watch, personnel employ visual search techniques, including the use of binoculars, using a scanning method in accordance with the U.S. Navy Lookout Training Handbook or civilian equivalent. After sunset and prior to sunrise, watch personnel employ night visual search techniques, which could include the use of night vision devices.

A primary duty of watch personnel is to detect and report all objects and disturbances sighted in the water that may be indicative of a threat to the ship and its crew, such as debris, a periscope, surfaced submarine, or surface disturbance. Per safety requirements, watch personnel also report any marine mammals sighted that have the potential to be in the direct path of the ship as a standard collision avoidance procedure. Because watch personnel are primarily posted for safety of navigation, range clearance, and man-overboard precautions, they are not normally posted while ships are moored to a pier. When anchored or moored to a buoy, a watch team is still maintained but with fewer personnel than when underway. When moored or at anchor, watch personnel may maintain security and safety of the ship by scanning the water for any indications of a threat (as described above).

While underway, Navy ships (with the exception of submarines) greater than 65 feet (ft.) (20 meters [m]) in length have at least two watch personnel; Navy ships less than 65 ft. (20 m) in length, surfaced submarines, and contractor ships have at least one watch person. While underway, watch personnel are alert at all times and have access to binoculars. Due to limited manning and space limitations, small boats do not have dedicated watch personnel, and the boat crew is responsible for maintaining the safety of the boat and surrounding environment.

All vessels use extreme caution and proceed at a "safe speed" so they can take proper and effective action to avoid a collision with any sighted object or disturbance, and can be stopped within a distance appropriate to the prevailing circumstances and conditions.

5.1.2 AIRCRAFT SAFETY

Pilots of Navy aircraft make every attempt to avoid large flocks of birds in order to reduce the safety risk involved with a potential bird strike.

5.1.3 LASER PROCEDURES

The following procedures are applicable to lasers of sufficient intensity to cause human eye damage.

5.1.3.1 Laser Operators

Only properly trained and authorized personnel operate lasers.

5.1.3.2 Laser Activity Clearance

Prior to commencing activities involving lasers, the operator ensures that the area is clear of unprotected or unauthorized personnel in the laser impact area by performing a personnel inspection or a flyover. The operator also ensures that any personnel within the area are aware of laser activities and are properly protected.

5.1.4 WEAPONS FIRING PROCEDURES

5.1.4.1 Notice to Mariners

A Notice to Mariners is routinely issued in advance of missile firing activities. A notice is also issued in advance of explosive bombing activities when they are conducted in an area that does not already have a standing Notice to Mariners. For activities involving large-caliber gunnery, the Navy evaluates the need to publish a Notice to Mariners based on the scale, location, and timing of the activity. More information on the Notices to Mariners is found in Section 3.12.2.1.1 (Sea Space).

5.1.4.2 Weapons Firing Range Clearance

The weapons firing hazard range must be clear of non-participating vessels and aircraft before firing activities will commence. The size of the firing hazard range is based on the farthest firing range capability of the weapon being used. All missile and rocket firing activities are carefully planned in advance and conducted under strict procedures that place the ultimate responsibility for range safety on the Officer Conducting the Exercise or civilian equivalent. All weapons firing is secured when cease fire orders are received from the Range Safety Officer or when the line of fire is endangering any object other than the designated target.

Pilots of Navy aircraft are not authorized to expend ordnance, fire missiles, or drop other airborne devices through extensive cloud cover where visual clearance of the air and surface area is not possible. The two exceptions to this requirement are: (1) when operating in the open ocean, air, and surface clearance through visual means or radar surveillance is acceptable; and (2) when the operational commander conducting the exercise accepts responsibility for the safeguarding of airborne and surface traffic.

During activities that involve recoverable targets (e.g., aerial drones), the Navy recovers the target and any associated parachutes to the maximum extent practicable consistent with operational requirements and personnel safety.

5.1.4.3 Target Deployment Safety

Firing exercises involving the integrated maritime portable acoustic scoring system are typically conducted in daylight hours in Beaufort number 4 conditions or better to ensure safe operating conditions during buoy deployment and recovery. The Beaufort sea state scale is a standardized measurement of the weather conditions, based primarily on wind speed. The scale is divided into levels from 0 to 12, with 12 indicating the most severe weather conditions (e.g., hurricane force winds). At Beaufort number 4, wave heights typically range from 3.5 to 5 ft. (1 to 1.5 m).

5.1.5 SWIMMER DEFENSE TESTING PROCEDURES

5.1.5.1 Notice to Mariners

A Notice to Mariners is issued in advance of all swimmer defense testing.

5.1.5.2 Swimmer Defense Testing Clearance

A daily in situ calibration of the source levels is used to establish a clearance area to the 145 decibels (dB) referenced to (re) 1 micro (µ) Pascal (Pa) sound pressure level threshold for non-participant personnel safety. A hydrophone is stationed during the calibration sequences in order to confirm the clearance area. Small boats patrol the 145 dB re 1 µPa sound pressure level area during all test activities. Boat crews are equipped with binoculars and remain vigilant for non-participant divers and boats, swimmers, snorkelers, and dive flags. If a non-participating swimmer, snorkeler, or diver is observed entering into the area of the swimmer defense system, the power levels of the defense system are reduced. An additional 100-yard (yd.) (91 m) buffer is applied to the initial sighting location of the non-participant as an additional precaution. If the area cannot be maintained free of non-participating swimmers, snorkelers, and divers, testing will cease until the non-participant has moved outside the area.

5.1.6 UNMANNED AERIAL AND UNDERWATER VEHICLE PROCEDURES

For activities involving unmanned aerial and underwater vehicles, the Navy evaluates the need to publish a Notice to Airmen or Mariners based on the scale, location, and timing of the activity. Unmanned aerial vehicles and unmanned aerial systems are operated in accordance with Federal Aviation Administration air traffic organization policy as issued in Office of the Chief of Naval Operations Instructions 3710, 3750, and 4790.

5.1.7 TOWED IN-WATER DEVICE PROCEDURES

Prior to deploying a towed device from a manned platform, there is a standard operating procedure to search the intended path of the device for any floating debris (e.g., driftwood) or other potential obstructions (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies] and animals), which have the potential to cause damage to the device.

5.2 INTRODUCTION TO MITIGATION

The Navy recognizes that the Proposed Action has the potential to impact the environment. Unlike standard operating procedures, which are established for reasons other than environmental benefit, mitigation measures are modifications to the Proposed Action that are implemented for the sole purpose of reducing a specific potential environmental impact on a particular resource. The procedures discussed in this chapter, most of which are currently or were previously implemented as a result of past environmental compliance documents, Endangered Species Act (ESA) Biological Opinions, Marine Mammal Protection Act (MMPA) Letters of Authorization, or other formal or informal consultations with regulatory agencies, have been coordinated with the National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service through the consultation and permitting processes.

5.2.1 REGULATORY REQUIREMENTS FOR MITIGATION

An Environmental Impact Statement (EIS) must analyze the affected environment, discuss the environmental impacts of the Proposed Action and each alternative, and assess the significance of the impacts on the environment. Mitigation measures are designed to help reduce the severity or intensity of impacts of the Proposed Action. Assessment of mitigation measures can occur early in the planning process. An agency may choose not to take the action or to move the location of the action. Mitigation measure development also occurs throughout the analysis process whenever an impact is minimized by limiting the degree or magnitude of the action or its implementation. Mitigation measures can also include actions that repair, rehabilitate, or restore the affected environment or reduce impacts over time through constant monitoring and corrective adjustments.

In accordance with the National Environmental Policy Act (NEPA) requirement, the environmental benefit of all Navy recommended proposed mitigation measures will apply to all alternatives analyzed in this Final EIS, and according to Navy policy, will also apply to the Final Overseas Environmental Impact Statement (OEIS) where applicable and appropriate. Additionally, the White House Council on Environmental Quality issued guidance for mitigation and monitoring on 14 January 2011. This guidance affirms that federal agencies, including the Navy, should:

- commit to mitigation in decision documents when they have based environmental analysis upon such mitigation (by including appropriate conditions on grants, permits, or other agency approvals, and making funding or approvals for implementing the Proposed Action contingent on implementation of the mitigation commitments);
- monitor the implementation and effectiveness of mitigation commitments;
- make information on mitigation and monitoring available to the public, preferably through agency web sites; and
- remedy ineffective mitigation when the federal action is not yet complete.

The Council on Environmental Quality guidance encourages federal agencies to develop internal processes for post-decision monitoring to ensure the implementation and effectiveness of the mitigation. It also states that federal agencies may use adaptive management as part of an agency's action. Adaptive management, when included in the NEPA analysis, allows for the agency to take alternate mitigation actions if mitigation commitments originally made in the planning and decision documents fail to achieve projected environmental outcomes. Adaptive management generally involves four phases: plan, act, monitor, and evaluate. This process allows the use of the results to update knowledge and adjust future management actions accordingly. Through implementing mitigation measures from the Navy's previous planning, consultations, permits, and monitoring of those efforts, the Navy has collected data to further refine its recommended mitigation measures.

Through the planning, consultation, and permitting processes, federal regulatory agencies suggested that the Navy analyze additional mitigation measures for inclusion in this Final EIS/OEIS and associated consultation and permitting documents. Proposals for additional mitigation measures were based on the federal agency's assessment of the likelihood that such measures will contribute to a notable reduction of the environmental impact. As additional measures were identified, the effectiveness and operational assessment protocols discussed in Section 5.3 (Mitigation Assessment) were applied to determine whether the Navy would recommend the additional measures for implementation. The final suite of mitigations resulting from the ongoing planning, consultation, and permitting processes will be documented in the Navy and NMFS Records of Decision, the MMPA Letters of Authorization, and the ESA Biological Opinions.

5.2.2 Overview of Mitigation Approach

This section describes the approach the Navy took to develop its recommended mitigation measures. The Navy's overall approach to assessing potential mitigation measures was based on two principles: (1) mitigations will be effective at reducing potential impacts on the resource, and (2) from a military perspective, the mitigations are practical to implement, executable, and personnel safety and readiness will not be impacted. The assessment process involved using information directly from Chapter 3 (Affected Environment and Environmental Consequences) and assessing all existing mitigation and proposals for new or modified mitigation in order to determine if recommending a mitigation measure for implementation would be appropriate.

This document organized, and where appropriate, analyzed training and testing activities separately. This separation was needed because the training and testing communities perform activities for differing purposes, and in some cases, with different personnel and in different locations. For example, there is a fundamental difference between the testing of a new mine warfare system with civilian scientists and engineers, and the eventual training of sailors and aviators with that same system. As such, mitigations that the Navy recommends for both training and testing activities are presented together, while mitigations that are designed for and executable only by the training or testing community are presented separately.

5.2.2.1 Lessons Learned from Previous Environmental Impact Statements/Overseas Environmental Impact Statements

In an effort to improve upon past processes, the Navy considered all mitigations previously implemented and adapted its mitigation assessment approach based on lessons learned from previous EISs, ESA Biological Opinions, MMPA Letters of Authorizations, and other formal or informal consultations with regulatory agencies. For example, one lesson learned during the development of the Hawaii Range Complex EIS/OEIS was that relocation of activities was not possible due to a number of factors. The Navy considered reduction or elimination of training in the Hawaii Range Complex, but determined that the amount and cost of travel to other range complexes to fulfill training requirements would result in an unacceptable increase in time away from the homeport. Additionally, the Hawaii Range Complex offers an invaluable facility on which to conduct training and testing in a realistic environment.

Navy planners, scientists, and the operational community assessed the effectiveness of a full suite of potential mitigation measures (a portion of which were specific mitigation areas) on a case-by-case basis, using information and lessons learned from the Navy's internal adaptive management process. The resulting assemblage of recommended measures is comprised of currently implemented measures, modifications of currently implemented measures, and newly proposed measures. Details on the assessment methods are provided in Section 5.2.3 (Assessment Method). The rationale for recommending, modifying, adding, or discontinuing each measure is provided in Section 5.3 (Mitigation Assessment).

5.2.2.2 Protective Measures Assessment Protocol

The Protective Measures Assessment Protocol is a decision support and situational awareness software tool that the Navy uses to facilitate compliance with mitigation measures when conducting certain training and testing activities at sea. The Navy runs the Protective Measures Assessment Protocol program during the event planning process to ensure that personnel involved in the activity are aware of the mitigation requirements and to help ensure that all mitigations are implemented appropriately. In addition to providing notification of the required mitigation, the tool also provides a visual display of the activity location, unit's position in relation to the target area, and any relevant environmental data. The final suite of mitigation measures contained in the Navy and NMFS Records of Decision, the MMPA Letters of Authorization, and the ESA Biological Opinions will be integrated into the Protective Measures Assessment Protocol. Section 5.3.1.1.1.1 (United States Navy Afloat Environmental Compliance Training

Series) contains information about the newly developed Protective Measures Assessment Protocol training module.

5.2.3 ASSESSMENT METHOD

As shown in Figure 5.2-1, the Navy undertook an effectiveness assessment and operational assessment for each potential mitigation measure to ensure its compatibility with Section 5.2.2 (Overview of Mitigation Approach). The Navy used information from published and readily available sources, as well as Navy after-action and monitoring reports. When available, these data were used when they represented the best available science and if they were generally accepted by the scientific community to ensure that they were applicable and contributed to the analysis.

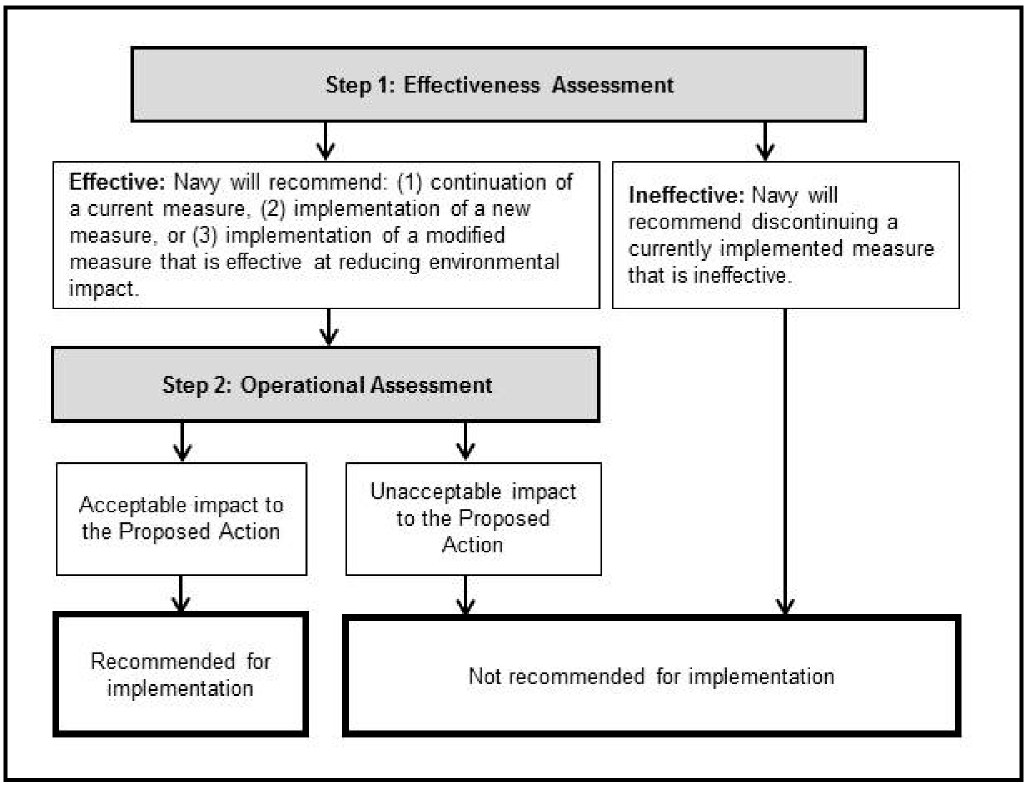

Figure 5.2-1: Flowchart of Process for Determining Recommended Mitigation Measures

5.2.3.1 Effectiveness Assessment

5.2.3.1.1 Procedural Measures

Procedural measures could involve employing techniques or technology during a training or testing activity in order to avoid or reduce a potential impact on a particular resource. For the purposes of organization, procedural measures are discussed within two subcategories: Lookouts and mitigation zones.

A proposed procedural measure was deemed effective if implementing the measure was likely to result in avoidance or reduction of an impact on a resource. The level of avoidance or reduction of the impact gained from implementing a procedural measure was weighed against the potential for a shift in impacts resulting from the activity modification. For example, if predictive modeling results indicate that the use of underwater explosives could cause unacceptable impacts on a particular resource; those impacts could possibly be reduced by substituting non-explosive activities for explosive activities. However, if the increased use of non-explosive activities would consequently produce an unacceptable impact on habitats due to an associated physical disturbance or strike risk from military expended materials, the measure would not necessarily be justifiable.

A proposed procedural measure was deemed ineffective if its implementation would not result in avoidance or reduction of an impact on a resource, or if an unacceptable impact will simply be shifted from one resource to another. For ineffective procedural measures that are currently being implemented, the rationale for terminating, modifying, or continuing to carry out the measure is included in the discussion.

5.2.3.1.2 Mitigation Areas

In order to avoid or reduce a potential impact on a particular resource the Navy would either limit the time of day or duration in which a particular activity could take place, or move or relocate a particular activity outside of a specific geographic area. Within mitigation areas, the measures would only apply to the specific activity that resulted in the requirement for mitigation, and would not prevent or restrict other activities from occurring during that time or in that area.

A proposed mitigation area was deemed effective if implementing the measure would likely result in avoidance or reduction of the impact on the resource. The specific season, time of day, or geographic area must be important to the resource. In determining importance, special consideration was given to time periods or geographic areas having characteristics such as especially high overall density or percent population use, seasonal bottlenecks for a migration corridor, and identifiable key foraging and reproduction areas.

Avoidance or reduction of the impact in the specific time period or geographic area was weighed against the potential for causing new impacts in alternative time periods or geographic areas. For example, if the use of underwater explosives was predicted to cause unacceptable impacts on a particular resource in a known foraging location, those impacts could possibly be reduced by relocating those activities to a new location. However, if the use of explosives at the new location would consequently produce an unacceptable impact on the same or a different resource at the new location, the measure would not necessarily be justifiable.

A proposed mitigation area was deemed ineffective if implementing the measure would not result in avoidance or reduction of an impact on a resource, or if an unacceptable impact would simply be shifted from one time period or location to another. For ineffective mitigation areas that are currently being implemented, the rationale for terminating, modifying, or continuing to carry out the measure is included in the discussion.

5.2.3.2 Operational Assessment

The Navy conducted the operational assessment for procedural measures and proposed mitigation areas using the criteria described below. The Navy deemed procedural and mitigation area measures to have acceptable operational impacts on a particular proposed activity if the following conclusions were reached:

1. Implementation of the measure will not increase safety risks to Navy personnel and equipment.

2. Implementation of the measure is practical. Practicality was defined by the following factors:
    - The measure does not result in an unacceptable increase in resource requirements (e.g., wear and tear on equipment, additional fuel, additional personnel, increased training or testing requirements, or additional reporting requirements).
    - The measure does not result in an unacceptable increase in time away from homeport for Navy personnel.
    - The measure does not result in national security concerns. Should national security require conducting more than the designated number of activities, or a change in how the Navy conducts those activities, the Navy reserves the right to provide the regulatory federal agency with prior notification and include the information in any associated exercise or monitoring reports.
    - The measure is consistent with Navy policy. Navy policy requires that mitigation measures are developed through consultation with regulatory agencies (e.g., the MMPA and ESA processes), would likely result in avoidance or reduction of an impact on a resource as determined by the effectiveness assessment, and would not negatively impact training and testing fidelity. This policy applies to the full suite of potential mitigation measures that the Navy assessed, including measures that were considered but eliminated, and as appropriate, to currently implemented measures that the Navy is no longer recommending to implement.

3. Implementation of the measure will not result in an unacceptable impact on the effectiveness of the military readiness activity. A primary factor that was considered for all mitigation measures is that the measure must not modify the activity in a way that no longer allows the activity to meet the intended objectives, and ultimately must not interfere with the Navy meeting all of its military readiness requirements. Specifically, for mitigation area measures, the following additional factors were considered:
    - The activity is not dependent on a specific range or range support structure within the mitigation area and there are alternate areas with the necessary environmental conditions (e.g., oceanographic conditions).
    - The mitigation area does not hold any current or foreseeable future readiness value. This assessment will be revisited if Navy operations or national security interests conclude that training or testing needs to occur within the mitigation area.
    - Implementation of the measure will not prohibit conducting shipboard maintenance, repair, and testing pierside prior to at-sea operations.

4. The Navy has legal authority to implement the measure.

If all four of the conditions above can be achieved, then the Navy will recommend the mitigation measure for implementation.

5.3 Mitigation Assessment

The effectiveness and operational assessments resulted in potential mitigation measures being organized into the following four sections:

- Section 5.3.1 (Lookout Procedural Measures) includes recommended measures specific to the use of Lookouts or trained marine species observers.

- Section 5.3.2 (Mitigation Zone Procedural Measures) includes recommended measures specific to visual observations with a mitigation zone.
- Section 5.3.3 (Mitigation Areas) includes recommended measures specific to particular locations.
- Section 5.3.4 (Mitigation Measures Considered but Eliminated) includes measures that the Navy does not recommended for implementation due to the measure being ineffective at reducing environmental impacts, having an unacceptable operational impact, or being incompatible with Section 5.2.2 (Overview of Mitigation Approach).

A summary of the Navy recommended measures is provided in Table 5.4-1.

5.3.1 Lookout Procedural Measures

As described in Section 5.1 (Standard Operating Procedures), ships have personnel assigned to stand watch at all times while underway. Watch personnel may perform watch duties in conjunction with job responsibilities that extend beyond looking at the water or air (such as supervision of other personnel). This section will introduce Lookouts, who perform similar duties to watch personnel and whose duties satisfy safety of navigation and mitigation requirements.

The Navy will have two types of Lookouts for the purposes of conducting visual observations: (1) those positioned on ships, and (2) those positioned in aircraft or on small boats. Lookouts positioned on ships will be dedicated solely to diligent observation of the air and surface of the water. They will have multiple observation objectives, which include but are not limited to detecting the presence of biological resources and recreational or fishing boats, observing the mitigation zones described in Section 5.3.2 (Mitigation Zone Procedural Measures), and monitoring for vessel and personnel safety concerns.

Due to aircraft, small boat manning and space restrictions, Lookouts positioned in aircraft or on small boats may include the aircraft crew, pilot, or boat crew. Lookouts positioned in aircraft and small boats may be responsible for tasks in addition to observing the air or surface of the water (e.g., navigation of a helicopter or small boat). However, aircraft and small boat Lookouts will, considering personnel safety, practicality of implementation, and impact on the effectiveness of the activity, comply with the observation objectives described above for Lookouts positioned on ships.

The procedural measures described below primarily consist of having Lookouts during specific training and testing activities.

5.3.1.1 Specialized Training

5.3.1.1.1 Training for Navy Personnel and Civilian Equivalents

5.3.1.1.1.1 United States Navy Afloat Environmental Compliance Training Series

<u>Recommended Mitigation and Comparison to Current Mitigation</u>

The Navy is proposing to continue implementing the Marine Species Awareness Training for watch personnel and Lookouts, and to add the requirement for additional Navy personnel and civilian equivalents to complete one or more environmental training modules.

The Navy has developed the U.S. Navy Afloat Environmental Compliance Training Series to help ensure Navy-wide compliance with environmental requirements, and to help Navy personnel gain a better understanding of their personal roles and responsibilities. The training series contains four interactive multimedia training modules. Personnel will be required to complete all modules identified in their career path training plan.

The first module is the Introduction to the U.S. Navy Afloat Environmental Compliance Training Series. The introduction module provides information on environmental laws (e.g., ESA and MMPA) and responsibilities relevant to Navy training and testing activities. The material is put into context of why environmental compliance is important to the Navy, from the most junior sailor to Commanding Officers. All personnel completing the U.S. Navy Marine Species Awareness Training will also be required to take this module.

The second module is the U.S. Navy Marine Species Awareness Training. Consistent with current requirements, all bridge watch personnel, Commanding Officers, Executive Officers, maritime patrol aircraft aircrews, anti-submarine warfare helicopter crews, civilian equivalents, and Lookouts will successfully complete the Marine Species Awareness Training prior to standing watch or serving as a Lookout. The module contained within the U.S. Navy Environmental Compliance Training Series is an update to the current Marine Species Awareness Training version 3.1. The updated training is designed to improve the effectiveness of visual observations for marine resources, including marine mammals and sea turtles. The Marine Species Awareness Training provides information on sighting cues, visual observation tools and techniques, and sighting notification procedures.

The third module is the U.S. Navy Protective Measures Assessment Protocol. The Protective Measures Assessment Protocol is a decision support and situational awareness software tool that the Navy uses to facilitate compliance with worldwide mitigation measures during the conduct of training and testing activities at sea. The module provides instruction for generating and reviewing Protective Measures Assessment Protocol reports. Section 5.2.2.2 (Protective Measures Assessment Protocol) contains additional information on the benefits of the software tool.

The fourth module is the U.S. Navy Sonar Positional Reporting System and marine mammal incident reporting. The Navy developed the Sonar Positional Reporting System as its official record of underwater sound sources (e.g., active sonar) used under its MMPA permits. Marine mammal incidents include vessel strikes and animal strandings. The module provides instruction on the reporting requirements and procedures for both the Sonar Positional Reporting System and marine mammal incident reporting.

Effectiveness and Operational Assessment

Navy personnel undergo extensive training in order to stand watch. Standard training includes on-the-job instruction under the supervision of experienced personnel, followed by completion of the Personal Qualification Standard program. The Personal Qualification Standard program certifies that personnel have demonstrated the skills needed to stand watch, such as detecting and reporting floating or partially submerged objects.

The U.S. Navy Afloat Environmental Compliance Training Series, including the updated Marine Species Awareness Training, is a specialized multimedia training program designed to help Navy operational and test communities best avoid potentially harmful interactions with marine species. The program provides training on how to sight marine species, focusing on marine mammals. The training also includes instruction for visually identifying sea turtles, concentrations of floating vegetation (*Sargassum* or kelp paddies), jellyfish aggregations, and flocks of seabirds, which are often indicators of marine mammal or sea turtle presence. The Marine Species Awareness Training also addresses the role that watch personnel and Lookouts play in helping the Navy maintain compliance with environmental protection requirements, as well as supporting Navy environmental stewardship commitments.

In summary, the Navy believes that the U.S. Navy Afloat Environmental Compliance Training Series, including the updated Marine Species Awareness Training, is the best and most appropriate forum for teaching watch personnel and Lookouts about their responsibilities for helping reduce impacts on the marine environment. The Marine Species Awareness Training provides the Navy with invaluable training for a relatively large number of personnel. Constantly shifting personnel assignments presents a real challenge; however, the format and structure of the U.S. Navy Afloat Environmental Compliance Training Series will help the Navy reduce costs during fiscally constrained periods and provide constant access to training. Overall, the Marine Species Awareness Training is an effective tool for improving the potential for Lookouts to detect marine species while on duty.

Implementation of the Marine Species Awareness Training has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.1.2 Lookouts

The Navy proposes to use one or more Lookouts during the training and testing activities described below, which are organized by stressor category. A comparison of the currently implemented mitigation measures and recommended mitigation measures are provided where applicable. The effectiveness and operational assessments are discussed for all Lookout measures collectively in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts) and Section 5.3.1.2.5 (Operational Assessment for Lookouts). A number of training and testing activities involve the participation of multiple vessels and aircraft, which could ultimately increase the cumulative number of personnel standing watch per standard operating procedures or Lookouts posted in the vicinity of the activity (e.g., sinking exercises). The following sections discuss the minimum number of Lookouts that the Navy will use during each activity.

5.3.1.2.1 Acoustic Stressors – Non-Impulsive Sound

5.3.1.2.1.1 Low-Frequency and Hull-Mounted Mid-Frequency Active Sonar

Mitigation measures do not currently exist for low-frequency active sonar sources analyzed in this Final EIS/OEIS, or new platforms or systems. The Navy is proposing to (1) add mitigation measures for low-frequency active sonar and new platforms and systems, and (2) maintain the number of Lookouts currently implemented for ships using hull-mounted mid-frequency active sonar. The recommended measures are provided below.

Ships using low-frequency or hull-mounted mid-frequency active sonar sources associated with anti-submarine warfare and mine warfare activities at sea (with the exception of ships less than 65 ft. [20 m] in length and ships that are minimally manned) will have two Lookouts at the forward position. For the purposes of this document, low-frequency active sonar does not include Surveillance Towed Array Sensor System (SURTASS) Low-Frequency Active (LFA) sonar.

While using low-frequency or hull-mounted mid-frequency active sonar sources associated with anti-submarine warfare and mine warfare activities at sea, ships less than 65 ft. (20 m) in length, and ships that are minimally manned will have one Lookout at the forward position due to space and manning restrictions.

Ships conducting active sonar activities while moored or at anchor (including pierside) will maintain one Lookout.

5.3.1.2.1.2 High-Frequency and Non-Hull Mounted Mid-frequency Active Sonar

Mitigation measures do not currently exist for high-frequency active sonar activities associated with anti-submarine warfare and mine warfare, or for new platforms, such as the Littoral Combat Ship; therefore, the Navy is proposing to add a new measure for these activities or platforms. The Navy is proposing to continue using the number of Lookouts currently implemented for ships or aircraft conducting non-hull mounted mid-frequency active sonar, such as helicopter dipping sonar systems. The recommended measure is provided below.

The Navy will have one Lookout on ships or aircraft conducting high-frequency or non-hull mounted mid-frequency active sonar activities associated with anti-submarine warfare and mine warfare activities at sea.

5.3.1.2.2 Acoustic Stressors – Explosives and Impulsive Sound

5.3.1.2.2.1 Improved Extended Echo Ranging Sonobuoys

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout in aircraft conducting improved extended echo ranging sonobuoy activities.

5.3.1.2.2.2 Explosive Sonobuoys Using 0.6–2.5 Pound Net Explosive Weight

Lookout measures do not currently exist for explosive sonobuoy activities using 0.6–2.5 pound (lb.) net explosive weight. The Navy is proposing to add this measure. Aircraft conducting explosive sonobuoy activities using 0.6–2.5 lb. net explosive weight will have one Lookout.

5.3.1.2.2.3 Anti-Swimmer Grenades

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout on the vessel conducting anti-swimmer grenade activities.

5.3.1.2.2.4 Mine Countermeasure and Neutralization Activities Using Positive Control Firing Devices

As background, mine countermeasure and neutralization activities can be divided into two main categories: (1) general activities that can be conducted from a variety of platforms and locations, and (2) activities involving the use of diver-placed charges that typically occur close to shore. When either of these activities are conducted using a positive control firing device, the detonation is controlled by the personnel conducting the activity and is not authorized until the area is clear at the time of detonation.

The Navy is proposing to modify the number of Lookouts currently implemented for general mine countermeasure and neutralization activities using positive control firing devices to account for additional categories of net explosive weights. The recommended measures are provided below.

- During general mine countermeasure and neutralization activities under positive control using up to a 500 lb. net explosive weight detonation (bin E10 and below), vessels greater than 200 ft. (61 m) will have two Lookouts, while vessels less than 200 ft. (61 m) or aircraft will have one Lookout.

- During general mine countermeasure and neutralization activities under positive control using a 501–650 lb. net explosive weight (bin E11) detonation, the Navy will have two Lookouts (one positioned in an aircraft and one in a small boat.

The Navy is proposing to (1) continue using the number of Lookouts currently implemented for mine neutralization activities involving positive control diver-placed charges up to a 29 lb. or 250–500 lb. net explosive weight, and (2) extend the implementation of its current mitigation to all additional categories of net explosive weights. Mitigation measures for activities involving diver-placed charges under positive control do not currently exist for 30–249 lb. net explosive weight detonations. The recommended measures are provided below.

- During activities involving diver-placed mines under positive control, activities using up to a 500 lb. net explosive weight (bin E10) detonation will have a total of two Lookouts (one Lookout positioned on two small boats, or one small boat in combination with either a helicopter or shore-based. The shore-based observer would be stationed at an elevated on-shore position and would only be used during activities conducted in very shallow waters.
- All divers placing the charges on mines will support the Lookouts while performing their regular duties. The divers will report all marine mammal and sea turtle sightings to their supporting small boat or Range Safety Officer.

5.3.1.2.2.5 Mine Neutralization Activities Using Diver-Placed Time-Delay Firing Devices

As background, when mine neutralization activities using diver-placed charges (up to a 29 lb. net explosive weight) are conducted with a time-delay firing device, the detonation is fused with a specified time-delay by the personnel conducting the activity and is not authorized until the area is clear at the time the fuse is initiated. During these activities, the detonation cannot be terminated once the fuse is initiated due to human safety concerns.

Current mitigation involves the use of six Lookouts and three small boats (two Lookouts positioned in each of the three boats) for mitigation zones equal to or larger than 1,400 yd. (1,280 m), or four Lookouts and two small boats for mitigation zones smaller than 1,400 yd. (1,280 m). The Navy is proposing to modify the number of Lookouts currently used for mine neutralization activities using diver-placed time-delay firing devices because the measure is impractical to implement and is currently resulting in an unacceptable impact on military readiness. The Navy does not have the resources to maintain six Lookouts and three small boats during mine neutralization activities using diver-placed time-delay firing devices. Due to a lack of personnel and small boats available for this activity, the requirement for six Lookouts and three small boats would require reassigning personnel from other assigned duties or training activities, thus impacting the ability of the reassigned personnel to complete his or her assigned duties or other training requirements. Therefore, the Navy is currently unable to conduct the activities that require six Lookouts and three small boats, which is reducing the Navy's ability to maintain military readiness for these activities. Four Lookouts and two small boats represent the maximum level of effort that the Navy can commit to observing mitigation zones for this activity given the number of personnel and assets available. To prevent these unacceptable impacts, the Navy recommends the following measures:

During activities using up to a 29 lb. net explosive weight (bin E7) detonation, the Navy will have four Lookouts and two small boats (two Lookouts positioned in each of the two boats). In addition, when aircraft are used, the pilot or member of the aircrew will serve as an additional Lookout. All divers placing the charges on mines will support the Lookouts while performing their regular duties. The divers will report all marine mammal and sea turtle sightings to their supporting small boat or Range Safety Officer.

5.3.1.2.2.6 Gunnery Exercises – Small- and Medium-Caliber Using a Surface Target

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout on the vessel or aircraft conducting small- or medium-caliber gunnery exercises against a surface target.

5.3.1.2.2.7 Gunnery Exercises – Large-Caliber Using a Surface Target

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout on the ship conducting large-caliber gunnery exercises against a surface target.

5.3.1.2.2.8 Missile Exercises (Including Rockets) up to 250 Pound Net Explosive Weight Using a Surface Target

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. When aircraft are conducting missile exercises up to 250 lb. net explosive weight against a surface target, the Navy will have one Lookout positioned in an aircraft.

5.3.1.2.2.9 Missile Exercises Using 251–500 Pound Net Explosive Weight Using a Surface Target

Lookout measures do not currently exist for missile exercises using 251–500 lb. net explosive weight. The Navy is proposing to add this measure. When aircraft are conducting missile exercises using 251–500 lb. net explosive weight against a surface target, the Navy will have one Lookout positioned in an aircraft.

5.3.1.2.2.10 Bombing Exercises

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout positioned in an aircraft conducting bombing exercises.

5.3.1.2.2.11 Torpedo (Explosive) Testing

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout positioned in an aircraft during torpedo (explosive) testing.

5.3.1.2.2.12 Sinking Exercises

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have two Lookouts (one positioned in an aircraft and one on a vessel) during sinking exercises.

5.3.1.2.2.13 At-Sea Explosive Testing

Lookout measures do not currently exist for at-sea explosive testing. The Navy is proposing to add this measure. The Navy will have a minimum of one Lookout on each vessel supporting at-sea explosive testing.

5.3.1.2.2.14 Elevated Causeway System – Pile Driving

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout positioned on the platform (which could include the shore, an elevated causeway, or on a small boat) that will maximize the potential for sightings during pile driving and pile removal.

5.3.1.2.2.15 Weapons Firing Noise During Gunnery Exercises – Large-Caliber

The Navy is proposing to continue using the number of Lookouts currently implemented for this activity. The Navy will have one Lookout on the ship conducting explosive and non-explosive large-caliber gunnery exercises. This may be the same Lookout described in Section 5.3.1.2.2.7 (Gunnery Exercises – Large-Caliber Using a Surface Target) or Section 5.3.1.2.3.3 (Non-Explosive Practice Munitions – Small-, Medium-, and Large-Caliber Gunnery Exercises Using a Surface Target) when the large-caliber gunnery exercise is conducted from a ship against a surface target.

5.3.1.2.3 Physical Disturbance and Strike

5.3.1.2.3.1 Vessels

The Navy is proposing to clarify the mitigation measures currently implemented for this activity (including full power propulsion testing). While underway, vessels will have a minimum of one Lookout.

5.3.1.2.3.2 Towed In-Water Devices

The Navy is proposing to continue using the number of Lookouts currently implemented for activities using towed in-water devices (e.g., towed mine neutralization). The Navy will have one Lookout during activities using towed in-water devices when towed from a manned platform.

5.3.1.2.3.3 Non-Explosive Practice Munitions – Small-, Medium-, and Large-Caliber Gunnery Exercises Using a Surface Target

The Navy is proposing to continue using the number of Lookouts currently implemented for these activities. The Navy will have one Lookout during activities involving non-explosive practice munitions (e.g., small-, medium-, and large-caliber gunnery exercises) against a surface target.

5.3.1.2.3.4 Non-Explosive Practice Munitions – Bombing Exercises

The Navy is proposing to continue using the number of Lookouts currently implemented for these activities. The Navy will have one Lookout positioned in an aircraft during non-explosive bombing exercises.

5.3.1.2.3.5 Non-Explosive Practice Munitions – Missile Exercises (Including Rockets) Using a Surface Target

The Navy is proposing to continue using the number of Lookouts currently implemented for these activities. When aircraft are conducting non-explosive missile exercises (including exercises using rockets) against a surface target, the Navy will have one Lookout positioned in an aircraft.

5.3.1.2.4 Effectiveness Assessment for Lookouts

Personnel standing watch in accordance with Navy standard operating procedures have multiple job responsibilities. While on duty, these standard watch personnel often conduct marine species observation in addition to their primary job duties (e.g., aiding in the navigation of a vessel). By having one or more Lookouts dedicated solely to observing the air and surface of the water during certain training and testing activities, the Navy increases the likelihood that marine species will be detected. It is also important to note that a number of training and testing activities involve multiple vessels and aircraft, thereby increasing the cumulative number of Lookouts or watch personnel that could potentially be present during a given activity.

Although using Lookouts is expected to increase the likelihood that marine species will be detected at the surface of the water, it is unlikely that using Lookouts will be able to help avoid impacts on all species entirely due to the inherent limitations of sighting marine mammals and sea turtles, as discussed in the sections below. Refer to Section 3.4.3.1.10 (Implementing Mitigation to Reduce Sound Exposures) for a quantitative discussion on the Navy's effectiveness assessment for Lookouts during sound-producing activities.

Pursuant to Phase I (e.g., Hawaii Range Complex EIS/OEIS) and in cooperation with NMFS, the Navy has undertaken monitoring efforts to track compliance with take authorizations, help evaluate the effectiveness of implemented mitigation measures, and gain a better understanding of the impacts of the Navy activities on marine resources. In 2010, the Navy initiated a study designed to evaluate the effectiveness of the Navy Lookout team. The University of St. Andrews, Scotland, under contract to the U.S. Navy, developed an initial data collection protocol for use during the study. Between 2010 and 2012, trained Navy marine mammal observers collected data during nine field trials as part of a "proof of concept" phase. The goal of the proof of concept phase was to develop a statistically valid protocol for quantitatively analyzing the effectiveness of Lookouts during Navy training exercises. Field trials were conducted in the Hawaii Range Complex, Southern California Range Complex, and Jacksonville Range Complex onboard one frigate, one cruiser, and seven destroyers. A preliminary analysis of the proof of concept data is ongoing. The Navy is also working to finalize the data collection process for use during the next phase of the study. While data was collected as part of this proof of concept phase, that data is not fairly comparable as protocols were being changed and assessed, nor is that data statistically significant. Therefore, it is improper to use this data to draw any conclusions on the effectiveness of Navy Lookouts.

5.3.1.2.4.1 Detection Probabilities of Marine Mammals in the Study Area

Until the results of the Navy's Lookout effectiveness study are available, the Navy must rely on the best available science to determine detection probabilities of marine mammals by Navy Lookouts. To do so, the Navy has compiled the results of available literature on line-transect analyses, which are typically used to estimate cetacean abundance. In line-transect analyses, the factors affecting the detection of an animal or group of animals directly on the transect line may be probabilistically quantified as g(0). As a reference, a g(0) value of 1 indicates that animals on the transect line are always detected. Table 5.3-1 provides detection probabilities for cetacean species based largely on g(0) values derived from shipboard and aerial surveys in the Study Area, which vary widely based on g(0) derivation factors (e.g., species, sighting platforms, group size, and sea state conditions). Refer to Section 3.4.3.1.10 (Implementing Mitigation to Reduce Sound Exposures) for additional background on g(0) and a discussion of how the Navy used g(0) to quantitatively assess the effectiveness of Lookouts during sound-producing activities.

Table 5.3-1: Sightability Based on Average g(0) Values for Marine Mammal Species in the Study Area

Species/Stocks	Family	Vessel Sightability	Aircraft Sightability
Baird's Beaked Whale	Ziphiidae	0.96	0.18
Blainville's Beaked Whale [1]	Ziphiidae	0.40	0.074
Blue Whale, Fin Whale; Sei Whale	Balaenopteridae	0.921	0.407
Bottlenose Dolphin, Fraser's Dolphin [2]	Delphinidae	0.808	0.96
Bryde's Whale [3]	Balaenopteridae	0.91	0.407
Cuvier's Beaked Whale	Ziphiidae	0.23	0.074

Table 5.3-1: Sightability Based on Average g(0) Values for Marine Mammal Species in the Study Area (continued)

Species/Stocks	Family	Vessel Sightability	Aircraft Sightability
Dall's Porpoise	Phocoenidae	0.822	0.221
Dwarf Sperm Whale, Pygmy Sperm Whale, *Kogia* spp. [1]	Kogiidae	0.35	0.074
False Killer Whale, Melon-headed Whale [2]	Delphinidae	0.76	0.96
Gray Whale	Eschichtiidae	0.921	0.482
Humpback Whale	Balaenopteridae	0.921	0.495
Killer Whale	Delphinidae	0.91	0.96
Long-Beaked Common Dolphin, Short-Beaked Common Dolphin	Delphinidae	0.97	0.99
Longman's Beaked Whale, Pygmy Killer Whale [1]	Ziphiidae, Delphinidae	0.76	0.074
Mesoplodon spp.	Ziphiidae	0.34	0.11
Minke Whale	Balaenopteridae	0.856	0.386
Northern Right Whale Dolphin	Delphinidae	0.856	0.96
Pacific White-Sided Dolphin	Delphinidae	0.856	0.96
Pantropical Spotted/Risso's/Rough Toothed/Spinner/Striped Dolphin [2]	Delphinidae	0.76	0.96
Short-finned Pilot Whale [2]	Delphinidae	0.76	0.96
Sperm Whale	Physeteridae	0.87	0.495

[1] For species having no data, the g(0) for Cuvier's aircraft value (where g(0) = 0.074) was used[1].
[2] This species aircraft sightability is an estimate for all delphinids.
[3] This species aircraft sightability is an estimate for blue and fin whales.
Notes: Values reported are averaged based on the data cited for the U.S. Atlantic coast, U.S. west coast, and Hawaii. Some g(0) values in the table above are estimates of perception bias only, some are estimates of availability bias only, and some reflect both, depending on the species and data that are currently available. Based on the Navy's analysis of: Barlow 1995; Barlow 2003; Barlow and Forney 2007; Barlow et al. 1997; Barlow and Gerrodette 1996; Barlow and Sexton 1996; Barlow and Taylor 2005; Blaylock et al. 1995; Carretta et al. 2000; Forney 2007; Forney et al. 1995; Hain et al. 1999; Mobley et al. 2001; Palka 1995a; Palka 1995b, 2005a, b, 2006.

Several variables that play into how easily a marine mammal may be detected by a dedicated observer are directly related to the animal, including its external appearance and size; surface, diving and social behavior; and life history. The following is a generalized discussion of the behavior and external appearance of the marine mammals with the potential to occur in the Study Area as these characters relate to the detectability of each species. The species are grouped loosely based on either taxonomic relatedness or commonalities in size and behavior, and include large whales, cryptic species delphinids, beluga whales, and pinnipeds. Not all statements may hold true for all species in a grouping and exceptions are mentioned where applicable. The information presented in this section may be found in Jefferson et al. (2008) and sources within unless otherwise noted.

Large Whales

Species of large whales found in the Study Area include all the baleen whales and the sperm whale. Baleen whales are generally large, with adults ranging in size from 30 to 89 ft. (9 to 27 m), often making them immediately detectable. Many species of baleen whales have a prominent blow ranging from 10 ft. (3 m) to as much as 39 ft. (12 m) above the surface. However, there are at least two species (Bryde's whale and common minke whale) that often have no visible blow. Baleen whales tend to travel singly or in small groups ranging from pairs to groups of five. The exception to this is the fin whale, which is known to travel in pods of seven or more individuals. All species of baleen whales are known to form larger-scale aggregations in areas of high localized productivity or on breeding grounds. Baleen whales may or may not fluke at the surface before they dive; some species fluke regularly (e.g., the humpback whale), some fluke variably (e.g., the blue whale and fin whale) and some rarely fluke (e.g., the sei whale, common minke whale, and Bryde's whale). Baleen whales may remain at the surface for extended periods of time as they forage or socialize. Humpback whales are known to corral prey at the surface. Dive behavior varies amongst species. Many species will dive and remain at depth for as long as 30 minutes (min.). Some will adjust their diving behavior according to the presence of vessels (e.g., the humpback whale and fin whale). Sei whales are known to sink just below the surface and remain there between breaths.

Sperm whales also belong to the large whales, with adult males reaching as much as 50 ft. (18 m) in total length. Sperm whales at the surface would likely be easy to detect. They have a prominent, 16 ft. (5 m) blow, and may remain at the surface for long periods of time. They are known to raft (i.e., loll at the surface) and to form surface-active groups when socializing. Sperm whales may travel or congregate in large groups of as many as 50 individuals. Although sperm whales engage in conspicuous surface behavior such as fluking, breaching, and tail-slapping, they are long, deep divers and may remain submerged for over 1 hour.

Cryptic Species

Cryptic and deep-diving species are those that do not surface for long periods of time and are often difficult to see when they surface, which ultimately limits the ability of observers to detect them even in good sighting conditions (Barlow et al. 2006). Cryptic species include beaked whales (family Ziphiidae), dwarf and pygmy sperm whales (*Kogia* species), and harbor porpoises. Beaked whales are difficult to detect at sea. In the Study Area, beaked whales may occur in a variety of group sizes, ranging from single individuals to groups of as many as 22 individuals (MacLeod and D'Amico 2006). Beaked whale diving behavior in general consists of long, deep dives that may last for nearly 90 min. followed by a series of shallower dives and intermittent surfacings (Tyack et al. 2006, Baird et al. 2008). Some individuals remain at the surface for an extended period of time (perhaps 1 hour or more) or make shorter dives (MacLeod and D'Amico, 2006). Detection of beaked whales is further complicated because beaked whales often dive and surface in a synchronous pattern and they travel below the surface of the water (MacLeod and D'Amico 2006).

Dwarf and pygmy sperm whales (referred to broadly as *Kogia* species) are small cetaceans (10–13 ft. [3–4 m] adult length) that are not commonly seen. *Kogia* species are some of the most commonly stranded species in some areas, which suggests that sightings are not indicative of their overall abundance. This supports the idea that they are cryptic, perhaps engaging in inconspicuous surface behavior or actively avoiding vessels. When *Kogia* species are sighted, they are typically seen in groups of no more than five to six individuals. They have no visible blow, do not fluke when they dive, and are known to log (i.e., lie motionless) at the surface. When they do dive, they often will sink out of sight with no prominent behavioral display.

Harbor porpoises are difficult to detect in all but the best of conditions (i.e., no swell, no whitecaps). Harbor porpoises travel singly or in small groups of less than six individuals, but may aggregate into groups of several hundred. They are inconspicuous at the surface, rarely lifting their heads above the surface and often lying motionless. They are small and may actively avoid vessels.

Delphinids

Delphinids are some of the most likely species to be detected at sea by observers. Many species of delphinids engage in very conspicuous surface behavior, including leaping, spinning, bow riding, and traveling along the surface in large groups. Delphinid group sizes may range from 10 to 10,000 individuals, depending on the species and the geographic region. Species such as pilot whales, rough-toothed dolphins, white-beaked dolphins, white-sided dolphins, bottlenose dolphins, stenellid dolphins, common dolphins, and Fraser's dolphins are known to either actively approach and investigate vessels, or bow ride along moving vessels. Fraser's dolphins and common dolphins form huge groups that travel quickly along the surface, churning up the water and making them visible from a great distance. Delphinids may dive for as little as 1 min. to more than 30 min., depending on the species.

Pinnipeds

Pinnipeds (seals and sea lions) are more difficult to detect at sea than cetaceans. Pinnipeds are much smaller, often solitary and generally do not engage in conspicuous surface behavior. There is not a lot of information regarding pinniped behavior at sea. Pinnipeds have a low profile, no dorsal appendage and small body size in comparison with most cetaceans, which limits accurate visual detection to sea states of less than 2 on the Beaufort scale (Carretta et al. 2000). Some species, such as harbor seals, are known to approach and observe human activities on land or on stationary vessels. Harbor seals and gray seals are solitary at sea. Harp seals appear to be an exception, traveling in large groups at the surface and churning up whitewater like dolphins. Gray seals are known to rest vertically at the surface with only the head exposed. Gray seals may dive for as long as 30 min. and hooded seals for up to 60 min.

5.3.1.2.4.2 Detection Probabilities of Sea Turtles in the Study Area

Sea turtles spend a majority of their time below the surface and are difficult to sight from a vessel until the animal is at close range (Hazel et al. 2007). Sea turtles often spend over 90 percent of their time underwater and are not visible more than 6.5 ft. (2 m) below the surface (Mansfield 2006). Sea turtles are generally much smaller than cetaceans, so while shipboard surveys designed for sighting marine mammals are adequate for detecting large sea turtles (e.g., adult leatherbacks), they are usually not adequate for detecting the smaller sized turtles (e.g., juveniles and Kemp's ridleys). Juvenile sea turtles may be especially difficult to detect. Aerial detection may be more effective in spotting sea turtles on the surface, particularly in calm seas and clear water, but it is possible that the smallest age classes are not detected even in good conditions (Marsh and Saalfeld 1989). Visual detection of sea turtles, especially small turtles, is further complicated by their startle behavior in the presence of vessels. Turtles on the surface may dive below the surface of the water in the presence of a vessel before it is detected by shipboard or aerial observers (Kenney 2005). The detection probability of sea turtles is generally lower than that of cetaceans. The use of Lookouts for visual detection of sea turtles is likely effective only at close range, and is thought to be less effective for small individuals than large individuals.

5.3.1.2.4.3 Summary of Lookout Effectiveness

Due to the various detection probabilities, levels of Lookout experience, and variability of sighting conditions, Lookouts will not always be effective at avoiding impacts on all species. However, Lookouts are expected to increase the overall likelihood that certain marine mammal species and some sea turtles will be detected at the surface of the water, when compared to the likelihood that these same species would be detected if Lookouts are not used. The Navy believes the continued use of Lookouts contributes to helping reduce potential impacts on these species from training and testing activities.

5.3.1.2.5 Operational Assessment for Lookouts

As written, implementation of the mitigation measures recommended in Section 5.3.1.2 (Lookouts) has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activities, and Navy policy. The number of Lookouts recommended for each measure often represents the maximum Lookout capacity based on limited resources (e.g., space and manning restrictions).

5.3.2 MITIGATION ZONE PROCEDURAL MEASURES

Safety zones described in Section 5.1 (Standard Operating Procedures) are zones designed for human safety, whereas this section will introduce mitigation zones. A mitigation zone is designed solely for the purpose of reducing potential impacts on marine mammals and sea turtles from training and testing activities. Mitigation zones are measured as the radius from a source. Unique to each activity category, each radius represents a distance that the Navy will visually observe to help reduce injury to marine species. Visual detections of applicable marine species will be communicated immediately to the appropriate watch station for information dissemination and appropriate action. If the presence of marine mammals is detected acoustically, Lookouts posted in aircraft and on vessels will increase the vigilance of their visual surveillance. As a reference, aerial surveys are typically made by flying at 1,500 ft. altitude or lower at the slowest safe speed.

Many of the proposed activities have mitigation measures that are currently being implemented, as required by previous environmental documents or consultations. Most of the current Phase I (e.g., Hawaii Range Complex EIS/OEIS) mitigation zones for activities that involve the use of impulsive and non-impulsive sources were originally designed to reduce the potential for onset of temporary threshold shift (TTS). For the HSTT EIS/OEIS, the Navy updated the acoustic propagation modeling to incorporate updated hearing threshold metrics (i.e., upper and lower frequency limits), updated density data for marine mammals, and factors such as an animal's likely presence at various depths. An explanation of the acoustic propagation modeling process can be found in the *Determination of Acoustic Effects on Marine Mammals and Sea Turtles for the Hawaii-Southern California Training and Testing Environmental Impact Statement/Overseas Environmental Impact Statement* technical report (Marine Species Modeling Team 2013).

As a result of the updates to the acoustic propagation modeling, in some cases the ranges to onset of TTS effects are much larger than those output by previous Phase I models. Due to the ineffectiveness and unacceptable operational impacts associated with mitigating these large areas, the Navy is unable to mitigate for onset of TTS for every activity. In this HSTT analysis, the Navy developed each recommended mitigation zone to avoid or reduce the potential for onset of the lowest level of injury, permanent threshold shift (PTS), out to the predicted maximum range. In some cases where the ranges to effects are smaller than previous models estimated, the mitigation zones were adjusted accordingly to provide consistency across the measures. Mitigating to the predicted maximum range to PTS consequently also mitigates to the predicted maximum range to onset mortality (1 percent mortality), onset slight lung injury, and onset slight gastrointestinal tract injury, since the maximum range to effects for these criteria are shorter than for PTS. Furthermore, in most cases, the predicted maximum range to PTS also consequently covers the predicted average range to TTS. Table 5.3-2 summarizes the predicted average range to TTS, average range to PTS, maximum range to PTS, and recommended mitigation zone for each activity category, based on the Navy's acoustic propagation modeling results.

The activity-specific mitigation zones are based on the longest range for all the functional hearing groups (based on the hearing threshold metrics described in Section 3.4, Marine Mammals, and Section 3.5, Sea Turtles). The mitigation zone for a majority of activities is driven by either the high-frequency cetacean or the sea turtle functional hearing groups. Therefore, the mitigation zones are even more protective for the remaining functional hearing groups (i.e., low-frequency cetaceans, mid-frequency cetaceans, and pinnipeds), and likely cover a larger portion of the potential range to onset of TTS.

In some instances, the Navy recommends mitigation zones that are larger or smaller than the predicted maximum range to PTS based on the effectiveness and operational assessments. The recommended mitigation zones and their associated assessments are provided throughout the remainder of this section. The recommended measures are either currently implemented, modifications of current measures, or new measures.

For some activities specified throughout the remainder of this section, Lookouts may be required to observe for concentrations of detached floating vegetation (*Sargassum* or kelp paddies), which are indicators of potential marine mammal and sea turtle presence, within the mitigation zone. Those specified activities will not commence if the floating vegetation (*Sargassum* or kelp paddies) is observed within the mitigation zone prior to the initial start of the activity. If floating vegetation is observed prior to the initial start of the activity, the activity will be relocated to an area where no floating vegetation is observed. Training and testing will not cease as a result of indicators entering the mitigation zone after activities have commenced. This measure is intended only for floating vegetation detached from the seafloor.

Table 5.3-2: Predicted Range to Effects and Recommended Mitigation Zones

Activity Category	Representative Source (Bin) [1]	Predicted Average (Longest) Range to TTS	Predicted Average (Longest) Range to PTS	Predicted Maximum Range to PTS	Recommended Mitigation Zone
Non-Impulsive Sound					
Low-Frequency and Hull-Mounted Mid-Frequency Active Sonar	SQS-53 ASW hull-mounted sonar (MF1)	3,821 yd. (3.5 km) for one ping	100 yd. (91 m) for one ping	Not Applicable	6 dB power down at 1,000 yd. (914 m); 4 dB power down at 500 yd. (457 m); and shutdown at 200 yd. (183 m)
	Low-frequency sonar (LF4 and LF5) [2]	3,821 yd. (3.5 km) for one ping	100 yd. (91 m) for one ping	Not Applicable	200 yd. (183 m) [2]
High-Frequency and Non-Hull Mounted Mid-Frequency Active Sonar	AQS-22 ASW dipping sonar (MF4)	230 yd. (210 m) for one ping	20 yd. (18 m) for one ping	Not applicable	200 yd. (183 m)
Explosive and Impulsive Sound					
Improved Extended Echo Ranging Sonobuoys	Explosive sonobuoy (E4)	434 yd. (397 m)	156 yd. (143 m)	563 yd. (515 m)	600 yd. (549 m)
Explosive Sonobuoys using 0.6–2.5 lb. NEW	Explosive sonobuoy (E3)	290 yd. (265 m)	113 yd. (103 m)	309 yd. (283 m)	350 yd. (320 m)
Anti-Swimmer Grenades	Up to 0.5 lb. NEW (E2)	190 yd. (174 m)	83 yd. (76 m)	182 yd. (167 m)	200 yd. (183 m)
Mine Countermeasure and Neutralization Activities Using Positive Control Firing Devices	NEW dependent (see Table 5.3-3)				
Mine Neutralization Diver-Placed Mines Using Time-Delay Firing Devices	Up to 29 lb. NEW (E7)	647 yd. (592 m)	232 yd. (212 m)	469 yd. (429 m)	1,000 yd. (915 m)
Gunnery Exercises – Small- and Medium-Caliber Using a Surface Target	40 mm projectile (E2)	190 yd. (174 m)	83 yd. (76 m)	182 yd. (167 m)	200 yd. (183 m)
Gunnery Exercises – Large-Caliber Using a Surface Target	5 in. projectiles (E5 at the surface [3])	453 yd. (414 m)	186 yd. (170 m)	526 yd. (481 m)	600 yd. (549 m)

[1] This table does not provide an inclusive list of source bins; bins presented here represent the source bin with the largest range to effects within the given activity category.
[2] The representative source bin and mitigation zone applies to sources that cannot be powered down (e.g., bins LF4 and LF5).
[3] The representative source bin E5 has different range to effects depending on the depth of activity occurrence (at the surface or at various depths).
Notes: ASW = anti-submarine warfare, in. = inches, lb. = pounds, m = meters, NEW = net explosive weight, PTS = permanent threshold shift, TTS = temporary threshold shift, yd. = yards

Table 5.3-2: Predicted Range to Effects and Recommended Mitigation Zones (continued)

Activity Category	Representative Source (Bin) [1]	Predicted Average (Longest) Range to TTS	Predicted Average (Longest) Range to PTS	Predicted Maximum Range to PTS	Recommended Mitigation Zone
Missile Exercises (Including Rockets) up to 250 lb. NEW Using a Surface Target	Maverick missile (E9)	949 yd. (868 m)	398 yd. (364 m)	699 yd. (639 m)	900 yd. (823 m)
Missile Exercises from 251 lb. to 500 lb. NEW Using a Surface Target	Harpoon missile (E10)	1,832 yd. (1.7 km)	731 yd. (668 m)	1,883 yd. (1.7 km)	2,000 yd. (1.8 km)
Bombing Exercises	MK-84 2,000 lb. bomb (E12)	2,513 yd. (2.3 km)	991 yd. (906 m)	2,474 yd. (2.3 km)	2,500 yd. (2.3 km) [2]
Torpedo (Explosive) Testing	MK-48 torpedo (E11)	1,632 yd. (1.5 km)	697 yd. (637 m)	2,021 yd. (1.8 km)	2,100 yd. (1.9 km)
Sinking Exercises	Various sources up to the MK-84 2,000 lb. bomb (E12)	2,513 yd. (2.3 km)	991 yd. (906 m)	2,474 yd. (2.3 km)	2.5 nm [2]
At-Sea Explosive Testing	Various sources less than 10 lb. NEW (E5 at various depths [3])	525 yd. (480 m)	204 yd. (187 m)	649 yd. (593 m)	1,600 yd. (1.4 km) [2]
Elevated Causeway System – Pile Driving	24 in. steel impact hammer	1,094 yd. (1.0 km)	51 yd. (46 m)	51 yd. (46 m)	60 yd. (55 m)

[1] This table does not provide an inclusive list of source bins; bins presented here represent the source bin with the largest range to effects within the given activity category.
[2] Recommended mitigation zones are larger than the modeled injury zones to account for multiple types of sources or charges being used.
[3] The representative source bin E5 has different range to effects depending on the depth of activity occurrence (at the surface or at various depths).
Notes: ASW = anti-submarine warfare, in. = inches, km = kilometers, lb. = pounds, m = meters, NEW = net explosive weight, PTS = permanent threshold shift, TTS = temporary threshold shift, yd. = yards

Table 5.3-3: Predicted Range to Effects and Mitigation Zone Radius for Mine Countermeasure And Neutralization Activities Using Positive Control Firing Devices

Charge Size Net Explosive Weight (Bins)	General Mine Countermeasure and Neutralization Activities Using Positive Control Firing Devices [1]				Mine Countermeasure and Neutralization Activities Using Diver-Placed Charges Under Positive Control [2]			
	Predicted Average Range to TTS	Predicted Average Range to PTS	Predicted Maximum Range to PTS	Recommended Mitigation Zone	Predicted Average Range to TTS	Predicted Average Range to PTS	Predicted Maximum Range to PTS	Recommended Mitigation Zone
2.6–5 lb. (E4)	434 yd. (397 m)	197 yd. (180 m)	563 yd. (515 m)	600 yd. (549 m)	545 yd. (498 m)	169 yd. (155 m)	301 yd. (275 m)	350 yd. (320 m)
6–10 lb. (E5)	525 yd. (480 m)	204 yd. (187 m)	649 yd. (593 m)	800 yd. (732 m)	587 yd. (537 m)	203 yd. (185 m)	464 yd. (424 m)	500 yd. (457 m)
11–20 lb. (E6)	766 yd. (700 m)	288 yd. (263 m)	648 yd. (593 m)	800 yd. (732 m)	647 yd. (592 m)	232 yd. (212 m)	469 yd. (429 m)	500 yd. (457 m)

501–650 lb. (E11)	1,632 yd. (1.5 km)	697 yd. (637 m)	2,021 yd. (1.8 km)	2,100 yd. (1.9 km)				Not Applicable

[1] These mitigation zones are applicable to all mine countermeasure and neutralization activities conducted in all locations specified in Tables 2.8-1 through 2.8-5.
[2] These mitigation zones are only applicable to mine countermeasure and neutralization activities involving the use of diver-placed charges. These activities are conducted in shallow water and the mitigation zones are based only on the functional hearing groups with species that occur in these areas (mid-frequency cetaceans and sea turtles).
[3] The E7 bin was only modeled in shallow-water locations so there is no difference for the diver-placed charges category.
[4] The E8 bin was only modeled for surface explosions, so some of the ranges are shorter than for sources modeled in the E7 bin which occur at depth.
[5] This mitigation zone for the E10 charge applies only to very shallow water detonations and is based on empirical data as described in Section 5.3.2.1.2.4 (Mine Countermeasure and Neutralization Activities Using Positive Control Firing Devices).
Notes: km = kilometers, lb. = pounds, m = meters, PTS = permanent threshold shift, TTS = temporary threshold shift, yd. = yards

5.3.2.1 Acoustic Stressors

5.3.2.1.1 Non-Impulsive Sound

5.3.2.1.1.1 Low-Frequency and Hull-Mounted Mid-Frequency Active Sonar

Recommended Mitigation and Comparison to Current Mitigation

Mitigation measures do not currently exist for low-frequency active sonar sources analyzed in this Final EIS/OEIS, or new platforms or systems. The Navy is proposing to (1) add mitigation measures for low-frequency active sonar, (2) continue implementing the current measures for mid-frequency active sonar, and (3) clarify the conditions needed to recommence an activity after a sighting. The recommended measures are provided below.

Training and testing activities that involve the use of low-frequency and hull-mounted mid-frequency active sonar (including pierside) will use Lookouts for visual observation from a ship immediately before and during the activity. Active sonar transmission will not begin if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. With the exception of certain low-frequency sources that are not able to be powered down during the activity (e.g., low-frequency sources within bins LF4 and LF5), mitigation will involve powering down the sonar by 6 dB when a marine mammal or sea turtle is sighted within 1,000 yd. (914 m), and by an additional 4 dB when sighted within 500 yd. (457 m) from the source, for a total reduction of 10 dB. If the source can be turned off during the activity, active transmission will cease if a marine mammal or sea turtle (low-frequency sources only) is sighted within 200 yd. (183 m). Active transmission will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 30 min., (4) the ship has transited more than 2,000 yd. (1.8 kilometers [km]) beyond the location of the last sighting, or (5) the ship concludes that dolphins are deliberately closing in on the ship to ride the ship's bow wave (and there are no other marine mammal sightings within the mitigation zone). Active transmission may resume when dolphins are bow riding because they are out of the main transmission axis of the active sonar while in the shallow-wave area of the bow.

If the source is not able to be powered down during the activity (e.g., low-frequency sources within bins LF4 and LF5), mitigation will involve ceasing active transmission if a marine mammal or sea turtle is sighted within 200 yd. (183 m). Active transmission will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 30 min., or (4) the ship has transited more than 400 yd. (366 m) beyond the location of the last sighting.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted average range to onset of PTS for low-frequency and hull- mounted mid-frequency active sonar sources is 100 yd. (91 m) for one ping. This range was determined by the high-frequency cetacean functional hearing group. The distance for all other marine mammal functional hearing groups is less than 80 yd. (73 m) for one ping, so the mitigation zone will provide further protection from injury (PTS) for these species. Therefore, implementation of the 200 yd. (183 m) shutdown zone will reduce the potential for exposure to higher levels of energy that would result in injury (PTS) and large threshold shifts that are recoverable (i.e., TTS) when individuals are sighted. Implementation of the 500 yd. (457 m) and 1,000 yd. (914 m) sonar power reductions will further reduce the potential for injury (PTS) and larger threshold shifts that would result in recovery (i.e., TTS) to occur when individual marine mammals are sighted within these zones, especially in cases where the ship and animal are approaching each other.

The mitigation zones the Navy has developed are within a range for which Lookouts can reasonably be expected to maintain situational awareness and visually observe during most conditions. Since the predicted average range to onset of TTS is 3,821 yd. (3.5 km), the entire predicted range to TTS is not reasonably observable. By establishing mitigation zones that can be realistically maintained from ships, Lookouts will be more effective at sighting individual animals. By keeping Lookouts focused within the ranges where exposure to higher levels of energy is possible, the effectiveness at reducing potential impacts on marine mammals and sea turtles will increase. As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), the likelihood of sighting individual animals, particularly sea turtles and some species of small or cryptic marine mammals, decreases at long distances. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles. Observations for sea turtles are required only during low-frequency active sonar activities because hull-mounted mid-frequency active sonar are not within the primary sea turtle hearing range.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.1 (Impacts from Sonar and Other Active Acoustic Sources) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would eliminate opportunities to detect submarines, objects, or other exercise targets as would be required in a real world combat situation, reduce the sonar operator's situational awareness of the environment where the training or testing is occurring, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles, and; (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.1.2 High-Frequency and Non-Hull Mounted Mid-Frequency Active Sonar

Recommended Mitigation and Comparison to Current Mitigation

Mitigation measures do not currently exist for all high-frequency and non-hull mounted mid-frequency active sonar activities (i.e., new sources or sources not previously analyzed). The Navy is proposing to (1) continue implementing the current mitigation measures for activities currently being executed, such as dipping sonar activities, (2) extend the implementation of its current mitigation to all other activities in this category, and (3) clarify the conditions needed to recommence an activity after a sighting. The recommended measures are provided below.

Mitigation will include visual observation from a vessel or aircraft (with the exception of platforms operating at high altitudes) immediately before and during active transmission within a mitigation zone of 200 yd. (183 m) from the active sonar source. For activities involving helicopter-deployed dipping sonar, visual observation will commence 10 min. before the first deployment of active dipping sonar. Helicopter dipping and sonobuoy deployment will not begin if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. If the source can be turned off during the activity, active transmission will cease if a marine mammal or sea turtle (for MF8, MF9, MF10, and MF12 only) is sighted within the mitigation zone. Active transmission will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. for an aircraft-deployed source, (4) the mitigation zone has been clear from any additional sightings for a period of 30 min. for a vessel-deployed source, (5) the vessel or aircraft has repositioned itself more than 400 yd. (366 m) away from the location of the last sighting, or (6) the vessel concludes that dolphins are deliberately closing in to ride the vessel's bow wave (and there are no other marine mammal sightings within the mitigation zone).

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted average range to onset of PTS for high-frequency and non-hull mounted mid-frequency active sonar sources is 20 yd. (18 m) for one ping. This range was determined by the high-frequency cetacean functional hearing group. The predicted average range to onset of TTS across all functional hearing groups is 230 yd. (210 m) for one ping. Implementation of the 200 yd. (183 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury (PTS) and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted. Lookouts often visually observe either close aboard a vessel or from directly above the source by aircraft (i.e., helicopters). Exceptions include when sonobuoys are deployed and when sources are deployed from high altitude aircraft. When sonobuoys are used, the sonobuoy field may be dispersed over a large distance. As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), the likelihood of sighting individual animals, particularly sea turtles and some species of small or cryptic marine mammals decreases at long distances. This measure should be effective at reducing risks to all marine mammals and sea turtles that are available to be observed within the mitigation zone. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles. Observations for sea turtles are required only during non-hull mounted mid-frequency active sonar activities within bins MF8, MF9, MF10, and MF12 because high-frequency active sonar and other bins of mid-frequency sonar are not within the primary sea turtle hearing range.

The post-sighting wait periods are designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 30 min. wait period for vessel-deployed sources more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving species. However, the analysis in Section 3.4.3.2.1 (Impacts from Sonar and Other Active Acoustic Sources) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur, with the exception of *Kogia* species. Requiring additional delay beyond 30 min. for vessel-deployed sources would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would eliminate opportunities to detect submarines, objects, or other exercise targets and would be required during a real world combat situation and reduce the sonar operator's situational awareness of the environment where the training or testing is occurring, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period for aircraft-deployed sources covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period for aircraft-deployed sources is based on fuel restrictions for the types of aircraft involved in this activity (e.g., helicopters). Requiring additional delay beyond 10 min. for these sources would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would eliminate opportunities to detect submarines, objects, or other exercise targets as would be required during a real world combat situation and reduce the sonar operator's situational awareness of the environment where the training or testing is occurring, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2 Explosives and Impulsive Sound

5.3.2.1.2.1 Improved Extended Echo Ranging Sonobuoys

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) modify the mitigation measures currently implemented for this activity by reducing the marine mammal and sea turtle mitigation zone from 1,000 yd. (914 m) to 600 yd. (549 m), (2) clarify the conditions needed to recommence an activity after a sighting, and (3) adopt the marine mammal and sea turtle mitigation zone size for floating vegetation for ease of implementation. The recommended measures are provided below.

Mitigation will include pre-exercise aerial observation and passive acoustic monitoring, which will begin 30 min. before the first source/receiver pair detonation and continue throughout the duration of the exercise within a mitigation zone of 600 yd. (549 m) around an Improved Extended Echo Ranging sonobuoy. The pre-exercise aerial observation will include the time it takes to deploy the sonobuoy pattern (deployment is conducted by aircraft dropping sonobuoys in the water). Improved Extended Echo Ranging sonobuoys will not be deployed if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone around the intended deployment location. Explosive detonations will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Detonations will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 min.

Passive acoustic monitoring would be conducted with Navy assets, such as sonobuoys, already participating in the activity. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to Lookouts posted in aircraft and on vessels in order to increase vigilance of their visual observation.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for Improved Extended Echo Ranging sonobuoys is 563 yd. (515 m). This range was determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had a shorter range to onset of PTS, so the mitigation zone will provide further protection for these species. The predicted average range to onset of TTS across all functional hearing groups is 434 yd. (397 m). Implementation of the 600 yd. (549 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted. The sonobuoy field may be dispersed over a large distance. As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), the likelihood of sighting individual animals, particularly sea turtles and some species of small or cryptic marine mammals, decreases at long distances. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The decrease in mitigation zone size will result in no mitigation for exposure to lower levels of potential onset of TTS; however, it will allow for a more focused survey effort over a smaller survey distance, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. for aircraft-deployed Improved Extended Echo Ranging sonobuoys would modify the activity in a way that it would no longer meet its intended objective. The 30 min. wait period represents the maximum wait period acceptable for the type of aircraft involved in this activity (e.g., maritime patrol aircraft) based on fuel restrictions. Any additional delay would result in an unacceptable increased risk to personnel safety, require aircraft to depart the activity location to refuel, eliminate opportunities to detect submarines as would be required in a real world combat situation, and reduce the aircrew's situational awareness of the environment where the activity is occurring, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.2 Explosive Sonobuoys Using 0.6–2.5 Pound Net Explosive Weight

Recommended Mitigation and Comparison to Current Mitigation

Mitigation measures do not currently exist for this activity. The Navy is proposing to add the recommended measures provided below.

Mitigation will include pre-exercise aerial monitoring during deployment of the field of sonobuoy pairs (typically up to 20 min.) and continue throughout the duration of the exercise within a mitigation zone of 350 yd. (320 m) around an explosive sonobuoy. Explosive sonobuoys will not be deployed if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone (around the intended deployment location). Explosive detonations will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Detonations will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min.

Passive acoustic monitoring will also be conducted with Navy assets, such as sonobuoys, already participating in the activity. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to Lookouts posted in aircraft in order to increase vigilance of their visual observation.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for explosive sonobuoys using 0.6–2.5 lb. net explosive weight is 309 yd. (283 m). This range was determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The predicted average range to onset of TTS across all functional hearing groups is 290 yd. (265 m). Implementation of the 350 yd. (320 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and large threshold shifts that are recoverable (i.e., TTS) when individuals are sighted. The sonobuoy field may be dispersed over a large distance. As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), the likelihood of sighting individual animals, particularly sea turtles and some species of small or cryptic marine mammals, decreases at long distances.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 10 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period for aircraft-deployed sources is based on fuel restrictions for the types of aircraft involved in this activity (e.g., helicopters). Requiring additional delay beyond 10 min. for these sources would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would eliminate opportunities to detect and track submarines or other exercise targets as would be required in a real world combat situation, reduce the sonar operator's situational awareness of the environment where the training or testing is occurring, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.3 Anti-Swimmer Grenades

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) continue implementing the current mitigation measures for this activity and (2) clarify the conditions needed to recommence an activity after a sighting. The recommended measures are provided below.

Mitigation will include visual observation from a small boat immediately before and during the exercise within a mitigation zone of 200 yd. (183 m) around an anti-swimmer grenade. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Explosive detonations will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Detonations will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 30 min., or (4) the activity has been repositioned more than 400 yd. (366 m) away from the location of the last sighting.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for anti-swimmer grenades is 182 yd. (167 m). This range was determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The predicted average range to onset of TTS across all functional hearing groups is 190 yd. (174 m). Implementation of the 200 yd. (183 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted. Since the Lookout is visually observing close aboard the boat, this measure should be effective at reducing the risk to all marine mammals and sea turtles that are available to be observed. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would eliminate opportunities for maritime security forces to detect, respond, to, and defend against enemy scuba divers as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.4 Mine Countermeasure and Neutralization Activities Using Positive Control Firing Devices

Recommended Mitigation and Comparison to Current Mitigation

As background, mine countermeasure and neutralization activities can be divided into two main categories: (1) general activities that can be conducted from a variety of platforms and locations, and (2) activities involving the use of diver-placed charges that typically occur close to shore. When either of these activities are conducted using a positive control firing device, the detonation is controlled by the personnel conducting the activity and is not authorized until the area is clear at the time of detonation. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef, live hardbottom, artificial reef, and shipwreck mitigation areas.

For general mine countermeasure and neutralization activities, the Navy is proposing to (1) modify the currently implemented mitigation measures to account for additional categories of net explosive weights and to align with the modeled explosive bins, (2) clarify the conditions needed to recommence an activity after a sighting, and (3) add a requirement to observe for floating vegetation. For comparison, the currently implemented mitigation zone for general mine countermeasure and neutralization is 700 yd. (640 m) when using up to a 20 lb. net explosive weight charge. The recommended general mine countermeasure and neutralization measures are provided below and summarized in Table 5.3-3.

The Navy is proposing to use the mitigation zones outlined in Table 5.3-3 during general mine countermeasure activities using positive control firing devices. General mine countermeasure and neutralization activity mitigation will include visual observation from small boats or aircraft beginning 10 min. before, during, and 10 min. after (when helicopters are involved in the activity) or 30 min. before, during, and 30 min. after (when helicopters are not involved in the activity) the completion of the exercise within the mitigation zones around the detonation site. For activities involving explosives in bin E11 (501-650 lb. net explosive weight), aerial observation of the mitigation zone will be conducted.

The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Explosive detonations will cease if a marine mammal, sea turtle, flock of seabirds, or individual foraging seabird is sighted within the mitigation zone. Detonations will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. when helicopters are involved in the activity, or (4) the mitigation zone has been clear from any additional sightings for a period of 30 min. when helicopters are not involved in the activity.

For activities involving positive control diver-placed charges, the Navy is proposing to (1) modify the currently implemented mitigation measures for activities involving up to a 29 lb. or 251–500 lb. net explosive weight detonation, (2) add mitigation to account for additional categories of net explosive weights and to align with the modeled explosive bins, (3) clarify the conditions needed to recommence an activity after a sighting, and (4) add a requirement to observe for floating vegetation. For comparison, the currently implemented mitigation zone for up to 29 lb. net explosive weight charges is 700 yd. (640 m). Mitigation measures for activities involving diver-placed charges under positive control do not currently exist for 30–249 lb. net explosive weight detonations. The recommended measures for activities involving positive control diver-placed activities are provided below.

The Navy is proposing to use the mitigation zones outlined in Table 5.3-3 during activities involving positive control diver-placed charges. Visual observation will be conducted by either two small boats, or by one small boat in combination with either one helicopter or one appropriate elevated shore-based platform. Boats will position themselves near the mid-point of the mitigation zone radius (but always outside the detonation plume radius and human safety zone) and travel in a circular pattern around the detonation location.

When using two boats, each boat will be positioned on opposite sides of the detonation location, separated by 180 degrees. If used, helicopters will travel in a circular pattern around the detonation location. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Explosive detonations will cease if a marine mammal, sea turtle, flock of seabirds, or an individual foraging seabird is sighted in the water portion of the mitigation zone (i.e., not on shore). Lookouts will be trained to survey the mitigation zone for seabirds prior to and after the detonation event. During activities conducted in shallow water, a shore-based observer will use binoculars to survey the mitigation zone to detect any seabirds prior to and after each detonation. Detonations will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 min. (10 min. for applicable helicopter activities).

Immediately following the detonation, visual monitoring (using binoculars) will be conducted to survey the mitigation zone for at least 30 min. The Navy will report all injured or dead seabirds sighted during the post-detonation observations to the appropriate Navy Region Environmental Director, Navy Pacific Fleet Environmental Office, and local base wildlife biologist.

For training exercises that include the use of multiple detonations, the second (or third, etc.) detonation will occur either immediately after the preceding detonation (i.e., within 10 seconds of the preceding detonation), or after 30 min. have passed. This measure is intended to reduce the potential impacts to any piscivorous (fish-eating) birds, including least terns and pelicans, that forage in ocean waters or are attracted by stunned fish within the sphere of influence of the detonation.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. The predicted range to effects shown in Table 5.3-3 for general mine countermeasure and neutralization activities using positive control firing devices were determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had shorter ranges to onset of PTS, so the mitigation zones will provide further protection for these species. Implementation of the mitigation zones outlined in Table 5.3-3 will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

As described in Section 5.3.1 (Lookout Procedural Measures), Lookouts positioned in aircraft or small boats may be responsible for tasks in addition to observing the air or surface of the water. For example, a Lookout for this activity may also be responsible for navigation or assistance with mine countermeasure and neutralization deployment. The decrease in mitigation zone size for activities using diver-placed charges will result in no mitigation for exposure to lower levels of potential onset of TTS;

however, it will allow for a more focused survey effort over a smaller area, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals. Having a Lookout observe a mitigation zone that is too large could potentially increase the safety risk due to an increased level of distraction from normal job duties. Observation of an area beyond what the Navy is proposing to implement would not be likely to result in avoidance or reduction of injury to marine mammals or sea turtles because the effort spent observing those more distant areas would inevitably be minimal.

As described in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), the ability of a Lookout to detect an animal can vary greatly based on what observing platform is being used. For large ranges, aerial observation is more effective. In addition, when observing from a small boat, sea turtle and cryptic marine mammal species can be very difficult to detect beyond a few meters. However, this measure should be effective at reducing potential impacts for individuals that are sighted.

Mine neutralization activities involving diver-placed charges occur primarily close to shore and in shallow water (concentrated in the SSTC and San Clemente Island). The range to effects shown in Table 5.3-3 for mine neutralization activities involving diver-placed charges under positive control were determined by the sea turtle functional hearing group. The mid-frequency hearing group had shorter ranges to onset of PTS, so the mitigation zones will provide further protection for these species. However, mitigation would be implemented for any species observed within the mitigation zone.

In particular for activities involving positive control diver-placed charges, the Navy is recommending different mitigation zones depending on the depth of the water in which the detonation takes place. The Navy used the Reflection and Refraction in a Multilayered Ocean/Ocean Bottoms with Shear Wave Effects model to predict the pressure-wave propagation for underwater detonations in deep and shallow water. Due to the complicated nature of propagation in very shallow water (less than 24 ft. [7 m]), as well as substantial differences between very shallow water sites, the Navy determined the most accurate estimates of underwater sound propagation in two specific areas would result from empirical data developed from explosives testing in these two areas. In order to establish accurate mitigation zones for determining physiological effects on marine mammals, measured waveform propagation data was collected at the actual very shallow water locations at San Clemente Island and the Silver Strand Training Complex, and were used to determine the zone of influence and mitigation zone for very shallow water detonations training and testing at these sites.

Implementation of the mitigation zones outlined in Table 5.3-3 will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted. The decrease in mitigation zone size for activities using diver-placed charges (up to 29 lb. net explosive weight) will result in no mitigation for exposure to lower levels of potential onset of TTS; however, it will allow for a more focused survey effort over a smaller area, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals.

During activities using diver-placed charges, Lookouts are visually observing from small boats, helicopters, or shore-based platforms. As discussed above, aerial observation (and observations from shore-based platforms with high vantage points) is more effective than observation from a small boat. Since small boats do not have a very elevated observing platform, the distance over which animals can be observed is much shorter. Sea turtles and cryptic marine mammal species would be very difficult to detect further than a few meters away from the boat.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. (when helicopters are not involved in the activity) would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would eliminate opportunities to detect, identify, evaluate, and neutralize mines as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period (when helicopters are involved in the activity) covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on helicopter fuel restrictions. Requiring additional delay beyond 10 min. for these sources would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would eliminate opportunities to detect, identify, evaluate, and neutralize mines, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of injury to most marine mammal species or seabirds; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.5 Mine Neutralization Using Diver-Placed Time-Delay Firing Devices

Recommended Mitigation and Comparison to Current Mitigation

As background, when mine neutralization activities using diver-placed charges (up to a 29 lb. net explosive weight) are conducted with a time-delay firing device, the detonation is fused with a specified time-delay by the personnel conducting the activity and is not authorized until the area is clear at the time the fuse is initiated. During these activities, the detonation cannot be terminated once the fuse is initiated due to human safety concerns. Refer to Section 5.3.2.1.2.4 (Mine Countermeasure and Neutralization Activities Using Positive Control Firing Devices) for a general discussion of mitigation measures applicable to mine neutralization activities using diver-placed mines. This section will specify unique mitigation zones and observation methods for diver-placed mine activities that use time-delay firing devices. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef, live hardbottom, artificial reef, and shipwreck mitigation areas.

The Navy is proposing to (1) modify the mitigation zones and observation requirements currently implemented for mine countermeasure and neutralization activities using diver-placed time-delay firing devices, (2) clarify the conditions needed to recommence an activity after a sighting, and (3) add a requirement to observe for floating vegetation. For comparison, the current mitigation zones are based on size of charge and length of time-delay, ranging from a 1,000 yd. (914 m) mitigation zone for a 5 lb. net explosive weight charge using a 5 min. time-delay to a 1,500 yd. (1,372 m) mitigation zone for a 29 lb. net explosive weight charge using a 10 min. time-delay. The current requirement is for six

Lookouts in three boats (two in each boat) for larger than 1,400 yd. (1,280 m) and four Lookouts in two small boats to be used for observation in mitigation zones that are less than 1,400 yd. (1,280 m). The recommended measures for activities involving diver-placed time-delay firing devices are provided below.

The Navy recommends one mitigation zone for all net explosive weights and lengths of time-delay. Mine neutralization activities involving diver-placed charges will not include time-delay longer than 10 min. Mitigation will include visual surveillance from small boats commencing 30 min. before, during, and until 30 min. after the completion of the exercise within a mitigation zone of 1,000 yd. (915 m) around the detonation site. During activities using time-delay firing devices involving up to a 29 lb. net explosive weight charge, visual observation will take place using two small boats. In addition, when aircraft are involved (e.g., during deployment of divers), the pilot or member of the aircrew will serve as an additional Lookout. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. The fuse initiation will cease if a marine mammal, sea turtle, flock of seabirds, or individual foraging seabird is sighted within the water portion of the mitigation zone (i.e., not on shore). Fuse initiation will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 min.

Survey boats will position themselves near the mid-point of the mitigation zone radius (but always outside the detonation plume radius/human safety zone) and travel in a circular pattern around the detonation location. One Lookout from each boat will look inward toward the detonation site and the other Lookout will look outward away from the detonation site. Each boat will be positioned on opposite sides of the detonation location, separated by 180 degrees. If available for use, helicopters will travel in a circular pattern around the detonation location. Lookouts will be trained to survey the mitigation zone for seabirds prior to and after the detonation event. During activities conducted in shallow water, a shore-based observer will use binoculars to survey the mitigation zone to detect any seabirds prior to and after each detonation.

Immediately following the detonation, visual monitoring (using binoculars) will be conducted to survey the mitigation zone for at least 30 min. The Navy will report all injured or dead seabirds sighted during the post-detonation observations to the appropriate Navy Region Environmental Director, Navy Pacific Fleet Environmental Office, and local base wildlife biologist.

For training exercises that include the use of multiple detonations, the second (or third, etc.) detonation will occur either immediately after the preceding detonation (i.e., within 10 seconds of the preceding detonation), or after 30 min. have passed. This measure is intended to reduce the potential impacts to any piscivorous (fish-eating) birds, including least terns and pelicans, that forage in ocean waters or are attracted by stunned fish within the sphere of influence of the detonation.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for mine neutralization diver-placed mines using time-delay firing devices is 469 yd. (429 m). This range was determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The predicted average range to onset of TTS across all functional hearing groups is 647 yd. (592 m). The time-delay firing device mitigation zone was determined by including additional distance on top of the predicted maximum range to onset of PTS to account for a portion of the time that a marine mammal or sea turtle could enter the mitigation zone during the time-delay. Implementation of the 1,000 yd. (915 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

A 1,000 yd. (915 m) mitigation zone represents the maximum distance that the Lookouts on small boats can adequately observe given the number of personnel that will be involved. As discussed in Section 5.3.1.2.2.5 (Mine Neutralization Activities Using Diver-Placed Time-Delay Firing Devices), the use of more than two small boats for observation during this activity presents an unacceptable impact on readiness due to limited personnel resources. Since small boats do not have an elevated observing platform, the distance over which animals can be observed is much shorter. Sea turtles and cryptic marine mammal species would be very difficult to detect further that a few meters away from the boat. Sighting a sea turtle is only likely if a helicopter is participating in the activity. In addition, even with the extended mitigation zone to account for as much of the time-delay as possible, there is still a remote chance that animals may swim into the area after the charge is already set. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. The 30 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would eliminate opportunities to detect, identify, evaluate, and neutralize mines as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measures described above because (1) they are likely to result in avoidance or reduction of injury to most marine mammal species; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.6 Gunnery Exercises – Small- and Medium-Caliber Using a Surface Target

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) continue implementing the current mitigation measures for this activity, (2) clarify the conditions needed to recommence an activity after a sighting, and (3) add a requirement to visually observe for kelp paddies. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef mitigation areas. The recommended measures are provided below.

Mitigation will include visual observation from a vessel or aircraft immediately before and during the exercise within a mitigation zone of 200 yd. (183 m) around the intended impact location. Vessels will observe the mitigation zone from the firing position. When aircraft are firing, the aircrew will maintain visual watch of the mitigation zone during the activity. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. for a firing aircraft, (4) the mitigation zone has been clear from any additional sightings for a period of 30 min. for a firing vessel, and (5) the intended target location has been repositioned more than 400 yd. (366 m) away from the location of the last sighting.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-3, the predicted maximum range to onset of PTS for small- and medium-caliber gunnery is 182 yd. (167 m). This range was determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The average range to onset of TTS across all functional hearing groups is 190 yd. (174 m). Implementation of the 200 yd. (183 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

Small- and medium-caliber gunnery exercises involve the participating vessel or aircraft firing munitions at a target location that may be up to 4,000 yd. (3.7 km) away, although typically much closer than this. Therefore, it is necessary for the Lookout to be able to visually observe the mitigation zone from varying distances. Large vessel or aircraft platforms would provide a more effective observation platform for Lookouts than small boats. However, as discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), it is highly unlikely that anything but a whale blow or large pod of dolphins will be seen at distances closer to 4,000 yd. (3.7 km). However, this measure is likely effective at reducing the risk of injury to marine mammals that may be observed from the typical target distances. This measure may be ineffective at reducing the risk of injury to sea turtles at large target distances; however, it does reduce the risk for those individuals that may be observed at closer distances. In addition, it is more likely that sea turtles will be observed when exercises involve aircraft versus vessels. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 30 min. wait period for a firing vessel more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. for a firing vessel would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would reduce the gun crews' abilities to engage surface targets and practice defensive marksmanship as would be required in a real world combat situation and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period for a firing aircraft covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on fuel restrictions for the types of aircraft involved in this activity (e.g., helicopters). Requiring additional delay beyond 10 min. for these sources would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would eliminate opportunities and reduce the gun crews' abilities to engage surface targets and practice defensive marksmanship as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to some marine mammal species; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.7 Gunnery Exercises – Large-Caliber Using a Surface Target

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) continue using the currently implemented mitigation zone for this activity, (2) clarify the conditions needed to recommence an activity after a sighting, (3) add a requirement to visually observe for kelp paddies, and (4) modify the seafloor habitat mitigation area. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef mitigation areas. The recommended measures are provided below.

Mitigation will include visual observation from a ship immediately before and during the exercise within a mitigation zone of 600 yd. (549 m) around the intended impact location. Ships will observe the mitigation zone from the firing position. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 min.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential effects they are designed to reduce. As shown in Table 5.3-3, the predicted maximum range to onset of PTS for large-caliber gunnery is 526 yd. (481 m). This range was determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The average predicted range to onset of TTS across all functional hearing groups is 453 yd. (414 m). Implementation of the 600 yd. (549 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted. Per the

Navy's current reporting requirements, any injured or dead marine mammals or sea turtles will be reported as appropriate.

Large-caliber gunnery exercises involve the participating ship firing munitions at a target location from ranges up to 6 nautical miles (nm) away. Therefore it is necessary for the Lookout to be able to visually observe the mitigation zone from this distance. Although the Lookout will observe for all marine mammals or sea turtles in the area, as discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), it is highly unlikely that anything but a whale blow or large pod of dolphins will be seen. Although this measure is likely ineffective at reducing the risk of injury to sea turtles and some species of marine mammals, it does reduce the risk for those individuals that may be observed. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would reduce the gun crews' abilities to engage surface targets and practice defensive marksmanship as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to some marine mammal species; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.8 Missile Exercises (Including Rockets) up to 250 Pound Net Explosive Weight Using a Surface Target

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) modify the mitigation measures currently implemented for this activity by reducing the mitigation zone from 1,800 yd. (1.6 km) to 900 yd. (823 m), (2) clarify the conditions needed to recommence an activity after a sighting, (3) adopt the marine mammal and sea turtle mitigation zone size for floating vegetation for ease of implementation**,** and (4) modify the platform of observation to eliminate the requirement to observe when ships are firing. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef mitigation areas. The recommended measures are provided below.

When aircraft are firing, mitigation will include visual observation by the aircrew or supporting aircraft prior to commencement of the activity within a mitigation zone of 900 yd. (823 m) around the deployed target. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. or 30 min. (depending on aircraft type).

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for a missile exercise (including rockets) up to 250 lb. net explosive weight (bin E9) is 699 yd. (639 m). This range was determined by the sea turtle functional hearing group. The marine mammal functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The average predicted range to onset of TTS across all functional hearing groups is 949 yd. (868 m). Implementation of the 900 yd. (823 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted. The decrease in mitigation zone size will result in no mitigation for exposure to lower levels of potential onset of TTS; however, it will allow for a more focused survey effort over a smaller survey distance, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals and sea turtles.

Missile exercises involve the participating ship or aircraft firing munitions at a target location typically up to 15 nm away and infrequently include ranges up to 75 nm away. When an aircraft is firing, the aircraft can travel close to the intended impact area so that it can be visually observed. Because that type of observation is not possible for a ship, visual observation is not suitable for activities that involve a ship-fired missile. Even with aircraft firing, there is a chance that animals could enter the impact area after the visual observations have been completed and the activity has commenced. Therefore, this measure is not effective at reducing the risk of injury to animals once the firing activity has begun; however, it does reduce the risk for those individuals that may be observed prior to commencement of the activity when aircraft are firing. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. The 30 min. wait period represents the maximum wait period acceptable for certain types of aircraft involved in this activity (e.g., maritime patrol aircraft) based on their specific fuel restrictions. Requiring additional delay beyond 30 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch missiles as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on the specific fuel restrictions for the other types of aircraft involved in this activity (e.g., helicopters).

Requiring additional delay beyond 10 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch missiles as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.9 Missile Exercises 251–500 Pound Net Explosive Weight Using a Surface Target

Recommended Mitigation and Comparison to Current Mitigation

Mitigation measures do not currently exist for this activity. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef mitigation areas. The recommended measures are provided below.

When aircraft are firing, mitigation will include visual observation by the aircrew or supporting aircraft prior to commencement of the activity within a mitigation zone of 2,000 yd. (1.8 km) around the intended impact location. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. or 30 min. (depending on aircraft type).

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-3, the predicted maximum range to onset of PTS for a missile exercise using 251–500 lb. net explosive weight (bin E10) is 1,883 yd. (1.7 km). This range was determined by the sea turtle functional hearing group. The marine mammal functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The predicted average range to onset of TTS across all functional hearing groups is 1,832 yd. (1.7 km). Implementation of the 2,000 yd. (1.8 km) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

Missile exercises involve the participating ship or aircraft firing munitions at a target location typically up to 15 nm away and infrequently include ranges up to 75 nm away. When an aircraft is firing, the aircraft can travel close to the intended impact area so that it can be visually observed. Because that type of observation is not possible for a ship, visual observation is not suitable for activities that involve a ship-fired missile. Even with aircraft firing, there is a chance that animals could enter the impact area after the visual observations have been completed and the activity has commenced. Therefore, this measure is not effective at reducing the risk of injury to animals once the firing activity has begun; however, it does reduce the risk for those individuals that may be observed prior to commencement of the activity when aircraft are firing. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. The 30 min. wait period represents the maximum wait period acceptable for certain types of aircraft involved in this activity (e.g., maritime patrol aircraft) based on their specific fuel restrictions. Requiring additional delay beyond 30 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch missiles as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on the specific fuel restrictions for the other types of aircraft involved in this activity (e.g., helicopters). Requiring additional delay beyond 10 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch missiles as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.10 Bombing Exercises

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) modify the mitigation measures currently implemented for this activity by increasing the mitigation zone from 1,000 yd. (914 m) to 2,500 yd. (2.3 km), (2) clarify the conditions needed to recommence an activity after a sighting, (3) add a requirement to visually observe for kelp paddies, and (4) adopt the marine mammal and sea turtle mitigation zone size for floating vegetation for ease of implementation. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef mitigation areas. The recommended measures are provided below.

Mitigation will include visual observation from the aircraft immediately before the exercise and during target approach within a mitigation zone of 2,500 yd. (2.3 km) around the intended impact location. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Bombing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Bombing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for bombing exercises is 2,474 yd. (2.3 km). This range was determined by the sea turtle functional hearing group. The marine mammal functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. For example, the predicted maximum range to onset of PTS to mid-frequency of cetaceans is less than 500 yd. (457 m). The predicted average range to onset of TTS across all functional hearing groups is 2,513 yd. (2.3 km). Implementation of the 2,500 yd. (2.3 km) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

The predicted maximum range to onset mortality across all functional hearing groups is less than 250 yd. (229 m). Therefore, this measure will be effective at reducing potential mortality to all marine mammals and sea turtles when individuals are sighted. As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), it is highly unlikely that anything but a whale blow or large pod of dolphins will be seen at distances closer to 2,500 yd. (2.3 km) near the perimeter of the mitigation zone. However, this measure is likely effective at reducing the risk of injury to marine mammals and sea turtles that may be observed from the smaller distances within the mitigation zone. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

As described in Section 5.3.1 (Lookout Procedural Measures), Lookouts positioned in aircraft may be responsible for tasks in addition to observing the air or surface of the water. For example, a Lookout for this activity may also be responsible for navigation of the aircraft. Having a Lookout observe a mitigation zone that is too large could potentially increase the safety risk due to an increased level of distraction from normal job duties. Similarly, Lookouts posted in aircraft during bombing activities will, by necessity, focus their attention on the water surface below and surrounding the location of bomb deployment. Due to the nature of this activity (e.g., aircraft maintaining a relatively steady altitude of approximately 1,500 ft. and approaching the intended impact location), Lookouts will be able to observe a larger area during bombing activities than other proposed activities that involve the use of Lookouts positioned in aircraft (e.g., Improved Extended Echo Ranging sonobuoy activities). However, observation of an area beyond what the Navy is proposing to implement for bombing activities is not practical and would not likely result in avoidance or reduction of injury to marine mammals or sea turtles because the effort spent observing those more distant areas would inevitably be minimal.

While the increase in mitigation zone size will not mitigate for exposures to lower levels of potential onset of TTS; it will allow for a more focused survey effort over a larger survey distance, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 10 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on fuel restrictions (factoring in the typical activity locations) for the types of aircraft involved in this activity (e.g., F/A-18). Requiring additional delay beyond 10 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and deliver bombs as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.11 Torpedo (Explosive) Testing

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) modify the mitigation measures currently implemented for this activity by reducing the mitigation zone from 5,063 yd. (4.6 km) to 2,100 yd. (1.9 km), (2) clarify the conditions needed to recommence an activity after a sighting, (3) add a requirement to visually observe for kelp paddies, and (4) remove the requirement to review remotely sensed sea surface temperature maps prior to conducting the activity. The recommended measures are provided below.

Mitigation will include visual observation by aircraft (with the exception of platforms operating at high altitudes) immediately before, during, and after the exercise within a mitigation zone of 2,100 yd. (1.9 km) around the intended impact location. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal, sea turtle, or aggregation of jellyfish is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. or 30 min. (depending on aircraft type).

In addition to visual observation, passive acoustic monitoring would be conducted with Navy assets, such as passive ships sonar systems or sonobuoys, already participating in the activity. Passive acoustic observation would be accomplished through the use of remote acoustic sensors or expendable sonobuoys, or via passive acoustic sensors on submarines when they participate in the Proposed Action. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to the Lookout posted in the aircraft in order to increase vigilance of the visual observation; and to the person in control of the activity for their consideration in determining when the mitigation zone is determined free of visible marine mammals.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for explosive torpedoes is 2,021 yd. (1.8 km). This range was determined by the sea turtle functional hearing group. The marine mammal functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The average predicted range to onset of TTS across all functional hearing groups is 1,632 yd. (1.5 km). Implementation of the 2,100 yd. (1.9 km) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

The predicted maximum range to onset mortality across all functional hearing groups is less than 600 yd. (549 m). Therefore, this measure will be effective at reducing potential mortality to all marine mammals and sea turtles when individuals are sighted. As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), it is highly unlikely that anything but a whale blow or large pod of dolphins will be seen at distances closer to 2,100 yd. (1.9 km) near the perimeter of the mitigation zone. However, this measure is likely effective at reducing the risk of injury to marine mammals and sea turtles that may be observed from the smaller distances within the mitigation zone.

As described in Section 5.3.1 (Lookout Procedural Measures), Lookouts positioned in aircraft may be responsible for tasks in addition to observing the air or surface of the water. For example, a Lookout for this activity may also be responsible for navigation of the aircraft. Having a Lookout observe a mitigation zone that is too large could potentially increase the safety risk due to an increased level of distraction from normal job duties. Observation of an area beyond what the Navy is proposing to implement for torpedo (explosive) testing activities is not practical and would not likely result in avoidance or reduction of injury to marine mammals or sea turtles because the effort spent observing those more distant areas would inevitably be minimal.

The decrease in mitigation zone size will result in no mitigation for exposure to lower levels of potential onset of TTS; however, it will allow for a more focused survey effort over a smaller survey distance, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals and sea turtles. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies] and jellyfish aggregations will further help avoid impacts to marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. The 30 min. wait period represents the maximum wait period acceptable for certain types of aircraft involved in this activity (e.g., maritime patrol aircraft) based on their specific fuel restrictions. Requiring additional delay beyond 30 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch torpedoes as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on the specific fuel restrictions for the other types of aircraft involved in this activity (e.g., helicopters).

Requiring additional delay beyond 10 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch torpedoes as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The original intent of the measure requiring the review of remotely sensed sea surface temperature maps was to help predict areas in which protected species could occur. However, while the presence of sea surface temperature fronts may indicate suitable habitat for marine species and may sometimes lead observers to pay more attention to an area of the ocean likely to be associated with a marine species, sea surface temperature fronts alone are insufficient to locate and prevent avoidance of marine species during this type of exercise.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.12 Sinking Exercises

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) modify the mitigation measures currently implemented for this activity by increasing the mitigation zone from 2.0 nm to 2.5 nm, (2) clarify the conditions needed to recommence an activity after a sighting, (3) add a requirement to visually observe for kelp paddies, and (4) adopt the marine mammal and sea turtle mitigation zone size for concentrations of floating vegetation and aggregation of jellyfish for ease of implementation. The recommended measures are provided below.

Mitigation will include visual observation within a mitigation zone of 2.5 nm around the target ship hulk. Sinking exercises will include aerial observation beginning 90 min. before the first firing, visual observations from vessels throughout the duration of the exercise, and both aerial and vessel observation immediately after any planned or unplanned breaks in weapons firing of longer than 2 hours. Prior to conducting the exercise, the Navy will review remotely sensed sea surface temperature and sea surface height maps to aid in deciding where to release the target ship hulk.

The Navy will also monitor using passive acoustics during the exercise. Passive acoustic monitoring would be conducted with Navy assets, such as passive ships sonar systems or sonobuoys, already participating in the activity. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to Lookouts posted in aircraft and on vessels in order to increase vigilance of their visual surveillance. Lookouts will also increase observation vigilance before the use of torpedoes or unguided ordnance with a net explosive weight of 500 lb. or greater, or if the Beaufort sea state is a 4 or above.

The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. The exercise will cease if a marine mammal, sea turtle, or aggregation of jellyfish is sighted within the mitigation zone. The exercise will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 min. Upon sinking the vessel, the Navy will conduct post-exercise visual surveillance of the mitigation zone for 2 hours (or until sunset, whichever comes first).

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. During a sinking exercise, multiple weapons sources may be used (projectiles, missiles, bombs, torpedoes), the largest of which is the 2,000 lb. bomb. The recommended mitigation zone is approximately double the predicted maximum range to onset of PTS of the largest weapon source and is designed to account for multiple detonations during the activity. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for a bombing exercise is 2,474 yd. (2.3 km). This range was determined by the sea turtle functional hearing group. The marine mammal functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. For example, the predicted maximum range to onset of PTS to mid-frequency of cetaceans is less than 500 yd. (457 m). The average range to onset of TTS across all functional hearing groups is 2,513 yd. (2.3 km). Implementation of the 2.5 nm mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

The predicted maximum range to onset mortality across all functional hearing groups is less than 250 yd. (229 m). Therefore, this measure will be effective at reducing potential mortality to all marine mammals and sea turtles when individuals are sighted. As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), it is highly unlikely that anything but a whale blow or large pod of dolphins will be seen at distances closer to 2.5 nm near the perimeter of the mitigation zone. However, this measure is likely effective at reducing the risk of injury to marine mammals and sea turtles that may be observed from the smaller distances within the mitigation zone.

As described in Section 5.3.1 (Lookout Procedural Measures), Lookouts positioned in aircraft or vessels may be responsible for tasks in addition to observing the air or surface of the water. For example, a Lookout for this activity may also be responsible for navigation of the aircraft. Having a Lookout observe a mitigation zone that is too large could potentially increase the safety risk due to an increased level of distraction from normal job duties. Observation of an area beyond what the Navy is proposing to implement for sinking exercises is not practical and would not likely result in avoidance or reduction of injury to marine mammals or sea turtles because the effort spent observing those more distant areas would inevitably be minimal. The decrease in mitigation zone size will result in no mitigation for exposure to lower levels of potential onset of TTS; however, it will allow for a more focused survey effort over a smaller survey distance, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals and sea turtles. The amount of time it takes for an aircraft to conduct line transects around a detonation point within the currently implemented 2 nm mitigation zone could result in animals entering the mitigation zone at one end while the aircraft completes the survey at the other end of the mitigation zone. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies] and jellyfish aggregations will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would reduce the ship and aircrews' abilities to coordinate attack tactics on a seaborne target as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise. Although activities involving certain types of aircraft (e.g., helicopters) typically employ a 10 min. wait period due to fuel restrictions, the Navy is able to make an exception for this particular activity due to the large variation and rotation of assets that could participate in this type of exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.13 At-Sea Explosive Testing

Recommended Mitigation and Comparison to Current Mitigation

Mitigation measures do not currently exist for at-sea explosive testing activities. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef mitigation areas. The Navy is proposing to add the recommended measures provided below.

Mitigation during at-sea explosive testing, such as the sinking of a vessel by a sequential firing of multiple small charges (e.g., explosives in bin E5) for use as an artificial reef, will include visual observation from supporting vessels immediately before and during the activity within a mitigation zone of 1,600 yd. (1.4 km) around the intended impact location. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Detonations will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Detonations will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 min.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. During at-sea explosive testing, multiple weapons sources or charges may be used (projectiles and charges), the largest of which is a 10 lb. net explosive weight charge. The recommended mitigation zone is approximately double the predicted maximum range to onset of PTS of the largest source, and is designed to account for multiple detonations during the activity. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for at-sea explosive testing is 649 yd. (593 m). This range was determined by the high-frequency cetacean functional hearing group. The remaining functional hearing groups had a shorter predicted range to onset of PTS, so the mitigation zone will provide further protection for these species. The average range to onset of TTS across all functional hearing groups is 525 yd. (480 m). Implementation of the 1,600 yd. (1.4 km) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted.

The predicted maximum range to onset mortality across all functional hearing groups is less than 60 yd. (55 m). Therefore, this measure will be effective at reducing potential mortality to all marine mammals and sea turtles when individuals are sighted. This measure is likely also effective at reducing the risk of injury to marine mammals and sea turtles within the predicted maximum range to onset of PTS (649 yd. [593 m]). As discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), the likelihood of sighting individual animals, particularly sea turtles and some species of small or cryptic marine mammals, from a vessel decreases at long distances; therefore, this measure is likely ineffective at reducing impacts on sea turtles and some species of marine mammals at distances closer to 1,600 yd. (1.5 km) near the perimeter of the mitigation zone. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.2 (Impacts from Explosives) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would reduce the vessel's ability to determine the pressure generated which is used to test the feasibility of using various net explosive weight sizes for different events, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of injury to some species of marine mammals; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.14 Elevated Causeway System – Pile Driving

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) modify the mitigation measures currently implemented for this activity by increasing the mitigation zone from 50 yd. (46 m) to 60 yd. (55 m), (2) clarify the conditions needed to recommence an activity after a sighting, and (3) add a requirement to visually observe for kelp paddies. The recommended measures are provided below.

Mitigation will include visual observation from a small boat, the elevated causeway, or from shore starting 30 min. prior to and during the exercise within a mitigation zone of 60 yd. (55 m) around the pile driver. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Pile driving will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Pile driving will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 min.

Effectiveness and Operational Assessments

See the introduction of Section 5.3.2 (Mitigation Zone Procedural Measures) for a general discussion of mitigation zones, how they are implemented, and the potential impacts they are designed to reduce. As shown in Table 5.3-2, the predicted maximum range to onset of PTS for pile-driving exercises is 51 yd. (46 m). This range was determined by the injury threshold of 180 dB root mean square for cetaceans. The predicted average range to onset of TTS is 1,094 yd. (1 km). Implementation of the 60 yd. (55 m) mitigation zone will reduce the potential for exposure to higher levels of energy that would result in injury and larger threshold shifts that would result in recovery (i.e., TTS) when individuals are sighted. Since the mitigation zone is so small, this measure should be effective at reducing the risk to all marine mammals and sea turtles that are available to be observed within the mitigation zone. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.2.3 (Impacts from Pile Driving) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would reduce the crew's ability to construct the causeway platform in a manner that would be expected during a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of injury to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.1.2.15 Weapons Firing Noise During Gunnery Exercises – Large-Caliber

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to implement the following mitigation measure, which only applies to the firing side of the ship as provided below.

For all explosive and non-explosive large-caliber gunnery exercises conducted from a ship, mitigation will include visual observation immediately before and during the exercise within a mitigation zone of 70 yd. (64 m) within 30 degrees on either side of the gun target line on the firing side. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 30 min., or (4) the ship has repositioned itself more than 140 yd. (128 m) away from the location of the last sighting.

Effectiveness Assessment

The mitigation zone is designed to reduce the potential for injury from weapons firing noise during large-caliber gunnery exercises conducted from a ship. The majority of the energy that an animal could be exposed to would occur on the firing side of the vessel and would follow in the direction of fire. It is not operationally feasible to have Lookouts stationed on all sides of the vessel to visually observe for marine mammals and sea turtles due to limited resources (e.g., manning restrictions). Since the Lookout is positioned aboard the firing ship and is visually observing nearby the ship (70 yd. [64 m]), this measure should be effective at reducing the risk to all marine mammals and sea turtles that are available to be observed. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for sea turtles. However, the analysis in Section 3.4.3.2.5 (Impacts from Weapons Firing, Launch, and Impact Noise) shows that injury to marine mammals is not expected to occur. Requiring additional delay beyond 30 min. would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would reduce the gun crews' abilities to engage surface targets and practice defensive marksmanship as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of exposure to high levels of energy to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.2 Physical Disturbance and Strike

5.3.2.2.1 Vessels and In-Water Devices

5.3.2.2.1.1 Vessels

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to continue using the mitigation measures currently implemented. The recommended measures are provided below.

Vessels will avoid approaching marine mammals head on and will maneuver to maintain a mitigation zone of 500 yd. (457 m) around observed whales, and 200 yd. (183 m) around all other marine mammals (except bow riding dolphins), providing it is safe to do so.

Effectiveness and Operational Assessments

Since the Lookout is visually observing within a reasonable distance of the vessel (within 500 yd. [457 m]), this measure should be effective at reducing the risk to marine mammals that are available to be observed. However, as discussed above in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), large whales and pods of dolphins are more likely to be seen than other more cryptic species, such as beaked whales.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of injury to marine mammals; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.2.1.2 Towed In-Water Devices

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to continue using the mitigation measures currently implemented. The recommended measure is provided below.

The Navy will ensure that towed in-water devices being towed from manned platforms avoid coming within a mitigation zone of 250 yd. (229 m) around any observed marine mammal, providing it is safe to do so.

Effectiveness and Operational Assessments

Since the Lookout is visually observing within a reasonable distance of the vessel (250 yd. [229 m]), this measure should be effective at reducing the risk to marine mammals that are observable. However, as discussed above in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), large whales and pods of dolphins are more likely to be seen than other more cryptic species such as beaked whales.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of injury to marine mammals; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.2.2 Non-Explosive Practice Munitions

5.3.2.2.2.1 Gunnery Exercises – Small-, Medium-, and Large-Caliber Using a Surface Target

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) continue using the mitigation measures currently implemented for this activity, and (2) clarify the conditions needed to recommence an activity after a sighting. The recommended measures are provided below.

Mitigation will include visual observation immediately before and during the exercise within a mitigation zone of 200 yd. (183 m) around the intended impact location. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. for a firing aircraft, (4) the mitigation zone has been clear from any additional sightings for a period of 30 min. for a firing vessel, or (5) the intended target location has been repositioned more than 400 yd. (366 m) away from the location of the last sighting.

Effectiveness and Operational Assessments

The mitigation zone is designed to reduce the potential for direct strike from a non-explosive projectile. Large-caliber gunnery exercises involve the participating ship firing munitions at a target location from ranges up to 6 nm away. Small- and medium-caliber gunnery exercises involve the participating vessel or aircraft firing munitions at a target location from up to 2 nm away, although typically closer. Therefore it is necessary for the Lookout to be able to visually observe the mitigation zone from these distances. Although the Lookout will observe for all marine mammals or sea turtles in the area, as discussed in Section 5.3.1.2.4 (Effectiveness Assessment for Lookouts), it is highly unlikely that anything but a whale blow or large pod of dolphins will be seen at distances closer to 6 nm (i.e., at the furthest target distance for large-caliber gunnery exercises) or 2 nm (i.e., at the furthest target distance for small- and medium-caliber gunnery exercises). Although this measure is likely ineffective at reducing the risk of injury to sea turtles and some species of marine mammals, it does reduce the risk for those individuals that may be observed. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. A 30 min. wait period when vessels are firing more than covers the average dive times of most marine mammal species but may not be for sea turtles. However, the analysis in Section 3.4.3.4.3 (Impacts from Military Expended Materials) shows that injury to marine mammals and sea turtles is not expected to occur. Requiring additional delay beyond 30 min. for a firing vessel would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would reduce the gun crews’ abilities to engage surface targets and practice defensive marksmanship as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period for a firing aircraft covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on fuel restrictions for the types of aircraft involved in this activity (e.g., helicopters). Requiring additional delay beyond 10 min. for these sources would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would eliminate opportunities and reduce the gun crews’ abilities to engage surface targets and practice defensive marksmanship as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of injury to some species of marine mammals; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.2.2.2 Bombing Exercises

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) continue using the mitigation measures currently implemented for this activity, and (2) clarify the conditions needed to recommence an activity after a sighting. The recommended measures are provided below.

Mitigation will include visual observation from the aircraft immediately before the exercise and during target approach within a mitigation zone of 1,000 yd. (914 m) around the intended impact location. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Bombing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Bombing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min.

Effectiveness and Operational Assessments

The mitigation zone is designed to reduce the potential for direct strike from a non-explosive bomb. The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 10 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on fuel restrictions for the types of aircraft involved in this activity (e.g., F/A-18). Requiring additional delay beyond 10 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and deliver bombs as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The Navy proposes implementing the recommended measure described above because: (1) it is likely to result in avoidance or reduction of injury to marine mammals or sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.2.2.2.3 Missile Exercises (Including Rockets) Using a Surface Target

The Navy is proposing to (1) modify the mitigation measures currently implemented for this activity by reducing the mitigation zone from 1,800 yd. (1.6 km) to 900 yd. (823 m), (2) clarify the conditions needed to recommence an activity after a sighting, (3) adopt the marine mammal and sea turtle mitigation zone size for floating vegetation for ease of implementation**,** and (4) modify the platform of observation to eliminate the requirement to observe when ships are firing. Refer to Section 5.3.3.2.2 (Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks) for information on mitigation designed to avoid or reduce potential impacts from military expended materials within shallow coral reef mitigation areas. The recommended measures are provided below.

When aircraft are firing, mitigation will include visual observation by the aircrew or supporting aircraft prior to commencement of the activity within a mitigation zone of 900 yd. (823 m) around the deployed target. The exercise will not commence if concentrations of floating vegetation (*Sargassum* or kelp paddies) are observed in the mitigation zone. Firing will cease if a marine mammal or sea turtle is sighted within the mitigation zone. Firing will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 min. or 30 min. (depending on aircraft type).

Effectiveness and Operational Assessments

The mitigation zone is designed to reduce the potential for direct strike from a non-explosive projectile. Activities using non-explosive missiles (including rockets) involve the participating ship or aircraft firing munitions at a target location typically up to 15 nm away and infrequently include ranges up to 75 nm away. When an aircraft is firing, the aircraft can travel close to the intended impact area so that it can be visually observed. Because that type of observation is not possible for a ship, visual observation is not suitable for activities that involve a ship-fired missile. Even with aircraft firing, there is a chance that animals could enter the impact area after the visual observations have been completed and the activity has commenced. Observation for indicators of marine mammal and sea turtle presence (e.g., concentrations of floating vegetation [*Sargassum* or kelp paddies]) will further help avoid impacts on marine mammals and sea turtles.

The post-sighting wait period is designed to give any animals that are sighted an opportunity to leave the area before the exercise recommences but will only be employed if one of the other conditions has not already been met. The 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.4.3 (Impacts from Military Expended Materials) shows that injury to marine mammals and sea turtles is not expected to occur. The 30 min. wait period represents the maximum wait period acceptable for certain types of aircraft involved in this activity (e.g., maritime patrol aircraft) based on their specific fuel restrictions. Requiring additional delay beyond 30 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch missiles as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The 10 min. wait period covers a portion of the average marine mammal and sea turtle dive times but may not be sufficient to cover the average dive times of all species. The 10 min. wait period is based on the specific fuel restrictions for the other types of aircraft involved in this activity (e.g., helicopters). Requiring additional delay beyond 10 min. for these platforms would modify the activity in a way that it would no longer meet its intended objective. Any additional delay would result in an unacceptable increased risk to personnel safety or would require aircraft to depart the activity location to refuel, which would reduce the aircrews' abilities to approach surface targets and launch missiles as would be required in a real world combat situation, and would therefore have an unacceptable impact on the realism and effectiveness of the exercise.

The Navy proposes implementing the recommended measure described above because (1) it is likely to result in avoidance or reduction of injury to marine mammals and sea turtles; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.3 MITIGATION AREAS

The Navy is proposing to implement several mitigation measures within pre-defined habitat areas in the Study Area. For the purposes of this document, the Navy will refer to these areas as "mitigation areas." As described throughout this section, these recommended mitigation areas may be based off endangered species critical habitats, endangered species reproductive areas, or bottom features. The size and location of certain habitat areas, such as the critical habitats, is subject to change over time; however, the Navy's effectiveness and operational assessments and resulting mitigation recommendations are entirely dependent on the mitigation area defined in this document. Therefore, it is important to note that the Navy is recommending implementing mitigation measures only within each area as described in this document. Applying these mitigations to additional or expanded areas could potentially result in an unacceptable impact on readiness.

5.3.3.1 Marine Mammal Habitats

5.3.3.1.1 Humpback Whale

5.3.3.1.1.1 Humpback Whale Cautionary Area

Recommended Mitigation and Comparison to Current Mitigation

To supplement the mitigation measures described in Section 5.3.2 (Mitigation Zone Procedural Measures), the Navy is proposing continuation of mitigation measures within the Hawaiian Islands Humpback Whale National Marine Sanctuary. Humpback whales migrate to the Hawaiian Islands each winter to mate and rear their calves. Data clearly indicate that, historically, high densities of humpback whales have concentrated in certain areas around the Hawaiian Islands. NMFS has reviewed the Navy's data on mid-frequency active sonar training in these dense humpback whale areas since June 2006 and found it to be rare and infrequent. While past data is no guarantee of future activity, it documents a history of low level mid-frequency active sonar activity in dense humpback areas. In order to be successful at operational missions and against the threat of quiet, diesel-electric submarines, the Navy has, for more than 40 years, routinely conducted anti-submarine warfare training in major exercises in the waters off the Hawaiian Islands, including the Hawaiian Islands Humpback Whale National Marine Sanctuary. During this period, no harmful effects to humpback whales attributed to mid-frequency active sonar use have been observed. Coincident with this use of mid-frequency active sonar, abundance estimates reflect an annual increase in the humpback whale stock (Mobley et al. 2001; Mobley 2004).

NMFS and the Navy have explored ways of reducing or avoiding impacts to humpback whales from exposure to mid-frequency active sonar. Factors including how practical the measure is to implement and how the measure could affect training fidelity are considered before implementing the measure. The Navy recognizes the significance of the Hawaiian Islands for humpback whales. The Navy has designated a humpback whale cautionary area (Figure 5.3-1), which consists of a 3.1 mi. (5 km) mitigation zone that has been identified as having one of the highest concentrations of humpback whales during the critical winter months. The Navy has agreed that training exercises in the humpback whale cautionary area will require a much higher level of clearance than is normal practice in planning and conducting mid-frequency active sonar training. Should national security needs require mid-frequency active sonar training and testing in the cautionary area between 15 December and 15 April, it shall be personally authorized by the Commander, U.S. Pacific Fleet. The Commander, U.S. Pacific Fleet shall base such authorization on the unique characteristics of the area from a military readiness perspective, taking into account the importance of the area for humpback whales and the need to reduce adverse impacts on humpback whales from mid-frequency active sonar whenever practicable. Approval at this level for this type of activity is extraordinary. The Commander, U.S. Pacific Fleet is a four-star Admiral and the highest ranking officer in the U.S. Pacific Fleet. This case-by-case authorization cannot be delegated and represents the Navy's commitment to fully consider and balance mission requirements with environmental stewardship. Further, the Commander, U.S. Pacific Fleet will provide specific direction on required mitigation prior to operational units transiting to and training in the cautionary area. This process will ensure the decisions to train in this area are made at the highest level in the Pacific Fleet, heighten awareness of humpback whale activities in the cautionary area, and serve to reemphasize that mitigation measures are to be scrupulously followed. The Navy will provide NMFS with advance notification of any such activities.

Effectiveness and Operational Assessments

Mid-frequency active sonar training will not regularly occur within the humpback whale cautionary area between 15 December and 15 April. This training can occur in this area during this time period only with approval by the Commander, U.S. Pacific Fleet. This approach will reduce potential interactions between humpback whales and U.S. Navy training activities during the critical winter months of highest concentrations of humpback whales.

The Navy proposes implementing the recommended measures described above because (1) they are likely to result in avoidance or reduction of injury to the humpback whale; and (2) they have acceptable operational impacts on the proposed activity with regard to safety, practicability, impact on readiness, and Navy policy.

5.3.3.2 Seafloor Resources

5.3.3.2.1 Marine Habitats and Cultural Resources

5.3.3.2.2 Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks

Recommended Mitigation and Comparison to Current Mitigation

The Navy is proposing to (1) modify some of the mitigation measures for seafloor habitats and shipwrecks and (2) discontinue the currently implemented measures for medium- and large-caliber gunnery exercises and missile exercises using airborne targets. The recommended measures are provided below.

To aid in the implementation of these measures, the Navy will include maps of surveyed shallow coral reefs, artificial reefs, and shipwrecks, in the Protective Measures Assessment Protocol. For mitigation, the term "surveyed" refers to habitat features where the available data indicate the natural boundary of the feature at a generally constant accuracy. Data that are generalized within large geometric areas (e.g., grid cells) are not included.

The Navy will not conduct precision anchoring within the anchor swing diameter, or explosive mine countermeasure and neutralization activities (except in near-shore areas of San Clemente Island in the SOCAL Range Complex and in the SSTC) within 350 yd. (320 m) of surveyed shallow coral reefs, live hardbottom, artificial reefs, and shipwrecks.

The Navy will not conduct explosive or non-explosive small-, medium-, and large-caliber gunnery exercises using a surface target, explosive missile exercises using a surface target, explosive and non-explosive bombing exercises, or at-sea explosive testing within 350 yd. (320 m) of surveyed shallow coral reefs.

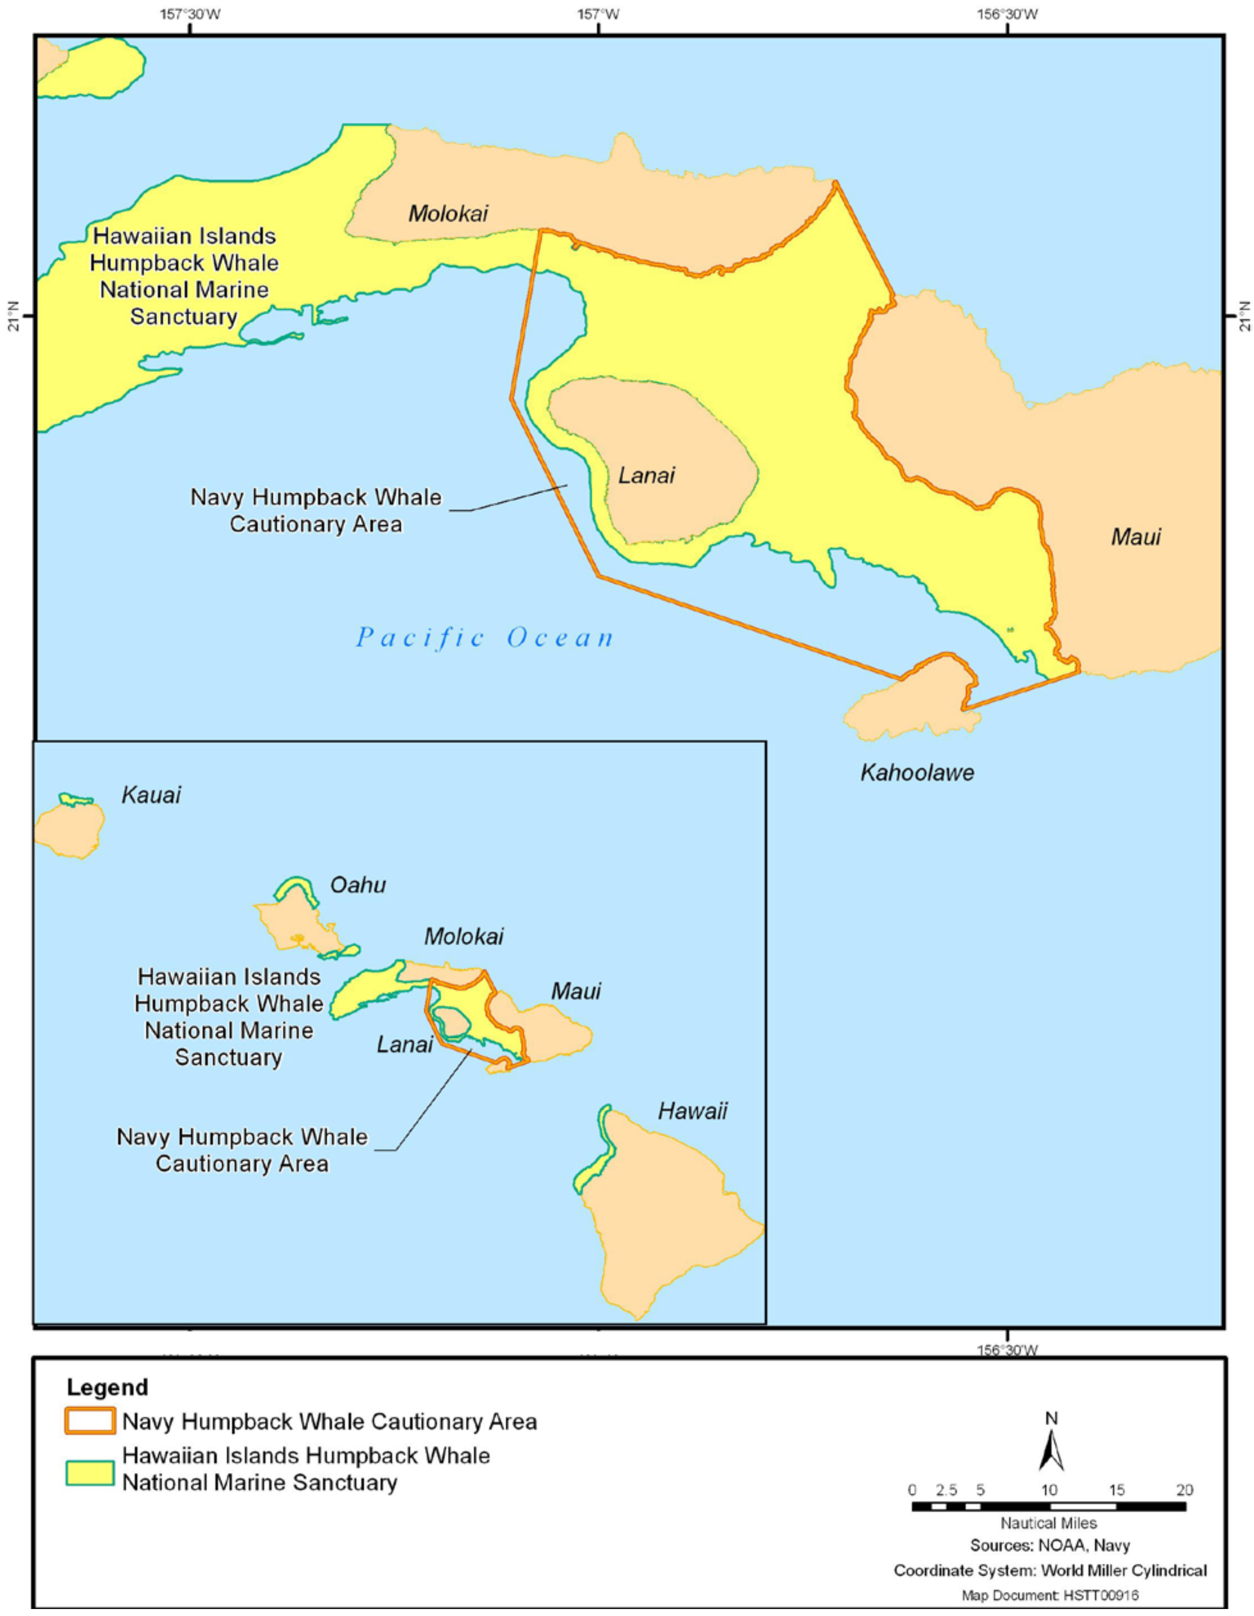

Figure 5.3-1: Navy Humpback Whale Cautionary Area

Effectiveness and Operational Assessments

The Navy's currently implemented seafloor habitats and shipwreck mitigation zones are based off the range to effects for marine mammals or sea turtles, which are driven by hearing thresholds. The Navy's recommended measures are modified to focus on reducing potential physical impacts on seafloor habitats and shipwrecks from explosives and physical strike from military expended materials. The recommended 350 yd. (320 m) mitigation zone is based off the estimated maximum seafloor impact zone for explosions discussed in Section 3.3 (Marine Habitats). The use of non-explosive military expended materials would result in a smaller footprint of potential impact; however, the Navy recommends applying the explosive mitigation zone to all explosive and non-explosive activities as listed above for ease of implementation. This standard mitigation zone will consequently result in an additional protection buffer during the non-explosive activities listed above.

It is not possible to definitively predict or to effectively monitor where the military expended materials from airborne gunnery and missile exercises using aerials targets would be likely to strike seafloor habitats and shipwrecks. The potential debris fall zone can only be predicted within tens of miles for long range events, which can be in excess of 80 nm from the firing location during some missile exercises, and thousands of yards for shorter events, which can occur within several thousand yards of the firing location.

Live hardbottom, shallow water coral reefs, artificial reefs, and shipwrecks fulfill important ecosystem functions. Avoiding or minimizing physical disturbance and strike of these resources will likely reduce the impact on these resources. This measure is only effective with regard to surveyed resources since the Navy needs specific locations to restrict the specified activities. It is not possible for the Navy to avoid these seafloor features when their exact locations are unknown.

The Navy proposes implementing the recommended measures described above because (1) they are likely to result in avoidance or reduction of physical disturbance and strike to seafloor habitats and shipwrecks; and (2) implementation has been analyzed as acceptable with regard to personnel safety, practicality of implementation, impact on effectiveness of the military readiness activity, and Navy policy.

5.3.3.2.3 Cultural Resources

Although effects on underwater cultural resources are not anticipated, the potential for unanticipated discovery of underwater resources always exists. To ensure that previously unidentified submerged cultural resources are adequately protected, the Commander, Naval Region, the Advisory Council on Historic Preservation (Council), and the Hawaii State Historic Preservation Office entered into a Programmatic Agreement in 2003 regarding Navy undertakings in Hawaii. Among the stipulations of the Programmatic Agreement is one focused on unanticipated discoveries: Stipulation XI(A). The Programmatic Agreement stipulates; "If during the performance of an undertaking, historic properties, including submerged archaeological sites and traditional cultural places, are discovered or unanticipated effects are found, or a previously unidentified property which may be eligible for listing on the National Register of Historic Places is discovered, Commander, Naval Region Hawaii will take all reasonable measures to avoid or minimize harm to the property until it concludes consultation with the State Historic Preservation Office and any Native Hawaiian organization, including the Oahu Council of Hawaiian Civic Clubs, which has made known to Commander, Naval Region Hawaii that it attaches religious and cultural significance to the historic property."

Under the existing Programmatic Agreement with the California State Historic Preservation Office, once a currently unidentified site is determined to be eligible for the National Registry of Historic Places, the State Historic Preservation Officer will be consulted to resolve potential adverse effects and identify appropriate treatments stipulated to address identified, unavoidable adverse effects.

5.3.4 Mitigation Measures Considered but Eliminated

A number of mitigation measures were suggested during the public comment periods of previous Navy environmental documents and throughout the development of this Final EIS/OEIS. As a result of the assessment process identified in Section 5.2 (Introduction to Mitigation), the Navy determined that some of the suggested measures would likely be ineffective at reducing environmental impacts, have an unacceptable operational impact based on the operational assessment, or be incompatible with Section 5.2.2 (Overview of Mitigation Approach). The measures that the Navy does not recommended for implementation are discussed in Section 5.3.4.1 (Previously Considered but Eliminated) and Section 5.3.4.2 (Previously Accepted but Now Eliminated). There is a distinction between effective and feasible observation procedures for data collection and measures employed to prevent impacts or otherwise serve as mitigation. The discussion below is in reference to those procedures meant to serve as mitigation measures.

5.3.4.1 Previously Considered but Eliminated

5.3.4.1.1 Reducing Amount of Training and Testing Activities

Reducing training and testing for the purpose of mitigation would result in an unacceptable impact on readiness for the following reasons:

The requirements to train are designed to provide the experience needed to ensure Sailors are properly prepared for operational success. Training requirements have been developed through many years of iteration and are designed to ensure Sailors achieve the levels of readiness needed to properly respond to the many contingencies that may occur during an actual mission. The Proposed Action does not include training beyond levels required for maintaining satisfactory levels of readiness due to the need to efficiently use limited resources (e.g., fuel, personnel, and time). Therefore, any reduction of training would not allow Sailors to achieve satisfactory levels of readiness needed to accomplish their mission.

The requirements to test systems prior to their implementation in military activities are identified in Department of Defense (DoD) Directive 5000.1. This directive states that test and evaluation support is to be integrated throughout the defense acquisition process. The Navy rigorously collected data during the developmental stages of this EIS/OEIS to accurately quantify test activities necessary to meet requirements of DoD Directive 5000.1. These testing requirements are designed to determine whether systems perform as expected and are operationally effective, suitable, survivable, and safe for their intended use. Any reduction of testing activities would not allow the Navy to meet its purpose and need to achieve requirements set forth in DoD Directive 5000.1.

5.3.4.1.2 Replacing Training and Testing with Simulated Activities

Replacing training and testing activities with simulated activities for the purpose of mitigation would result in an unacceptable impact on readiness for the following reasons:

As described in Section 2.5.1.3 (Simulated Training and Testing), the Navy currently uses computer simulation for training and testing whenever possible. Computer simulation can provide familiarity and complement live training; however, it cannot provide the fidelity and level of training necessary to prepare naval forces for deployment.

The Navy is required by law to operationally test major platforms, systems, and components of these platforms and systems in realistic combat conditions before full-scale production can occur. Substituting simulation for live training and testing fails to meet the purpose of and need for the Proposed Action and therefore was eliminated from consideration as a mitigation measure.

5.3.4.1.3 Reducing Sonar Source Levels and Total Number of Hours

Active sonar is only used when required by the mission since it has the potential to alert opposing forces to the sonar platform's presence. Passive sonar and all other sensors are used in concert with active sonar to the maximum extent practicable when available and when required by the mission. Reducing active sonar source levels and the total number of active sonar hours used during training and testing activities for the purpose of mitigation would adversely impact the effectiveness of military readiness activities and increase safety risks to personnel for the following reasons:

Sonar operators need to train as they would operate during real combat situations. Operators of sonar equipment are always cognizant of the environmental variables affecting sound propagation. In this regard, sonar equipment power levels are always set consistent with mission requirements. Reducing sonar source levels for the purpose of mitigation precludes sonar operators from learning to operate the sonar systems with their entire range of capabilities throughout the extremely diverse range of environmental conditions they may encounter. Failure to train with the entire range of capabilities will reduce the effectiveness of the sonar operators should their skills be required during real world events. Not only would they not develop the skills necessary to identify and track submarines at the maximum distances of their systems capabilities, they would not learn how to use their systems' capabilities during the entire range of environmental conditions they may encounter. Likewise, they would not develop the knowledge of how to fully integrate multiple anti-submarine warfare capabilities, including other ships and aircraft into an integrated anti-submarine warfare team.

Failure to train with the entire range of capabilities also compromises training by reducing the ability for a sonar operator to detect, track, and hold an enemy target, mine, or other object, and by reducing the realism of other training scenarios (e.g., navigation training). Particularly during a strike group exercise, sonar operators need to learn to handle real world combat situations (e.g., the ability to manage sonar operations during periods of mutual interference, which can occur when more than one sonar system is operating simultaneously). Training with reduced sonar source levels would ultimately condition Sailors to expect conditions that they would not experience in a real world combat situation, thereby resulting in an unacceptable increased risk to personnel safety and the strike group's ability to achieve mission success. The Navy must test its systems in the same way they would be used for military readiness activities. Reducing sonar source levels during testing would impact the ability to determine whether systems are operationally effective, suitable, survivable, and safe. Ultimately, reducing sonar source levels would reduce training and testing realism. Reducing the total number of sonar hours used during training and testing would prevent the Navy from meeting its military readiness qualification standards.

5.3.4.1.4 Implementing Active Sonar Ramp-Up Procedures during Training

Implementing active sonar ramp-up procedures (slowly increasing the sound in the water to necessary levels) in an attempt to clear the range prior to conducting activities for the purpose of mitigation during training activities would result in an unacceptable impact on readiness and would not necessarily be effective at reducing potential impacts on marine species for the following reason:

Ramp-up procedures would alert opponents to the participants' presence. This would consequently negatively affect the realism of training because the target submarine could detect the searching unit before the searching unit could detect the target submarine, enabling the target submarine to take evasive measures. This is not representative of a real world situation and thereby would impact training realism and effectiveness. Training with reduced realism would alter Sailors' abilities to effectively operate in a real world combat situation, thereby resulting in an unacceptable increased risk to personnel safety and the sonar operator's ability to achieve mission success.

Although ramp-up procedures have been used for some testing activities, effectiveness at avoiding or reducing impacts on marine mammals has not been demonstrated. Until evidence suggests that ramp-up procedures are effective means of avoiding or reducing potential impacts on marine mammals, the Navy is proposing to eliminate the implementation of this measure for testing activities as part of the Proposed Action.

5.3.4.1.5 Reducing Vessel Speed

As described in Section 5.1.1 (Vessel Safety), as a standard operating procedure, Navy personnel are required to use extreme caution and operate at a slow, safe speed consistent with mission and safety. These standard operating procedures are designed to allow a vessel to take proper and effective action to avoid a collision with any sighted object or disturbance (which may include a marine mammal), and to stop within a distance appropriate to the prevailing circumstances and conditions. Implementing widespread reductions in vessel speed throughout the Study Area for the purpose of mitigation would be impractical with regard to military readiness activities, and result in an unacceptable impact on readiness for the following reasons:

Vessel operators need to be able to react to changing tactical situations and evaluate system capabilities in training and testing as they would in actual combat. Widespread speed restrictions would not allow the Navy to properly test vessel capabilities, for example, during full power propulsion testing during sea trials. Training with reduced realism would alter Sailors' abilities to effectively operate in a real world combat situation, thereby resulting in an unacceptable increased risk to personnel safety and the vessel operator's ability to achieve mission success.

5.3.4.1.6 Limiting Access to Training and Testing Locations

Limiting training and testing activities to specific locations for the purpose of mitigation would be impractical with regard to implementation, would adversely impact the effectiveness of military readiness activities, and would increase safety risks to personnel for the following reasons:

As described in Section 2.5.1.1 (Alternative Training and Testing Locations), the ability to use the diverse and multidimensional capabilities of each range complex and testing range results in the Navy's ability to develop and maintain high levels of readiness. Major exercises using integrated warfare components require large areas of the littorals, open ocean, and certain nearshore areas for realistic and safe training. Limiting training and testing (including the use of sonar and other active acoustic sources or explosives) to specific locations (e.g., abyssal waters and surveyed offshore waters) and avoiding areas (e.g., embayments or large areas of the littorals and open ocean) would be impractical to implement with regard to the need to conduct activities in proximity to certain facilities and range complexes. These restrictions would also adversely impact the safety of the training and testing activities by requiring activities to take place in more remote areas where safety support may be limited.

Training and testing activities require continuous access to large areas consisting potentially of thousands of square miles of ocean and air space to provide naval personnel the ability to train with and develop competence and confidence in their capabilities and their entire suite of weapons and sensors. Exercises may change mid-stream based on evaluators' assessments of performance and other conditions including weather or mechanical issues. These may preclude use of a permission scheme for access to water space. Threats to national security are constantly evolving and the Navy requires the ability to adapt training to meet these emerging threats as well as develop and test systems to effectively operate in these environments. Restricting access to limited locations would impact the ability of Navy training and testing to evolve as the threat evolves. Operational units already incorporate requirements for safety of personnel including air space and shipping routes. Safety restrictions may include limits on distance from military air fields during carrier flight operations and air traffic corridors for safety of military and civilian aviation. These types of limitations shape how exercise planners develop and implement training scenarios including those involving defense of aircraft carriers from submarines.

Therefore, limiting access to training and testing locations would reduce realism of training by restricting access to important real world combat situations, such as bathymetric features and varying oceanographic features. As described in Section 5.3.4.1.7 (Avoiding Locations Based on Bathymetry and Environmental Conditions), Sailors must be trained to handle bottom bounce, sound passing through changing currents, eddies, or across changes in ocean temperature, pressure, or salinity. Training in a few specific locations would alter Sailors' abilities to effectively operate in varying real world combat situations, thereby resulting in an unacceptable increased risk to personnel safety and the ability to achieve mission success.

5.3.4.1.7 Avoiding Locations Based on Bathymetry and Environmental Conditions

Avoiding locations for training and testing activities based on bathymetry and environmental conditions for the purpose of mitigation would increase safety risks to personnel and result in an unacceptable impact on readiness for the following reasons:

Areas where training and testing activities are scheduled to occur are carefully chosen to provide safety and allow realism of events. As described in Section 2.5.1.1 (Alternative Training and Testing Locations), the varying environmental conditions of the Study Area (e.g., bathymetry and topography) maximize the training realism and testing effectiveness. Limiting training and testing, including the use of sonar and other active acoustic sources or explosives, to avoid steep or complex bathymetric features (e.g., submarine canyons and large seamounts) and oceanographic features (e.g., surface fronts and variations in sea surface temperatures) would reduce the realism of the military readiness activity. Systems must be tested in a variety of bathymetric and environmental conditions to ensure functionality and accuracy in a variety of environments. Sonar operators need to train as they would operate during real world combat situations. Because real world combat situations include diverse bathymetric and environmental conditions, Sailors must be trained to handle bottom bounce, sound passing through changing currents, eddies, or across changes in ocean temperature, pressure, or salinity. Training with reduced realism would alter Sailors' abilities to effectively operate in a real world combat situation, thereby resulting in an unacceptable increased risk to personnel safety and the sonar operator's ability to achieve mission success.

5.3.4.1.8 Avoiding or Reducing Active Sonar at Night and During Periods of Low Visibility

Avoiding or reducing active sonar at night and during periods of low visibility for the purpose of mitigation would result in an unacceptable impact on readiness for the following reasons:

The Navy must train in the same manner as it will fight. Anti-submarine warfare can require a significant amount of time to develop the "tactical picture," or an understanding of the battle space (e.g., area searched or unsearched, identifying false contacts, and understanding the water conditions). Reducing or securing power in low-visibility conditions would affect a commander's ability to develop this tactical picture and would not provide the needed training realism. Training differently from what would be needed in an actual combat scenario would decrease training effectiveness, reduce the crew's abilities, and introduce an increased safety risk to personnel.

Mid-frequency active sonar training is required year-round in all environments, including night and low-visibility conditions. Training occurs over many hours or days, which requires large teams of personnel working together in shifts around the clock to work through a scenario. Training at night is vital because environmental differences between day and night affect the detection capabilities of sonar. Temperature layers that move up and down in the water column and ambient noise levels can vary significantly between night and day, which affects sound propagation and could affect how sonar systems are operated. Consequently, personnel must train during all hours of the day to ensure they identify and respond to changing environmental conditions, and not doing so would unacceptably decrease training effectiveness and reduce the crews' abilities. Therefore, the Navy cannot operate only in daylight hours or wait for the weather to clear before training.

The Navy must test its systems in the same way they would be used for military readiness activities. Reducing or securing power in adverse weather conditions or at night would impact the ability to determine whether systems are operationally effective, suitable, survivable, and safe. Additionally, some systems have a nighttime testing requirement. Therefore, Navy personnel cannot operate only in daylight hours or wait for the weather to clear before or during all test events.

5.3.4.1.9 Avoiding or Reducing Active Sonar during Strong Surface Ducts

Avoiding or reducing active sonar during strong surface ducts for the purpose of mitigation would increase safety risks to personnel, be impractical with regard to implementation of military readiness activities, and result in an unacceptable impact on readiness for the following reasons:

The Navy must train in the same manner as it will fight. Anti-submarine warfare can require a significant amount of time to develop the "tactical picture," or an understanding of the battle space such as area searched or unsearched, identifying false contacts, understanding the water conditions, etc. Surface ducting is a condition when water conditions (e.g., temperature layers, lack of wave action) result in little sound energy penetrating beyond a narrow layer near the surface of the water. Submarines have long been known to exploit the phenomena associated with surface ducting. Therefore, training in surface ducting conditions is a critical component to military readiness because sonar operators need to learn how sonar transmissions are altered due to surface ducting, how submarines may take advantage of them, and how to operate sonar effectively in this environment. Avoiding or reducing active sonar during surface ducting conditions would affect a commander's ability to develop this tactical picture and would not provide the needed training realism. Diminished realism would reduce a sonar operator's ability to effectively operate in a real world combat situation, thereby resulting in an unacceptable increased risk to personnel safety and the ability to achieve mission success.

Furthermore, avoiding surface ducting would be impractical to implement because ocean conditions contributing to surface ducting change frequently, and surface ducts can be of varying duration. Surface ducting can also lack uniformity and may or may not extend over a large geographic area, making it difficult to determine where to reduce power and for what periods.

5.3.4.1.10 Avoiding Locations Based on Distances from Isobaths or Shorelines

Avoiding locations for training and testing activities within the Study Area based on wide-scale distances from isobaths or the shoreline for the purpose of mitigation would be impractical with regard to implementation of military readiness activities, result in unacceptable impact on readiness, and would not be an effective means of mitigation, and would increase safety risks to personnel for the following reasons:

A measure requiring avoidance of mid-frequency active sonar within 13 nm of the 656 ft. (200 m) isobaths was part of the Rim of the Pacific exercise 2006 authorization by NMFS. This measure, as well as similar measures of like distances, lacks any scientific basis when applied to the context of the Study Area (e.g., bathymetry, sound propagation, and width of channels). There is no scientific analysis indicating this measure is protective and no known basis for these specific metrics. The Rim of the Pacific 2006 exercise mitigation measure precluded active anti-submarine training in the littoral region, which significantly impacted realism and training effectiveness (e.g., protecting ships from submarine threats during amphibious landings). This mitigation procedure had no observable effect on the protection of marine mammals during Rim of the Pacific 2006 exercises, and its value is unclear; however, its adverse effect on realistic training, as with all arbitrary distance from land restrictions, is significant.

Training in shallower water is an essential component to maintaining military readiness. Sound propagates differently in shallower water and operators must learn to train in this environment. Additionally, submarines have become quieter through the use of improved technology and have learned to hide in the higher ambient noise levels of the shallow waters of coastal environments. In real world events, it is highly likely Sailors would be working in, and therefore must train in, these types of areas.

Areas where training and testing activities are scheduled to occur are carefully chosen to provide safety and allow realism of events. The proximity to facilities, range complexes, and testing ranges is essential to the training and testing realism and effectiveness required to train and certify naval forces ready for combat operations. Limiting access to nearshore areas would restrict access to certain training and testing locations and would increase transit time for these activities, which would result in an increased risk to personnel safety, particularly for platforms with fuel restrictions (e.g., aircraft) or for certain activities such as mine countermeasures and neutralization activities using diver-placed mines.

The ability to use the diverse and multi-dimensional capabilities of each range complex and testing range results in the Navy's ability to develop and maintain high levels of readiness. Otherwise limiting training and testing (including the use of sonar and other active acoustic sources or explosives) to avoid arbitrary distances from isobaths or the shoreline would adversely impact the effectiveness of the training and testing. This includes avoiding conducting activities within 12 nm from shore, 25 nm from shore, between shore and the 20 m isobath, and 13 nm out from the 656 ft. (200 m) isobath. Operating in shallow water is essential in order to provide realistic training on real world combat conditions with regard to shallow water sound propagation.

5.3.4.1.11 Avoiding Marine Species Habitats

Navy has recommended measures within several mitigation areas (Section 5.3.3, Mitigation Areas) that have been well-documented as important habitats for particular species and in which implementation of mitigation would not result in unacceptable impacts on readiness. These mitigation areas have been carefully selected on a case-by-case basis through consultation with NMFS and the U.S. Fish and Wildlife

Service. Otherwise avoiding all marine species habitats (e.g., foraging locations, reproductive locations, migration corridors, and locations of modeled takes) for the purpose of mitigation would be impractical with regard to implementation of military readiness activities, would result in unacceptable impact on readiness, and would increase safety risks to personnel for the following reasons:

As described in Section 5.3.4.1.6 (Limiting Access to Training and Testing Locations) and Section 5.3.4.1.7 (Avoiding Locations Based on Bathymetry and Environmental Conditions), areas where training and testing activities are scheduled to occur are carefully chosen to provide safety and allow realism of events, and the varying environmental conditions of these areas maximize the training realism and testing effectiveness. Activity locations inevitably overlap a wide array of marine species habitats, including foraging habitats, reproductive areas, and migration corridors. Otherwise limiting activities to avoid these habitats would adversely impact the effectiveness of the training or testing activity, and would therefore result in an unacceptable increased risk to personnel safety and the ability to achieve mission success.

As described in the *Determination of Acoustic Effects on Marine Mammals and Sea Turtles for the Hawaii-Southern California Training and Testing Environmental Impact Statement/Overseas Environmental Impact Statement* technical report (Marine Species Modeling Team 2013), modeling locations were developed based on historical data and anticipated future needs. The model does not provide information detailed enough to analyze or compare locations based on potential take levels for each activity; therefore, applying the modeling results to inform development of mitigation areas would not be appropriate.

5.3.4.1.12 Avoiding Marine Protected Areas

The Navy recommends conducting special mitigation within areas (Section 5.3.3, Mitigation Areas) that have been well-documented as important habitats for particular species. Otherwise avoiding marine protected areas for the purpose of mitigation would increase safety risks to personnel, be impractical with regard to implementation, and would not be warranted based on the discussions presented in the Chapter 3 (Affected Environment and Environmental Consequences) environmental analyses for biological resources and Section 6.1.2 (Marine Protected Areas).

Areas where training and testing activities are scheduled to occur are carefully chosen to provide safety and allow realism of events. The proximity to facilities, range complexes, and testing ranges is essential to the training and testing realism and effectiveness required to train and certify naval forces ready for combat operations. Limiting access to marine protected areas would restrict access to training and testing locations and would increase transit time, which would result in an increased risk to personnel safety, particularly for platforms with fuel restrictions (e.g., aircraft).

As described in Section 6.1.2 (Marine Protected Areas), due to the nature of most training and testing activities (e.g., requiring deep water), proposed activities are unlikely to occur in the extremely shallow nearshore waters typical of most marine protected areas. Within most marine protected areas, the only activity likely to occur is an aircraft overflight during transit from an airfield to an offshore training or testing location. Exposure of marine protected area resources to aircraft overflights would be brief and is expected to cause only a minor and temporary behavioral reaction due to noise for marine mammals, sea turtles, birds, or fish that may be present in the area. There is potential for birds to be struck by aircraft; however, the Navy implements standard operating procedures that require pilots of Navy aircraft to make every attempt to avoid large flocks of birds in order to reduce the safety risk involved with a potential bird strike. Additional mitigation or avoidance of these marine protection areas would be unnecessary, and limiting passage through the areas would restrict direct access to training and testing locations. Such avoidance would ultimately increase transit time and for platforms with fuel restrictions (e.g., aircraft) would therefore result in an unacceptable increased risk to personnel safety.

For marine protected areas (e.g., gear restricted areas) located further offshore, activities in addition to aircraft overflights may occur. Refer to Section 6.1.2 (Marine Protected Areas) for a more detailed discussion on the activities that are expected to occur within marine protected areas in the Study Area. Ultimately, limiting access to training and testing locations that overlap, are contained within, or are adjacent to marine protected areas would reduce realism of training by restricting access to important real world combat situations, such as bathymetric features and varying oceanographic features. As described in Section 2.5.1.1 (Alternative Training and Testing Locations), the ability to use the diverse and multidimensional capabilities of each range complex and testing range results in the Navy's ability to develop and maintain high levels of readiness. Major exercises using integrated warfare components require large areas of the littorals, open ocean, and certain nearshore areas for realistic and safe training. Limiting training and testing to specific locations and avoiding all marine protected areas would be impractical to implement with regard to the need to conduct activities in proximity to certain facilities, range complexes, and testing ranges. The Navy typically conducts activities in proximity to certain facilities, range complexes, and testing ranges in order to reduce travel time and funding required to conduct training away from a unit's home base. Activities involving the use of helicopters typically occur in proximity to shore or refueling stations due to fuel restrictions and personnel safety. Training and testing location limitations would also adversely impact the safety of the training and testing activities by requiring activities to take place in more remote areas where safety support may be limited. Refer to Section 5.3.4.1.6 (Limiting Access to Training and Testing Locations) for further discussion on the impacts of limiting access to training and testing locations on the Navy's ability to maintain military readiness.

5.3.4.1.13 Increasing Visual and Passive Acoustic Observations

Increasing visual and passive acoustic observations for the purpose of mitigation would be impractical with regard to implementation of military readiness activities and result in unacceptable impact on readiness for the following reasons:

The Navy recommended mitigation measures already represent the maximum level of effort (e.g., numbers of Lookouts and passive sonobuoys) that the Navy can commit to observing mitigation zones given the number of personnel that will be involved and the number and type of assets and resources available. The number of Lookouts that the Navy recommends for each measure often represents the maximum capacity based on limited resources (e.g., space and manning restrictions). For example, platforms such as the Littoral Combat Ship are minimally manned and are therefore physically unable to accommodate more than one Lookout. Furthermore, training and testing activities are carefully planned with regard to personnel duties. Requiring additional Lookouts would either require adding personnel, for which there would be no additional space, or reassigning duties, which would divert Navy personnel from essential tasks required to meet mission objectives.

The Navy will conduct passive acoustic monitoring during several activities with Navy assets, such as sonobuoys, already participating in the activity (e.g., sinking exercises, torpedo [explosive] testing, and improved extended echo ranging sonobuoys). Refer to Section 5.3.2 (Mitigation Zone Procedural Measures) for additional information on the use of passive acoustics during training and testing activities. The Navy does not have the resources to construct and maintain additional passive acoustic monitoring systems for each training and testing activity.

5.3.4.1.14 Increasing the Size of Observed Mitigation Zones

Increasing the size of observed mitigation zones for the purpose of mitigation would be impractical with regard to implementation of military readiness activities and result in unacceptable impact on readiness for the following reasons:

The Navy developed activity-specific mitigation zones based on the Navy's acoustic propagation model. In this HSTT analysis, the Navy developed each recommended mitigation zone to avoid or reduce the potential for onset of the lowest level of injury, PTS, out to the predicted maximum range. Mitigating to the predicted maximum range to PTS consequently also mitigates to the predicted maximum range to onset mortality (1 percent mortality), onset slight lung injury, and onset slight gastrointestinal tract injury, since the maximum range to effects for these criteria are shorter than for PTS. Furthermore, in most cases, the predicted maximum range to PTS also covers the predicted average range to TTS. In some instances, the Navy recommends mitigation zones that are larger or smaller than the predicted maximum range to PTS based on the associated effectiveness and operational assessments presented in Section 5.3.2 (Mitigation Zone Procedural Measures).

The Navy recommended mitigation zones represent the maximum area the Navy can effectively observe based on the platform of observation, number of personnel that will be involved, and the number and type of assets and resources available. As mitigation zone sizes increase, the potential for reducing impacts decreases. For instance, if a mitigation zone increases from 1,000 to 4,000 yd. (914 to 3,658 m), the area that must be observed increases sixteen-fold. The Navy recommended mitigation measures balance the need to reduce potential impacts with the ability to provide effective observations throughout a given mitigation zone. Implementation of mitigation zones is most effective when the zone is appropriately sized to be realistically observed. The Navy does not have the resources to maintain additional Lookouts or observer platforms that would be needed to effectively observe mitigation zones of increased size. Further, as explained above, the number of Lookouts that the Navy recommends for each measure often represents the maximum capacity based on limited resources (e.g., space and manning restrictions). For example, platforms such as the Littoral Combat Ship are minimally manned and are therefore physically unable to accommodate more than one Lookout. Training and testing activities are carefully planned with regard to personnel duties. Requiring observation of mitigation zones of increased size would either require adding personnel, for which there would be no additional space or resources, or reassigning duties, which would divert Navy personnel from essential tasks required to meet mission objectives. For most activities, Lookouts are required to observe for concentrations of detached floating vegetation (*Sargassum* or kelp paddies), which are indicators of potential marine mammal and sea turtle presence, within the mitigation zone to further help reduce the potential for injury to occur.

5.3.4.1.15 Conducting Visual Observations Using Third-Party Observers

With limited exceptions, use of third-party observers (e.g., trained marine species observers) in air or on surface platforms in addition to existing Navy Lookouts for the purposes of mitigation would be impractical with regard to implementation of military readiness activities and result in unacceptable impact on readiness for the following reasons:

Navy personnel are extensively trained in spotting items on or near the water surface. Use of Navy Lookouts ensures immediate implementation of mitigation if marine species are sighted. A critical skill set of effective Navy training is communication. Navy Lookouts are trained to act swiftly and decisively to ensure that appropriate actions are taken. Additionally, multiple training and testing events can occur simultaneously and in various regions throughout the Study Area, and can last for days or weeks at a time. The Navy does not have the resources to maintain third-party observers to accomplish the task for every event.

The use of third-party observers would compromise security for some activities involving active sonar due to the requirement to provide advance notification of specific times and locations of Navy platforms. Reliance on the availability of third-party personnel would impact training and testing flexibility. The presence of other aircraft in the vicinity of naval activities would raise safety concerns for both the commercial observers and naval aircraft. Furthermore, vessels have limited passenger capacity. Training and testing event planning includes careful consideration of this limited capacity in the placement of personnel on ships involved in the event. Inclusion of non-Navy observers onboard these vessels would require that in some cases there would be no additional space for essential Navy personnel required to meet the exercise objectives.

The areas where training events will most likely occur in the Study Area cover approximately 1 million square nautical miles. Contiguous anti-submarine warfare events may cover many hundreds or even thousands of square miles. The number of civilian vessels or aircraft required to monitor the area of these events would be considerable. It is, thus, not feasible to survey or monitor the large exercise areas in the time required. In addition, marine mammals may move into or out of an area, if surveyed before an event, or an animal could move into an area after an event took place. Given that there are no adequate controls to account for these or other possibilities, there is little utility to performing extensive before or after event surveys of large exercise areas as a mitigation measure.

Surveying during an event raises safety issues with multiple, slow civilian aircraft operating in the same airspace as military aircraft engaged in combat training activities. In addition, many of the training and testing events take place far from land, limiting both the time available for civilian aircraft to be in the event area and presenting a concern should aircraft mechanical problems arise. Scheduling civilian vessels or aircraft to coincide with training events would impact training effectiveness, since exercise event timetables cannot be precisely fixed and are instead based on the free-flow development of tactical situations. Waiting for civilian aircraft or vessels to complete surveys, refuel, or be on station would slow the progress of the exercise and impact the effectiveness of the military readiness activity.

5.3.4.1.16 Adopting Mitigation Measures of Foreign Navies

Adopting mitigation measures of foreign navies generally for the purpose of mitigation, such as expanding the mitigation zones to match those used by a particular foreign navy, would be impractical with regard to implementation of military readiness activities and result in unacceptable impact on readiness for the following reasons:

Mitigation measures are carefully customized for and agreed upon by each individual navy based on potential impacts of the activities on marine species and the impacts of the mitigation measures on military readiness. The mitigation measures developed for one navy would not necessarily be effective at reducing potential impacts on marine species by all navies. Similarly, mitigation measures that do not cause an unacceptable impact on one navy may cause an unacceptable impact on another. For example, most other navies do not possess an integrated strike group and do not have integrated training requirements. The Navy’s training is built around the integrated warfare concept and is based on the Navy’s capabilities, the threats faced, the operating environment, and the overall mission. Implementing other navies’ mitigation would be incompatible with U.S. Navy requirements. The U.S. Navy’s recommended mitigation measures have been carefully designed to reduce potential impacts on marine species while not causing an unacceptable impact on readiness.

5.3.4.1.17 Increasing Reporting Requirements

The Navy has extensive reporting requirements, including exercise, testing, and monitoring reporting designed to verify implementation of mitigation, comply with current permits, and improve future environmental assessments (Section 5.5.2, Reporting). Increasing the requirement to report marine species sightings to augment scientific data collection and to further verify the implementation of mitigation measures is unnecessary and would increase safety risks to personnel, be impractical with regard to implementation of military readiness activities, and result in unacceptable impact on readiness for the following reasons:

Vessels, aircraft, and personnel engaged in training and testing events are intensively employed throughout the duration of training and testing activities. Any additional workload assigned that is unrelated to their primary duty would adversely impact personnel safety and the effectiveness of the military readiness activity they are undertaking. Lookouts are not trained to make accurate species-specific identification and would not be able to provide the detailed information that the scientific community would use. Alternatively, the Navy has an integrated comprehensive monitoring program (Section 5.4, Mitigation Summary) that does provide information that is available and useful to the scientific community in annual monitoring reports.

5.3.4.2 Previously Accepted but Now Eliminated

5.3.4.2.1 Implementing Active Sonar Ramp-Up Procedures During Testing

Some testing activities have implemented active sonar ramp-up procedures (slowly increasing the sound in the water to necessary levels) in an attempt to clear the range prior to conduct of activities for the purpose of mitigation. Although ramp-up procedures have been used for some testing activities, the effectiveness at avoiding or reducing impacts on marine mammals has not been demonstrated. Until evidence suggests that ramp-up procedures are an effective means of avoiding or reducing potential impacts on marine mammals, and for reasons discussed in section 5.3.4.1.4 (Implementing Active Sonar Ramp-Up Procedures During Training), the Navy is proposing to eliminate the implementation of this measure for testing activities as part of the Proposed Action.

5.3.4.2.2 Implementing a Mitigation Zone for Missile Exercises with Airborne Targets

Per current mitigation, a mitigation zone of 1,000 yd. (915 m) is observed around the expected expended material field. The Navy is proposing to eliminate the need for a Lookout to maintain a mitigation zone for missile exercises involving airborne targets. Most airborne targets are recoverable aerial drones, and missile impact with the target does not typically occur. Most anti-air missiles used in training are telemetry configured (i.e., they do not have an actual warhead). Impact of a target is unlikely because missiles are designed to detonate (simulated detonation for telemetry missiles) in the vicinity of the target and not as a result of a direct strike on the target. Given the speed of the missile and the target, the high altitudes involved, and the long ranges of missile travel possible, it is not possible to definitively predict or to effectively observe where the missile fragments will fall. The potential expended material fall zone can only be predicted within tens of miles for long range events, which can be in excess of 80 nm from the firing location, and thousands of yards for shorter events, which can occur within several thousand yards from the firing location. Establishment of a mitigation zone for activities involving airborne targets would be ineffective at reducing potential impacts.

Furthermore, the potential risk to any marine mammal or sea turtle from a missile exercise with an airborne target is a direct strike from falling expended material. Based on the extremely low potential for a target strike and associated expended material field to co-occur in space and time with a marine species at or near the surface of the water, the potential for a direct strike is negligible.

5.3.4.2.3 Implementing a Mitigation Zone for Medium and Large-Caliber Gunnery Exercises with Airborne Targets

Per current mitigation, a mitigation zone is observed in the vicinity of the expected military expended materials field. The Navy is proposing to eliminate the need for a Lookout to observe the vicinity of the expected military expended materials for medium- and large-caliber gunnery exercises involving airborne targets. The potential military expended materials fall zone can only be predicted within thousands of yards, which can be up to 7 nm from the firing location. Establishment of a mitigation zone for activities involving airborne targets would be ineffective at reducing potential impacts.

Furthermore, the potential risk to any marine mammal or sea turtle from a gunnery exercise with an airborne target is a direct strike from falling military expended materials. Based on the extremely low potential for military expended materials to co-occur in space and time with a marine species at or near the surface of the water, the potential for a direct strike is negligible.

5.3.4.2.4 Implementing Measures for Laser Test Operations

Visual surveys would be conducted for all testing activities involving laser line scan, light imaging detection, and ranging lasers. Per current standard operating procedures, only trained personnel operate lasers and visual observation of the area is conducted to ensure human safety. The Navy is proposing to discontinue this procedure as a mitigation measure because: (1) it is currently a standard operating procedure conducted for human safety, and (2) the environmental consequences analysis suggests that impacts on resources from laser activities are not expected.

5.4 Mitigation Summary

Table 5.4-1 provides a summary of the Navy's recommended mitigation measures. For reference, currently implemented mitigation measures for each activity category are also summarized in the table. The process for developing each of these measures is detailed in Section 5.2.3 (Assessment Method) and involved: (1) an effectiveness assessment to determine if implementation of the measure will likely result in avoidance or reduction of an impact on a resource, and (2) an operational assessment to determine if implementation of the measures will have acceptable operational impacts on the Proposed Action with regard to personnel safety, practicality of implementation, readiness, and Navy policy. Measures are intended to meet applicable regulatory compliance requirements for NEPA, Executive Order 12114, and Council on Environmental Quality guidance. The Navy recommended mitigation measures were also developed consistent with resource-specific environmental requirements, as follows:

- Measures specifying marine mammals and indicators of marine mammal presence (e.g. floating vegetation [*Sargassum* or kelp paddies], large schools of fish, or flocks of seabirds) as the protection focus are intended to meet MMPA requirements.
- Measures specifying marine mammals, sea turtles, flocks of seabirds, floating vegetation (*Sargassum* or kelp paddies), large schools of fish, jellyfish aggregations, or shallow coral reefs as the protection focus are intended to meet ESA requirements.
- Measures specifying shallow coral reefs, live hardbottom, artificial reefs, or shipwrecks as the protection focus are intended to meet Essential Fish Habitat requirements of the Magnuson-Stevens Fishery Conservation and Management Act.

- Measures specifying shipwrecks is an additional protection focus intended to meet Abandoned Shipwreck Act and National Historic Preservation Act requirements.

The measures presented in Table 5.4-1 are discussed in greater detail in Section 5.3.1 (Lookout Procedural Measures), Section 5.3.2 (Mitigation Zone Procedural Measures), and Section 5.3.3 (Mitigation Areas). As discussed in Section 5.2.2.2 (Protective Measures Assessment Protocol), the final suite of mitigations resulting from the ongoing planning for this Final EIS/OEIS, as well as the regulatory consultation and permitting processes will be integrated into the Protective Measures Assessment Protocol for implementation purposes. Section 5.5 (Monitoring and Reporting) describes the monitoring and reporting efforts the Navy will undertake to investigate the effectiveness of implemented mitigation measures and to better understand the impacts of the Proposed Action on marine resources..

Table 5.4-1: Summary of Recommended Mitigation Measures

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus	Current Measure and Protection Focus
Specialized Training	Lookouts will complete the Introduction to the U.S. Navy Afloat Environmental Compliance Training Series and the U.S. Navy Marine Species Awareness Training (or civilian equivalent).	The mitigation zones observed by Lookouts are specified for each Mitigation Zone Procedural Measure below.	Applicable personnel will complete the U.S. Navy Marine Species Awareness Training prior to standing watch or serving as a Lookout.
Low-Frequency and Hull-Mounted Mid-Frequency Active Sonar during Anti-Submarine Warfare and Mine Warfare	2 Lookouts (general) 1 Lookout (minimally manned, moored, or anchored)	Sources that can be powered down: 1,000 yd. (914 m) and 500 yd. (457 m) power downs and 200 yd. (183 m) shutdown for marine mammals (hull-mounted mid-frequency and low-frequency) and sea turtles (low-frequency only). Sources that cannot be powered down: 200 yd. (183 m) shutdown for marine mammals and sea turtles. Both: observation for concentrations of floating vegetation (*Sargassum* or kelp paddies).	Hull-mounted mid-frequency: 1,000 yd. (914 m) and 500 yd. (457 m) power downs and 200 yd. (183 m) shutdown for marine mammals and sea turtles; avoidance of *Sargassum* rafts. Low-frequency: None
High-Frequency and Non-Hull Mounted Mid-Frequency Active Sonar	1 Lookout	200 yd. (183 m) for marine mammals (high-frequency and mid-frequency), sea turtles (bins MF8, MF9, MF10, and MF12 only), and concentrations of floating vegetation (*Sargassum* or kelp paddies).	Non-hull mounted mid-frequency: 200 yd. (183 m) for marine mammals, floating vegetation, and kelp paddies. High-frequency: None
Improved Extended Echo Ranging Sonobuoys	1 Lookout	600 yd. (549 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Passive acoustic monitoring conducted with Navy assets participating in the activity.	1,000 yd. (914 m) for marine mammals and sea turtles; 400 yd. (366 m) for floating vegetation and kelp paddies. Passive acoustic monitoring conducted with Navy assets participating in the activity.

Table 5.4-1: Summary of Recommended Mitigation Measures (continued)

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus	Current Measure and Protection Focus
Explosive Sonobuoys using 0.6–2.5 lb. NEW	1 Lookout	350 yd. (320 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Passive acoustic monitoring conducted with Navy assets participating in the activity.	None
Anti-Swimmer Grenades	1 Lookout	200 yd. (183 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies).	None.
Mine Countermeasures and Mine Neutralization using Positive Control	General: 1 or 2 Lookouts (NEW dependent) Diver-placed: 2 Lookouts Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs, and artificial reefs, shipwrecks. Lookouts will survey the mitigation zone for seabirds prior to and after the detonation event.	NEW dependent for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). SOCAL and HRC (except near-shore areas of San Clemente Island and in the SSTC): 350 yd. (320 m) from surveyed shallow coral reefs, live hardbottom, artificial reefs, and shipwrecks.	General: NEW dependent for marine mammals and sea turtles. Diver-placed: 700 yd. (640 m) for up to 29 lb. or 250–500 lb. charge for marine mammals and turtles. 1,000 ft. (305 m) from surveyed live hardbottom, artificial reefs, and shipwrecks.
Mine Neutralization Activities Using Diver-Placed Time-Delay Firing Devices	4 Lookouts Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs, and artificial reefs, shipwrecks. Lookouts will survey the mitigation zone for seabirds prior to and after the detonation event.	Up to 10 min. time-delay using up to 29 lb. NEW: 1,000 yd. (915 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies).	10 min. time-day on 29 lb. NEW: 1,450 yd. (1,326 m) for marine mammals and sea turtles.

Table 5.4-1: Summary of Recommended Mitigation Measures (continued)

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus	Current Measure and Protection Focus
Explosive and Non-Explosive Gunnery Exercises – Small- and Medium-Caliber Using a Surface Target	1 Lookout Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs.	200 yd. (183 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). 350 yd. (320 m) for surveyed shallow coral reefs.	200 yd. (183 m) for marine mammals, sea turtles, floating vegetation and surveyed shallow coral reefs.
Explosive and Non-Explosive Gunnery Exercises – Large-Caliber Using a Surface Target	1 Lookout Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs.	Explosive: 600 yd. (549 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Non-Explosive: 200 yd. (183 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Both: 70 yd. (64 m) within 30 degrees on either side of the gun target line on the firing side for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Both: 350 yd. (320 m) for surveyed shallow coral reefs.	Explosive: 600 yd. (549 m) for marine mammals, sea turtles, floating vegetation, and surveyed shallow coral reefs. Non-Explosive: 200 yd. (183 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Both: 70 yd. (64 m) around entire ship for marine mammals and sea turtles.
Non-Explosive Missile Exercises and Explosive Missile Exercises (Including Rockets) up to 250 lb. NEW Using a Surface Target	1 Lookout Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs.	900 yd. (823 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). 350 yd. (320 m) for surveyed shallow coral reefs.	1,800 yd. (1.6 km) for marine mammals, sea turtles, floating vegetation and kelp paddies.

Table 5.4-1: Summary of Recommended Mitigation Measures (continued)

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus	Current Measure and Protection Focus
Explosive Missile Exercises Using 251–500 lb. NEW Using a Surface Target	1 Lookout Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs.	2,000 yd. (1.8 km) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). 350 yd. (320 m) for surveyed shallow coral reefs.	None.
Explosive and Non-Explosive Bombing Exercises	1 Lookout Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs.	Explosive: 2,500 yd. (2.3 km) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Non-Explosive: 1,000 yd. (914 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). Both: 350 yd. (320 m) for surveyed shallow coral reefs.	Explosive: 1,000 yd. (914 m) for marine mammals, sea turtles, and floating vegetation. Non-Explosive: 1,000 yd. (914 m) for marine mammals, sea turtles, floating vegetation and kelp paddies.
Torpedo (Explosive) Testing	1 Lookout	2,100 yd. (1.9 km) for marine mammals, sea turtles, concentrations of floating vegetation (*Sargassum* or kelp paddies), and jellyfish aggregations. Passive acoustic monitoring conducted with Navy assets participating in the activity.	5,063 yd. (4.6 km) for marine mammals, sea turtles, floating vegetation and jellyfish aggregations
Sinking Exercises	2 Lookouts	2.5 nm for marine mammals, sea turtles, concentrations of floating vegetation (*Sargassum* or kelp paddies), and jellyfish aggregations. Passive acoustic monitoring conducted with Navy assets participating in the activity.	2.0 nm for marine mammals, sea turtles, floating vegetation and jellyfish aggregations.

Table 5.4-1: Summary of Recommended Mitigation Measures (continued)

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus	Current Measure and Protection Focus
At-Sea Explosive Testing	1 Lookout Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs.	1,600 yd. (1.4 km) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies). 350 yd. (320 m) for surveyed shallow coral reefs.	None.
Elevated Causeway System – Pile Driving	1 Lookout	60 yd. (55 m) for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies).	50 yd. for marine mammals, sea turtles, and concentrations of floating vegetation (*Sargassum* or kelp paddies).
Vessel Movements	1 Lookout	500 yd. (457 m) for whales. 200 yd. (183 m) for all other marine mammals (except bow riding dolphins).	500 yd. (457 m) for whales. 200 yd. (183 m) for all other marine mammals (except bow riding dolphins).
Towed In-Water Device Use	1 Lookout	250 yd. (229 m) for marine mammals	250 yd. (229 m) for marine mammals.
Humpback Whale Cautionary Area	Activity-specific measures described in the Lookout Procedural Measures and Mitigation Zone Procedural Measures	Mid-frequency active sonar training will not occur within the humpback whale cautionary area between 15 December and 15 April without prior approval by the Commander, U.S. Pacific Fleet.	Mid-frequency active sonar training will not occur within the humpback whale cautionary area between 15 December and 15 April without prior approval by the Commander, U.S. Pacific Fleet.

Table 5.4-1: Summary of Recommended Mitigation Measures (continued)

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus	Current Measure and Protection Focus
Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks	No Lookouts in addition to standard personnel standing watch Protective Measures Assessment Protocol will contain maps of surveyed shallow coral reefs, and artificial reefs, shipwrecks.	No precision anchoring within the anchor swing diameter and no explosive mine countermeasure and neutralization activities (except in near-shore areas of San Clemente Island in the SOCAL Range Complex and in the SSTC) within 350 yd. (320 m) of surveyed shallow coral reefs, live hardbottom, artificial reefs, and shipwrecks. No explosive or non-explosive small-, medium-, and large-caliber gunnery exercises using a surface target, explosive or non-explosive missile exercises using a surface target, explosive and non-explosive bombing exercises, or at-sea explosive testing within 350 yd. (320 m) of surveyed shallow coral reefs.	Varying mitigation zone distances based on marine mammal ranges to effects.

Notes: ft. = feet, km = kilometers, lb. = pounds, m = meters, mi. = miles, min. = minutes, NEW = net explosive weight, nm = nautical miles, yd. = yards

5.5 Monitoring and Reporting

5.5.1 Approach to Monitoring

The Navy is committed to demonstrating environmental stewardship while executing its National Defense Mission and complying with the suite of federal environmental laws and regulations. As a complement to the Navy's commitment to avoiding and reducing impacts of the Proposed Action through mitigation, the Navy will undertake monitoring efforts to track compliance with take authorizations, help evaluate the effectiveness of implemented mitigation measures, and gain a better understanding of the effects of the Proposed Action on marine resources. Taken together, mitigation and monitoring comprise the Navy's integrated approach for reducing environmental impacts from the Proposed Action. The Navy's overall monitoring approach will seek to leverage and build on existing research efforts whenever possible.

Consistent with the cooperating agency agreement with NMFS, mitigation and monitoring measures presented in this Final EIS/OEIS focus on the requirements for protection and management of marine resources. A well-designed monitoring program can provide important feedback for validating assumptions made in analyses and allow for adaptive management of marine resources. Since monitoring will be required for compliance with the Letters of Authorization issued for the Proposed Action under the MMPA, details of the monitoring program will be developed in coordination with NMFS through the regulatory process. Discussions with resource agencies during the consultation and permitting processes may result in changes to the mitigation as described in this document. Such changes will be reflected in the Records of Decision and consultation documents such as the ESA Biological Opinion.

5.5.1.1 Integrated Comprehensive Monitoring Program

The Integrated Comprehensive Monitoring Program is intended to coordinate monitoring efforts across all regions where the Navy trains and tests and to allocate the most appropriate level and type of effort for each range complex (U.S. Department of the Navy 2010). The current Navy monitoring program is composed of a collection of range-specific monitoring plans, each of which was developed individually as part of MMPA and ESA compliance processes as environmental documentation was completed. These individual plans establish range- or activity-specific monitoring requirements for each range complex, testing range, or activity and are collectively intended to address the Integrated Comprehensive Monitoring Plan top-level goals.

A 2010 Navy-sponsored monitoring meeting in Arlington, Virginia, initiated a process to critically evaluate the current Navy monitoring plans and begin development of revisions and updates to both existing region-specific plans as well as the Integrated Comprehensive Monitoring Plan. Discussions at that meeting as well as the following Navy and NMFS annual adaptive management meeting established a way ahead for continued refinement of the Navy's monitoring program. This process included establishing a Scientific Advisory Group of leading marine mammal scientists with the initial task of developing recommendations that would serve as the basis for a Strategic Plan for Navy monitoring. The Strategic Plan is intended to be a primary component of the Integrated Comprehensive Monitoring Program, provide a "vision" for Navy monitoring across geographic regions, and serve as guidance for determining how to most efficiently and effectively invest the marine species monitoring resources to address Integrated Comprehensive Monitoring Plan top-level goals and satisfy MMPA Letter of Authorization regulatory requirements.

The objective of the Strategic Plan is to continue the evolution of Navy marine species monitoring towards a single integrated program, incorporating Scientific Advisory Group recommendations, and establishing a more transparent framework for soliciting, evaluating, and implementing monitoring work across the range complexes and testing ranges. The Strategic Plan must consider a range of factors in addition to the scientific recommendations including logistic, operational, and funding considerations and will be revised regularly as part of the annual adaptive management process.

The Integrated Comprehensive Monitoring Plan establishes top-level goals that have been developed in coordination with NMFS (U.S. Department of the Navy 2010). The following top-level goals will become more specific with regard to identifying potential projects and monitoring field work through the Strategic Plan process as projects are evaluated and initiated in the Study Area.

- An increase in the understanding of the likely occurrence of marine mammals or ESA-listed marine species in the vicinity of the action (i.e., presence, abundance, distribution, and density of species).
- An increase in the understanding of the nature, scope, or context of the likely exposure of marine mammals and ESA-listed species to any of the potential stressor(s) associated with the action (e.g., tonal and impulsive sound), through better understanding of one or more of the following: (1) the action and the environment in which it occurs (e.g., sound source characterization, propagation, and ambient noise levels); (2) the affected species (e.g., life history or dive patterns); (3) the likely co-occurrence of marine mammals and ESA-listed marine species with the action (in whole or part) associated with specific adverse impacts; or (4) the likely biological or behavioral context of exposure to the stressor for the marine mammal and ESA-listed marine species (e.g., age class of exposed animals or known pupping, calving or feeding areas).
- An increase in the understanding of how individual marine mammals or ESA-listed marine species respond (behaviorally or physiologically) to the specific stressors associated with the action (in specific contexts, where possible, e.g., at what distance or received level).
- An increase in the understanding of how anticipated individual responses, to individual stressors or anticipated combinations of stressors, may impact either: (1) the long-term fitness and survival of an individual; or (2) the population, species, or stock (e.g., through impacts on annual rates of recruitment or survival).
- An increase in the understanding of the effectiveness of mitigation and monitoring measures;
- A better understanding and record of the manner in which the authorized entity complies with the Incidental Take Authorization and Incidental Take Statement.
- An increase in the probability of detecting marine mammals (through improved technology or methods), both specifically within the mitigation zone (thus allowing for more effective implementation of the mitigation) and in general, to better achieve the above goals.
- A reduction in the adverse impact of activities to the least practicable level, as defined in the MMPA.

5.5.1.2 Scientific Advisory Group Recommendations

Navy established the Scientific Advisory Group in 2011 with the initial task of evaluating current Navy monitoring approaches under the Integrated Comprehensive Monitoring Plan and existing MMPA Letters of Authorization and developing objective scientific recommendations that would form the basis for the Strategic Plan. While recommendations were fairly broad and not prescriptive from a range complex perspective, the Scientific Advisory Group did provide specific programmatic recommendations that serve as guiding principles for the continued evolution of the Navy Marine Species Monitoring Program and provide a direction for the Strategic Plan to move this development. Key recommendations include:

- Working within a conceptual framework of knowledge, from basic information on the occurrence of species within each range complex, to more specific matters of exposure, response, and consequences.
- Facilitating collaboration among researchers in each region, with the intent to develop a coherent and synergistic regional monitoring and research effort.
- Striving to move away from a "box-checking" mentality. Monitoring studies should be designed and conducted according to scientific objectives, rather than on merely cataloging effort expended.
- Approach the monitoring program holistically and select projects that offer the best opportunity to advance understanding of the issues, as opposed to establishing range-specific requirements.

5.5.2 Reporting

The Navy is committed to documenting and reporting relevant aspects of training and testing activities to verify implementation of mitigation, comply with current permits, and improve future environmental assessments. Navy reporting initiatives are described below.

5.5.2.1 Exercise, Testing, and Monitoring Reporting

The Navy will submit annual exercise, testing, and monitoring reports to the Office of Protected Resources at NMFS. The exercise reports will describe the level of training and testing conducted during the reporting period, and the monitoring reports will describe both the nature of the monitoring that has been conducted and the actual results of the monitoring. All of the details regarding the content of the annual reports will be coordinated with NMFS through the permitting process. All reports submitted to date can be found on the NMFS Office of Protected Resources webpage.

5.5.2.2 Stranding Response Plan

In coordination with NMFS, the Navy will have a stranding response plan. All of the details regarding the content of the stranding response plan will be coordinated with NMFS through the permitting process.

5.5.2.3 Bird Strike Reporting

The Navy will report all damaging and non-damaging bird strikes to the Naval Safety Center.

5.5.2.4 Marine Mammal Incident Reporting

If any injury or death of a marine mammal is observed during training or testing activities, the Navy will immediately halt the activity and report the incident, including dead for injured animals, to NMFS or the United States Fish and Wildlife Service, as appropriate.

6 ADDITIONAL REGULATORY CONSIDERATIONS

In accordance with the Council on Environmental Quality regulations for implementing the National Environmental Policy Act (NEPA), federal agencies shall, to the fullest extent possible, integrate the requirements of NEPA with other planning and environmental review procedures required by law or by agency practice so that all such procedures run concurrently rather than consecutively. This chapter summarizes environmental compliance for the Proposed Action, consistency with other federal, state, and local plans, policies, and regulations not considered in Chapter 3 (Affected Environment and Environmental Consequences); the relationship between short-term impacts; and the maintenance and enhancement of long-term productivity in the affected environment; irreversible and irretrievable commitments of resources, and energy conservation.

6.1 CONSISTENCY WITH OTHER APPLICABLE FEDERAL, STATE, AND LOCAL PLANS, POLICIES, AND REGULATIONS

Implementation of the Proposed Action for the Hawaii-Southern California Training and Testing (HSTT) Environmental Impact Statement (EIS)/Overseas Environmental Impact Statement (OEIS), would comply with applicable federal, state, and local laws, regulations, and executive orders. The Navy is consulting with and will continue to consult with regulatory agencies, as appropriate, during the NEPA process and prior to implementation of the Proposed Action to ensure that requirements are met. Table 6.1-1 summarizes environmental compliance requirements that that were considered in preparing this EIS/OEIS (including those that may be secondary considerations in the resource evaluations) not considered in Chapter 3 (Affected Environment and Environmental Consequences). Section 3.0.1 (Regulatory Framework) provides brief excerpts of the primary federal statutes, executive orders, international standards, and guidance that form the regulatory framework for the resource evaluations. Documentation of consultation and coordination with regulatory agencies is provided in Appendix C. Formal Endangered Species Act (ESA) and Marine Mammal Protection Act (MMPA) consultation began following the Draft EIS/OEIS release and has been completed. Because consultation is currently ongoing, not all consultation documentation is included in Appendix C or the website at this time, but all compliance will be completed prior to the signing of the Record of Decision for the Proposed Action.

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action

Laws, Executive Orders, International Standards, and Guidance	Status of Compliance
Laws	
Abandoned Shipwreck Act (43 United States Code [U.S.C.] §§ 2101-2106)	The 1987 Abandoned Shipwreck Act establishes requirements for educational and recreational access to abandoned shipwrecks; the protection of such resources through the establishment of underwater parks and protected areas; the development of specific guidelines for management and protection in consultation with various stakeholders; defines the jurisdiction and responsibility of federal and state agencies; and explicitly states that the law of salvage and the law of finds do not apply. Under the Act, the Department of the Interior and National Park Service issued guidelines in 2007 to help states manage shipwrecks in their waters. The Act defines the federal government's title to any abandoned shipwreck that meets criteria for inclusion in the National Register of Historic Places within state submerged lands, with the stipulation that the federal government transfer the title of the shipwreck to the state whose submerged lands contain the shipwreck. For abandoned shipwrecks in United States (U.S.) Territorial Waters, the federal government asserts title to the resource. See Section 3.10 (Cultural Resources) for assessment and conclusion that the Proposed Action is consistent with the Act.
Act to Prevent Pollution from Ships (33 U.S.C. §1901 et seq.)	Requirements associated with the Act to Prevent Pollution from Ships are implemented by the Navy Environmental Readiness Program Manual and related Navy guidance documents governing waste management, pollution prevention, and recycling. At sea, the Navy complies with these regulations and operates in a manner that minimizes or eliminates any adverse affects to the marine environment.
Antiquities Act (16 U.S.C. § 431)	The Proposed Action is consistent with the Act's objectives for protection of archaeological and historical sites and objects, preservation of cultural resources, and the public's access to them. See Section 3.10 (Cultural Resources) for the assessment.
Coastal Zone Management Act (16 U.S.C. §1451 et seq.)	The Navy has undergone the federal consistency determination process with the California and Hawaii Coastal Zone Management Act (CZMA) offices. See Section 6.1.1 (Coastal Zone Management Act Compliance) for further details.
Historic Sites Act (16 U.S.C. §§ 461-467)	The Proposed Action is consistent with the national policy for the preservation of historic sites, buildings, and objects of national significance. See Chapter 3.10 (Cultural Resources) for assessment.
National Fishery Enhancement Act (33 U.S.C. § 2101 et seq.)	The Proposed Action is consistent with regulations administered by National Marine and Fisheries Service (NMFS) and U.S. Army Corps of Engineers concerning artificial reefs in the navigable waters of the United States. See Section 3.9 (Fish) for the assessment.
National Marine Sanctuaries Act (16 U.S.C. § 1431 et seq.)	Two National Marine Sanctuaries administered by National Oceanic and Atmospheric Administration Office of National Marine Sanctuaries lie within the Study Area. These are discussed further in Section 6.1.2 (Marine Protected Areas).
Rivers and Harbors Act (33 U.S.C. § 401 et seq.)	Under the Rivers and Harbors Act, a permit is required when construction is proposed in navigable waterways. The Navy will acquire Army Corps of Engineer permits where applicable.
Submerged Lands Act of 1953 (43 U.S.C. §§ 1301-1315)	The Proposed Action is consistent with regulations concerning the Submerged Lands Act.

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action (continued)

Laws, Executive Orders, International Standards, and Guidance	Status of Compliance
Laws	
Sunken Military Craft Act (Public Law 108-375, 10 U.S.C. § 113 Note and 118 Stat. 2094-2098)	The Proposed Action would have no adverse effects on sunken U.S. military ships and aircraft within the Study Area. If a site is determined to be eligible for the National Register of Historic Places, the State Historic Preservation Officer would be consulted to address potential effects. See Section 3.10 (Cultural Resources) for the assessment.
California Coastal National Monument Designation (Presidential Proclamation, January 11, 2000)	The proclamation designates all non-major U.S.-owned lands (rocks, islands, etc.) along the coast of California from mean high tide out to a distance of 12 nm as national monuments. The Southern California Range Complex includes resources designated as part of the California Coastal National Monument area. The Navy and the Bureau of Land Management have agreed on the terms of a Memorandum of Understanding dated 5 November 2007 regarding Navy activities in the vicinity of monument resources. Implementation of the Proposed Action would be consistent with the Memorandum of Understanding and would not affect monument resources.
California Marine Life Protection Act and Marine Managed Areas Improvement Act (California Fish and Game Code §§ 2850-2863)	California Marine Life Protection Act requires California Department of Fish and Game to confer with the Navy regarding issues related to Navy activities that may affect Marine Managed Areas.
Military Munitions Rule	The Military Munitions Rule identifies when conventional and chemical military munitions are considered solid waste under the Resource Conservation and Recovery Act (42 U.S.C. § 6901 et seq.). Military munitions are not considered solid waste based on two conditions stated at 40 Code of Federal Regulations (C.F.R.) § 266.202(a)(1)(i-iii). These two conditions are when munitions are used for their intended purpose and when unused munitions or a component of are subject to materials recovery activities. These two conditions cover the uses of munitions included in the Proposed Action; therefore, the Resource Conservation and Recovery Act does not apply.
Executive Orders	
Executive Order 11990*, Protection of Wetlands*	Implementation of the Proposed Action would not affect wetlands as defined in Executive Order 11990.
Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*	Because all of the proposed activities occur in the ocean where there are no minority or low-income populations present, there are no disproportionately high and adverse human health or environmental impacts from the Proposed Action on minority populations or low-income populations. See Section 3.0.5.2 (Resources and Issues Eliminated from Further Consideration) for the assessment.
Executive Order 12962*, Recreational Fisheries*	The Proposed Action would not affect federal agencies' ability to fulfill certain duties with regard to promoting the health and access of the public to recreational fishing areas. See Section 3.11 (Socioeconomics) for the assessment.
Executive Order 13045*, Protection of Children from Environmental Health Risks and Safety Risks*	Because all of the proposed activities occur in the ocean where there are no child populations present, the Proposed Action would not lead to disproportionate risks to children that result from environmental health risks or safety risks. See Section 3.0.5.2 (Resources and Issues Eliminated from Further Consideration) for the assessment.

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action (continued)

Laws, Executive Orders, International Standards, and Guidance	Status of Compliance
Executive Orders	
Executive Order 13089, *Coral Reef Protection*	The Navy has prepared this EIS/OEIS in accordance with requirements that federal agencies whose actions affect U.S. coral reef ecosystems shall provide for implementation of measures needed to research, monitor, manage, and restore them, including reducing impacts from pollution and sedimentation. See Section 3.8 (Marine Invertebrates) for assessment.
Executive Order 13112, *Invasive Species*	The Proposed Action would not increase the number of or introduce new invasive species nor require the Navy to take measures to avoid introduction and spread of those species. Naval vessels are exempt from 33 C.F.R. 151 Subpart D, Ballast Water Management for Control of Nonindigenous Species in Waters of the United States.
Executive Order 13158, *Marine Protected Areas*	The Navy has prepared this EIS/OEIS in accordance with requirements for the protection of existing national system marine protected areas. See Section 6.1.2 (Marine Protected Areas) for more information.
Executive Order 13514, *Federal Leadership in Environmental, Energy, and Economic Performance*	The Proposed Action is consistent with the integrated strategy toward sustainability in the federal government and to making reduction of greenhouse gas emissions a priority for federal agencies.
Executive Order 13547, *Stewardship of the Ocean, Our Coasts, and the Great Lakes*	The Proposed Action is consistent with the comprehensive national policy for the Stewardship of the Ocean, Our Coasts, and the Great Lakes.
International Standards	
International Convention for the Prevention of Pollution from Ships	This standard prohibits certain discharges of oil, garbage, and other substances from vessels. The convention and its annexes are implemented by national legislation, including the Act to Prevent Pollution from Ships (33 U.S.C. §§ 1901 to 1915) and the Federal Water Pollution Control Act (33 U.S.C. §§ 1321 to 1322). The Proposed Action does not include vessel operation and discharge from ships; however, the Navy vessels operating in the Study Area would comply with the discharge requirements established in this program, minimizing or eliminating potential impacts from discharges from ships.

Note: nm = nautical mile(s)

6.1.1 Coastal Zone Management Act Compliance

The Coastal Zone Management Act of 1972 (16 United States Code [U.S.C.] § 1451, et seq.) encourages coastal states to be proactive in managing coastal zone uses and resources. The Act established a voluntary coastal planning program under which participating states submit a Coastal Management Plan to the National Oceanographic and Atmospheric Administration for approval. Under the Act, federal actions that have an effect on a coastal use or resource are required to be consistent, to the maximum extent practicable, with the enforceable policies of federally approved Coastal Management Plans.

The Coastal Zone Management Act defines the coastal zone as extending “to the outer limit of State title and ownership under the Submerged Lands Act” (i.e., 3 nautical miles [nm] or 9 nm from the shoreline, depending on the location). The extent of the coastal zone inland varies from state to state, but the shoreward extent is not relevant to this Proposed Action.

A Consistency Determination, or a Negative Determination, may be submitted for review of federal agency activities. A federal agency submits a consistency determination when it determines that its activity may have either a direct or an indirect effect on a state coastal use or resource. In accordance with 15 Code of Federal Regulations (C.F.R.) § 930.39, the consistency determination will include a brief statement indicating whether the proposed activity will be undertaken in a manner consistent to the maximum extent practicable with the enforceable policies of the management program. The consistency determination should be based on evaluation of the relevant enforceable policies of the management program. In accordance with 15 C.F.R. §930.35, "if a Federal agency determines that there will not be coastal effects, then the Federal agency shall provide the State agencies with a negative determination for a Federal agency activity: (1) Identified by a State agency on its list, as described in §930.34(b), or through case-by-case monitoring of unlisted activities; or (2) Which is the same as or is similar to activities for which consistency determinations have been prepared in the past; or (3) For which the Federal agency undertook a thorough consistency assessment and developed initial findings on the coastal effects of the activity." Thus, a negative determination must be submitted to a state if the agency determines no coastal effects and one or more of the triggers above is met.

6.1.1.1 California Coastal Management Program

The state of California has an approved Coastal Management Plan, administered by the California Coastal Commission. The California Coastal Act of 1976 (California Public Resources Code, § 30000 et seq.) implements California's Coastal Management Program. The California Coastal Act includes policies to protect and expand public access to shorelines, and to protect, enhance, and restore environmentally sensitive habitats, including intertidal and nearshore waters, wetlands, bays and estuaries, riparian habitat, certain woods and grasslands, streams, lakes, and habitat for rare and endangered plants and animals.

Under the Coastal Zone Management Act, the California Coastal Commission must provide an opportunity for public comment and involvement in the federal coastal consistency determination process.

In January 2013, the Navy (Commander, U.S. Pacific Fleet) submitted a Consistency Determination for activities within the California portion of the Study Area to the California Coastal Commission. In March 2013, the California Coastal Commission notified the Commander, U.S. Pacific Fleet that it objected to the Navy's Consistency Determination based on a lack of sufficient information. In March 2013, Commander, U.S. Pacific Fleet replied to the California Coastal Commission, responding to each specific objection raised in the Commission's March 2013 letter. The Navy used the remainder of the federal consistency review period to attempt to resolve the differences with the California Coastal Commission. Under 15 C.F.R. §930.43, if the Navy concludes that its proposed action is fully consistent with the enforceable policies of the management program, it may proceed with the activity, but must notify the State agency of its decision to proceed before the project commences. HSTT activities are fully consistent with the enforceable polices of the California Coastal Management Program. In the event that Navy is not able to reach an agreement on the consistency of its activities with the California Coastal Commission, the Navy will comply with 15 C.F.R. §930.43(e) and notify the California Coastal Commission if the Navy decides to proceed over California Coastal Commission's objection. The correspondence between the Navy and the California Coastal Commission can be found in Appendix C (Agency Correspondence).

6.1.1.2 Hawaii Coastal Zone Management Program

Hawaii has an approved Coastal Zone Management Program (Chapter 205A, Hawaii Revised Statutes), administered by the Hawaii Office of Planning. The program meets the federal coastal zone management requirements in managing coastal areas and resources, including beaches, fishponds, scenic areas, marinas, wetlands, harbors, recreational areas, historic sites, and marine resources.

Hawaii's Coastal Zone Management Program employs a wide variety of regulatory and non-regulatory techniques to address coastal issues and uphold environmental law. Among them are stewardship, planning, permitting, education, and outreach.

In January 2013, the Navy (Commander, U.S. Pacific Fleet) submitted a Consistency Determination for activities within the Hawaii portion of the Study Area to the State of Hawaii Office of Planning. In March 2013, the Office of Planning conditionally concurred with the Navy's Consistency Determination. The condition placed on the concurrence was that during training and testing activities, the Navy "within the State of Hawaii Coastal Zone Management area shall not harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect endangered or threatened species of aquatic life or wildlife, or cut, collect, uproot, destroy, injure, or possess endangered or threatened species of aquatic life or land plants, or attempt to engage in any such conduct." The Navy responded to the Office of Planning's letter to clarify that the Navy's activities are consistent with the enforceable policies under Hawaii Revised Statutes Chapter 195 (e) and (g) because any take would be incidental to, and not the purpose of, an otherwise lawful activity and confirmed the Navy has consulted with the National Marine and Fisheries Service (NMFS) for take authorizations under the MMPA and ESA. The correspondence between the Navy and the Hawaii Office of Planning can be found in Appendix C (Agency Correspondence).

6.1.2 MARINE PROTECTED AREAS

Many areas of the marine environment have some level of federal, state, or local management or protection. Marine protected areas have conservation or management purposes, defined boundaries, and some legal authority to protect resources. Marine protected areas vary widely in purpose, managing agency, management approaches, level of protection, and restrictions on human uses. They have been designated to achieve objectives ranging from conservation of biodiversity, to preservation of sunken historic vessels, to protection of spawning habitats important to commercial and recreational fisheries. Executive Order (EO) 13158*, Marine Protected Areas,* was created to "strengthen the management, protection, and conservation of existing marine protected areas and establish new or expanded marine protected areas; develop a scientifically based, comprehensive national system of marine protected areas representing diverse U.S. marine ecosystems, and the nation's natural and cultural resources; and avoid causing harm to marine protected areas through federally conducted, approved, or funded activities."

Executive Order 13158 requires each Federal agency whose actions affect the natural or cultural resources that are protected by a national system of marine protected areas to identify such actions, and in taking such actions, avoid harm to those natural and cultural resources. Pursuant to Section 5 of EO 13158, agency requirements apply only to the natural or cultural resources specifically afforded protection by the site as described by the List of National System Marine Protected Areas. For sites that have both a terrestrial and marine area, only the marine portion and its associated protected resources are included on the List of National System Marine Protected Areas and subject to Section 5 of EO 13158. A full list and map of areas accepted in the National System of Marine Protected Areas is available from the National Marine Protected Areas Center.

The National Marine Protected Areas Center, which is federally managed through the National Oceanic and Atmospheric Administration, is tasked with implementing EO 13158. In order to meet the qualifications for the various terms within EO 13158, the National Marine Protected Areas Center developed a Marine Protected Areas Classification system. This system uses six criteria to describe the key features of most marine protected areas, as follows:

1. Primary conservation focus, such as natural heritage, cultural heritage, or sustainable production
2. Level of protection (e.g., no access, no impact, no take, zoned with no-take areas, zoned multiple use, or uniform multiple use)
3. Permanence of protection
4. Constancy of protection
5. Ecological scale of protection
6. Restrictions on extraction

The National Marine Protected Areas Center utilizes these criteria to evaluate marine protected areas for inclusion in the National System of Marine Protected Areas. Implementation of the National System of Marine Protected Areas is managed by the Department of Commerce and the Department of the Interior. Executive Order 13158 requires the Department of Commerce and the Department of the Interior to consult with other federal agencies about the inclusion of sites into the National System of Marine Protected Areas, including the Department of Defense. The National System of Marine Protected Areas includes marine protected areas managed under the following six systems:

National Marine Sanctuary System. Under the National Marine Sanctuaries Act, the National Oceanic and Atmospheric Administration established national marine sanctuaries for marine areas with special conservation, recreational, ecological, historical, cultural, archaeological, scientific, educational, or aesthetic qualities. Within the Study Area there are three National Marine Sanctuary System sites (two national marine sanctuaries [Hawaiian Islands Humpback Whale National Marine Sanctuary, Channel Islands National Marine Sanctuary] and one marine national monument [Papahanaumokuakea Marine National Monument]) all of which are included in the National System of Marine Protected Areas.

Marine National Monuments. Marine national monuments are designated through Presidential Proclamation under the authority of the Antiquities Act of 1906 (16 U.S.C. § 431). Marine national monuments are often co-managed by state, federal, and local governments, in order to preserve diverse habitats and ecosystem functions. Within the Study Area there is one marine national monument, Papahanaumokuakea Marine National Monument, which is also included in the National Marine Sanctuary System and the National System of Marine Protected Areas. In the proclamation designating the Monument, specific language was included that stated: "The prohibitions required by this proclamation shall not apply to activities and exercises of the Armed Forces (including those carried out by the United States Coast Guard) that are consistent with applicable laws."

National Wildlife Refuge System. The U.S. Fish and Wildlife Service manages ocean and Great Lakes refuges for the conservation, management, and, where appropriate, restoration of the fish, wildlife, and plant resources and their habitats. There are two national wildlife refuge areas within the Study Area, Johnston Island National Wildlife Refuge and Midway Atoll National Wildlife Refuge, both of which are included in the National System of Marine Protected Areas.

State and Local Marine Protected Areas. State and local governments have established marine protected areas for the management of fisheries, nursery grounds, shellfish beds, recreation, tourism, and other uses; these areas have a diverse array of conservation focuses, from protecting ecological functions, to preserving shipwrecks, to maintaining traditional or cultural interaction with the marine environment. There are 18 state or local marine protected areas within the Study Area that are included in the National System of Marine Protected Areas (see Table 6.1-2). Within the Study Area, there are California Marine Protected Areas not yet included in the National Marine Protected Areas Center inventory: Begg Rock State Marine Reserve, Santa Barbara Island State Marine Reserve, nine separate areas on Catalina Island, Dana Point State Marine Conservation Area, Swami's State Marine Conservation Area, San Diego-Scripps Coastal State Marine Conservation Area, Matlahuayl State Marine Conservation Area, South La Jolla State Marine Conservation Area, South La Jolla State Marine Reserve, and Cabrillo State Marine Reserve.

The Navy has had direct participation in the California Marine Protected Areas process and the establishment of the Marine Protected Areas in the Study Area. The development process includes the recognition of the Navy's ongoing activities within those areas, with a finding that those activities are compatible with the Marine Protected Areas. For the California Marine Protected Areas, California Title 14, Section 632 states: "Nothing in this section expressly or implicitly precludes, restricts or requires modification of current or future uses of the waters identified as marine protected areas, special closures, or the lands or waters adjacent to these designated areas by the Department of Defense, its allies or agents."

National Parks System. The National Park System contains ocean and Great Lakes parks, including some national monuments, administered by the U.S. Department of the Interior National Park Service to conserve the scenery and the natural and historic objects and wildlife contained within. There is one National Parks System site, Channel Islands National Park, within the Study Area that is included in the National System of Marine Protected Areas.

National Estuarine Research Reserve System. National Estuarine Research Reserve System sites protect estuarine land and water and provide essential habitat for wildlife; educational opportunities for student, teachers, and the public; and living laboratories for scientists. There are no National Estuarine Research Reserve System sites within the Study Area.

This EIS/OEIS has been prepared in accordance with requirements for natural or cultural resources protected under the National System of Marine Protected Areas. While several marine protected areas are located within the Study Area and are included in the National System of Marine Protected Areas, it is important to note that the Navy rarely trains or tests in many of these areas. The Navy, when conducting activities within these marine protected areas, abides by the regulations of the individual marine protected area. Table 6.1-2 provides information on the individual marine protected area regulations and the Navy activities that occur in these areas. Additionally, there are two National Marine Sanctuaries within the Study Area that are included in the National System of Marine Protected Areas the (Channel Islands National Marine Sanctuary and the Hawaiian Islands Humpback Whale National Marine Sanctuary) and one marine national monument, the Papahanaumokuakea Marine National Monument. These areas receive protection under EO 13158, the National Marine Sanctuaries Act, or both, and are described in more detail below.

Table 6.1-2: Marine Protected Areas within the Hawaii-Southern California Training and Testing Study Area

Marine Protected Area	Location Within the Study Area	Protection Focus	Regulations Applicable to Navy Activities	Navy Proposed Activities and Potential Impacts
Channel Islands National Marine Sanctuary (CINMS)	California	Ecosystem	Prohibitions "…do not apply to military activities carried out by DoD [Department of Defense] as of the effective date (22 September 1980) of these regulations. (15 C.F.R. § 922.73)" However, if any activities "modified in such a way that requires the preparation of an environmental assessment or environmental impact statement…relevant to a Sanctuary resource or quality" said activity is not considered a pre-existing activity under these regulations. The regulations also state that "all DoD activities must be carried out in a manner that avoids to the maximum extent practicable any adverse impacts on sanctuary resources and qualities." If a DoD activity causes any destruction, loss, or injury to a Sanctuary resource then the "DoD, in coordination with the Director, must promptly prevent and mitigate further damage and must restore or replace the Sanctuary resource or quality in a manner approved by the Director."	For the Hawaii-Southern California Training and Testing (HSTT) Environmental Impact Statement (EIS),[1] the Navy will continue to conduct anti-submarine warfare training in the vicinity of the Santa Barbara Island portion of the sanctuary. Navy activities within the CINMS are specifically identified in Section 3.5.9 of the Channel Islands National Marine Sanctuary Final Management Plan/Final EIS Volume II (National Oceanic and Atmospheric Administration 2008). These Navy activities are exempt from the prohibitions in the Sanctuary. The sanctuary regulations require that all DoD military activities shall be carried out in a manner that avoids to the maximum extent practicable any adverse impacts on sanctuary resources and qualities. The Navy does not propose new, modified, or increased frequency of activities in the CINMS, or activities that are different from those currently conducted in this area. Therefore, proposed activities are consistent with those activities currently conducted in this area, and those described in the Sanctuary's Final Management Plan/Final EIS. These HSTT activities would continue to be exempt from the prohibitions identified in the Sanctuary's regulations. HSTT activities within the Sanctuary would be conducted with an extensive set of mitigations measures (see Chapter 5, Standard Operating Procedures, Mitigation, and Monitoring) and will avoid to the maximum extent practicable any adverse impacts on the Sanctuary resources and qualities.

[1] As described in Section 2.1.2.2, the area around Santa Barbara Island is a part of the Point Mugu Sea Range (PMSR) which is the subject of a separate EIS. For HSTT this area is addressed because it is used as a part of the HSTT activities, specifically anti-submarine warfare. The PMSR overlaps a larger portion of the Channel Islands National Marine Sanctuary—see the PMSR EIS for additional details.

Table 6.1-2: Marine Protected Areas within the Hawaii-Southern California Training and Testing Study Area (continued)

Marine Protected Area	Location Within the Study Area	Protection Focus	Regulations Applicable to Navy Activities	Navy Proposed Activities and Potential Impacts
Channel Islands National Park (CNIP)	California	Ecosystem	This CINP extends one mile around the islands within the Channel Islands National Marine Sanctuary. Within the Study Area, this is a small portion around Santa Barbara Island.	The Navy continues to conduct sonar-related activities in the vicinity of the Santa Barbara Island No other activities are conducted in the vicinity of this area. The Navy complies with all applicable National Park Service regulations within the CINP.
Farnsworth Bank ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including sonar-related activities outside of, but in the vicinity of, this area. The Navy does not discharge waste in or near this area.
Heisler Park ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including amphibious activities south of this area in the Camp Pendleton Amphibious Assault Area. The Navy does not discharge waste in or near this area.
La Jolla ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including mine warfare training activities and underwater communications testing activities just offshore (within 3 nm) of this water quality protection area. The Navy does not discharge any waste in or near this area.
Northwestern Santa Catalina Island ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including sonar-related activities outside of this, but in the vicinity of this area. The Navy does not discharge waste in or near this area.

[2] ASBS is an Area of Special Biological Significance.

Table 6.1-2: Marine Protected Areas within the Hawaii-Southern California Training and Testing Study Area (continued)

Marine Protected Area	Location Within the Study Area	Protection Focus	Regulations Applicable to Navy Activities	Navy Proposed Activities and Potential Impacts
Robert E. Badham ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited. However, discharges incidental to military training and research, development, test, and evaluation operations are allowed. Discharges incidental to underwater demolition and other in-water explosions are not allowed in the two military closure areas in the vicinity of Wilson Cove and Castle Rock. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.	The Navy conducts training and testing in all warfare areas, including amphibious activities in this area. The Navy does not discharge waste in or near this area. in violation of the site specific regulations.
San Clemente Island ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited. However, discharges incidental to military training and research, development, test, and evaluation operations are allowed. Discharges incidental to underwater demolition and other in-water explosions are not allowed in the two military closure areas in the vicinity of Wilson Cove and Castle Rock. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.	The Navy conducts training and testing in all warfare areas, including amphibious, anti-surface warfare, anti-submarine warfare, electronic warfare, mine warfare, and naval special warfare training and testing activities in this area. The Navy does not discharge waste in or near this area in violation of the site specific regulations.
San Diego-Scripps ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including mine warfare training activities and underwater communications testing activities just offshore (within 3 nm) of this water quality protection area. The Navy does not discharge any waste in or near this area.
Santa Barbara and Anacapa Islands ASBS[2] State Water Quality Protection Area	California (Santa Barbara Island only)	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including sonar-related activities in and near this area. The Navy does not discharge waste in or near this area.

Table 6.1-2: Marine Protected Areas within the Hawaii-Southern California Training and Testing Study Area (continued)

Marine Protected Area	Location Within the Study Area	Protection Focus	Regulations Applicable to Navy Activities	Navy Proposed Activities and Potential Impacts
San Nicolas Island and Begg Rock ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited. However, discharges incidental to military research, development, testing, and evaluation of, and training with, guided missile and other weapons systems, fleet training exercises, small-scale amphibious warfare training, and special warfare training are allowed. Discharges incidental to underwater demolition and other in-water explosions are not allowed. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.	The Navy conducts training and testing in all warfare areas, including sonar-related activities outside of, but in the vicinity of this area, primarily to the southeast. The Navy does not discharge waste in or near this area in violation of the site specific regulations.
Southeast Santa Catalina Island ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including sonar-related activities outside of this, but in the vicinity of this area. The Navy does not discharge waste in or near this area.
Western Santa Catalina Island ASBS[2] State Water Quality Protection Area	California	Ecosystem	Waste discharges are prohibited.	The Navy conducts training and testing in all warfare areas, including sonar-related activities outside of this, but in the vicinity of this area. The Navy does not discharge waste in or near this area.
Ahihi-Kinau Natural Area Reserve	Hawaii	Ecosystem	Prohibited: anchoring in any manner, injuring or removing any marine organism, damaging or disturbing any geological features, moving or damaging historic or prehistoric remains.	The Navy conducts no activities in this area.
Kalaupapa National Historical Park	Hawaii	Ecosystem	Prohibited: restrictions on commercial and recreational fishing.	The Navy conducts no activities near Kalaupapa National Historical Park.
Hanauma Bay Marine Life Conservation District	Hawaii	Ecosystem	Prohibited: operating any watercraft, injuring or removing any marine organism, damaging or disturbing any geological features.	The Navy conducts no activities in or near Hanauma Bay.

Table 6.1-2: Marine Protected Areas within the Hawaii-Southern California Training and Testing Study Area (continued)

Marine Protected Area	Location Within the Study Area	Protection Focus	Regulations Applicable to Navy Activities	Navy Proposed Activities and Potential Impacts
Kahoolawe Island Reserve	Hawaii	Ecosystem	Prohibited: all entrance into and activities within the reserve (such as boating, fishing and diving) unless specifically authorized by the Island Reserve Commission.	The Navy conducts no activities on or near Kahoolawe Island. Submarines may conduct underwater mine detection activities several nautical miles west of Kahoolawe.
Kaloko-Honokohau National Historical Park	Hawaii	Ecosystem	Prohibited: unpermitted uses of lay nets and aquarium collections.	The Navy conducts no activities near Kaloko-Honokohau National Historical Park.
Hawaiian Islands Humpback Whale National Marine Sanctuary (HIHWNMS)	Hawaii	Focal Resource	Prohibitions on activities within the sanctuary, as outlined in the National Marine Sanctuary Program Regulations for the Hawaiian Islands Humpback Whale National Marine Sanctuary (15 C.F.R. § 922.183), do not apply to "…all classes of military activities, internal or external to the Sanctuary, that are being or have been conducted before the effective date of these regulations." (2 June 1997) and as identified in the Final EIS and Management Plan. Additionally, any activity that is "modified in such a way that it is likely to destroy, cause the loss of, or injure a Sanctuary resource in manner significantly greater than was considered in a previous consultation under section 304(d) of the National Marine Sanctuary Act and § 922.187 of this subpart, the modified activity will be treated as a new military activity under paragraph (c) of this section."	For the HSTT EIS activities, the Navy will continue to conduct anti-submarine warfare training and testing, consisting of mid- and high-frequency active sonar use. This type of activity occurs throughout the range complex and overlaps with the boundaries of the sanctuary primarily around the islands of Maui, Lanai, and Molokai. Navy activities within the HIHWNMS are specifically identified in Appendix F of the Final Management Plan/Final EIS Volume II (National Oceanic and Atmospheric Administration 1997). These Navy activities are exempt from the prohibitions in the Sanctuary. The Navy does not propose new, modified, or an increased frequency of activities in the HIHWNMS or activities that are different from those currently conducted in this area. Therefore, proposed activities are consistent with those activities currently conducted in this area and those described in the sanctuary's Final Management Plan/Final EIS. These HSTT activities would continue to be exempt from the prohibitions identified in the Sanctuary's regulations. HSTT activities within the HIHWNMS would be conducted with an extensive set of mitigations measures (see Chapter 5) and will avoid to the maximum extent practicable any adverse impacts on the Sanctuary resources and qualities.

Table 6.1-2: Marine Protected Areas within the Hawaii-Southern California Training and Testing Study Area (continued)

Marine Protected Area	Location Within the Study Area	Protection Focus	Regulations Applicable to Navy Activities	Navy Proposed Activities and Potential Impacts
Johnston Island National Wildlife Refuge	U.S. Territory	Ecosystem	Prohibitions do not apply to activities and exercises of the Armed Forces. Any activities carried forward within the area will be conducted in a manner consistent "so far as is reasonable and practical" with the prohibitions. If an activity causes any destruction, loss, or injury to a resource within the refuge then the DoD will coordinate with the Secretary of the Interior or Commerce, to take appropriate actions respond, mitigate, restore or replace the affected areas.	The Navy conducts no activities in or near the Johnston Island National Wildlife Refuge. Ships may transit in the vicinity of the refuge.
Molokini Shoal Marine Life Conservation District	Hawaii	Ecosystem	Prohibited: injuring or removing any marine organism (except in Subzone B), damaging or disturbing any geological features, moor and anchoring of boats.	The Navy conducts no activities on or near Molokini.
Midway Atoll National Wildlife Refuge	Hawaii	Ecosystem	Same prohibitions as listed under the Papahanaumokuakea Marine National Monument.	The Navy's proposed action includes activities conducted east of Nihoa Island and inside the eastern edge of the monument boundaries. These activities may include: - Anti-air warfare - Anti-surface warfare - Anti-submarine warfare - Electronic warfare
Pupukea Marine Life Conservation District	Hawaii	Ecosystem	Prohibited: injuring or removing any marine organism (outside of species and gear specific regulations), damaging or disturbing any geological features.	The Navy conducts no activities in this area.

Table 6.1-2: Marine Protected Areas within the Hawaii-Southern California Training and Testing Study Area (continued)

Marine Protected Area	Location Within the Study Area	Protection Focus	Regulations Applicable to Navy Activities	Navy Proposed Activities and Potential Impacts
Papahanaumokuakea Marine National Monument and World Heritage Site	Hawaii	Ecosystem	Prohibitions on activities within the Papahanaumokuakea Marine National Monument and World Heritage Site (50 C.F.R. § 404), state that "all activities and exercises of the Armed Forces shall be carried out in a manner that avoids, to the extent practicable and consistent with operational requirements, adverse impacts on Monument resources and qualities." Additionally, these regulations require that "in the event of threatened or actual destruction of, loss of, or injury to a Monument resource or quality resulting from an incident, including but not limited to spill and groundings, caused by a component of the [DoD] or the United States Coast Guard, the cognizant component shall promptly coordinate with the Secretaries for the purpose of taking appropriate actions to respond to and mitigate the harm and, if possible, restore or replace the Monument resource or quality."	The Navy's proposed action includes activities conducted east of Nihoa Island and inside the eastern edge of the monument boundaries. These activities may include: - Anti-air warfare - Anti-surface warfare - Anti-submarine warfare - Electronic warfare
Kealakekua Bay Marine Life Conservation District	Hawaii	Ecosystem	Prohibited: injuring or removing any marine organism (except within Subzone B), damaging or disturbing any geological features, anchoring of boats in Subzone A (may be anchored in Subzone B only in sand).	The Navy conducts no activities in this area.
West Hawaii Regional Fishery Management Area	Hawaii	Focal Resource	Prohibited: unpermitted uses of lay nets and aquarium collections.	The Navy conducts no activities in this area.

6.1.2.1.1 Channel Islands National Marine Sanctuary

The Channel Islands National Marine Sanctuary consists of an area of 1,109 square nautical miles (nm^2) around Anacapa Island, Santa Cruz Island, Santa Rosa Island, San Miguel Island and, Santa Barbara Island to the south (Figure 6.1-1). Only 92 nm^2 of Santa Barbara Island, or about eight percent of the sanctuary, occurs within the Southern California portion of the Study Area.

Key habitats within the sanctuary include kelp forest, surfgrass and eelgrass, intertidal zone, nearshore subtidal, deepwater benthic, and water column habitat. The diversity of habitats onshore and offshore contributes to the high species diversity in the Channel Islands National Marine Sanctuary, with more than 195 species of birds using open water, shore, or island habitats in the area (National Marine Sanctuaries 2009a). At least 33 species of cetaceans have been reported in the Channel Islands National Marine Sanctuary (National Marine Sanctuaries 2009a). Four species of sea turtles have been reported in the region—green, loggerhead, olive ridley, and leatherback—and all four species may be found within the sanctuary at any time of year. At least 492 species of algae and four species of sea grasses make up the marine plants of the sanctuary (National Marine Sanctuaries 2009a). Due to its transitional location between cold and warm water currents and the diversity of bottom habitats, the Channel Islands National Marine Sanctuary supports a variety of invertebrates, including two endangered species (black abalone and the white abalone). Of the 481 species of fish commonly found in the region, many occur in the sanctuary. See Section 3.4 (Marine Mammals), Section 3.5 (Sea Turtles), Section 3.6 (Sea Birds), Section 3.7 (Marine Vegetation), Section 3.8 (Marine Invertebrates), and Section 3.9 (Fish) for additional information on these species.

General regulations for the Channel Islands National Marine Sanctuary prohibit the following (15 C.F.R. § 922.72(a)):

> (1) Exploring for, developing, or producing hydrocarbons within the Sanctuary, except pursuant to leases executed prior to March 30, 1981, and except the laying of pipeline pursuant to exploring for, developing, or producing hydrocarbons.
>
> (2) Exploring for, developing, or producing minerals within the Sanctuary, except producing byproducts incidental to hydrocarbon production allowed by paragraph (a)(1) of this section.
>
> (3)(i) Discharging or depositing from within or into the Sanctuary any material or other matter except:
>
>> (A) Fish, fish parts, or chumming materials (bait) used in or resulting from lawful fishing activity within the Sanctuary, provided that such discharge or deposit is during the conduct of lawful fishing activity within the Sanctuary;
>>
>> (B) For a vessel less than 300 gross registered tons (GRT), or an oceangoing ship without sufficient holding tank capacity to hold sewage while within the Sanctuary, biodegradable effluent generated incidental to vessel use by an operable Type I or II marine sanitation device (U.S. Coast Guard classification) approved in accordance with section 312 of the Federal Water Pollution Control Act, as amended, (FWPCA), 33 U.S.C. 1321 et seq. Vessel operators must lock all marine sanitation devices in a manner that prevents discharge or deposit of untreated sewage;

(C) Biodegradable matter from:

(1) Vessel deck wash down;
(2) Vessel engine cooling water;
(3) Graywater from a vessel less than 300 gross registered tons;
(4) Graywater from an oceangoing ship without sufficient holding tank capacity to hold graywater while within the Sanctuary;

(D) Vessel engine or generator exhaust;

(E) Effluent routinely and necessarily discharged or deposited incidental to hydrocarbon exploration, development, or production allowed by paragraph (a)(1) of this section; or

(F) Discharge allowed under section 312(n) of the FWPCA.

(3)(ii) Discharging or depositing from beyond the boundary of the Sanctuary any material or other matter that subsequently enters the Sanctuary and injures a Sanctuary resource or quality, except those listed in paragraphs (a)(3)(i)(B) through (F) of this section and fish, fish parts, or chumming materials (bait) used in or resulting from lawful fishing activity beyond the boundary of the Sanctuary, provided that such discharge or deposit is during the conduct of lawful fishing activity there.

(4) Drilling into, dredging, or otherwise altering the submerged lands of the Sanctuary; or constructing or placing any structure, material, or other matter on or in the submerged lands of the Sanctuary, except as incidental to and necessary to:

(i) Anchor a vessel;
(ii) Install an authorized navigational aid;
(iii) Conduct lawful fishing activity;
(iv) Lay pipeline pursuant to exploring for, developing, or producing hydrocarbons; or
(v) Explore for, develop, or produce hydrocarbons as allowed by paragraph (a)(1) of this section.

(5) Abandoning any structure, material, or other matter on or in the submerged lands of the Sanctuary.

(6) Except to transport persons or supplies to or from any Island, operating within one nmi of any Island any vessel engaged in the trade of carrying cargo, including, but not limited to, tankers and other bulk carriers and barges, any vessel engaged in the trade of servicing offshore installations, or any vessel of three hundred gross registered tons or more, except fishing or kelp harvesting vessels.

(7) Disturbing a seabird or marine mammal by flying a motorized aircraft at less than 1,000 feet over the waters within one nautical mile of any Island, except to engage in kelp bed surveys or to transport persons or supplies to or from an Island. Failure to maintain a minimum altitude of 1,000 feet above ground level over such waters is presumed to disturb marine mammals or seabirds.

(8) Moving, removing, injuring, or possessing, or attempting to move, remove, injure, or possess a Sanctuary historical resource.

(9) Taking any marine mammal, sea turtle, or seabird within or above the Sanctuary, except as authorized by the Marine Mammal Protection Act, as amended, (MMPA), 16 U.S.C. 1361 et seq., Endangered Species Act, as amended, (ESA), 16 U.S.C. 1531 et seq., Migratory Bird Treaty Act, as amended, (MBTA), 16 U.S.C. 703 et seq., or any regulation, as amended, promulgated under the MMPA, ESA, or MBTA.

(10) Possessing within the Sanctuary (regardless of where taken from, moved, or removed from) any marine mammal, sea turtle, or seabird, except as authorized by the MMPA, ESA, MBTA, or any regulation, as amended, promulgated under the MMPA, ESA, or MBTA.

(11) Marking, defacing, damaging, moving, removing, or tampering with any sign, notice, or placard, whether temporary or permanent, or any monument, stake, post, or other boundary marker related to the Sanctuary.

(12) Introducing or otherwise releasing from within or into the Sanctuary an introduced species, except striped bass (*Morone saxatilis*) released during catch and release fishing activity.

(13) Operating a motorized personal watercraft within waters of the Sanctuary that are coextensive with the Channel Islands National Park, established by 16 U.S.C. 410(ff).

According to the National Marine Sanctuary Program Regulations for the Channel Islands National Marine Sanctuary (15 C.F.R., § 922.73), the prohibitions "…do not apply to military activities carried out by DoD [Department of Defense] as of the effective date of these regulations." However, any activity that is "modified in such a way that requires the preparation of an environmental assessment or environmental impact statement…relevant to a Sanctuary resource or quality" is not considered a pre-existing activity. The National Marine Sanctuary Program Regulations also states "all DoD activities must be carried out in a manner that avoids to the maximum extent practicable any adverse impacts on sanctuary resources and qualities." If a DoD activity causes any destruction, loss or injury to a Sanctuary resource then the "DoD, in coordination with the Director, must promptly prevent and mitigate further damage and must restore or replace the Sanctuary resource or quality in a manner approve by the Director."

The Navy does not propose new or an increase in activities in the Channel Islands National Marine Sanctuary, or activities that are different from those currently conducted in this area. Increases to military activities described in the Proposed Action would not occur in the sanctuary. Therefore, proposed activities are consistent with those activities currently conducted in this area, are consistent with those described in the sanctuary's designation document and in Section 3.5.9 (Department of Defense Activities, pre-existing activities) of the *Final Channel Islands National Marine Sanctuary Management Plan/Final Environmental Impact Statement (FMP/FEIS), Volume II: Environmental Impact Statement* (2008), authored and published by the National Oceanic and Atmospheric Administration, and would continue to be exempt from the prohibitions identified in the Sanctuary's regulations. HSTT activities within the Sanctuary would be conducted with an extensive set of mitigations measures (see Chapter 5, Standard Operating Procedures, Mitigation, and Monitoring) and will avoid to the maximum extent practicable any adverse impacts on the Sanctuary resources and qualities.

To ensure compliance with the National Marine Sanctuary Program Regulations, the Navy considered all proposed training and testing activities to determine which activities may destroy, cause the loss of, or injure sanctuary resources, or result in adverse impacts on sanctuary resources or qualities. The Navy concluded that the proposed activities could fall into the following three categories:

1. The following platforms, sources, or items that are part of Navy activities may be used within the Channel Islands National Marine Sanctuary because they were specifically exempted:

    - Aircraft and Aerial Targets

    Aircraft and aerial targets are expected to cause only a minor and temporary behavioral reaction due to noise for marine mammals, sea turtles, birds, or fish that may be present in the area. However, in addition to behavioral reactions due to noise, seabirds could potentially be struck by aircraft or aerial targets. The Navy implements standard operating procedures that require pilots of Navy aircraft to make every attempt to avoid large flocks of birds in order to reduce the safety risk involved with a potential bird strike. For a more detailed discussion of potential impacts to these resources from the use of aircraft and aerial targets, see the following sections:
        - Section 3.4.3.2.7 (Impacts from Aircraft Noise) for marine mammals
        - Section 3.5.3.1.12 (Impacts from Vessel and Aircraft Noise) for sea turtles
        - Section 3.6.3.1.5 (Impacts from Aircraft and Vessel Noise) and Section 3.6.3.3.1 (Impacts from Aircraft and Aerial Target Strikes) for birds
        - Section 3.9.3.1.2 (Impacts from Sonar and Other Active Sources) for fish

    - Vessels and in-water devices (that do not make contact with seafloor)

    Noise (other than sonar or radiated and induced noise) from vessels and in-water devices is expected to cause only a minor and temporary behavioral reaction for marine mammals, sea turtles, seabirds, or fish that may be present in the area. Marine mammals, sea turtles, seabirds, floating vegetation, and invertebrates could potentially be struck by or collide with vessels. However, the Navy implements mitigation measures to reduce the potential for vessel strikes of marine mammals (Section 5.3.2.2, Physical Disturbance and Strike, and Section 5.3.3.1, Marine Mammal Habitats). In addition, all vessels use extreme caution and proceed at a "safe speed" so they can take proper and effective action to avoid a collision with any sighted object or disturbance and can be stopped within a distance appropriate to the prevailing circumstances and conditions. For a more detailed discussion of potential impacts to these resources from the use of vessels and in-water devices, see the following sections:
        - Section 3.4.3.4.1 (Impacts from Vessel Strike) and Section 3.4.3.4.2 (Impacts from In-Water Devices) for marine mammals
        - Section 3.5.3.3.1 (Impacts from Vessels) and Section 3.5.3.3.2 (Impacts from In-Water Devices) for sea turtles
        - Section 3.6.3.3.2 (Impacts from Vessels and In-Water Devices) for birds
        - Section 3.7.3.2.1 (Impacts from Vessels and In-Water Devices) for vegetation
        - Section 3.8.3.3.1 (Impacts from Vessels and In-Water Devices) for invertebrates
        - Section 3.9.3.3.1 (Impacts from Vessels and In-Water Devices) for fish

    - Explosives detonated in-air, at the surface, or in the water (includes gunnery, bombing, torpedoes, missiles, and mine countermeasures)

Explosives detonated in-air, at the surface, or in the water could impact marine mammals, sea turtles, birds, invertebrates, floating vegetation, or fish that may be present in the area. Impacts are expected to range from temporary behavioral reactions to injury, damage, or death. However, the Navy implements mitigation measures to reduce the potential for impacts from the use of explosives (Section 5.3.1.2.2, Acoustic Stressors—Explosives and Impulsive Sound, and Section 5.3.2.1.2, Explosives and Impulsive Sound). For a more detailed discussion of potential impacts to these resources from the use of explosives detonated in-air, at the surface, or in the water, see the following sections:

- Section 3.4.3.2.2 (Impacts from Explosives) for marine mammals
- Section 3.5.3.1.8 (Impacts from Explosives) for sea turtles
- Section 3.6.3.1.2 (Impacts from Explosives and Swimmer Defense Airguns) for birds
- Section 3.7.3.1.1 (Impacts from Explosives) for vegetation
- Section 3.8.3.1.2 (Impacts from Explosives and Other Impulsive Sources) for invertebrates
- Section 3.9.3.1.3 (Impacts from Explosives and Other Impulsive Acoustic Sources) for fish

- Military expended materials resulting from exempted activities

Military expended materials resulting from exempted activities include fragments from high-explosive munitions, non-explosive practice munitions, and targets. These items could directly strike marine mammals, sea turtles, birds, invertebrates, floating vegetation, or fish that may be present in the area. However, the probability of military expended materials directly striking a marine resource is extremely low. In addition, the Navy implements mitigation measures to reduce the potential for direct strike from non-explosive practice munitions (Section 5.3.1.2.3, Physical Disturbance and Strike, and Section 5.3.2.2.2, Non-Explosive Practice Munitions). In addition to biological resources, military expended materials can land on marine substrates. The Navy implements mitigation measures to reduce the potential for direct strike to shallow coral reefs from non-explosive practice munitions (Section 5.3.3.2, Seafloor Resources). For a more detailed discussion of potential impacts to these resources from the use of non-explosive practice munitions fired in-air or at the surface, see the following sections:

- Section 3.3.3.2.4 (Impacts from Military Expended Materials) for marine habitats
- Section 3.4.3.4.3 (Impacts from Military Expended Materials) for marine mammals
- Section 3.5.3.3.3 (Impacts from Military Expended Materials) for sea turtles
- Section 3.6.3.3.3 (Impacts from Military Expended Materials) for birds
- Section 3.7.3.2.2 (Impacts from Military Expended Materials) for vegetation
- Section 3.8.3.3.2 (Impacts from Military Expended Materials) for invertebrates
- Section 3.9.3.3.2 (Impacts from Military Expended Materials) for fish

2. The following platforms, sources, or items that are part of Navy activities may be used within the Channel Islands National Marine Sanctuary because they (1) are not likely to destroy, cause the loss of, or injure sanctuary resources or qualities; and (2) would not cause <u>significant impacts</u> on sanctuary resources:

- Sonar and other active acoustic sources

Sonar and other active acoustic sources are expected to cause only a minor and temporary behavioral reaction for invertebrates (cephalopods and crustaceans), diving birds, or fish that may be present in the area. No effect is anticipated to corals. Marine mammals and sea turtles could potentially be injured (permanent threshold shifts in hearing) from sonar and other active acoustic sources. However, although marine mammals and sea turtles may occur within the Channel Islands National Marine Sanctuary, there is no evidence to suggest that they would be concentrated in this area; therefore, the likelihood of injury is low. Furthermore, the Navy implements mitigation measures to reduce the potential for marine mammals and sea turtles to be exposed to sonar and other active acoustic sources throughout the entire Study Area (Section 5.3.1.2.1, Acoustic Stressors – Non-Impulsive Sound, and Section 5.3.2.1.1, Non-Impulsive Sound). For a more detailed discussion of potential impacts to these resources from the use of sonar and other active acoustic sources, see the following sections:

  - Section 3.4.3.2.1 (Impacts from Sonar and Other Active Acoustic Sources) for marine mammals
  - Section 3.5.3.1.7 (Impacts from Sonar and Other Active Acoustic Sources) for sea turtles
  - Section 3.6.3.1.1 (Impacts from Sonar and Other Active Acoustic Sources) for birds
  - Section 3.8.3.1.1 (Impacts from Sonar and Other Active Acoustic Sources) for invertebrates
  - Section 3.9.3.1.2 (Impacts from Sonar and Other Active Sources) for fish

- Electromagnetic devices

Electromagnetic devices are expected to cause only a minor and temporary behavioral reaction for marine mammals, sea turtles, birds, invertebrates (arthropods, such as lobsters), or fish that may be present in the area. For a more detailed discussion of potential impacts to these resources from the use of electromagnetic devices, see the following sections:

  - Section 3.4.3.3.1 (Impacts from Electromagnetic Devices) for marine mammals
  - Section 3.5.3.2.1 (Impacts from Electromagnetic Devices) for sea turtles
  - Section 3.6.3.2.1 (Impacts from Electromagnetic Devices) for birds
  - Section 3.8.3.2.1 (Impacts from Electromagnetic Devices) for invertebrates
  - Section 3.9.3.2.1 (Impacts from Electromagnetic Devices) for fish

3. The following platforms, sources, or items that are part of Navy activities, but are not planned to be used within the Channel Islands National Marine Sanctuary (including a 2.7 nm buffer) as part of the Proposed Action:

   - Military expended materials resulting from non-exempted activities
   - Seafloor devices

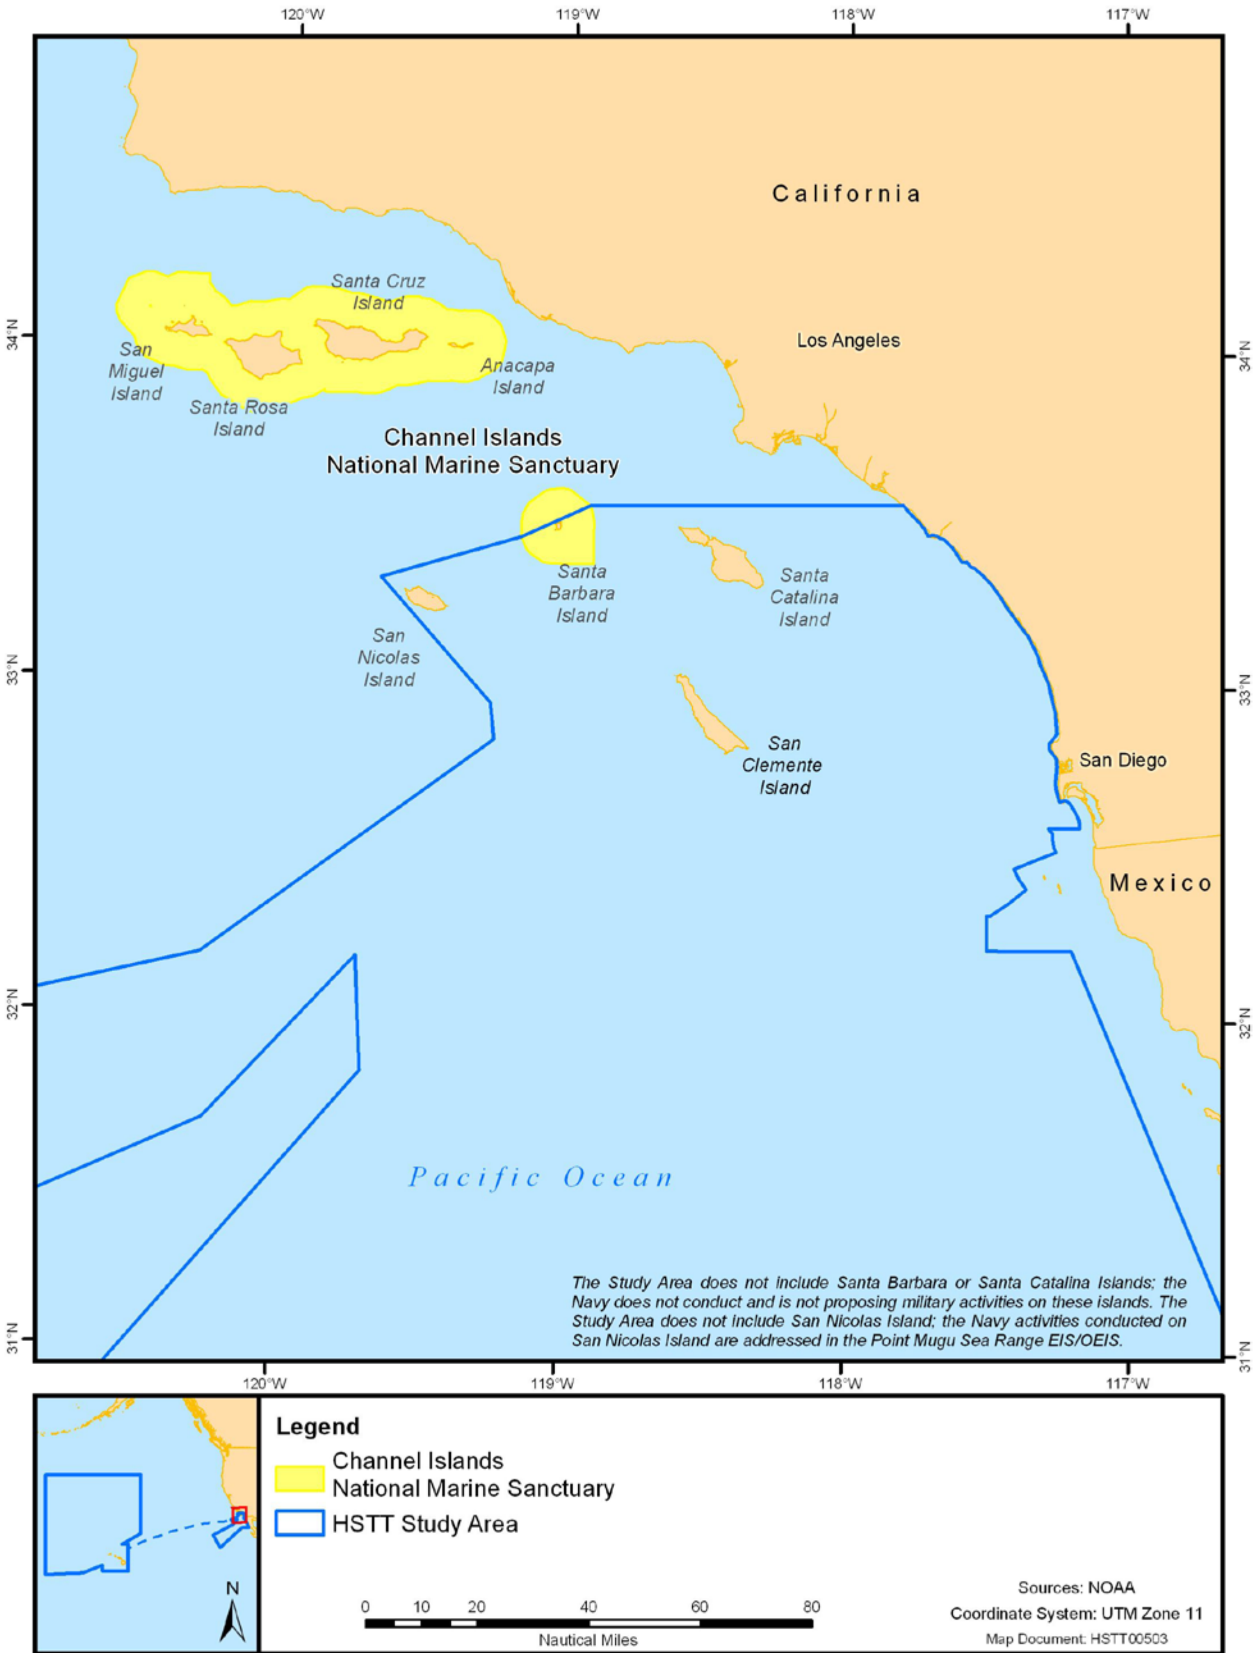

Figure 6.1-1: Channel Islands National Marine Sanctuary

6.1.2.1.2 Hawaiian Islands Humpback Whale National Marine Sanctuary

Scientists estimate that more than 50 percent of the entire North Pacific humpback whale population migrates to Hawaiian waters each winter to mate, calve, and nurse their young. The continued protection of humpback whales and their habitat is crucial to the long-term recovery of this endangered species. In addition to protection under the MMPA and the ESA, the humpback whale is protected in Hawaiian waters by the Hawaiian Islands National Marine Sanctuary Act.

The Hawaiian Islands National Marine Sanctuary Act established the Hawaiian Islands Humpback Whale National Marine Sanctuary. The sanctuary is composed of 1,035 nm^2 of the waters around Maui, Lanai, and Molokai; and smaller areas off the north shore of Kauai, off Hawaii's west coast, and off the north and southeast coasts of Oahu (Figure 6.1-2). The Sanctuary is entirely within the Hawaii portion of the Study Area, constitutes one of the world's most important North Pacific humpback whale (*Megaptera novaeangliae*) habitats, and is a primary region for humpback reproduction in the U.S. (National Marine Sanctuary Program 2002).

The sanctuary boundaries extend from the shoreline to 600 feet (ft.) (183 meters [m]) deep in many areas, encompassing a variety of marine ecosystems, including sea grass beds and coral reefs. Corals and coralline algae are the dominant reef-building organisms in Hawaii's reef ecosystems. Endangered Hawaiian monk seals and sea turtles are found in the sanctuary (Office of National Marine Sanctuaries 2010). Important reef biota include finger coral, cauliflower coral, lobe coral, algae, and marine invertebrates, such as shrimp, lobsters, crabs, and sea urchins. Fish populations on the sanctuary reefs include parrotfish, wrasses, damselfish, surgeon fish, goatfish, jacks, and sharks. See Section 3.4 (Marine Mammals), Section 3.5 (Sea Turtles), Section 3.7 (Marine Vegetation), Section 3.8 (Marine Invertebrates), and Section 3.9 (Fish) for additional information on these species.

A management review process for the Hawaiian Islands Humpback Whale National Marine Sanctuary is underway. A proposal to expand the scope of the sanctuary to conserve other living marine resources was made available to the public for comment between July and October 2010, and public scoping meetings were held in August 2010 (National Oceanic and Atmospheric Administration 2010). According to the National Marine Sanctuary Program Regulations for the Hawaiian Islands Humpback Whale National Marine Sanctuary (15 C.F.R., § 922.184), there are no prohibitions specifically related to military activities.

General regulations for the Hawaiian Islands Humpback Whale National Marine Sanctuary prohibit the following (15 C.F.R. § 922.184(a)):

> (1) Approaching, or causing a vessel or other object to approach, within the Sanctuary, by any means, within 100 yards of any humpback whale except as authorized under the Marine Mammal Protection Act, as amended (MMPA), 16 U.S.C. 1361 et seq., and the Endangered Species Act, as amended (ESA), 16 U.S.C. 1531 et seq.;
>
> (2) Operating any aircraft above the Sanctuary within 1,000 feet of any humpback whale except as necessary for takeoff or landing from an airport or runway, or as authorized under the MMPA and the ESA;
>
> (3) Taking any humpback whale in the Sanctuary except as authorized under the MMPA and the ESA;

(4) Possessing within the Sanctuary (regardless of where taken) any living or dead humpback whale or part thereof taken in violation of the MMPA or the ESA;

(5) Discharging or depositing any material or other matter in the Sanctuary; altering the seabed of the Sanctuary; or discharging or depositing any material or other matter outside the Sanctuary if the discharge or deposit subsequently enters and injures a humpback whale or humpback whale habitat, provided that such activity:

(i) requires a Federal or State permit, license, lease, or other authorization; and

(ii) is conducted:

(A) without such permit, license, lease, or other authorization, or

(B) not in compliance with the terms or conditions of such permit, license, lease, or other authorization.

(6) Interfering with, obstructing, delaying or preventing an investigation, search, seizure or disposition of seized property in connection with enforcement of either of the Acts or any regulations issued under either of the Acts.

According to the National Marine Sanctuary Program Regulations for the Hawaiian Islands Humpback Whale National Marine Sanctuary (15 C.F.R., § 922.183), "…all classes of military activities, internal or external to the Sanctuary, that are being or have been conducted before the effective date of these regulations …[the prohibitions] do not apply to these classes of activities." Additionally, any activity that is "modified in such a way that it is likely to destroy, cause the loss of, or injure a Sanctuary resource in manner significantly greater than was considered in a previous consultation under section 304(d) of the National Marine Sanctuary Act and § 922.187 of this subpart, the modified activity will be treated as a new military activity under paragraph (c) of this section." Navy activities within the Hawaiian Islands Humpback Whale National Marine Sanctuary are specifically identified in Appendix F of the Final Management Plan/Final EIS Volume II (National Oceanic and Atmospheric Administration 1997). These Navy activities are exempt from the prohibitions in the Sanctuary. Within the sanctuary, the Navy conducts primarily anti-submarine warfare training and testing, consisting of mid- and high-frequency active sonar use. This type of training occurs throughout the range complex, but overlaps with the boundaries of the sanctuary only in that portion around the islands of Maui, Lanai, and Molokai. The Navy does not propose new or modified activities in the Hawaiian Islands Humpback Whale National Marine Sanctuary, or activities that are different from those currently conducted in this area. Increases to military activities described in the Proposed Action would not occur in the sanctuary. Therefore, proposed activities are consistent with those activities currently conducted in this area and those described in the sanctuary's Final Management Plan/Final EIS. These HSTT activities would continue to be exempt from the prohibitions identified in the Sanctuary's regulations. HSTT activities within the Hawaiian Islands Humpback Whale National Marine Sanctuary would be conducted with an extensive set of mitigation measures (see Chapter 5, Standard Operating Procedures, Mitigation, and Monitoring) and will avoid to the maximum extent practicable any adverse impacts on the Sanctuary resources and qualities.

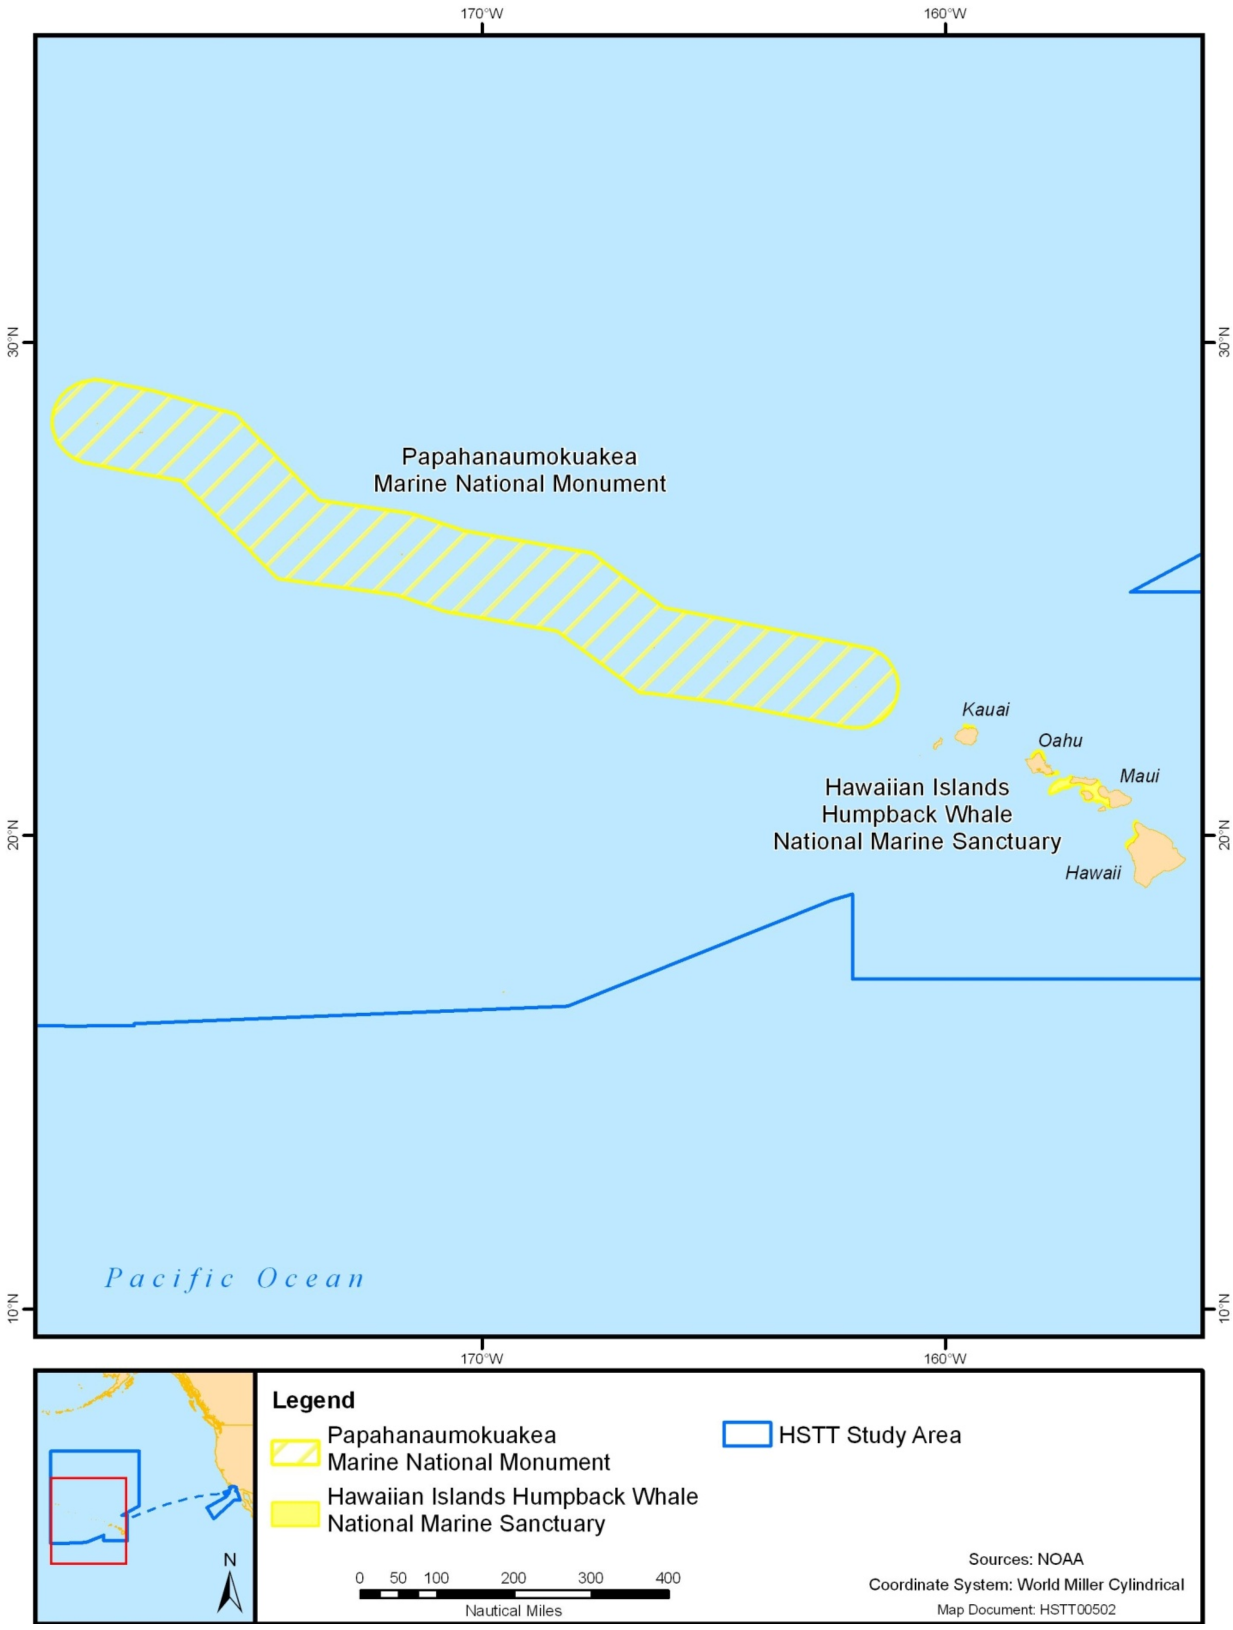

Figure 6.1-2: Papahanaumokuakea Marine National Monument and the Hawaiian Islands Humpback Whale National Marine Sanctuary

The Navy does not propose new or an increase in activities in the Hawaiian Islands Humpback Whale National Marine Sanctuary, or activities that are different from those currently conducted in this area. Therefore, proposed activities are consistent with those activities currently conducted in this area, are consistent with those described in the sanctuary's designation document, and are not being changed or modified in a way that would require consultation. Additionally, the Navy has designated a humpback whale cautionary area within the sanctuary, around an area that has been identified as having one of the highest concentrations of humpback whales during the critical winter months. Should national security needs require MFA sonar training and testing in the cautionary area between 15 December and 15 April, it shall be personally authorized by the Commander, U.S. Pacific Fleet. Further, the Navy will provide specific direction on required mitigation prior to operational units transiting to and training in the cautionary area. The Navy will provide the National Marine Fisheries Service with advance notification of any such activities.

To ensure compliance with the National Marine Sanctuary Program Regulations, the Navy considered all proposed training and testing activities to determine which activities may destroy, cause the loss of, or injure sanctuary resources, or result in adverse impacts on sanctuary resources or qualities. The Navy concluded that the proposed activities could fall into the following three categories:

1. The following platforms, sources, or items that are part of Navy activities may be used within the Hawaiian Islands Humpback Whale National Marine Sanctuary because they were specifically exempted:

   - Aircraft and Aerial Targets

   Aircraft and aerial targets are expected to cause only a minor and temporary behavioral reaction due to noise for marine mammals, sea turtles, birds, or fish that may be present in the area. However, in addition to behavioral reactions due to noise, seabirds could potentially be struck by aircraft or aerial targets. The Navy implements standard operating procedures that require pilots of Navy aircraft to make every attempt to avoid large flocks of birds in order to reduce the safety risk involved with a potential bird strike. For a more detailed discussion of potential impacts to these resources from the use of aircraft and aerial targets, see the following sections:
     - Section 3.4.3.2.7 (Impacts from Aircraft Noise) for marine mammals
     - Section 3.5.3.1.12 (Impacts from Vessel and Aircraft Noise) for sea turtles
     - Section 3.6.3.1.5 (Impacts from Aircraft and Vessel Noise) and Section 3.6.3.3.1 (Impacts from Aircraft and Aerial Target Strikes) for birds
     - Section 3.9.3.1.2 (Impacts from Sonar and Other Active Sources) for fish

   - Vessels and in-water devices (that do not make contact with seafloor)

   Noise (other than sonar or radiated and induced noise) from vessels and in-water devices is expected to cause only a minor and temporary behavioral reaction for marine mammals, sea turtles, seabirds, or fish that may be present in the area. Marine mammals, sea turtles, seabirds, floating vegetation, and invertebrates could potentially be struck by or collide with vessels. However, the Navy implements mitigation measures to reduce the potential for vessel strikes of marine mammals (Section 5.3.2.2, Physical Disturbance and Strike, and Section 5.3.3.1, Marine Mammal Habitats). In addition, all vessels use extreme caution and proceed at a "safe speed" so they can take proper and effective action to avoid a collision with any sighted object or disturbance and can be stopped within a distance appropriate to the prevailing circumstances and conditions. For a more detailed discussion of potential impacts to these resources from the use of vessels and in-water devices, see the following sections:

- o Section 3.4.3.4.1 (Impacts from Vessels) and Section 3.4.3.4.2 (Impacts from In-Water Devices) for marine mammals
- o Section 3.5.3.3.1 (Impacts from Vessels) and Section 3.5.3.3.2 (Impacts from In-Water Devices) for sea turtles
- o Section 3.6.3.3.2 (Impacts from Vessels and In-Water Devices) for birds
- o Section 3.7.3.2.1 (Impacts from Vessels and In-Water Devices) for vegetation
- o Section 3.8.3.3.1 (Impacts from Vessels and In-Water Devices) for invertebrates
- o Section 3.9.3.3.1 (Impacts from Vessels and In-Water Devices) for fish

- Explosives detonated in-air, at the surface, or in the water (includes gunnery, bombing, torpedoes, missiles, and mine countermeasures)

Explosives detonated in-air, at the surface, or in the water could impact marine mammals, sea turtles, birds, invertebrates, floating vegetation, or fish that may be present in the area. Impacts are expected to range from temporary behavioral reactions to injury, damage, or death. However, the Navy implements mitigation measures to reduce the potential for impacts from the use of explosives (Section 5.3.1.2.2, Acoustic Stressors—Explosives and Impulsive Sound, and Section 5.3.2.1.2, Explosives and Impulsive Sound). For a more detailed discussion of potential impacts to these resources from the use of explosives detonated in-air, at the surface, or in the water, see the following sections:

- o Section 3.4.3.2.2 (Impacts from Explosives) for marine mammals
- o Section 3.5.3.1.8 (Impacts from Explosives) for sea turtles
- o Section 3.6.3.1.2 (Impacts from Explosives and Swimmer Defense Airguns) for birds
- o Section 3.7.3.1.1 (Impacts from Explosives) for vegetation
- o Section 3.8.3.1.2 (Impacts from Explosives and Other Impulsive Sources) for invertebrates
- o Section 3.9.3.1.3 (Impacts from Explosives and Other Impulsive Acoustic Sources) for fish

- Military expended materials resulting from exempted activities

Military expended materials resulting from exempted activities include fragments from high-explosive munitions, non-explosive practice munitions, and targets. These items could directly strike marine mammals, sea turtles, birds, invertebrates, floating vegetation, or fish that may be present in the area. However, the probability of military expended materials directly striking a marine resource is extremely low. In addition, the Navy implements mitigation measures to reduce the potential for direct strike from non-explosive practice munitions (Section 5.3.1.2.3, Physical Disturbance and Strike, and Section 5.3.2.2.2, Non-Explosive Practice Munitions). In addition to biological resources, military expended materials can land on marine substrates. The Navy implements mitigation measures to reduce the potential for direct strike to shallow coral reefs from non-explosive practice munitions (Section 5.3.3.2, Seafloor Resources). For a more detailed discussion of potential impacts to these resources from the use of non-explosive practice munitions fired in-air or at the surface, see the following sections:

- o Section 3.3.3.2.4 (Impacts from Military Expended Materials) for marine habitats
- o Section 3.4.3.4.3 (Impacts from Military Expended Materials) for marine mammals
- o Section 3.5.3.3.3 (Impacts from Military Expended Materials) for sea turtles
- o Section 3.6.3.3.3 (Impacts from Military Expended Materials) for birds

- Section 3.7.3.2.2 (Impacts from Military Expended Materials) for vegetation
- Section 3.8.3.3.2 (Impacts from Military Expended Materials) for invertebrates
- Section 3.9.3.3.2 (Impacts from Military Expended Materials) for fish

2. The following platforms, sources, or items that are part of Navy activities may be used within the Hawaiian Islands Humpback Whale National Marine Sanctuary because they (1) are not likely to destroy, cause the loss of, or injure sanctuary resources or qualities; and (2) would not cause significant impacts on sanctuary resources:

   - Sonar and other active acoustic sources

   Sonar and other active acoustic sources are expected to cause only a minor and temporary behavioral reaction for invertebrates (cephalopods and crustaceans), diving birds, or fish that may be present in the area. No effect is anticipated to corals. Marine mammals and sea turtles could potentially be injured (permanent threshold shifts in hearing) from sonar and other active acoustic sources. However, although marine mammals and sea turtles may occur within the Hawaiian Islands Humpback Whale National Marine Sanctuary, there is no evidence to suggest that they would be concentrated in this area; therefore, the likelihood of injury is low. Furthermore, the Navy implements mitigation measures to reduce the potential for marine mammals and sea turtles to be exposed to sonar and other active acoustic sources throughout the entire Study Area (Section 5.3.1.2.1, Acoustic Stressors – Non-Impulsive Sound, and Section 5.3.2.1.1, Non-Impulsive Sound). For a more detailed discussion of potential impacts to these resources from the use of sonar and other active acoustic sources, see the following sections:
     - Section 3.4.3.2.1 (Impacts from Sonar and Other Active Acoustic Sources) for marine mammals
     - Section 3.5.3.1.7 (Impacts from Sonar and Other Active Acoustic Sources) for sea turtles
     - Section 3.6.3.1.1 (Impacts from Sonar and Other Active Acoustic Sources) for birds
     - Section 3.8.3.1.1 (Impacts from Sonar and Other Active Acoustic Sources) for invertebrates
     - Section 3.9.3.1.2 (Impacts from Sonar and Other Active Sources) for fish

   - Electromagnetic devices

   Electromagnetic devices are expected to cause only a minor and temporary behavioral reaction for marine mammals, sea turtles, birds, invertebrates (arthropods, such as lobsters), or fish that may be present in the area. For a more detailed discussion of potential impacts to these resources from the use of electromagnetic devices, see the following sections:
     - Section 3.4.3.3.1 (Impacts from Electromagnetic Devices) for marine mammals
     - Section 3.5.3.2.1 (Impacts from Electromagnetic Devices) for sea turtles
     - Section 3.6.3.2.1 (Impacts from Electromagnetic Devices) for birds
     - Section 3.8.3.2.1 (Impacts from Electromagnetic Devices) for invertebrates
     - Section 3.9.3.2.1 (Impacts from Electromagnetic Devices) for fish

3. The following platforms, sources, or items are part of Navy activities, but are not planned to be used within the Hawaiian Islands Humpback Whale National Marine Sanctuary (including a 2.7 nm buffer) as part of the Proposed Action:

- Military expended materials resulting from non-exempted activities
- Seafloor devices

6.1.2.1.3 Papahanaumokuakea Marine National Monument

Papahanaumokuakea Marine National Monument, established by Presidential Proclamation 8031 in June 2006, is the single largest conservation area in the U.S., encompassing 105,560 nm^2 in a chain of islands, reefs, and banks that extends to the northwest of the main Hawaiian Islands (Figure 6.1-2) (National Marine Sanctuaries 2009b). This monument is entirely within the Hawaii portion of the Study Area. The monument hosts a complex mix of reef, slope, bank, seamount (underwater mountains/volcanoes), abyssal (deep sea), and open ocean environments, and is managed by the monument's advisory council; the Department of Defense is a member of this council. The Papahanaumokuakea Marine National Monument also contains seamounts and approximately 30 submerged banks (U.S. Fish and Wildlife Service et al. 2008). The more than 4,450 square miles (m^2) (11,525 square kilometers) of shallow-water coral reef contains at least 57 coral species, 355 algae species, and 838 invertebrate species, with an exceptionally high number of corals and algae found only in the Hawaiian Islands (National Marine Sanctuaries 2009b). More than 260 fish species inhabit the reefs, with relatively fewer herbivores, such as surgeonfishes, and an abundance of carnivores, such as damselfishes, goatfishes, and scorpionfishes. Predators such as sharks and jacks dominate the reef fish communities. Most of the area is in the open ocean, with oceanic fish species, such as tuna, marlin, and wahoo. See Section 3.7 (Marine Vegetation), Section 3.8 (Marine Invertebrates), and Section 3.9 (Fish) for additional information on species and bathymetry in the Study Area.

The monument's ecosystem supports a range of marine mammals, including the Hawaiian monk seal, the Hawaiian spinner dolphin, and bottlenose dolphins (National Marine Sanctuaries 2009b). The Hawaiian monk seal, which does not exist outside of this area, is the most endangered marine mammal in the U.S. and the only seal that depends on coral reefs. Transient marine mammals in the Papahanaumokuakea Marine National Monument include spotted dolphins and humpback whales. Seasonally or periodically present whales include the sperm, blue, fin, sei, and North Pacific right whales. See Section 3.4 (Marine Mammals) for additional information on these species.

Five species of sea turtles occur in the monument: the loggerhead, olive ridley, leatherback, hawksbill, and green sea turtles (U.S. Fish and Wildlife Service et al. 2008). The Papahanaumokuakea Marine National Monument islands provide important nesting habitat for the threatened green sea turtle, with French Frigate Shoals alone supporting more than 80 percent of the nesting population for all the Hawaiian Islands. See Section 3.5 (Sea Turtles) for additional information on these species.

The regulations implementing the Papahanaumokuakea Marine National Monument (50 C.F.R., § 404), state that "all activities and exercises of the Armed Forces shall be carried out in a manner that avoids, to the extent practicable and consistent with operational requirements, adverse impacts on monument resources and qualities." Additionally, these regulations require that "in the event of threatened or actual destruction of, loss of, or injury to a monument resource or quality resulting from an incident, including but not limited to spill and groundings, caused by a component of the [DoD] or the United States Coast Guard, the cognizant component shall promptly coordinate with the Secretaries for the purpose of taking appropriate actions to respond to and mitigate the harm and, if possible, restore or replace the monument resource or quality." The Navy's proposed action includes activities conducted east of Nihoa Island and just inside the eastern edge of the monument boundaries. These activities may include:

- Anti-air warfare
- Anti-surface warfare
- Anti-submarine warfare
- Electronic warfare

The Navy does not propose new activities in the Papahanaumokuakea Marine National Monument, or activities that are different from those currently conducted in this area. Increases to military activities described in the proposed action would not occur in the monument. Therefore, proposed activities are consistent with those activities currently conducted in this area when the monument was designated, and are not being changed or modified in a way that would require consultation.

6.2 Relationship Between Short-Term Use of the Environment and Maintenance and Enhancement of long-Term Productivity

In accordance with the Council on Environmental Quality regulations (Part 1502), this EIS/OEIS analyzes of the relationship between the short-term impacts on the environment and the effects those impacts may have on the maintenance and enhancement of the long-term productivity of the affected environment. Impacts that narrow the range of beneficial uses of the environment are of particular concern. This means that choosing one option may reduce future flexibility in pursuing other options, or that committing a resource to a certain use may often eliminate the possibility for other uses of that resource. The Navy, in partnership with NMFS, is committed to furthering the understanding of marine resources and developing ways to lessen or eliminate the impacts Navy training and testing activities may have on these resources. For example, the Navy and NMFS collaborate on the Integrated Comprehensive Monitoring Program for marine species to assess the impacts of training activities on marine species and investigate population-level trends in marine species distribution, abundance, and habitat use in various range complexes and geographic locations where Navy training occurs.

The Proposed Action could result in both short- and long-term environmental impacts. However, these are not expected to result in any impacts that would reduce environmental productivity, permanently narrow the range of beneficial uses of the environment, or pose long-term risks to health, safety, or general welfare of the public. The Navy is committed to sustainable military range management, including co-use of the Study Area with the general public and commercial and recreational interests. This commitment to co-use of the Study Area will maintain long-term accessibility of the HSTT EIS/OEIS training and testing areas. Sustainable range management practices are specified in range complex management plans under the Navy's Tactical Training Theater Assessment and Planning Program. Among other benefits, these practices protect and conserve natural and cultural resources and preserve access to training areas for current and future training requirements while addressing potential encroachments that threaten to impact range and training area capabilities.

6.3 Irreversible or Irretrievable Commitment of Resources

The National Environmental Policy Act requires that environmental analysis include identification of "any irreversible and irretrievable commitments of resources which would be involved in the Proposed Action should it be implemented" (42 U.S.C. § 4332). Irreversible and irretrievable resource commitments are related to the use of nonrenewable resources and the effects that the uses of these resources have on future generations. Irreversible effects primarily result from the use or destruction of a specific resource (e.g., energy or minerals) that cannot be replaced within a reasonable time frame. Irretrievable resource commitments involve the loss in value of an affected resource that cannot be restored as a result of the action (e.g., the disturbance of a cultural site).

For the Proposed Action, most resource commitments would be neither irreversible nor irretrievable. Most impacts would be short term and temporary, or long lasting but within historical or desired conditions. Because there would be no building or facility construction, the consumption of material typically associated with such construction (e.g., concrete, metal, sand, fuel) would not occur. Energy typically associated with construction activities would not be expended and irretrievably lost.

Implementation of the Proposed Action would require fuels used by aircraft and vessels. Since fixed- and rotary-wing aircraft and ship activities could increase relative to the baseline, total fuel use would increase. Therefore, total fuel consumption would increase under the Proposed Action (see Section 6.4), and this nonrenewable resource would be considered irretrievably lost (see Chapter 4, Cumulative Impacts) and the following discussion on the Navy's Climate Change Roadmap).

6.4 ENERGY REQUIREMENTS AND CONSERVATION POTENTIAL OF ALTERNATIVES AND MITIGATION MEASURES

The federal government consumes two percent of the total U.S. energy share (Jean 2010). Of that 2 percent, the DoD consumes 93 percent. The Navy consumes one quarter of the total DoD share. The Navy consumes 1.2 billion to 1.6 billion gallons of fuel each year. The Navy expects a 25 percent increase in fuel consumption in the future because of new ships coming into the fleet and the growth in mission areas (Jean 2010).

Increased training and testing activities within the Study Area would result in an increase in energy demand over the No Action Alternative. The increased energy demand would arise from an increase in fuel consumption, mainly from aircraft and vessels participating in training and testing. Details of fuel consumption by training and testing activities on an annual basis are set forth in the air quality emissions calculation spreadsheets available on the project website. Vessel and aircraft fuel consumption is estimated to increase by 6.9 and 5.8 million gallons per year under Alternative 1 and Alternative 2, respectively, when compared to the No Action Alternative. Conservative assumptions were made in developing the estimates, and therefore the actual amount of fuel consumed during training and testing events may be less than estimated. Nevertheless, the demand for fuel consumption would increase from baseline levels, given the proposed increases in training and testing activities.

Energy requirements would be subject to any established energy conservation practices. The use of energy sources has been minimized wherever possible without compromising safety, training, or testing activities. No additional conservation measures related to direct energy consumption by the proposed activities are identified.

The Navy is committed to improving energy security and environmental stewardship by reducing its reliance on fossil fuels. The Navy is actively developing and participating in energy, environmental, and climate change initiatives that will increase use of alternative energy and help conserve the world's resources for future generations. The Navy Climate Change Roadmap identifies actions the Environmental Readiness Division is taking to implement EO 13514, *Federal Leadership in Environmental, Energy, and Economic Performance*. The Navy's Task Force Energy is responding to the Secretary of the Navy's Energy Goals through energy security initiatives that reduce the Navy's carbon footprint.

Two Navy programs—the Incentivized Energy Conservation Program and the Naval Sea Systems Command's Fleet Readiness, Research and Development Program—are helping the fleet conserve fuel via improved operating procedures and long-term initiatives. The Incentivized Energy Conservation

Program encourages the operation of ships in the most efficient manner while conducting their mission and supporting the Secretary of the Navy's efforts to reduce total energy consumption on naval ships. The Naval Sea Systems Command's Fleet Readiness, Research, and Development Program includes the High-Efficiency Heating, Ventilating, and Air Conditioning and the Hybrid Electric Drive for DDG-51 class ships, which are improvements to existing shipboard technologies that will both help with fleet readiness and decrease the ships' energy consumption and greenhouse gas emissions. These initiatives are expected to greatly reduce the consumption of fossil fuels (see Section 3.2, Air Quality). Furthermore, to offset the impact of its expected near-term increased fuel demands and achieve its goals to reduce fossil fuel consumption and greenhouse gas emissions, the Navy plans to deploy by 2016 a green strike group (a "great green fleet") composed of nuclear vessels and ships powered by biofuel in local operations and with aircraft flying only with biofuels (Jean 2010).

7 LIST OF PREPARERS

7.1 GOVERNMENT PREPARERS

Christiana Boerger (Naval Facilities Engineering Command South West), Marine Resource Specialist, Marine Resource Coordinator
M.S., Biology, California State University, Northridge
B.S., Marine Science, University of Hawaii, Hilo

Meghan Byrne (Naval Facilities Engineering Command Pacific), Project Manager
B.S., Environmental Policy and Planning, Virginia Polytechnic Institute and State University

Angela D'Amico (SPAWAR Systems Center Pacific and Naval Mine and ASW Command), Scientist
M.A., Physical Oceanography, College of William and Mary, Virginia
B.S., Mathematics, St. Thomas Aquinas College, New York

Meredith Fagan (Naval Facilities Engineering Command Pacific), Natural Resources Management Specialist, Marine Resource Coordinator
B.A., Biology, University of Virginia

Amy Farak (Naval Undersea Warfare Center Division, Newport), Biologist and Environmental Planner
B.S., Marine Biology, Roger Williams University

Joshua Frederickson (Naval Undersea Warfare Center Division Newport), Biologist and Environmental Planner
M.S., Environmental Science, University of Rhode Island
B.S., Environmental Science, University of Massachusetts

Robert H. Headrick (Office of Naval Research), Ocean Acoustics Team Leader
Ph.D., Oceanographic Engineering, MIT/WHOI Joint Program
M.S., Ocean Engineering, Massachusetts Institute of Technology/Woods Hole Oceanographic Institution (MIT/WHOI) Joint Program
O.E., Ocean Engineering, MIT/WHOI Joint Program
B.S., Chemical Engineering, Oklahoma State University

Keith Jenkins (Space & Naval Warfare Systems Command), Marine Scientist
M.S., Fisheries Oceanography, Old Dominion University
B.S., Marine Biology, Old Dominion University

Chip Johnson (U.S. Navy Pacific Fleet), Marine Species Advisor and Staff Marine Biologist
M.A., Marine Science, Virginia Institute of Marine Science, College of William and Mary
B.S., Biology, University of North Carolina, Wilmington

Susan Levitt (Naval Sea Systems Command), Environmental Planning – Environmental Engineer
B.S., Environmental Science, Allegheny College

Ken MacDowell (U.S. Navy Pacific Fleet), Training/Operations Environmental Support
B.S., University of the State of New York
Commander, USN (ret).

Jerry Olen (Space & Naval Warfare Systems Command), Environmental Readiness Program Manager
M.A., Political Science, Midwestern University
B.S., Environmental Engineering, California State University

Julie Rivers (U.S. Navy Pacific Fleet), Natural and Marine Resources Program Manager – Biologist
B.S., Biology, Beloit College

Robert Schnoor (Office of Naval Research), Ocean Research Facilities Team Leader
M.S., Meteorology, U.S. Naval Postgraduate School
B.S., Oceanography, U.S. Naval Academy

Cory Scott (Naval Facilities Engineering Command Pacific), Project Manager
B.S., Ecosystem Management and Restoration, Natural Resources Planning, Humboldt State University

Neil Sheehan (U.S. Navy Pacific Fleet), Project Lead
LL.M (International and Environmental Law), George Washington University School of Law
J.D., University of Dayton
B.A., State University of New York, Buffalo

Roy Sokolowski (U.S. Navy Pacific Fleet), Environmental Protection Specialist – Acoustician
Submarine Sonar Technician Senior Chief Petty Officer, USN (ret).

Alex Stone (U.S. Navy Pacific Fleet), Project Lead
B.S., Environmental Studies, George Washington University

Deborah Verderame (Naval Sea Systems Command), Environmental Planning – Environmental Engineer
M.S., Chemical/Environmental Engineering, University of Maryland
B.S., Biology, Fordham University
B.S., Chemical Engineering, Drexel University

7.2 CONTRACTOR PREPARERS

Maren Anderson (Tetra Tech, Inc.), Marine Mammal Scientist
B.A., Ecology and Evolutionary Biology, University of Colorado
Years of Experience: 4

Bruce Campbell (Parsons Infrastructure and Technology), Lead Analyst
M.S., Environmental Management, University of San Francisco
B.S., Environmental Biology, University of California, Santa Barbara
Years of Experience: 29

Brian Dresser (Tetra Tech, Inc.), Senior Scientist
M.S., Ecology, University of Georgia
Years of Experience: 15

Conrad Erkelens (ManTech SRS Technologies, Inc.), Senior Scientist
M.A., Anthropology, University of Hawaii
B.A., Anthropology, University of Hawaii
Years of Experience: 16

Jeremy Farr (Parsons Infrastructure and Technology), Environmental Planner
B.S., Environmental Management & Protection, California Polytechnic State University
Years of Experience: 3

Lauren Gilpatrick (Tetra Tech, Inc.), Wildlife Biologist
B.S., Wildlife Biology, University of Montana
Years of Experience: 3

Matt Hahn (ManTech SRS Technologies, Inc.), Military Operations Specialist
B.A., Business, University of St. Thomas
Years of Experience: 19

Paul Holthus (Tetra Tech, Inc.), Natural Resource Management Specialist
M.A., Geography, University of Hawaii
Years of Experience: 30

Lawrence Honma (Merkel & Associates, Inc.), Senior Marine Scientist
M.S., Marine Science, Moss Landing Marine Labs, San Francisco State University
B.S., Wildlife and Fisheries Biology, University of California at Davis
Years of Experience: 20

Taylor Houston (Parsons Infrastructure and Technology), Natural Resource Specialist/Project Manager
B.S., Natural Resource Management
Years of Experience: 12

Donald Jolly (Parsons Infrastructure and Technology), Principal Archaeologist
M.S., Quaternary Studies
Years of Experience: 25

Kevin Kelly (Tetra Tech, Inc.), Marine Resource Specialist
M.S., Oceanography, University of Hawaii
Years of Experience: 12 years

Tina Kuroiwa (Tetra Tech, Inc.), Marine Scientist
Ph.D., Ecology, Evolution & Behavior, The Graduate School, City University of New York
Years of Experience: 6

Kate Lomac MacNair (Tetra Tech, Inc.), Marine Mammal Scientist
B.S., in progress
Years of Experience: 3

Mandi McElroy (Tetra Tech, Inc.), Wildlife Biologist
M.S., Wildlife Ecology and Management, University of Georgia
Years of Experience: 9

June Mire (Tetra Tech, Inc.), Subject Matter Expert
Ph.D., Zoology, University of California, Berkeley
Years of Experience: 26

Karyn Palma (ManTech SRS Technologies, Inc.), Technical Editor
B.A., Environmental Studies, University of California, Santa Barbara
Years of Experience: 15

Colleena Perez (Tetra Tech, Inc.), Scientist IV
M.S., Marine Science, Moss Landing Marine Labs, San Francisco State University
Years of Experience: 7

Noelle Ronan (Tetra Tech, Inc.), Wildlife Biologist
M.S., Wildlife Science, Oregon State University
Years of Experience: 13

James Stribling (Tetra Tech, Inc.), Director
Ph.D., Entomology, Ohio State University
Years of Experience: 24

Philip Thorson (ManTech SRS Technologies, Inc.), Senior Research Biologist/Marine Mammal Biologist
Ph.D., Biology, University of California at Santa Cruz
B.A., Biology, University of California at Santa Cruz
Years of Experience: 28

Heather Turner (ManTech SRS Technologies, Inc.), Marine Biologist
M.A.S., Marine Biodiversity and Conservation, Scripps Institution of Oceanography, University of California, San Diego
B.S., Environmental Science, University of California, Berkeley
Years of Experience: 4

Suzanne Villacorta (Tetra Tech, Inc.), Regulatory Analyst and Environmental Scientist
J.D., Syracuse University College of Law
Years of Experience: 15

Karen Waller (ManTech SRS Technologies, Inc.), Vice President/Quality Assurance
B.S., Public Affairs, Indiana University
Years of Experience: 22

Brian D. Wauer (ManTech SRS Technologies, Inc.), Director, Range and Environmental Services
B.S., Administrative Management, University of Arkansas
B.S., Industrial Management, University of Arkansas
Years of Experience: 26

Lawrence Wolski (ManTech SRS Technologies, Inc.), Marine Scientist
M.S., 1999, Marine Sciences, University of San Diego
B.S., 1994, Biology, Loyola Marymount University
Years of Experience: 14

Mike Zickel (Ecosystem Management and Associates, Inc.), Senior Technical Manager

APPENDIX A NAVY ACTIVITIES DESCRIPTIONS

The United States (U.S.) Department of the Navy has been conducting military readiness activities throughout the Hawaii and Southern California Range Complexes and the Pacific Ocean for decades. The tempo and types of training and testing activities have fluctuated within the Hawaii-Southern California Training and Testing (HSTT) Study Area (Study Area) due to changing requirements, the introduction of new technologies, the dynamic nature of international events, advances in warfighting doctrine and procedures, and force structure changes. Such developments have influenced the frequency, duration, intensity, and location of required training and testing.

A.1 TRAINING ACTIVITIES

The Navy's training activities are organized generally into eight primary mission areas and a miscellaneous category (other training) that includes those activities that do not fall within one of the eight primary mission areas, but are an essential part of Navy training. Many of the activities described here may have a land component, occurring both at sea and on or over land. In this Environmental Impact Statement (EIS)/Overseas EIS (OEIS), only the at-sea component is analyzed.

In addition, because the Navy conducts a number of activities within major range events, descriptions of those major range events are also included in this appendix. It is important to note that these major range events are comprised entirely of individual activities described in the primary mission areas.

A.1.1 ANTI-AIR WARFARE TRAINING

Anti-air warfare is the primary mission area that addresses combat operations by air and surface forces against hostile aircraft. Navy ships contain an array of modern anti-aircraft weapon systems, including naval guns linked to radar-directed fire-control systems, surface-to-air missile systems, and radar-controlled cannons for close-in point defense. Strike/fighter aircraft carry anti-aircraft weapons, including air-to-air missiles and aircraft cannons. Anti-air warfare training encompasses events and exercises to train ship and aircraft crews in employment of these weapons systems against simulated threat aircraft or targets. Anti-air warfare training includes surface-to-air gunnery, surface-to-air and air-to-air missile exercises, and aircraft force-on-force combat maneuvers.

A.1.1.1 Air Combat Maneuver

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Anti-Air Warfare</td></tr>
<tr><td>Air Combat Maneuver (ACM)</td><td colspan="2">Aircrews engage in flight maneuvers designed to gain a tactical advantage during combat.</td></tr>
<tr><td>Long Description</td><td colspan="2">Basic flight maneuvers where aircrew engage in offensive and defensive maneuvering against each other. During an air combat maneuver engagement, no ordnance is fired, countermeasures such as chaff and flares may be used. These maneuvers typically involve two aircraft; however, based upon the training requirement, air combat maneuver exercises may involve over a dozen aircraft.
Participants typically are two or more aircraft. No weapons are fired.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Fixed-wing aircraft (e.g., F/A-18, F-35, F-5)
Systems: None

A.1.1.2 Air Defense Exercise

Activity Name	Activity Description	
Anti-Air Warfare		
Air Defense Exercises (ADEX)	Aircrew and ship crews conduct defensive measures against threat aircraft or missiles.	
Long Description	Aircrew and ship personnel perform measures designed to defend against attacking threat aircraft or missiles or reduce the effectiveness of such attack. This exercise involves full detection though engagement sequence. Aircraft operate at varying altitudes and speeds. This exercise may include Air Intercept Control exercises which involve aircraft controllers on vessels, in fixed-wing aircraft or at land based locations, use search radars to track and direct friendly aircraft to intercept the threat aircraft, and Detect to Engage exercises in which personnel on vessels use their search radars in the process of detecting, classifying, and tracking enemy aircraft or missiles up to the point of engagement.	
Information Typical to the Event	**Platform:** Fixed-wing aircraft (e.g., F/A-18, F-35, E-2), surface vessels (all) **Systems:** None **Ordnance/Munitions:** None **Targets:** Other aircraft, unmanned drones **Duration:** 1 to 4 hours	**Location:** Hawaii Range Complex : Warning Areas: 188,189, 190,192, 193, 194 Southern California Range Complex: Warning Area 291
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	No weapons fired	

A.1.1.3 Gunnery Exercise (Air-to-Air) – Medium-Caliber

Activity Name	Activity Description	
Anti-Air Warfare		
Gunnery Exercise (Air-to-Air) Medium Caliber **(GUNEX [A-A]) – medium-caliber**	Aircrews defend against threat aircraft with cannons (machine gun).	
Long Description	Fighter jet aircrews defend against threat aircraft with cannons (machine gun). An event involves two or more fighter aircrafts and a target banner towed by a contracted aircraft (e.g., Lear jet). The banner target is recovered after the event.	
Information Typical to the Event	**Platform:** Fixed- wing aircraft (e.g., F/A-18C, F-35) **Systems:** None **Ordnance/Munitions:** Medium-caliber munition (non-explosive) **Targets:** Towed banner **Duration:** 1 to 2 hours	**Location:** Southern California Range Complex: Warning Area 291
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material (non-explosive projectile) strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** Medium-caliber projectiles, casings	
Detailed Military Expended Material Information	Projectiles Casings	
Assumptions used for Analysis	Only non-explosive munitions used Target is recovered	

A.1.1.4 Missile Exercise (Air-to-Air)

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Anti-Air Warfare</td></tr>
<tr><td>Missile Exercise (Air-to-Air)</td><td colspan="2">Aircrews defend against threat aircraft with missiles.</td></tr>
<tr><td>Long Description</td><td colspan="2">An event involves two or more jet aircraft and a target. Missiles have either a high explosive warhead or are non-explosive practice munitions. The target is either an unmanned aerial target drone (e.g.: BQM-34, BQM-74), a Tactical Air-Launched Decoy, or a parachute suspended illumination flare. Target drones deploy parachutes and are recovered by boat or helicopter; Tactical Air-Launched Decoys and illumination flares are expended and not recovered. These events typically occur at high altitudes.
Anti-air missiles may also be employed when training against threat missiles.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Fixed-wing aircraft (e.g., F/A-18C, F-35)
Systems: None
Ordnance/Munitions: Anti-air missiles (e.g., AIM-7, AIM-9, AIM-120, AIM-132 [non-explosive and high explosive])
Targets: BQM-34, BQM-74 (Figure A-1), illumination flare (e.g., LUU-2) (Figure A-2), Tactical Air-Launched Decoy (Figure A-3)
Duration: 1 to 2 hours</td><td>Location:
Hawaii Range Complex: Warning Area 188
Southern California: Warning Area 291, Southern California Anti-submarine Warfare Range, Fleet Training Area Hot, Missile Range</td></tr>
<tr><td>Potential Impact Concerns
(Information regarding deconstruct categories and stressors)</td><td colspan="2">Acoustic: In-air explosives; aircraft noise
Energy: None
Physical Disturbance and Strike: Military expended material strike (target and missile fragment), Aircraft strike (birds only), missiles (non-explosive)

Ingestion: Military expended materials (missile fragments, parachute, flare casing, target fragments)</td></tr>
<tr><td>Detailed Military Expended Material Information</td><td colspan="2">Missile and target fragments
Parachutes
Flare casings</td></tr>
<tr><td>Assumptions used for Analysis</td><td colspan="2">All missiles are explosive (Alternatives 1 and 2), and all missiles explode at high altitude
All propellant and explosives are consumed
Assume 1.5 flares per Missile Exercise event</td></tr>
</table>

Figure A-1: BQM-74 (Aerial Target)

Figure A-2: LUU-2B/B Illuminating Flare (Aerial Target)

Figure A-3: Tactical Air-Launched Decoy (Aerial Target)

A.1.1.5 Gunnery Exercise (Surface-to-Air) – Large Caliber

Activity Name	Activity Description	
Anti-Air Warfare		
Gunnery Exercise (Surface-to-Air) – Large Caliber **(GUNEX [S-A]) – Large Caliber**	Surface vessel crews defend against threat aircraft or missiles with large-caliber guns.	
Long Description	Surface vessel personnel defend against threat aircraft or missile targets with guns to disable or destroy the threat. An event involves one vessel and a simulated threat aircraft or anti-vessel missile that is detected by the vessel's radar. Large-caliber guns fire projectiles, either non-explosive or high explosive (configured to explode in air); to disable or destroy the threat before it reaches the vessel. The target is towed by a commercial air services jet.	
Information Typical to the Event	**Platform:** Surface combatant vessel (e.g., CG, DDG, FFG, Littoral Combat Ship), fixed-wing aircraft **Systems:** None **Ordnance/Munitions:** Large caliber (e.g., 5-inch gun, 76 mm, 57 mm [non-explosive] under the No Action Alternative and high explosive under Alternatives 1 and 2) **Targets:** Towed banners behind aircraft **Duration:** 1 to 2 hours	**Location:** Hawaii Range Complex: Warning Areas 188, 192, Mela South Southern California Range Complex: Warning Area 291
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise, vessel noise, weapons firing noise, in-air explosives **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (projectiles), vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** Projectile fragments, target fragments	
Detailed Military Expended Material Information	Projectiles Projectile fragments Target fragments	
Assumptions used for Analysis	All projectiles under the No Action Alternative are assumed to be non-explosive All projectiles under Alternatives 1 and 2 assumed to be high explosive. All projectiles explode well above surface	

A.1.1.6 Gunnery Exercise (Surface-to-Air) – Medium Caliber

Activity Name	Activity Description	
Anti-Air Warfare		
Gunnery Exercise (Surface-to-Air) – Medium Caliber **(GUNEX [S-A]) – Medium Caliber**	Surface vessel crews defend against threat aircraft or missiles with medium-caliber guns.	
Long Description	Surface vessel personnel defend against threat aircraft or missile targets with guns to disable or destroy the threat. An event involves one vessel and a simulated threat aircraft or anti-vessel missile that is detected by the vessel's radar. Medium-caliber guns fire projectiles, typically non-explosive, to disable or destroy the threat before it reaches the vessel. The target is towed by a commercial air services jet.	
Information Typical to the Event	**Platform:** Surface vessel (all), fixed-wing aircraft **Systems:** None **Ordnance/Munitions:** Medium-caliber munitions (non-explosive) **Targets:** Towed banners behind aircraft **Duration:** 1 to 2 hours	**Location:** Hawaii Range Complex: Warning Areas 188, 192, Mela South Southern California Range Complex: Warning Area 291
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise, Vessel noise, Weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (projectiles), vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** Projectiles, casings	
Detailed Military Expended Material Information	Projectiles Casings	
Assumptions used for Analysis	All projectiles non-explosive. Close-In Weapon System employed in all events. Routine Close-In Weapon System maintenance related firing can occur throughout study area, as long as a clear range is established.	

A.1.1.7 Missile Exercise (Surface-to-Air)

Activity Name	Activity Description
Anti-Air Warfare	
Missile Exercise (Surface-to-Air) (MISSILEX [S-A])	Surface vessel crews engage threat missiles and aircraft with missiles.
Long Description	Surface vessel crews defend against threat missiles and aircraft with vessel launched missiles. The event involves a simulated threat aircraft or anti-ship missile which is detected by the vessel's radar. Vessel launched anti-air missiles are fired (high explosive) to disable or destroy the threat. The target typically is a remote controlled drone. Anti-Air missiles may also be used to train against land attack missiles.
Information Typical to the Event	**Platform:** Surface vessels (all) **Systems:** None **Ordnance/Munitions:** Anti-air missiles (e.g., Sea Sparrow, Standard Missile SM-2, Rolling Airframe Missile [high explosive]) **Targets:** Unmanned drones (e.g., BQM-34, BQM-74) **Duration:** 1 to 2 hours **Location:** Hawaii Range Complex: Warning Area 188 Southern California Range Complex: Warning Area 291
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise, in-air explosives **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (missile fragments), vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** Missile fragments
Detailed Military Expended Material Information	Missile fragments
Assumptions used for Analysis	Assume all anti-air missiles are high explosive. Missile explodes well above surface. All explosive and propellant consumed. Target typically not destroyed, unmanned drones are recovered.

A.1.1.8 Missile Exercise – Man Portable Air Defense System

Activity Name	Activity Description	
Anti-Air Warfare		
Missile Exercise-Man Portable Air Defense System (MISSILEX-MANPADS)	Marines employ the man portable air defense systems, a shoulder fired surface to air missile, against threat missiles or aircraft.	
Long Description	Marines employ the man-portable air defense systems, a shoulder fired surface to air missile, against threat missiles or aircraft. An event involves Marines firing the man-portable air defense system at remote piloted or ballistic aerial targets. Missile Exercise-Man Portable Air Defense System may also be conducted by combat forces from shore locations. The exercise may involve live fire or tracking only, without the firing of an actual missile.	
Information Typical to the Event	**Platform:** None **Systems:** Man Portable Defense Systems **Ordnance/Munitions:** Stinger or other man portable missiles (explosive) **Targets:** Remotely piloted target, ballistic aerial target **Duration:** Varies	**Location:** Southern California Range Complex: Shore Bombardment Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** In-air explosives **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (missile and target fragments) **Entanglement:** None **Ingestion:** Missile and target fragments	
Detailed Military Expended Material Information	Missile and target fragments	
Assumptions used for Analysis	None	

A.1.2 AMPHIBIOUS WARFARE TRAINING

Amphibious warfare is a type of naval warfare involving the utilization of naval firepower and logistics, and Marine Corps landing forces to project military power ashore. Amphibious warfare encompasses a broad spectrum of operations involving maneuver from the sea to objectives ashore, ranging from reconnaissance or raid missions involving a small unit, to large-scale amphibious operations involving over one thousand Marines and Sailors, and multiple ships and aircraft embarked in a Strike Group.

Amphibious warfare training includes tasks at increasing levels of complexity, from individual, crew, and small unit events to large task force exercises. Individual and crew training include the operation of amphibious vehicles and naval gunfire support training. Small-unit training operations include events leading to the certification of a Marine Expeditionary Unit as “deployment ready” or “special operations capable,” depending on if Marine Special Forces are attached to the unit. Such training includes shore assaults, boat raids, airfield or port seizures, and reconnaissance. Larger-scale amphibious exercises involve ship-to-shore maneuver, shore bombardment and other naval fire support, and air strike and close air support training.

A.1.2.1 Naval Surface Fire Support Exercise Land-Based Target

Activity Name	**Activity Description**	
Amphibious Warfare		
Naval Surface Fire Support Exercise (Land) **(FIREX [Land])**	Surface vessel crews use small-, medium-, and large-caliber guns to fire on land-based targets in support of forces ashore.	
Long Description	Surface vessel crews use small-, medium-, and large-caliber (main battery) guns to support forces ashore. One or more vessels position themselves up to six nautical miles from the target area and a land based spotter relays type and exact location of the target. After observing the fall of the shot, the spotter relays any adjustments needed to reach the target. Once the rounds are on target, the spotter requests a sufficient number to effectively destroy the target. This exercise occurs on land ranges where high explosive and non-explosive practice ordnance is authorized and is often supported by target shapes such as tanks, truck, trains, or aircraft on the ground.	
Information Typical to the Event	**Platform:** Surface combatant vessels (e.g., CG, DDG) **Systems:** None **Ordnance/Munitions:** Small, medium, and large caliber (explosive and non-explosive) **Targets:** Other aircraft, unmanned drones **Duration:** 4 to 6 hours	**Location:** Southern California Range Complex: Shore Bombardment Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, MEM strike **Entanglement:** None **Ingestion:** Projectile casings	
Detailed Military Expended Material Information	Casings	
Assumptions used for Analysis	NO LAND BASED IMPACTS INCLUDED IN THIS DOCUMENT-Projectile impact is on the land and is not further analyzed for this DEIS/OEIS	

A.1.2.2 Naval Surface Fire Support Exercise at Sea

Activity Name	Activity Description	
Amphibious Warfare		
Naval Surface Fire Support Exercise (At Sea) **(FIREX at Sea)**	Surface vessel crews use large-caliber guns to support forces ashore; however, the land target is simulated at sea. Rounds are scored by passive acoustic hydrophones located at or near the target area.	
Long Description	Surface vessel crews use large-caliber guns to support forces ashore; however, the land target is simulated at sea. Rounds are scored by passive acoustic hydrophones located at or near the target area. The scoring system is comprised of hydrophones permanently installed on the ocean floor as part of the Barking Sands Tactical Underwater Range west of Kauai. A scoring system provides a realistic presentation, such as a land mass with topography, to the vessel's combat system. This virtual land target area overlays the hydrophone array. The vessel fires its ordnance into the target area and the acoustic noise resulting from the impact of the round landing in the water is detected by the hydrophones. The scoring system triangulates the exact point of impact of the round, allowing the exercise to be conducted as if the vessel were firing at an actual land target. Surface vessel crews use large-caliber (main battery) guns to support forces ashore.	
Information Typical to the Event	**Platform:** Surface combatant vessels (e.g., DDG, CG), rigid-hull inflatable boat (for recovering buoys) **Systems:** None **Ordnance/Munitions:** Large caliber (5-inch rounds) explosive and non-explosive **Targets:** None **Duration:** 2 to 4 hours of firing, 18 hours total	**Location:** Hawaii Range Complex: Warning Area-188 (including Barking Sands Underwater Range Extension and Barking Sands Tactical Underwater Range)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise, underwater explosives (E5) **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (projectiles and projectile fragments), vessel strike **Entanglement:** None **Ingestion:** Projectile fragments	
Detailed Military Expended Material Information	Projectiles Projectile fragments	
Assumptions used for Analysis	Events occur greater than 12 nautical miles from shore Non-explosive practice munitions may be used. Acoustic sensors can detect projectile splash. High explosives may be used. Assume all explosive rounds detonate on impact with water surface	

A.1.2.3 Amphibious Assault

Activity Name	Activity Description	
Amphibious Warfare		
Amphibious Assault	Forces move ashore from vessels at sea for the immediate execution of inland objectives.	
Long Description	Landing forces embarked in vessels, craft, or helicopters launch an attack from the sea onto a hostile shore. Amphibious assault is conducted for the purposes of prosecuting further combat operations, obtaining a site for an advanced naval or airbase, or denying the enemy use of an area. Unit Level Training exercises involve one or more amphibious vessels, and their associated watercraft and aircraft, to move personnel and equipment from vessel to shore without the command and control and supporting elements involved in a full scale event. The goal is to practice loading, unloading, and movement and to develop the timing required for a full-scale exercise.	
Information Typical to the Event	**Platform:** Amphibious vessels and landing craft (e.g., LHA, LHD, LPD, LSD), amphibious vehicles, rotary-wing aircraft **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** Up to 2 weeks	**Location:** Hawaii Range Complex: Pacific Missiles Range Facility (Main Base), Marine Corps Base Hawaii, Marine Corps Training Area Bellows Southern California Range Complex Silver Strand Training Complex: Boat Lanes 11–14
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike; aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None anticipated	
Assumptions used for Analysis	Typical event: 1 to 3 amphibious vessels (e.g., LHA or LHD, LPD, LSD); 2 to 8 landing craft (Landing Craft, Air Cushioned; Landing Craft, Utility); 4 to 14 amphibious assault vehicles; up to 22 aircraft (e.g., MH-53, H-46/MV-22, AH-1, UH-1, AV-8); a Marine Expeditionary Unit (2,200 Marines)	

A.1.2.4 Amphibious Assault – Battalion Landing

Activity Name	Activity Description	
Amphibious Warfare		
Amphibious Assault – Battalion Landing	Marine Corps Battalion Landing Team forces launch an attack from sea to a hostile or potentially hostile shore for the immediate execution of inland maneuver.	
Long Description	Marine Corps Battalion Landing Team moves from amphibious vessels at sea, into hostile territory, establish a beachhead, then occupy the area, or move further inland for an extended period. Battalion Landing Team is a task organization composed of an infantry battalion reinforced by combat support and Combat Service Support units for amphibious assaults. The Battalion Landing Team is the ground force element of a Marine expeditionary unit when formed into a Marine air-ground task force.	
Information Typical to the Event	**Platform:** Amphibious vessels **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** 4 days	**Location:** Southern California Range Complex: San Clemente Island, Shore Bombardment Area, Shallow Water Training Range (Nearshore),Eel Cove, West Cove, Wilson Cove
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.1.2.5 Amphibious Raid

Activity Name	Activity Description
Amphibious Warfare	
Amphibious Raid	Small unit forces move swiftly from vessels at sea for a specific short term mission. These are quick operations with as few personnel as possible.
Long Description	Small unit forces swiftly move from amphibious vessels at sea into hostile territory for a specific mission, including a planned withdrawal. Raids are conducted to inflict loss or damage, secure information, create a diversion, confuse the enemy, or capture or evacuate individuals or material. Amphibious raid forces are kept as small as possible to maximize stealth and speed of the operation. An event may employ assault amphibian vehicle units, small boat units, small unit live-fire and non-live-fire operations. Surveillance or reconnaissance unmanned surface and aerial vehicles may be used during this event.
Information Typical to the Event	**Platform:** Amphibious assault vessels (e.g., LHA, LHD), amphibious transport dock and dock landing ships (e.g., LPD, LSD), amphibious vehicles (landing crafts, air cushioned, and amphibious assault vehicles), small boats (e.g., rigid-hull inflatable boats) **Systems:** Unmanned surface and aerial vehicles **Ordnance/Munitions:** Non-explosive practice munitions **Targets:** None **Duration:** 4 to 8 hours **Location:** Hawaii Range Complex: Pacific Missile Range Facility (Main Base), Marine Corps Base Hawaii, Marine Corps Training Area Bellows Silver Strand Training Complex: Boat Lanes 1–8, 11–14 (Bravo, Delta I, II, III, Echo, Fox, Golf, Hotel) Southern California Range Complex: West Cove, Horse Beach Cove, North West Harbor, Camp Pendleton Amphibious Assault Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None
Detailed Military Expended Material Information	None anticipated
Assumptions used for Analysis	Firing of weapons during these events accounted for in gunnery exercises, surface to surface activities

A.1.2.6 Expeditionary Fires Exercise/Supporting Arms Coordination Exercise

Activity Name	**Activity Description**	
Amphibious Warfare		
Expeditionary Fires Exercise/Supporting Arms Coordination Exercise	Military units provide integrated and effective close air support, Naval Surface Fire Support fire, and Marine Corps artillery fire in support of amphibious operations.	
Long Description	Military units provide integrated and effective close air support, Naval Surface Fire Support fire, and Marine Corps artillery fire in support of amphibious operations. The mission of the exercises is to achieve effective integration of Naval gunfire, close air support, and Marine Corps artillery fire support.	
Information Typical to the Event	**Platform:** Surface vessels, amphibious vessels, 4 AH-1Ws attack rotary-wing aircraft, 6 fixed-wing strike fighter or attack aircraft **Systems:** None **Ordnance/Munitions:** Large caliber (e.g., howitzers, 81 mm mortars, 5-inch rounds, MK-80 series bombs [explosive and non-explosive]) **Targets:** None **Duration:** 8 days	**Location:** Southern California Range Complex: San Clemente Island, Shore Bombardment Area, Shallow Water Training Range (Nearshore)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike, vessel strike **Entanglement:** None **Ingestion:**	
Detailed Military Expended Material Information	Shell casings from large-caliber rounds	
Assumptions used for Analysis	Only the at-sea components of this activity are analyzed in this document.	

A.1.2.7 Humanitarian Assistance Operations

Activity Name	Activity Description	
Amphibious Warfare		
Humanitarian Assistance Operation/Non-Combatant Evacuation Operation	Military units evacuate noncombatants from hostile or unsafe areas or provide humanitarian assistance in times of disaster.	
Long Description	Military units evacuate noncombatants from hostile or unsafe areas to safe havens or to provide humanitarian assistance in times of disaster. Non-Combatant Evacuation Operation is conducted by military units (generally Marine Corps) usually operating in conjunction with Navy ships and aircraft. Non-combatants are evacuated when their lives are endangered by war, civil unrest, or natural disaster. Marine Corps Marine expeditionary unit train for evacuations in hostile environments that require the use of force, though usually there is no opposition to evacuation from the host country. Helicopters and landing crafts could be expected to participate in this operation during day or night. No ordnance is used.	
Information Typical to the Event	**Platform: Systems:** Rotary and fixed-wing aircraft, amphibious vessels **Ordnance/Munitions:** None **Targets:** None **Duration:** Varies	**Location:** Hawaii Range Complex: Pacific Missiles Range Facility (Main Base), Niihau, Marine Corps Base Hawaii, Marine Corps Training Area Bellows Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike, vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.1.3 STRIKE WARFARE TRAINING

Strike warfare includes training of fixed-wing fighter/attack aircraft or rotary-wing aircraft in delivery of precision guided munitions, non-guided munitions, rockets, and other ordnance against land targets in all weather and light conditions. Training events typically involve a simulated strike mission with a flight of four or more aircraft. The strike mission may simulate attacks on "deep targets" (i.e., those geographically distant from friendly ground forces), or may simulate close air support of targets within close range of friendly ground forces. Laser designators from aircraft or ground personnel may be employed for delivery of precision guided munitions. Some strike missions involve no-drop events in which prosecution of targets is simulated, but video footage is often obtained by onboard sensors.

A.1.3.1 Bombing Exercise (Air-to-Ground)

Activity Name	Activity Description	
Strike Warfare		
Bombing Exercise (Air-to-Ground)	Bombing exercise involves training of strike fighter aircraft delivery of ordnance against land targets in day or night conditions.	
Long Description	Bombing exercise involves training of strike fighter aircraft delivery of ordnance against land targets in day or night conditions. The bombing exercise may involve close air support training in direct support of and in close proximity to forces on the ground, such as Navy or Marine forces engaged in training exercises on land, and may include the use of targeting laser.	
Information Typical to the Event	**Platform:** Fixed-wing strike fighter aircraft **Systems:** Targeting laser systems **Ordnance/Munitions:** MK-76, BDU-45, and BDU-45 (non-explosive), MK-80 series bombs (explosive) **Targets:** Land targets **Duration:** 1 to 2 hours	**Location:** Hawaii Range Complex: Kaula Island
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** Targeting laser **Physical Disturbance and Strike:** Military expended materials (non-explosive munitions), aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Bomb and target fragments	
Assumptions used for Analysis	The typical bomb release altitude is below 3,000 feet (ft.) (914 meters [m]) and within a range of 1,000 yards (914 m) for unguided munitions Only the in-water impacts of strike warfare activities are analyzed in the EIS/OEIS – NO LAND BASED IMPACTS INCLUDED IN THIS DOCUMENT	

A.1.3.2 Gunnery Exercise (Air-to-Ground)

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Strike Warfare</td></tr>
<tr><td>Gunnery Exercise (Air-to-Ground)</td><td colspan="2">Strike fighter aircraft and helicopter crews use guns to attack ground targets, day or night, with the goal of destroying or disabling enemy vehicles, structures, or personnel.</td></tr>
<tr><td>Long Description</td><td colspan="2">Strike fighter aircraft and helicopter crews use guns to attack ground targets, day or night, with the goal of destroying or disabling enemy vehicles, structures, or personnel.
A flight of two strike fighter aircraft will begin its descent to the target from an altitude of about 3,000 ft. (914 m) while still several miles away. Within a distance of 4,000 ft. (1,219 m) from the target, each aircraft will fire a burst of rounds before reaching an altitude of 1,000 ft. (305 m), then break off and reposition for another strafing run until each aircraft expends its exercise ordnance allowance. This exercise may include the use of targeting laser.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Fixed-wing strike fighter, rotary-wing aircraft
Systems:

A.1.4 ANTI-SURFACE WARFARE TRAINING

Anti-surface warfare is a type of naval warfare in which aircraft, surface ships, and submarines employ weapons and sensors in operations directed against enemy surface ships or boats. Air-to-surface exercises are conducted by long-range attacks using air-launched cruise missiles or other precision guided munitions, or using aircraft cannon. Anti-surface warfare also is conducted by warships employing torpedoes, naval guns, and surface-to-surface missiles. Submarines attack surface ships using torpedoes or submarine-launched, anti-ship cruise missiles. Training in anti-surface warfare includes surface-to-surface gunnery and missile exercises, air-to-surface gunnery and missile exercises, and submarine missile or torpedo launch events. Gunnery and missile training generally involves expenditure of ordnance against a towed target. A sinking exercise is a specialized training event that provides an opportunity for ship, submarine, and aircraft crews to use multiple weapons systems to deliver high explosive ordnance on a deactivated vessel, which is deliberately sunk.

Anti-surface warfare also encompasses maritime security, that is, the interception of a suspect surface ship by a Navy ship for the purpose of boarding-party inspection or the seizure of the suspect ship. Training in these tasks is conducted in visit, board, search and seizure exercises.

A.1.4.1 Maritime Security Operations

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Anti-Surface Warfare</td></tr>
<tr><td>Maritime Security Operations</td><td colspan="2">Helicopter and surface vessel crews conduct a suite of Maritime Security Operations (e.g., visit, search, board, and seizure; maritime interdiction operations; force protection; and anti-piracy operation).</td></tr>
<tr><td>Long Description</td><td colspan="2">Helicopter and surface ship crews conduct a suite of Maritime Security Operations (e.g., visit search, board, and seizure; maritime interdiction operations; force protection; and anti piracy operation). These activities involve training of boarding parties delivered by helicopters and surface ships to surface vessels for the purpose of simulating vessel search and seizure operations. Various training scenarios are employed and may include small arms with non-explosive blanks and surveillance or reconnaissance unmanned surface and aerial vehicles. The entire exercise may last two to three hours.
Vessel Visit, Board, Search, and Seizure: Military personnel from vessels and aircraft board suspect vessels, potentially under hostile conditions.
Maritime Interdiction Operations: Vessels and aircraft train in pursuing, intercepting, and ultimately detaining suspect vessels.
Oil Platform Defense: Naval personnel train to defend oil platforms or other similar at sea structures.
Warning Shot/Disabling Fire: Naval personnel train in the use of weapons to force fleeing or threatening small boats (typically operating at high speeds) to come to a stop.
Ship Force Protection: Vessel crews train in tracking multiple approaching, circling small craft, assessing threat potential, and communicating amongst crewmates and other vessels to ensure vessels are protected against attack.
Anti Piracy Training: Naval personnel train in deterring and interrupting piracy activity. Training includes large vessels (pirate “mother ships”), and multiple small, maneuverable, and fast craft.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Surface vessel (any), rotary-wing aircraft, small boats, high speed vessels, unmanned vehicles (surface and aerial)
Systems: None
Ordnance/Munitions: Small caliber (non-explosive)
Targets: Range support vessel, high performance boats, remote controlled high speed targets (Figure A-5 and Figure A-6) towing surface targets
Duration: Up to 3 hours</td><td>Location:

Ingestion: Small-caliber projectiles, casings</td></tr>
</table>

Activity Name	Activity Description
Anti-Surface Warfare	
Maritime Security Operations	Helicopter and surface vessel crews conduct a suite of Maritime Security Operations (e.g., visit, search, board, and seizure; maritime interdiction operations; force protection; and anti-piracy operation).
Detailed Military Expended Material Information	Small-caliber projectiles Casings
Assumptions used for Analysis	Maritime security operations is a broad term used to describe activities intended train naval forces in the skills necessary to protect naval vessels from small boat attack, counter piracy and drug operations (maritime interdiction operations and visit, board, search, and seizure), and protect key infrastructure (e.g. oil platforms). Maritime security operations need to remain broad as naval forces need to be able to tailor training events to respond to emergent threats. Maritime security operations events typically do not involve live fire of weapons. All maritime security operations events involve vessel movement, sometimes at high rates of speed (naval vessels maneuvering to overtake suspect vessel and/or small boats (targets) closing in and maneuvering around naval vessels), and some event involve helicopters and boarding parties. Maritime security operations training events are conducted proximate to naval homeports (San Diego, California) including during times of transit in and out of port, as well as during major training events.

A.1.4.2 Gunnery Exercise Surface-to-Surface (Ship) – Small Caliber

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>

A.1.4.3 Gunnery Exercise Surface-to-Surface (Ship) – Medium Caliber

Activity Name	Activity Description	
Anti-Surface Warfare		
Gunnery Exercise Surface-to-Surface (Ship) – Medium Caliber	Vessel crews engage surface targets with vessel's medium-caliber guns designed to provide close range defense against patrol boats, smaller boats, swimmers, and floating mines.	
Long Description	This exercise involves vessel crews engaging surface targets at sea with medium-caliber (larger than 0.50 calibers up to 56 mm) weapons. Vessels use medium-caliber weapons to practice defensive marksmanship, typically against a stationary floating target (a 10 ft. diameter red balloon [Killer Tomato]) and high speed mobile targets. Some targets are expended during the exercise and are not recovered. Shipboard protection systems (Close-In Weapon System) utilizing medium-caliber projectiles will train against high speed mobile targets.	
Information Typical to the Event	**Platform:** Surface vessels **Systems:** None **Ordnance/Munitions:** Medium caliber (high explosive or non-explosive) **Targets:** Recoverable and expendable floating target (stationary or towed), remote control high-speed targets **Duration:** 2 to 3 hours	**Location:** Hawaii Range Complex: Warning Areas -188, 191, 192, 193, 194, 196, Mela South Southern California Range Complex: Warning Area-291, Southern California Anti-Submarine Warfare Range, Shore Bombardment Area HSTT Transit Corridor
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E1, E2), vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike, military expended material strike (projectiles and casings, projectile and target fragments) **Entanglement:** None **Ingestion:** Medium-caliber projectiles and casings, target fragments, projectile fragments	
Detailed Military Expended Material Information	Medium-caliber projectiles and casings, target fragments, projectile fragments Approximately 200 medium-caliber rounds per event One target used per event. Approximately 50 percent of targets are “Killer Tomatoes” (usually recovered). Approximately 35 percent are high-speed maneuvering targets, which are recovered. Approximately 15 percent of targets are other stationary targets such as a steel drum	
Assumptions used for Analysis	None	

A.1.4.4 Gunnery Exercise Surface-to-Surface (Ship) – Large Caliber

Activity Name	Activity Description
Anti-Surface Warfare	
Gunnery Exercise Surface-to-Surface (Ship) – Large Caliber	Vessel crews engage surface targets with vessel's large-caliber guns designed to provide defense against vessels, patrol boats, smaller boats.
Long Description	This exercise involves vessels' gun crews engaging surface targets at sea with their main battery large-caliber (typically 57 mm, 76 mm, and 5-inch) guns. Targets include the QST-35 seaborne powered target, high speed maneuverable surface target, or a specially configured remote controlled water craft. Some targets are expended during the exercise and are not recovered. The exercise proceeds with the target boat approaching from about 10 nm distance. The target is tracked by radar and when within a predetermined range, it is engaged first with "warning shots". As threats get closer all weapons may be used to disable the threat. This exercise may involve a single firing vessel, or be undertaken in the context of a coordinated larger exercise involving multiple ships, including a major training event. Large-caliber guns will also be fired during weapon certification events and in conjunction with weapon maintenance. During all events, either high explosive or non-explosive rounds may be used. High explosive rounds can either be fused for detonation on impact (with water surface or target), or for proximity to the target (in air detonation).
Information Typical to the Event	**Platform:** Surface vessels (e.g., CG, DDG, FFG, LCS) **Systems:** None **Ordnance/Munitions:** Large caliber (e.g., 57 mm, 76 mm, and 5-inch [high explosive and non-explosive]) **Targets:** Remote controlled high speed targets **Duration:** Up to 3 hours **Location:** Hawaii Range Complex: Warning Areas -188, 191, 192, 193, 194, 196, Mela South Southern California Range Complex: Warning Area-291, Southern California Anti-Submarine Warfare Range, Shore Bombardment Area HSTT Transit Corridor
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E3, E5), vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike, military expended material strike (projectile, target fragments) **Entanglement:** None **Ingestion:** Target fragments, projectile fragments
Detailed Military Expended Material Information	Large-caliber projectiles and casings Target fragments Projectile fragments
Assumptions used for Analysis	For analytical purposes assume all high explosive rounds are fused to detonate upon impact with water surface or target After impacting the water, the high explosive rounds are expected to detonate within three feet of the surface. Non-explosive rounds and fragments from the high explosive rounds will sink to the bottom of the ocean For Alternative 2, analysis considers the introduction of (two) kinetic weapon equipped vessels being introduced to the fleet. Increases in events (six) and projectiles expended (240) reflect the likely training requirements of this new weapon system Assume each non-explosive projectile will be up to 5-inch diameter and 30-inch length, and each firing will also expend a metallic sleeve used to convey the projectile down the gun barrel

A.1.4.5 Gunnery Exercise Surface-to-Surface (Boat) – Small Caliber

Activity Name	Activity Description
Anti-Surface Warfare	
Gunnery Exercise Surface-to-Surface (Boat) – Small Caliber	Small boat crews engage surface targets with small-caliber weapons.
Long Description	Boat crews engage surface targets with small-caliber weapons. Boat crews may use high or low speeds to approach and engage targets simulating other boats, swimmers, floating mines, or near shore land targets with small-caliber (up to and including .50 caliber) weapons. A commonly used target is an empty steel drum. A number of different types of boats are used depending on the unit using the boat and their mission. Boats are most used to protect ships in harbors and high value units, such as: aircraft carriers, nuclear submarines, liquid natural gas tankers, etc., while entering and leaving ports, as well as to conduct riverine operations, and various naval special warfare operations. The boats used by these units include: small unit river craft, combat rubber raiding craft, rigid-hull inflatable boats, patrol craft, and many other versions of these types of boats. These boats use inboard or outboard, diesel or gasoline engines with either propeller or water jet propulsion.
Information Typical to the Event	**Platform:** Boats **Systems:** None **Ordnance/Munitions:** Small caliber (non-explosive), anti-swimmer grenades **Targets:** Recoverable or expendable floating target **Duration:** 1 hour **Location:** Southern California Range Complex: Warning Area-291, Southern California Anti-Submarine Warfare Range, Shore Bombardment Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise, in-water explosives (E4) **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike, military expended material strike (projectile, target fragments) **Entanglement:** None **Ingestion:** Projectiles, casings, and target fragments
Detailed Military Expended Material Information	Small-caliber projectiles Casings Target fragments
Assumptions used for Analysis	*The specific areas are where activities typically occur. They can occur throughout the full area listed in Table 2.8-1 of Chapter 2. Majority of events will occur proximate to naval stations. Events will occur relatively near shore due to short range of boats and safety concerns. Events mostly occur within three nm of the shoreline, but can occur further from shore.

A.1.4.6 Gunnery Exercise Surface-to-Surface (Boat) – Medium Caliber

Activity Name	Activity Description	
Anti-Surface Warfare		
Gunnery Exercise Surface-to-Surface (Boat) – Medium Caliber	Small boat crews engage surface targets with medium-caliber weapons.	
Long Description	Boat crews engage surface targets with medium-caliber weapons. Boat crews may use high or low speeds to approach and engage targets simulating other boats, floating mines, or near shore land targets with medium-caliber (up to and including 40 mm) weapons. A commonly used target is an empty steel drum. A number of different types of boats are used depending on the unit using the boat and their mission. Boats are most used to protect ships in harbors and high value units, such as: aircraft carriers, nuclear submarines, liquid natural gas tankers, etc., while entering and leaving ports, as well as to conduct riverine operations, and various naval special warfare operations. The boats used by these units include: small unit river craft, combat rubber raiding craft, rigid-hull inflatable boats, patrol craft, and many other versions of these types of boats. These boats use inboard or outboard, diesel or gasoline engines with either propeller or water jet propulsion.	
Information Typical to the Event	**Platform:** Boats **Systems:** None **Ordnance/Munitions:** Medium caliber (up to and including 40 mm [explosive and non-explosive]) **Targets:** Recoverable or expendable floating target (stationary or towed) **Duration:** 1 hour	**Location:** Hawaii Range Complex: Warning Area 188 Southern California Range Complex: Warning Area-291, Shore Bombardment Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E1, E2), vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (projectile, target fragments), vessel and in-water device strike **Entanglement:** None **Ingestion:** Projectiles and target fragments, projectiles, casings	
Detailed Military Expended Material Information	Projectiles and target fragments, projectiles, casings One target used per event, typically a stationary target such as a 50-gallon (189 liter) steel drum	
Assumptions used for Analysis	Assume all Alternatives 1 and 2 events include the use of some explosive rounds Most events will involve boat crews training with MK 203 40 mm grenade launcher Most events will occur proximate to Navy homeports (San Diego)	

A.1.4.7 Missile Exercise Surface-to-Surface

Activity Name	Activity Description	
Anti-Surface Warfare		
Missile Exercise (Surface-to-Surface)	Surface vessel crews defend against surface threats (vessels or boats) with missiles.	
Long Description	Surface vessels launch missiles at surface maritime targets with the goal of destroying or disabling enemy vessels or boats. After detecting and confirming a surface threat, the vessel will fire precision guided anti-surface missile. Events with destroyers and cruisers will involve long range (over the horizon) harpoon (or similar) anti surface missiles. While past harpoon events occurred during sinking exercises, requirement exists for non sinking exercise events to certify ship crews. If a sinking exercise target is unavailable, towed sled would likely be used. Events with Littoral Combat Ships will involve shorter range anti-surface missiles. Events with Littoral Combat Ships would be to certify vessel's crew to defend against "close-in" (less than 10 miles) surface threats. These exercises are live fire, that is, a missile is fired down range. Anti-surface missiles could be equipped with either high explosive or non-explosive warheads.	
Information Typical to the Event	**Platform:** Surface vessels (e.g., CG, DDG, LCS) **Systems:** None **Ordnance/Munitions:** Anti-surface missiles, Harpoons (explosive and non-explosive) **Targets:** High speed surface targets, towed sleds **Duration:** 2 to 4 hours	**Location:** Hawaii Range Complex: Warning Area 188 Southern California Range Complex: Warning Area 291
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E10), vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike; military expended material strike (missiles and target fragments) **Entanglement:** None **Ingestion:** Missile fragments, target fragments	
Detailed Military Expended Material Information	Missiles, missile fragments Target fragments	
Assumptions used for Analysis	Assume one missile and one target per event While missile could explode above water's surface after contacting target, analysis assumes all warheads explode at or just below surface	

A.1.4.8 Gunnery Exercise Air-to-Surface – Small Caliber

Activity Name	Activity Description	
Anti-Surface Warfare		
Gunnery Exercise (Air-to-Surface) – Small Caliber	Helicopter aircrews, including embarked personnel, use small-caliber guns to engage surface targets.	
Long Description	Helicopters, carrying several air crewmen, fly a racetrack pattern around an at-sea target. Each gunner will engage the target with small-caliber weapons. Targets range from a smoke float, an empty steel drum, to high speed remote controlled boats and jet-skis.	
Information Typical to the Event	**Platform:** Helicopter **Systems:** None **Ordnance/Munitions:** Small caliber (non-explosive) **Targets:** Recoverable or expendable floating target (stationary or towed), remote high speed target **Duration:** 1 hour	**Location:** Hawaii Range Complex: Warning Areas 188, 191, 192, 193, 194, 196, Mela South Southern California Range Complex: Southern California Anti-Submarine Warfare Range, (T-3, T-4, T-5, Mine Training Range-2), Warning Area-291, Shore Bombardment Area,
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** In-water device strike, military expended material strike (projectiles), aircraft strike (birds only) **Entanglement:** None **Ingestion:** Projectiles, target fragments, casings	
Detailed Military Expended Material Information	Projectiles, Target fragments, casings One target used per event. Expendable smoke float (50 percent), stationary target (45 percent), or remote controlled target (5 percent)	
Assumptions used for Analysis	Most events will occur proximate to Naval Stations where MH-60 helicopters are home based and target services are available

A.1.4.10 Missile Exercise Air-to-Surface – Rocket

Activity Name	Activity Description	
Anti-Surface Warfare		
Missile Exercise (Air-to-Surface) Rocket	Fixed-wing and helicopter aircrew fire both precision-guided and unguided rockets against surface targets.	
Long Description	Fighter, maritime patrol aircraft, and helicopter aircrews fire both precision-guided and unguided rockets against surface targets. Aircraft involved may be unmanned. Fixed-wing aircraft (fighters or maritime patrol aircraft) approach an at-sea surface target from high altitude and launch high explosive non-explosive precision guided rockets. Helicopters designate an at-sea surface target with a laser or optics for precision guided high explosive or non-explosive practice munitions rockets.	
Information Typical to the Event	**Platform:** Fixed-wing (e.g., F/A-18, F-35, P-8, P-3, unmanned aerial vehicle) Helicopters (MH-60, Fire Scout) **Systems:** None **Ordnance/Munitions:** Rockets (non-explosive for No Action Alternative; high explosive for Alternatives 1 and 2) **Targets:** Recoverable floating target (stationary or towed) **Duration:** 1 hour	**Location:** Hawaii Range Complex: Warning Area 188 Southern California Range Complex: Warning Area 291, Southern California Anti-Submarine Warfare Range, Fleet Training Area Hot, Missile Ranges
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E5), aircraft noise **Energy:** target Laser **Physical Disturbance and Strike:** In-water device strike, military expended material strike (rocket, rocket and target fragments) **Entanglement:** None **Ingestion:** Target fragments, rocket fragments	
Detailed Military Expended Material Information	Rockets, rocket fragments Target fragments	
Assumptions used for Analysis	Assume all explosive rockets detonate in water. Assume all rockets under the No Action Alternative are non-explosive. Assume all rockets under Alternatives 1 and 2 are explosive Rockets may be used in conjunction with force protection events	

A.1.4.11 Missile Exercise Air-to-Surface

Activity Name	Activity Description	
Anti-Surface Warfare		
Missile Exercise (Air-to-Surface)	Fixed-wing and helicopter aircrew fire precision-guided missiles against surface targets.	
Long Description	Fighter, maritime patrol aircraft, and helicopter aircrews fire both precision-guided missiles and unguided rockets against surface targets. Aircraft involved may be unmanned. Fixed-wing aircraft (fighters or maritime patrol aircraft) approach an at-sea surface target from high altitude, and launch high explosive precision guided missiles. Helicopters designate an at-sea surface target with a laser or optics for a precision guided high explosive or non-explosive missile. Helicopter launched missiles typically pass through the target's "sail," and detonate at, or just below, the water's surface.	
Information Typical to the Event	**Platform:** Fixed-wing aircraft and helicopters **Systems:** None **Ordnance/Munitions:** Missiles (high explosive or non-explosive) **Targets:** Recoverable floating target (stationary or towed), Remotely operated target **Duration:** 2 hours	**Location:** Hawaii Range Complex: Warning Area-188 Southern California range Complex: Shore Bombardment Area, Southern California Anti-Submarine Warfare Range (Laser Training Range 1/2)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E6, E8), aircraft noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** In-water device strike, Military expended material strike (missile fragment), Aircraft strike (birds only) **Entanglement:** None **Ingestion:** Missile fragments, target fragments	
Detailed Military Expended Material Information	Missile fragments Target fragments	
Assumptions used for Analysis	Assume one missile and one target per event While missile could explode above water's surface after contacting target, analysis assumes all warheads explode at or just below surface	

A.1.4.12 Bombing Exercise Air-to-Surface

Activity Name	Activity Description	
Anti-Surface Warfare		
Bombing Exercise (Air-to-Surface)	Fixed-wing aircrews deliver bombs against surface targets.	
Long Description	Fixed-wing aircrews deliver bombs against surface targets. Fixed-wing aircraft conduct a bombing exercise against stationary floating targets (e.g.: MK-58 smoke buoy). An aircraft clears the area, deploys a smoke buoy or other floating target, and then delivers high explosive or non-explosive practice munitions bomb(s) on the target. A range boat may be used to deploy targets for an aircraft to attack. Exercises for strike fighters typically involve a flight of two aircraft delivering unguided or guided munitions that may be either high explosive or non-explosive practice munitions. The following munitions may be employed by strike fighter aircraft in the course of the bombing exercise: Unguided munitions: Non explosive Sub Scale Bombs (MK-76 and BDU-45); explosive and non-explosive general purpose bombs (MK-80 series); MK-20 Cluster Bomb (explosive, non-explosive). Precision-guided munitions: Laser-guided bombs (explosive, non-explosive); Laser-guided Training Rounds (non-explosive); Joint Direct Attack Munition (explosive, non-explosive).	
Information Typical to the Event	**Platform:** Fixed-wing (e.g., F/A-18, F-35, P-8, P-3) **Systems:** None **Ordnance/Munitions:** Bombs (e.g., MK-76, BDU-45, MK-80 series, MK-20 [high explosive, non-explosive]) **Targets:** Expendable floating target (e.g., smoke float) **Duration:** 1 hour	**Location:** Hawaii Range Complex: Hawaii Operating Area Southern California Range Complex: Southern California Anti-Submarine Warfare Range T-3, T-4, T-5, Mine Training Range-2, Shore Bombardment Area HSTT Transit Corridor
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E8, E9, E10, E12), aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive bomb), aircraft strike (birds only) **Entanglement:** None **Ingestion:** Bomb fragments, target fragments, smoke floats	
Detailed Military Expended Material Information	Bomb fragments Target fragments Smoke floats	
Assumptions used for Analysis	Approximately 90 percent of non-explosive bombs are the sub-scale bombs such as the MK-76 and BDU-48	

A.1.4.13 Laser Targeting

Activity Name	**Activity Description**	
Anti-Surface Warfare		
Laser Targeting	Fixed-winged, helicopter, and vessel crews illuminate enemy targets with lasers.	
Long Description	Fixed-winged and helicopter aircrew and shipboard personnel illuminate enemy targets with lasers for engagement by aircraft with laser guided bombs or missiles. This exercise may be conducted alone or in conjunction with other events utilizing precision guided munitions, such as anti surface missiles and guided rockets. Events where weapons are fired are addressed in the appropriate activity (e.g. air-to-surface missile exercise). Lower powered lasers may also be used as non-lethal deterrents during maritime security operations (force protection).	
Information Typical to the Event	**Platform:** Vessels, fixed-wing aircraft, rotary-wing aircraft **Systems:** None **Ordnance/Munitions:** None unless conducted with other event (e.g., missile exercise) **Targets:** Land targets, Remote-controlled surface targets **Duration:** 1 to 2 hours	**Location:** Hawaii Range Complex: Warning Area 188 Southern California Range Complex: Southern California Anti-Submarine Warfare Range, Shore Bombardment Area, (Laser Training Range 1/2)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** In-air low energy lasers **Physical Disturbance and Strike:** Vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	Laser targeting for missile/rocket guidance will occur in areas where these events also occur Use of lasers as force protection non-lethal deterrents will primarily occur proximate to Navy homeports Land target impacts are not analyzed within this EIS/OEIS	

A.1.4.14 Sinking Exercise

Activity Name	Activity Description	
Anti-Surface Warfare		
Sinking Exercise	Aircraft, vessel, and submarine crews deliver ordnance on a seaborne target, usually a deactivated ship, which is deliberately sunk using multiple weapon systems.	
Long Description	Ship personnel and aircrew deliver high explosive ordnance on a seaborne target, (large deactivated vessel), which is deliberately sunk using multiple weapon systems. A sinking exercise is typically conducted by aircraft, surface vessels, and submarines in order to take advantage of the ability to fire high explosive ordnance on a full size ship target. The target is typically a decommissioned ship made environmentally safe for sinking according to U.S. Environmental Protection Agency standards. The location is greater than 50 nautical miles from shore and in water depths greater than 6,000 ft. Vessel, aircraft, and submarine crews attack with coordinated tactics and deliver live high explosive ordnance to sink the target. Non-explosive practice munitions may be used during the initial stages to extend target life. Typically, the exercise lasts for four to eight hours and possibly over 1 to 2 days, however it is unpredictable, and ultimately ends when the ship sinks.	
Information Typical to the Event	**Platform:** Vessels, Aircraft, Submarines **Systems:** None **Ordnance/Munitions:** Potentially all available (explosive and non-explosive), torpedo **Targets:** Decommissioned ship made environmentally safe for sinking (according to U.S. Environmental Protection Agency standards) **Duration:** 4 to 8 hours, possibly over 1 to 2 days (unpredictable and ultimately ends when the ship sinks)	**Location:** Hawaii Range Complex: Hawaii Operating Area Southern California Range Complex: Warning Area 291
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E3, E5, E9, E10, E11, E12), vessel noise, aircraft noise, weapons firing noise **Energy:** In-air low energy lasers **Physical Disturbance and Strike:** Military expended material strike (non-explosive projectiles, projectile fragments), vessel strike, aircraft strike (birds only) **Entanglement:** Guidance wires **Ingestion:** Munitions fragments, casings	

Activity Name	**Activity Description**
Anti-Surface Warfare	
Sinking Exercise	Aircraft, vessel, and submarine crews deliver ordnance on a seaborne target, usually a deactivated ship, which is deliberately sunk using multiple weapon systems.
Detailed Military Expended Material Information	Munitions fragments, non-explosive ordnance, guidance wires, casings Ship hulk (decommissioned ship made environmentally safe for sinking according to U.S. Environmental Protection Agency standards)
Assumptions used for Analysis	Greater than 50 nautical miles from shore and in water depths greater than 6,000 ft. The participants and assets could include: • One full-size target ship hulk • One to five CG, DDG, or FFG ships • One to 10 F/A-18, or MPA aircraft • One or two HH-60H, MH-60R/S, or SH-60B helicopters • One E-2 aircraft for Command and Control • One submarine • One to three range clearance aircraft. • Two to four Harpoon surface-to-surface or air-to-surface missiles • Two to eight air-to-surface Maverick missiles • Two to sixteen MK-82 general purpose bombs • Two to four Hellfire air-to-surface missiles • One or two SLAM-ER air-to-surface missiles • Two to six AGM-88 High-speed Anti-Radiation Missiles (HARM) • Fifty to 500 rounds 5-inch and 76 mm gun • One to two MK-48 heavyweight submarine-launched torpedo • Two Thousand medium-caliber rounds • Assume 2 guidance wires expended per event

A.1.5 Anti-Submarine Warfare Training

Anti-submarine warfare involves helicopter and maritime patrol aircraft, ships, and submarines. These units operate alone or in combination, in operations to locate, track, and neutralize submarines. Controlling the undersea battlespace is a unique naval capability and a vital aspect of sea control. Undersea battlespace dominance requires proficiency in anti-submarine warfare. Every deploying strike group and individual surface combatant must possess this capability.

Various types of active and passive sonar are used by the Navy to determine water depth, locate mines, and identify, track, and target submarines. Passive sonar "listens" for sound waves by using underwater microphones, called hydrophones, which receive, amplify, and process underwater sounds. No sound is introduced into the water when using passive sonar. Passive sonar can indicate the presence, character, and movement of submarines. However, passive sonar provides only a bearing (direction) to a sound-emitting source; it does not provide an accurate range (distance) to the source. Active sonar is needed to locate objects because active sonar provides both bearing and range to the detected contact (such as an enemy submarine).

Active sonar transmits pulses of sound that travel through the water, reflect off objects and return to a receiver. By knowing the speed of sound in water and the time taken for the sound wave to travel to the object and back, active sonar systems can quickly calculate direction and distance from the sonar platform to the underwater object. Active sonar is necessary to detect and track submarines that do not emit detectable levels of noise, either because of noise reduction design features or because of the presence of overwhelming background noise levels.

The Navy's anti-submarine warfare training plan, including the use of active sonar in at-sea training scenarios, includes multiple levels of training. Individual-level anti-submarine warfare training addresses basic skills such as detection and classification of contacts, distinguishing discrete acoustic signatures including those of ships, submarines, and marine life, and identifying the characteristics, functions, and effects of controlled jamming and evasion devices.

More advanced, integrated anti-submarine warfare training exercises involving active sonar is conducted in coordinated, at-sea operations during multi-dimensional training events involving submarines, ships, aircraft, and helicopters. This training integrates the full anti-submarine warfare continuum from detecting and tracking a submarine to attacking a target using either exercise torpedoes or simulated weapons. Training events include detection and tracking exercises against "enemy" submarine contacts; torpedo employment exercises against the target; and exercising command and control tasks in a multi-dimensional battlespace.

A.1.5.1 Tracking Exercise/Torpedo Exercise – Submarine

Activity Name	Activity Description	
Anti-Submarine Warfare		
Tracking Exercise/Torpedo Exercise – Submarine	Submarine crews search, track, and detect submarines. Exercise torpedoes may be used during this event.	
Long Description	The anti-submarine warfare tracking/torpedo exercise-submarine involves a submarine employing hull mounted and/or towed array sonar against an anti-submarine warfare target such as a MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, a MK-30, or another submarine. During this event, passive sonar is used almost exclusively; active sonar use is restricted because it would reveal the tracking submarine’s presence to the target submarine. The preferred type of range for this exercise is an instrumented underwater training range with the capability to track the locations of submarines and targets, to enhance the after-action learning component of the training. Three such ranges exist in the Hawaii-Southern California Training and Test (HSTT) Study Area; the Barking Sands Tactical Underwater Range and Barking Sands Underwater Range Extension west of Kauai under the control of the Pacific Missile Range Facility, and the Southern California Anti-submarine Warfare Range west of San Clemente Island. This exercise may involve a single submarine, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft, ships, and submarines, including a major range event. The tracking exercise becomes a torpedo exercise when the submarine launches an exercise torpedo. Torpedo exercises typically have a range support vessel (surface craft or a support helicopter) to launch and recover targets and torpedoes. The exercise torpedo is recovered by helicopter or small craft. The preferred range for this exercise is an instrumented underwater range, but it may be conducted in other Operating Areas (OPAREAs) depending on training requirements and available assets.	
Information Typical to the Event	**Platform:** One or more submarines, support craft **Systems:** Mid-frequency (primarily passive) and high-frequency sonar **Ordnance/Munitions:** Exercise torpedoes (non-explosive torpedo exercise only) **Targets:** Submarine MK-30, MK-39 Expendable Mobile Anti-Submarine Warfare Training Target **Duration:** 8 hours	**Location:** Hawaii Operating Area, (including Barking Sands Underwater Range Extension; Barking Sands Tactical Underwater Range; Shallow Water Training Range, North Maui Submarine Operating Area Southern California Operating Area, Southern California Anti-submarine Warfare Range, Shallow Water Training Range (Offshore/Nearshore) HSTT Transit Corridor

Activity Name	**Activity Description**
Anti-Submarine Warfare	
Tracking Exercise/Torpedo Exercise – Submarine	Submarine crews search, track, and detect submarines. Exercise torpedoes may be used during this event.
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency acoustic countermeasure (ASW4), hull-mounted sonar (MF3), high-frequency sonar (HF1, HF3, HF8), heavyweight torpedo (TORP2), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike, aircraft strike (birds only), and military expended material strike (torpedo accessories) **Entanglement:** Guidance wires **Ingestion:** None
Detailed Military Expended Material Information	Torpedo accessories (guidance wires, ballast weights, flex tubing) Expended countermeasures
Assumptions used for Analysis	Tracking exercise can occur in all locations, torpedo exercise will not occur in Hawaii-Southern California Training and Test Transit Corridor. Torpedoes are recovered Guidance wire has a low breaking strength and breaks easily. Weights and flex tubing sink rapidly Other Hawaii-Southern California Training and Test area events typically refer to those events that occur while vessels are in transit (e.g., HSTT Transit Corridor)

A.1.5.2 Tracking Exercise/Torpedo Exercise – Surface

Activity Name	Activity Description	
Anti-Submarine Warfare		
Tracking Exercise/Torpedo Exercise – Surface	Surface vessel crews search, track, and detect submarines. Exercise torpedoes may be used during this event.	
Long Description	Surface ships search, detect, and track threat submarines to determine a firing position to launch a torpedo and attack the submarine. A surface vessel operates at slow speeds while employing hull mounted and/or towed array sonar. Passive or active sonar is employed depending on the type of threat submarine, the tactical situation, and environmental conditions. The target for this exercise is a MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, MK-30 Recoverable Training Target, or live submarine. Tracking exercise/torpedo exercise – surface could occur anywhere throughout the Hawaii-Southern California Training and Test Study Area. This exercise may involve a single ship, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft, ships, and submarines, including a major range event. The tracking exercise becomes a torpedo exercise when the ship launches an exercise torpedo. The exercise torpedo is recovered by helicopter or small craft. The preferred range for this exercise is an instrumented underwater range, but it may be conducted in other operating areas depending on training requirements and available assets.	
Information Typical to the Event	**Platform:** One or more surface vessels, rotary-wing aircraft **Systems:** Mid-frequency sonar, Nixie (countermeasure system) **Ordnance/Munitions:** Exercise torpedoes (non-explosive only) **Targets:** Submarine MK-30 or MK-39 Expendable Mobile Anti-Submarine Warfare Training Target **Duration:** 2 to 4 hours	**Location:** Hawaii Range Complex: Hawaii Operating Area (including Barking Sands Underwater Range Extension; Barking Sands Tactical Underwater Range; Shallow Water Training Range Southern California Range Complex: Southern California Operating Areas, Point Mugu Sea Range (overlap area only)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (ASW1), mid-frequency acoustic countermeasure (ASW3, ASW4), high-frequency sonar (HF1), hull mounted sonar (MF1, MF2, MF3, MF11), helicopter dipping sonar (MF4), high duty cycle variable depth sonar (MF12), lightweight torpedo (TORP1), vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike; military expended material strike **Entanglement:** None **Ingestion:** Target fragments	
Detailed Military Expended Material Information	MK-39 Expendable Mobile Anti-Submarine Warfare Training Target Torpedo accessories (ballast weights) from exercise torpedoes	
Assumptions used for Analysis	Tracking exercise can occur in all locations, torpedo exercise will <u>not</u> occur in Point Mugu Sea Range portion of Southern California. Submarines may provide service as the target except for torpedo exercise events. Torpedoes are recovered Other Hawaii-Southern California Training and Test area events typically refer to those events that occur while vessels are in transit	

A.1.5.3 Tracking Exercise/Torpedo Exercise – Helicopter

Activity Name	**Activity Description**
Anti-Submarine Warfare	
Tracking Exercise/ Torpedo Exercise-Helicopter	Helicopter crews search, track, and detect submarines. Recoverable air launched torpedoes may be employed against submarine targets.
Long Description	This exercise involves helicopters using sonobuoys and dipping sonar to search for, detect, classify, localize, and track a simulated threat submarine with the goal of determining a firing solution that could be used to launch a torpedo and destroy the submarine. Sonobuoys are typically employed by a helicopter operating at altitudes below 3,000 ft. (914 m). Both passive and active sonobuoys are employed. The dipping sonar is employed from an altitude of about 50 ft. (15 m) after the search area has been narrowed based on the sonobuoy search. Both passive and active sonar are employed. The anti-submarine warfare target used for this exercise will likely be an Expendable Mobile Anti-submarine Warfare Training Target, a MK-30 recoverable exercise target or a live submarine if available. This exercise may involve a single aircraft, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and vessels, including a major range event. The tracking exercise becomes a torpedo exercise when the helicopter launches an exercise torpedo. The exercise torpedo is recovered by a special recovery helicopter or small craft. The preferred range for this exercise is an instrumented range, but it may be conducted in other operating areas depending on training requirements and available assets.
Information Typical to the Event	**Platform:** Helicopters, surface vessels **Systems:** Mid-frequency helicopter dipping sonar, sonobuoys **Ordnance/Munitions:** Exercise torpedoes (non-explosive) **Targets: MK-39** Expendable Mobile Anti-Submarine Warfare Training Target or MK-30 recoverable target, or live submarine **Duration:** 2 to 4 hours **Location:** Hawaii Range Complex: Hawaii Operating Area (including Barking Sands Underwater Range Extension; Barking Sands Tactical Underwater Range; Shallow Water Training Range Southern California Range Complex: Southern California Anti-submarine Warfare Range, Shallow Water Training Range, San Clemente Island Underwater Range HSTT Transit Corridor
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Helicopter dipping sonar (MF4), sonobuoy (MF5), mid-frequency acoustic countermeasure (ASW4), lightweight torpedo (TORP1]), aircraft noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, aircraft strike (birds only), vessel and in-water device strike **Entanglement:** Parachutes **Ingestion:** Parachutes
Detailed Military Expended Material Information	One Expendable Mobile Anti-Submarine Warfare Training Target If target is air-dropped, one parachute per target Up to 20 sonobuoys per event (one parachute for each sonobuoy) Torpedo accessories (ballast weights, parachutes)
Assumptions used for Analysis	Tracking exercise can occur in all locations, torpedo exercise will not occur in Hawaii-Southern California Training and Testing Transit Corridor or Point Mugu Sea Range portion of Southern California. Submarines may provide service as the target.

A.1.5.4 Tracking Exercise/Torpedo Exercise – Maritime Patrol Aircraft

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>

A.1.5.6 Kilo Dip – Helicopter

Activity Name	Activity Description	
Anti-Submarine Warfare		
Kilo Dip-Helicopter	Helicopter crews briefly deploy their dipping acoustic sources to ensure the system's operational status.	
Long Description	This brief exercise involves an MH-60 helicopter and its dipping sonar. The helicopter transits to one of the Helicopter Offshore Training Areas located off the coast of southern California. There, the helicopter lowers its dipping sonar into the ocean and transmits the sonar briefly to ensure that the sonar system is operating correctly.	
Information Typical to the Event	**Platform:** MH-60 helicopter **Systems:** Mid-frequency helicopter dipping sonar **Ordnance/Munitions:** None **Targets:** None **Duration:** 20 minutes	**Location:** Southern California Range Complex: Helicopter Offshore Training Areas
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency helicopter dipping sonar (e.g., MF4) **Energy:** None **Physical Disturbance and Strike:** Helicopter strike (birds only) **Entanglement:** None **Ingestion:** None

A.1.6 ELECTRONIC WARFARE TRAINING

Electronic warfare is the mission area of naval warfare that aims to control use of the electromagnetic spectrum and to deny its use by an adversary. Typical electronic warfare activities include threat avoidance training, signals analysis for intelligence purposes, and use of airborne and surface electronic jamming devices to defeat tracking systems.

A.1.6.1 Electronic Warfare Operations

Activity Name	**Activity Description**
Electronic Warfare	
Electronic Warfare Operations	Aircraft, surface vessel, and submarine personnel attempt to control portions of the electromagnetic spectrum used by enemy systems to degrade or deny the enemy's ability to take defensive actions.
Long Description	Aircraft, surface ship, and submarine personnel attempt to control critical portions of the electromagnetic spectrum used by enemy systems to degrade or deny their ability to defend its forces from attack or recognize an emerging threat early enough to take defensive actions. Electronic Warfare Operations can be active or passive, offensive or defensive. Fixed-wing aircraft employ active jamming and deception against enemy search radars to mask the friendly inbound strike aircraft mission. Surface vessels and submarines detect and evaluate enemy electronic signals from enemy aircraft or missile radars, evaluate courses of action concerning the use of passive or active countermeasures, then use vessel maneuvers and either chaff, flares, active electronic countermeasures, or a combination of them to defeat the threat.
Information Typical to the Event	**Platform:** Fixed and rotary-wing aircraft, surface combatant vessels **Systems:** None **Ordnance/Munitions:** None **Targets:** Land based fixed/mobile threat emitters **Duration:** 1 to 2 hours **Location:** Hawaii Operating Area Southern California Waters (Electronic Warfare Range)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None
Detailed Military Expended Material Information	None
Assumptions used for Analysis	All chaff and flares involved in this event are covered under chaff exercise and flare exercises, respectively

A.1.6.2 Counter Targeting Flare Exercise

Activity Name	Activity Description	
Electronic Warfare		
Counter Targeting-Flare Exercise	Fixed-winged aircraft and helicopters defend against an attack by deploying flares to disrupt threat infrared missile guidance systems.	
Long Description	Train fixed-winged aircraft and helicopter crews to deploy flares to disrupt threat infrared missile guidance systems to defend against an attack. Aircraft detect electronic targeting signals from threat radars or missiles or a threat missile plume when it is launched; dispense flares; and immediately maneuver to defeat the threat. This exercise trains aircraft personnel in the use of defensive flares designed to confuse infrared sensors or infrared homing missiles, thereby causing the sensor or missile to lock onto the flares instead of the real aircraft. Typically an aircraft will expend five flares in an exercise while operating above 3,000 ft. Flare exercises are often conducted with chaff exercises, rather than as a stand-alone exercise. Pyrotechnics are used on the range to simulate missile firings.	
Information Typical to the Event	**Platform:** Fixed-wing aircraft, rotary-wing aircraft **Systems:** None **Ordnance/Munitions:** Flares and pyrotechnics **Targets:** None **Duration:** 1 to 2 hours	**Location:** Hawaii Operating Area Southern California Waters (Electronic Warfare Range)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft Noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only) **Entanglement:** None **Ingestion:** Expended components of flares (pistons)	
Detailed Military Expended Material Information	Flares and residuals from pyrotechnics	
Assumptions used for Analysis	Approximately five flares per aircraft	

A.1.6.3 Counter Targeting Chaff Exercise – Ship

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Electronic Warfare</td></tr>
<tr><td>Counter Targeting Chaff Exercise – Ship</td><td colspan="2">Surface vessel crews defend against an attack by deploying chaff, a radar reflective material, which disrupt threat targeting and missile guidance radars.</td></tr>
<tr><td>Long Description</td><td colspan="2">Surface vessel crews deploy chaff to disrupt threat targeting and missile guidance radars to defend against an attack.
Surface vessel crews detect electronic targeting signals from threat radars or missiles, dispense chaff, and immediately maneuver to defeat the threat. The chaff cloud deceives the inbound missile, and the vessel clears away from the threat.
Chaff is a radar reflector material made of thin, narrow, metallic strips cut in various lengths to elicit frequency responses, which deceive enemy radars. Chaff is employed create a target from the chaff that will lure enemy radar and weapons system away from the actual friendly platform.
Ships may also train with advanced countermeasure systems, such as the MK 53 Decoy Launching System (Nulka).</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Surface vessels

A.1.6.4 Counter Targeting Chaff Exercise – Aircraft

Activity Name	**Activity Description**	
Electronic Warfare		
Counter Targeting Chaff Exercise – Aircraft	Fixed-winged aircraft and helicopter crews defend against an attack by deploying chaff, a radar reflective material, which disrupt threat targeting and missile guidance radars.	
Long Description	Fixed-winged aircraft and helicopter crews deploy chaff to disrupt threat targeting and missile guidance radars and to defend against an attack. Fixed-winged aircraft and helicopter crews detect electronic targeting signals from threat radars or missiles, dispense chaff, and immediately maneuver to defeat the threat. The chaff cloud deceives the inbound missile and the aircraft clears away from the threat. Chaff is a radar reflector material made of thin, narrow, metallic strips cut in various lengths used to lure an enemy radar and weapons system away from the actual friendly platform.	
Information Typical to the Event	**Platform:** Fixed-wing aircraft, rotary-wing aircraft **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** 1.5 hours	**Location:** Hawaii Operating Area Southern California Waters (Electronic Warfare Range)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only) **Entanglement:** None **Ingestion:** Expended components of chaff (end caps, pistons, chaff)	
Detailed Military Expended Material Information	Chaff cartridges Plastic end caps Pistons	
Assumptions used for Analysis	Chaff is usually expended while conducting other training activities, such as air combat maneuvering	

A.1.7 MINE WARFARE TRAINING

Mine warfare training is the naval warfare area involving the detection, avoidance, and neutralization of mines to protect Navy ships and submarines, and offensive mine laying in naval operations. A naval mine is a self-contained explosive device placed in water to destroy ships or submarines. Naval mines are deposited and left in place until triggered by the approach of, or a contact with an enemy ship, or are destroyed or removed. Naval mines can be laid by purpose-built minelayers, other ships, submarines, or airplanes. Mine warfare training includes mine countermeasures exercises and mine laying exercises.

A.1.7.1 Mine Countermeasure Exercise – Ship Sonar

Activity Name	Activity Description	
Mine Warfare		
Mine Countermeasure Exercise – Ship Sonar	Surface vessel crews detect and avoid mines while navigating restricted areas or channels using active sonar.	
Long Description	Surface vessel crews detect and avoid mines or other underwater hazardous objects while navigating restricted areas or channels using active sonar. Littoral Combat Ship utilizes unmanned surface vehicles and remotely operated vehicles to tow mine detection (hunting) equipment. Systems will operate from shallow zone greater than 40 ft. to deep water. Events could be embedded in major training events.	
Information Typical to the Event	**Platform:** Surface combatant vessels (e.g., Littoral Combat Ships), unmanned surface vehicles **Systems:** AN/AQS-20, Remote Mine hunting System, AN/AQS-24, SQS-53 and SQS-56 **Ordnance/Munitions:** None **Targets:** Minefields, Temporary placed mine (training to deploy or operate gear) **Duration:** 1.5 to 4 hours	**Location:** Hawaii Range Complex: Hawaii Operating Area, Kingfisher, Shallow-water Minefield Sonar Training Area Southern California Range Complex: Kingfisher, Shallow Water Training Range -Offshore or Shallow Water Minefield
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Sonar and other acoustic sources (MF1K, MF2K HF4) vessel noise **Energy:** Sub-surface laser imaging **Physical Disturbance and Strike:** Vessel and in-water device strike, seafloor device strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None anticipated Temporary placed mines will be recovered	
Assumptions used for Analysis	No explosives used Constraints: Assume system will be operated in areas free of obstructions, and will be towed well above the seafloor. Towed system will be operated in a manner to avoid entanglement and damage. Events will take place in water depths 40 ft. and greater Existing placed mineshapes to be used. Potential for temporary placement of mineshapes	

A.1.7.2 Mine Countermeasure Exercise – Surface

Activity Name	Activity Description	
Mine Warfare		
Mine Countermeasure Exercise – Surface	Mine countermeasure ship crews detect, locate, identify, and avoid mines while navigating restricted areas or channels, such as while entering or leaving port.	
Long Description	This event trains mine countermeasure ship crews to detect mines for future neutralization or to alert other ships. Training utilizes simulated minefields constructed of moored or bottom mines, or instrumented mines that can record effectiveness of mine detection efforts. Ships will accurately fix their position while navigating through the restricted mine threat area at slow speeds of about 5 to 10 knots or less, while using active sonar to search the area ahead of the ship for moored mines or other hazards of navigation.	
Information Typical to the Event	**Platform:** Surface combatant vessel **Systems:** Sonar (e.g., AN/SQQ-32) **Ordnance/Munitions:** None **Targets:** None **Duration:** The exercise may last as long as 15 hours	**Location:** Southern California Range Complex: Kingfisher, Shallow Water Training Range-Offshore, Shallow Water Minefield, Silver Strand Training Complex, Camp Pendleton Amphibious Assault Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mine detection sonar (HF4), vessel noise **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.1.7.3 Mine Neutralization – Explosive Ordnance Disposal

Activity Name	Activity Description	
Mine Warfare		
Mine Neutralization – Explosive Ordnance Disposal	Personnel disable threat mines. Explosive charges are used.	
Long Description	Navy divers, typically explosive ordnance disposal personnel, disable threat mines with explosive charges to create a safe channel for friendly vessels to transit. Personnel detect, identify, evaluate, and neutralize mines in the water with an explosive device and may involve detonation of one or more explosive charges from 10 to 60 pounds of TNT equivalent. These operations are normally conducted during daylight hours for safety reasons. Time delay fuses may be used for these events.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft, small boats **Systems:** None **Ordnance/Munitions:** Underwater detonation charges **Targets:** Minefields **Duration:** Up to 4 hours	**Location:** Hawaii Range Complex: Puuloa Underwater Range, Marine Corps Base Hawaii, Marine Corps Training Area Bellows, Barbers Point Underwater Range, Naval Inactive Ship Maintenance Facility, Lima Landing, Ewa Training Minefield Southern California Range Complex: Northwest Harbor, Horse Beach Cove, Southern California Anti-submarine Warfare Range, Shallow Water Training Range, in Special Warfare Training Area, Offshore waters Silver Strand Training Complex: Boat Lanes 1–14
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E1, E4, E5, E6, E7, E8), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, aircraft strike (birds only), seafloor device strike **Entanglement:** None **Ingestion:** Target fragments	
Detailed Military Expended Material Information	Target fragments; mooring blocks	
Assumptions used for Analysis	Time delayed fuses may be used (up to 15 minutes). Charge placed anywhere in water column, including bottom Mine shapes will be recovered	

A.1.7.4 Mine Countermeasure – Towed Mine Neutralization

Activity Name	Activity Description	
Mine Warfare		
Mine Countermeasures – Towed Mine Neutralization	Helicopter aircrews employ towed mine neutralization systems (e.g. Organic Airborne and Surface Influence Sweep [OASIS], MK-103/104/105)	
Long Description	Naval helicopters use towed devices to clear minefields by triggering mines that sense and explode when they detect ships/submarines by engine/propeller sounds or magnetic (steel construction) signature. Towed devices can also employ cable cutters to detach floating moored mines. Training will either be conducted against non-explosive training mineshapes, or, without any mineshapes. A high degree of pilot skill is required in deploying devices, safely towing them at relatively low speeds and altitudes, and then recovering devices. Devices used include the following: Organic Airborne and Surface Influence Sweep (OASIS). The Organic Airborne and Surface Influence Sweep is a towed device that imitates the magnetic and acoustic signatures of naval ships and submarines. MK 105 sled: the MK 105 sled, similar to the Organic Airborne and Surface Influence Sweep, creates a magnetic field used to trigger mines. The MK 105 sled can also be used in conjunction with the MK 103 cable cutter system and the MK 104 acoustic countermeasure. AN/SPU-1/W “Magnetic Orange Pipe”: As the name implies, the AN/SPU-1/W is a magnetic pipe that is used to trigger magnetically influenced mines.	
Information Typical to the Event	**Platform:** Surface combatant vessel (e.g., Littoral Combat Ship), unmanned surface vehicle, unmanned underwater vehicles, rotary-wing aircraft **Systems:** None **Ordnance/Munitions:** Cable cutters (MK-103) **Targets:** Existing minefields, temporary placed mines, or no targets (training to deploy/operate gear) **Duration:** Typically 1.5 hours, up to 4 hours	**Location:** Southern California Range Complex: Pyramid Cove, Northwest Harbor, Kingfisher Training Range, Mine Training Range-1/2, Shallow Water Minefield, Helicopter Offshore Training Area, Camp Pendleton Amphibious Assault Area All Silver Strand Training Complex Boat Lanes 1–14, in water greater than 40 ft. deep
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** Electromagnetics **Physical Disturbance and Strike:** Vessel and in-water device strike, seafloor device strike (bottom placed mine shapes) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Mooring blocks	
Assumptions used for Analysis	Towed from helicopters, ships, unmanned surface vehicles and unmanned underwater vehicles. Mechanical sweeping (cable cutting), acoustic, and magnetic influence sweeping. Cable cutters utilize an insignificant charge (similar to shotgun shell). Acoustic sweeps generate ship type noise via mechanical system. Towing systems though minefields (or without mines, to train to deploy, tow, and recover). May involve instrumented mines (VIMS).	

A.1.7.5 Airborne Mine Countermeasure – Mine Detection

Activity Name	Activity Description	
Mine Warfare		
Airborne Mine Countermeasure – Mine Detection	Vessel crews and helicopter aircrews detect mines using towed or laser mine detection systems (e.g., AN/AQS-20, Airborne Laser Mine Detection System).	
Long Description	Helicopter crews use towed and airborne devices to detect, locate, and classify potential mines. Towed devices employ active acoustic sources, such as high frequency and side scanning sonar. These devices are similar in function to systems used to map the seafloor or locate submerged structures or items. Airborne devices utilize laser systems to locate mines located below the surface. Devices used include the AN/AQS-20/A, towed minehunting sonar used to detect and classify bottom and floating/moored mines in deep and shallow water, and the Airborne Laser Mine Detection System, developed to detect and classify floating and near-surface, moored mines.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft, Unmanned surface vehicles, Unmanned underwater vehicles **Systems:** Airborne Laser Mine Detection System (AN/AQS-20A, AN/AQS-24A) **Ordnance/Munitions:** None **Targets:** Existing minefields, temporary placed mines, or no targets (training to deploy/operate gear) **Duration:** Typically 1.5 hours, up to 4 hours	**Location:** Southern California Range Complex: Pyramid cove, Northwest Harbor, Kingfisher Training Range, Mine Training Range-1/2, Shallow Water Minefield, Helicopter Offshore Training Area, Camp Pendleton Amphibious Assault Area Silver Strand Training Complex: Boat Lanes 1–14, in water greater than 40 ft. deep
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mine detection sonar (HF4), vessel noise, aircraft noise **Energy:** In-air low energy laser **Physical Disturbance and Strike:** Vessel and in-water device strike, aircraft strike (birds only), seafloor device strike (bottom placed mine shapes) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	Sonar mine detection systems towed from helicopters, vessels, unmanned surface vehicles Use of airborne laser systems to detect mine shapes Laser systems similar to commercial Light Detection And Ranging (LIDAR) systems Mine shapes will be recovered	

A.1.7.6 Mine Countermeasure – Mine Neutralization

Activity Name	Activity Description	
Mine Warfare		
Mine Countermeasure (MCM) – Mine Neutralization	Vessel crews or helicopter aircrews disable mines by firing small- and medium-caliber projectiles.	
Long Description	Vessel and helicopter crews utilize small- and medium- caliber weapons to neutralize potential mines. Weapons may employ laser detection and targeting systems. Small- and medium- caliper projectiles are non-explosive, and neutralize mines by breaching casing, causing the mine to flood or detonate.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft, surface combatant vessels **Systems:** None **Ordnance/Munitions:** Small-caliber and medium-caliber (non-explosive) **Targets:** Existing minefields, Temporarily placed mines **Duration:** Typically 1.5 hours, up to 4 hours	**Location:** Southern California Range Complex: Pyramid cove, Northwest Harbor, Kingfisher Training Range, Mine Training Range-1/2, Shallow Water Minefield
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** In-air low energy laser **Physical Disturbance and Strike:** Vessel and in-water device strike; military expended material strike (projectiles); seafloor device strike (bottom placed mine shapes); aircraft strike (birds only) **Entanglement:** None **Ingestion:** Small- and medium-caliber projectiles, Casings	
Detailed Military Expended Material Information	Small- and medium-caliber projectiles Casings	
Assumptions used for Analysis	None	

A.1.7.7 Mine Neutralization – Remotely Operated Vehicle

Activity Name	Activity Description	
Mine Warfare		
Mine Countermeasures – Mine Neutralization – Remotely Operated Vehicles	Vessel crews or helicopter aircrews disable mines using remotely operated underwater vehicles.	
Long Description	Vessel and helicopter crews utilize remotely operated vehicles to neutralize potential mines. Remotely operated vehicles will use sonar and optical systems to locate and target mine shapes. Explosive mine neutralizers may be used during live fire events.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft, surface combatant vessels **Systems:** Acoustic mine targeting system **Ordnance/Munitions:** High explosive neutralizers (possibly) **Targets:** Existing minefields, temporary placed mines **Duration:** Typically 1.5 hours, up to 4 hours	**Location:** Southern California Range Complex: Kingfisher, Shallow Water Training Range-Offshore, Shallow Water Minefield, Camp Pendleton Amphibious Assault Area Silver Strand Training Complex: Boat Lanes 1–14; Breakers Beach, Delta I, II, and Delta North, Echo
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E4), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike, sea floor device strike (bottom placed mine shapes), aircraft strike (birds only) **Entanglement:** Fiber optic cable **Ingestion:** Neutralizer fragments	
Detailed Military Expended Material Information	Neutralizer fragments Fiber optic cables	
Assumptions used for Analysis	Acoustic sources associated with remotely operated vehicle mine neutralization systems do not require quantitative analysis. See Section 2.3.7.2.	

A.1.7.8 Mine Laying

Activity Name	Activity Description	
Mine Warfare		
Mine Laying	Fixed-winged aircraft and submarine crews drop or launch non-explosive mine shapes.	
Long Description	Fixed-winged aircraft and submarine crews lay offensive or defensive mines for a tactical advantage for friendly forces. Fixed-winged aircraft lay a precise minefield pattern for specific tactical situations. The aircrew typically makes multiple passes in the same flight pattern, and drops one or more training shapes (four shapes total). Training shapes are non-explosive and are recovered when possible.	
Information Typical to the Event	**Platform:** Fixed-wing aircraft (e.g., F/A-18, P-3, P-8, F-35, B-52, B1B) **Systems:** None **Ordnance/Munitions:** Non-explosive mine shapes, "Quick-strike" mines **Targets:** None **Duration:** 1 hour	**Location:** Hawaii Range Complex: R-3101 Southern California Range Complex: Mine Training Range, Shallow Water Training Ranges, Pyramid Cove, China Point
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive mine shapes), aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Non-explosive mine shapes	
Assumptions used for Analysis	Similar to non-explosive bombing exercise These events primarily occur during major training exercises While mineshapes will be recovered if possible, assume they will not for the analysis Mine laying will take place in waters less than 100 ft. Assume 12 mineshapes used per event	

A.1.7.9 Marine Mammal System

Activity Name	Activity Description	
Mine Warfare		
Marine Mammal Systems Operations	Navy personnel and Navy marine mammals work together to detect specified underwater objects.	
Long Description	The Navy deploys trained bottlenose dolphins (*Tursiops trucatus)* and California sea lions (*Zalophus californianus*) as part of the marine mammal mine-hunting and object-recovery system. Each system consists of a motorized small craft, several crewmembers and a trained dolphin or sea lion. Self-Contained Underwater Breathing Apparatus (SCUBA) assisted personnel and Navy marine mammals work together to detect specified underwater objects. Personnel work with the help of marine mammals to detect underwater objects. Approximately 10 percent of training involves the setting of a 13 or 29 lb. (5.9- or 13-kilogram) Net Explosive Weight charge to detonate the objects.	
Information Typical to the Event	**Platform:** Small boats **Systems:** None **Ordnance/Munitions:** 13- or 29-lb. Net Explosive Weight Charge **Targets:** None **Duration:** Varies	**Location:** Hawaii Range Complex: Hawaii Operating Area, Kingfisher, Shallow Waters Minefield, Sonar Training Area Silver Strand Training Complex: Boat Lanes 1–14; Breakers Beach
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E6, E7), vessel noise **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Minimal mine detonation residue (only during the 10 percent of training that includes an explosive charge)	
Assumptions used for Analysis	Sequential detonations at water depths of 10 to 72 ft. (3 to 22 m) and are bottom laid. Single charges are laid within water depths of 24 to 72 ft. (7 to 22 m), 20 ft. (6 m) from the surface or below.	

A.1.7.10 Shock Wave Action Generator

Activity Name	Activity Description	
Mine Warfare (MIW)		
Shock Wave Action Generator	Navy divers place a small charge on a simulated underwater mine.	
Long Description	For shock wave action generator training, a metal sheet containing a non-explosive limpet mine is lowered into the water, sometimes from the side of a small vessel, such as an LCM-8 craft. Divers place a single shock wave generator on the mine that is located mid-water column, within water depths of 10 to 20 ft. (3 to 6 m). A bag is placed over the mine to catch falling debris.	
Information Typical to the Event	**Platform:** None **Systems:** None **Ordnance/Munitions:** One 15 gram explosive charge **Targets:** Metal sheet with limpet mine **Duration:** 2 hours	**Location:** Silver Strand Training Complex: Boat Lanes 1–14; San Diego Bay-Echo
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives, vessel noise **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** Mine detonation residue	
Detailed Military Expended Material Information	Minimal mine detonation residue (most materials are recovered after each event)	
Assumptions Used for Analysis	None	

A.1.7.11 Surf Zone Test Detachment/Equipment Test and Evaluation

Activity Name	Activity Description	
Mine Warfare (MIW)		
Surf Zone Test Detachment/Equipment Test and Evaluation	Navy personnel test and evaluate the effectiveness of new detection and neutralization equipment designated for surf conditions.	
Long Description	Navy personnel test and evaluate the effectiveness of new detection and neutralization equipment designated for surf conditions. To support clearance capability in the surf zone (out to 10 ft. [3 m] of water), Explosive Ordnance Disposal personnel would test and evaluate the effectiveness of new detection and neutralization equipment designated for surf conditions. Use of explosives will occur during 1 percent of training activities (0.1 to 29 lb. [.045 to 9 kg] Net Explosive Weight) and will only occur in the Silver Strand Training Complex Boat Lanes. Time delay fuses may be used for these events.	
Information Typical to the Event	**Platform:** None **Systems:** Hand-held sonar systems **Ordnance/Munitions:** Explosive charges **Targets:** Simulated mines **Duration:** 3 hours	**Location:** Silver Strand Training Complex: Boat Lanes 1–14; San Diego Bay-Echo
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Hand-held sonar systems (HHS1) and explosives (E7) **Energy:** None **Physical Disturbance and Strike:** None. **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Minimal mine detonation residue (only during the 1 percent of training that includes an explosive charge)	
Assumptions Used for Analysis	None	

A.1.7.12 Submarine Mine Exercise

Activity Name	Activity Description	
Mine Warfare (MIW)		
Submarine Mine Exercise	Submarine crews practice detecting mines in a designated area.	
Long Description	Submarine crews use active sonar to detect and avoid mines or other underwater hazardous objects, while navigating restricted areas or channels, such as while entering or leaving port. This event trains submarine crews to detect and avoid mines. Training utilizes simulated minefields constructed of moored or bottom mines, or instrumented mines that can record effectiveness of mine detection efforts. In a typical training exercise, submarine crews will use the AN/BQS-15 high-frequency active sonar to locate and avoid the mine shapes. Each mine avoidance exercise involves one submarine operating the AN/BQS-15 sonar for 6 hours to navigate through the training minefield. During mine warfare exercises submarines will expend several submarine-launched expendable bathythermographs to determine water conditions affecting sonar performance.	
Information Typical to the Event	**Platform:** Submarine **Systems:** Sonar (AN/BQS-15) **Ordnance/Munitions:** None **Targets:** Mine shapes **Duration:** 6 hours	**Location:** Hawaii Operating Area, Kahoolawe Submarine Training Minefield Advanced Research Projects Agency Training Minefield, Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High-frequency sonar (e.g., AN/BQS-15) **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None	

A.1.7.13 Civilian Port Defense

Activity Name	Activity Description
Mine Warfare	
Civilian Port Defense	Maritime security activities for military and civilian ports and harbors.
Long Description	Naval forces provide Mine Warfare capabilities to Department of Homeland Security led event. The three pillars of Mine Warfare, Airborne (helicopter), Surface (ships and unmanned vehicles), and Undersea (divers, marine mammals, and unmanned vehicles) mine countermeasures will be brought to bear in order to ensure strategic U.S. ports remain free of mine threats. Various Mine Warfare sensors, which utilize active acoustics, will be employed in the detection, classification, and neutralization of mines. Along with traditional Mine Warfare techniques, such as helicopter towed mine countermeasures, new technologies (unmanned vehicles) will be utilized. Event locations and scenarios will vary according to Department of Homeland Security strategic goals and evolving world events. Purpose of HSTT analysis is to ensure adequate Marine Mammal Protection Act (MMPA) authorizations are in place to support the use of acoustic mine detection sensors. Additional analysis and regulatory engagement will be conducted as appropriate as planning for the actual events begin.
Information Typical to the Event	**Platform:** Surface combatant vessels, Small boats, Rotary-wing aircraft **Systems:** Unmanned underwater and surface vehicles, various mine detection sensors **Ordnance/Munitions:** High explosive charges **Targets:** Temporary mineshapes **Duration:** Multiple days **Location:** San Diego Bay Pearl Harbor
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Sonar ([HF4] e.g., AN/AQS-20, AN/AQS-24), underwater explosives (E2, E4); vessel noise; aircraft noise **Energy:** Electromagnetic (magnetic influence mine sweeping) **Physical Disturbance and Strike:** Vessel and in-water device strikes; seafloor device strike (bottom placed mine shapes); aircraft strike (birds only) **Entanglement:** None **Ingestion:** None
Detailed Military Expended Material Information	None
Assumptions used for Analysis	Non-permanent mine shapes will be laid in various places on the bottom of San Diego Bay. Shapes are varied, from about 1 m circular to about 2.5 m long by 1 m wide. They will be recovered using normal assets, with diver involvement. Programmatic analysis for acoustic effects only. While goal is to conduct once per year, alternating east/west coast, assume that a West Coast event will occur every year with a total of three per five year period.

A.1.8 NAVAL SPECIAL WARFARE TRAINING

Naval special warfare and other Navy forces train to conduct military operations in five Special Operations mission areas: unconventional warfare, direct action, special reconnaissance, foreign internal defense, and counterterrorism. Naval special warfare training involves specialized tactics, techniques, and procedures, employed in training events that include: insertion/extraction operations using parachutes rubber boats, or helicopters; boat-to-shore and boat-to-boat gunnery; underwater demolition training; reconnaissance; and small arms training.

A.1.8.1 Personnel Insertion/Extraction – Non-Submarine

Activity Name	Activity Description	
Naval Special Warfare		
Personnel Insertion/Extraction – Non-Submarine	Personnel train to approach or depart an objective area using various transportation methods and tactics.	
Long Description	Personnel train to approach or depart an objective area using various transportation methods and tactics. These activities train forces to insert and extract personnel and equipment day or night. Tactics and techniques employed include insertion from aircraft by parachute, by rope, or from low, slow-flying helicopters from which personnel jump into the water. Parachute training is required to be conducted on surveyed drop zones to enhance safety. Insertion and extraction methods also employ small inflatable boats.	
Information Typical to the Event	**Platform:** Fixed and rotary-wing aircraft **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** 2 to 8 hours	**Location:** Southern California Range Complex: Southern California Operating Area, San Clemente Island Silver Strand Training Complex: Boat Lanes 1–14, Echo
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None	

A.1.8.2 Personnel Insertion/Extraction – Submarine

Activity Name	Activity Description	
Naval Special Warfare		
Personnel Insertion/Extraction - Submarine	Military personnel train for covert insertion and extraction into target areas using submarines.	
Long Description	Military personnel train for covert insertion and extraction into target areas using submarines. Often, an undersea delivery vehicle, similar to a "mini-sub" may be used to transfer the personnel from the submarine to their objective near shore. Several methods are used by submarines and embarked personnel to move from the submarine to the objective area: • The lock-in/lock-out procedure allows personnel to swim out of submerged submarines. • The Sea, Air, Land (SEAL) Delivery Vehicle may be used by Naval Special Warfare personnel to move from the submarine to an underwater area closer to shore. Submarines approach a hostile area and move at a very slow speed while inserting or extracting Naval Special Warfare or other personnel by using one, or a combination of the procedures discussed above. Once the personnel have inserted or extracted, the submarine will leave the area. Opposition force personnel may be employed as well as small arms with blanks or live ammunition once the personnel reach the beach area. These operations will vary in length depending on the transportation method and systems being used. Training may include navigation runs into and out of the San Diego Bay or Pearl Harbor that may be conducted in coordination with other training activities.	
Information Typical to the Event	**Platform:** Sea, Air, Land Delivery Vehicle **Systems:** None **Ordnance/Munitions:** None (if used, small-caliber) **Targets:** None **Duration:** 2 to 8 hours	**Location:** Hawaii Range Complex: Hawaii Operating Area, Marine Corps Training Area Bellows; Pacific Missile Range Facility (Main Base) Silver Strand Training Complex: Boat Lanes 1-10, Delta III, Echo, Foxtrot, Golf, Hotel
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Small-caliber projectiles, if used	
Assumptions Used for Analysis	None	

A.1.8.3 Underwater Demolition Multiple Charge – Mat Weave and Obstacle Loading

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Naval Special Warfare</td></tr>
<tr><td>Underwater Demolitions Multiple Charge-Mat Weave and Obstacle Loading</td><td colspan="2">Military personnel use explosive charges to destroy barriers or obstacles to amphibious vehicle access to beach areas.</td></tr>
<tr><td>Long Description</td><td colspan="2">Navy personnel train to construct, place, and safely detonate multiple charges laid in a pattern for underwater obstacle clearance.
Naval Special Warfare or Explosive Ordnance Disposal personnel locate barriers or obstacles designed to block amphibious vehicle access to beach areas, then use explosive charges to destroy them. Pattern charges (mat weaves) may use as much as 500 lb. (227 kg) of high explosive.
Time delay fuses may be used for these events.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Small boats

A.1.8.4 Underwater Demolition Qualification/Certification

Activity Name	**Activity Description**	
Naval Special Warfare		
Underwater Demolition Qualification/Certification	Navy divers conduct training and certification in placing underwater demolition charges.	
Long Description	Demolition re-qualifications and training provides teams with experience in underwater detonations by conducting detonations on metal plates near the shoreline. At water depths of 10 to 72 ft. (3 to 22 m), two sequential 12.5 to 13.75 lb. (5.7 to 6.2 kg) Net Explosive Weight charges are placed on the bottom or a single 25.5 lb. (11.5 kilogram) charge is placed from a depth of 20 ft. (6 m) to the bottom.	
Information Typical to the Event	**Platform:** Small boats **Systems:** None **Ordnance/Munitions:** High-explosive charges (up to 29 lb.) **Targets:** None **Duration:** Varies	**Location:** Southern California Range Complex Silver Strand Training Complex: Boat and Beach Lanes 1–14
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E7) **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Minimal mine detonation residue (most materials are recovered after each event)	
Assumptions Used for Analysis	None	

A.1.9 OTHER TRAINING

</table>

A.1.9.2 Small Boat Attack

Activity Name	Activity Description	
Other		
Small Boat Attack	Small attacks are conducted on boats. For this activity, one or two small boats or personal watercraft conduct attack activities on units afloat.	
Long Description	Small attacks are conducted on boats, usually within anchorages or boat lanes. For this activity, one or two small boats or personal watercraft conduct attack activities on units afloat, firing blank small-caliber rounds. The activity will usually include observers.	
Information Typical to the Event	**Platform:** Small boats or watercraft **Systems:** **Ordnance/Munitions:** Small caliber (non-explosive) **Targets:** High-performance small boats and unmanned vehicles **Duration:** Varies	**Location:** Hawaii Operating Areas Silver Strand Training Complex: Boat Lanes 1-10
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** Vessel strike, military expended material strike (non-explosive projectiles) **Entanglement:** None **Ingestion:** Small-caliber projectiles	
Detailed Military Expended Material Information	Small-caliber projectiles	
Assumptions used for Analysis	None	

A.1.9.3 Offshore Petroleum Discharge System

Activity Name	**Activity Description**	
Other		
Offshore Petroleum Discharge System	This activity trains personnel in the transfer of petroleum (though only sea water is used during training) from ship to shore.	
Long Description	Offshore petroleum discharge system training consists of five training subcomponents including the beach termination unit; operation utility boat technicians; boat coxswain; dive boat operation technician; and single anchor leg moor training. This activity trains personnel in the transfer of petroleum (though only sea water is used during training) from ship to shore. From approximately one mile offshore, technicians and underwater construction team divers roll out conduit from a ship offshore, deploy the single anchor leg mooring which sinks to and settles on the ocean floor, and use anchors at various points along the conduit to secure it to the seafloor. The conduit terminates at the shore location of the termination unit manifold. The current training at Silver Strand Training Complex consists of rolling out a four mile fluid-transfer conduit from the beach out to approximately one mile offshore and anchoring it to the seafloor with a Single Anchor Leg Moor. The improved offshore petroleum discharge system would have a self-sinking hose that could extend up to eight miles offshore, but like the current system, would still be rolled out to approximately one mile offshore during training activities at Silver Strand Training Complex.	
Information Typical to the Event	**Platform:** Surface combatant vessels, small boats, support craft/other **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** Varies	**Location:** Silver Strand Training Complex: Boat Lanes 1-10, Bravo, Waters outside of boat lanes
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None	

A.1.9.4 Elevated Causeway System

Activity Name	**Activity Description**	
Other		
Elevated causeway System	A temporary pier is constructed off of the beach. Piles are driven into the sand and then later removed.	
Long Description	A pier is constructed off of the beach. The pier is designed to allow for offload of materials and equipment from supply ships. Piles are driven into the sand with an impact hammer. Causeway platforms are then hoisted and secured onto the piles with hydraulic jacks and cranes. It is assembled by joining standard causeway sections together and can be assembled in 10 days. The pier, including associated piles, is removed at the conclusion of training.	
Information Typical to the Event	**Platform:** Support craft/other **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** Up to 10 days for assembly	**Location:** Silver Strand Training Complex: Boat Lanes 1-10, Designated Bravo Beach training lane; Camp Pendleton Amphibious Assault Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Pile driving and removal **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	Programmatic analysis (only assessing acoustic impacts from the pile driving)	

A.1.9.5 Submarine Navigation

Activity Name	**Activity Description**	
Other		
Submarine Navigational	Submarine crews operate sonar for navigation and object detection while transiting in and out of port during reduced visibility.	
Long Description	Submarine crews train to operate sonar for navigation. The ability to navigate using sonar is critical for object detection while transiting in and out of port during periods of reduced visibility. Submarine Navigation training activities conducted while transiting in and out of port are done so while surfaced, with bridge watches and a single lookout.	
Information Typical to the Event	**Platform:** Submarines **Systems:** High frequency submarine sonar system **Ordnance/Munitions:** None **Targets:** None **Duration:** Up to 2 hours	**Location:** Hawaii Range Complex: Pearl Harbor Channel and virtual channel south of Pearl Harbor Southern California Range Complex: Naval Base Point Loma and seaward virtual channel
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High frequency submarine sonar system (HF1); hull-mounted sonar (MF3) **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.1.9.6 Submarine Under Ice Certification

Activity Name	Activity Description	
Other		
Submarine Under Ice Certification	Submarine crews train to operate under ice. Ice conditions are simulated during training and certification events.	
Long Description	Submarine crews train to operate under ice. Ice conditions are simulated during training and certification events.	
Information Typical to the Event	**Platform:** Submarine **Systems:** Submarine high frequency sources **Ordnance/Munitions:** None **Targets:** None **Duration:** A single exercise is comprised of 36 hours of training, spread out over 6 days in 6-hour training sessions.	**Location:** Hawaii Operating Areas Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High–frequency submarine sonar (HF1) **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.1.9.7 Salvage Operations

Activity Name	Activity Description	
Other		
Salvage Operations	Navy divers train to tow disabled ships, repair damaged ships, remove sunken ships, and conduct deep ocean recovery.	
Long Description	Navy divers train to tow disabled ships, repair damaged ships, remove sunken ships, and conduct deep ocean recovery. The Navy's Mobile Diving and Salvage Unit One and divers from other countries practice swift and mobile ship and barge salvage, towing, battle damage repair, deep ocean recovery, harbor clearance, removal of objects from navigable waters, and underwater ship repair capabilities.	
Information Typical to the Event	**Platform:** Surface vessels, other support vessels **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** Varies	**Location:** Hawaii Range Complex: Puuloa Underwater Range, Pearl Harbor Defensive Sea Area, Keehi Lagoon, Pearl Harbor
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.1.9.8 Surface Ship Sonar Maintenance

Activity Name	**Activity Description**	
Other		
Surface Ship Sonar Maintenance	Pierside and at-sea maintenance of sonar systems.	
Long Description	This scenario consists of surface combatant vessels performing periodic maintenance to the hull mounted sonar systems while in port or at sea. This maintenance takes up to four hours. Surface vessels operate active sonar systems for maintenance while in shallow water near their homeport, however, sonar maintenance could occur anywhere as the system's performance may warrant.	
Information Typical to the Event	**Platform:** Surface combatant vessels **Systems:** Hull mounted sonar systems **Ordnance/Munitions:** None **Targets:** None **Duration:** Up to 4 hours	**Location:** Hawaii Range Complex: Hawaii Operating Area; Pearl Harbor; Fleet Operational Readiness Accuracy Check Site Range Southern California Range Complex: Southern California Operating Area; San Diego Bay and ports HSTT Transit Corridor
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency hull mounted sonar (MF1, MF2), vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None

A.1.10 Integrated Training and Major Range Events

A major range event is comprised of several unit-level range operations conducted by several units operating together while commanded and controlled by a single commander. These exercises typically employ an exercise scenario developed to train and evaluate the Strike Group/Force in required naval tactical tasks. In a major range event, most of the operations and activities being directed and coordinated by the Strike Group commander are identical in nature to the operations conducted in the course in individual, crew, and smaller-unit training events. In a major range event, however, these disparate training tasks are conducted in concert, rather than in isolation.

A.1.10.1 Composite Training Unit Exercise

Activity Name	Activity Description	
Major Training Events		
Anti-Submarine Warfare for Composite Unit Training Exercise	Anti-submarine warfare activities conducted during a Composite Training Unit Exercise	
Long Description	Intermediate level battle group exercise designed to create a cohesive Strike Group prior to deployment or Joint Task Force Exercise. Typically seven surface ships, helicopters, maritime patrol aircraft, two submarines, and various unmanned vehicles. Each Strike Group performs a rehearsal called Composite Training Unit Exercise before deployment. Prior to the Composite Training Unit Exercise, each ship and aircraft in the strike group trains in their specialty. The Composite Training Unit Exercise is an intermediate-level strike group exercise designed to forge the group into a cohesive fighting team. Composite Training Unit Exercise is normally conducted during a 1 to 3 week period 6 to 8 weeks before Joint Task Force Exercise and consists of an 18 day schedule of event driven exercise, and a 3 day Final Battle Problem. The Composite Training Unit Exercise is an integration phase, at-sea, major range event. For the carrier strike group, this exercise integrates the aircraft carrier and carrier air wing with surface and submarine units in a challenging operational environment. For the expeditionary strike group/amphibious readiness group, this exercise integrates amphibious ships with their associated air wing, surface ships, submarines, and the Marine Expeditionary Unit. Live-fire operations that may take place during Composite Training Unit Exercise include long-range air strikes, Naval Surface Fire Support, and surface-to-air, surface-to-surface, and air-to-surface missile exercises. The Marine Expeditionary Unit also conducts realistic training based on anticipated operational requirements and to further develop the required coordination between Navy and Marine Corps forces. Special Operations training may also be integrated with the exercise scenario.	
Information Typical to the Event	**Platform:** Surface vessels, Fixed-wing aircraft, rotary-wing aircraft, unmanned vehicles, submarines **Systems:** All sonar systems **Ordnance/Munitions:** All ship and aircraft weapons, explosive sonobuoys may be used **Targets:** All surface, air, and anti-submarine warfare targets (e.g., MK-39 Expendable Mobile Anti-submarine Warfare Training Targets) **Duration:** 21 days	**Location:** Southern California Operating Area and Point Mugu Sea Range (overlap area only)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency hull-mounted sonar (MF1, MF2, MF3), helicopter dipping sonar (MF4), sonobuoy (MF5), high duty cycle variable depth sonar (MF12), multistatic active coherent sonobuoy (ASW2),mid-frequency acoustic countermeasure (ASW3, ASW4), signal devices (MF6), high-frequency hull-mounted sonar (HF1), explosive sonobuoys (E4); vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, vessel and in-water device strike, aircraft strike (birds only) **Entanglement:** Parachutes **Ingestion:** Parachutes, countermeasures, sonobuoy fragments	
Detailed Military Expended Material Information	One MK-39 Expendable Mobile Anti-submarine Warfare Training Targets Air deployed sonobuoy will have a parachute Expended countermeasures	
Assumptions used for Analysis	For Composite Training Unit Exercise only the anti-submarine warfare activities were analyzed as a Composite Training Unit Exercise. Other warfare area training conducted during the Composite Training Unit Exercise was analyzed as unit level training (gunnery exercise, missile exercise, etc.)	

A.1.10.2 Joint Task Force Exercise/Sustainment Exercise

Activity Name	Activity Description
Major Training Events	
Joint Task Force Exercise	Final Fleet exercise prior to deployment of the Strike Group. Serves as a ready-to-deploy certification for all units involved. Typically nine surface ships, helicopters, maritime patrol aircraft, two submarines, and various unmanned vehicles.
Long Description	The Joint Task Force Exercise is a dynamic and complex major range event that is the culminating exercise in the Sustainment Phase training for the Carrier Strike Groups and Expeditionary Strike Groups. For an Expeditionary Strike Group, the exercise incorporates an Amphibious Ready Group Certification Exercise for the amphibious ships and a Special Operations Capable Certification for the Marine Expeditionary Unit. When schedules align, the Joint Task Force Exercise may be conducted concurrently for an Expeditionary Strike Group and Carrier Strike Group. Joint Task Force Exercise emphasizes mission planning and effective execution by all primary and support warfare commanders, including command and control, surveillance, intelligence, logistics support, and the integration of tactical fires. Joint Task Force Exercises are complex scenario-driven exercises that evaluate a strike group in all warfare areas. Joint Task Force Exercise is normally 10 days long, not including a 3-day in-port Force Protection Exercise, and is the final at-sea exercise for the Carrier Strike Group or Expeditionary Strike Group prior to deployment. Joint Task Force Exercise occurs 3 to 4 times per year.
Information Typical to the Event	**Platform:** Multiple surface combatant vessels, Fixed-wing aircraft, Rotary-wing aircraft, unmanned vehicles, and submarines **Systems:** Anti-Submarine Warfare systems, Anti-Surface Warfare and Anti-Air Warfare gun and missile systems **Ordnance/Munitions:** Numerous gun rounds, bombs, and missiles, all captured in specific events **Targets:** MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, MK-30 Recoverable Training Target, submarine **Duration:** Up to 10 days **Location:** Southern California Operating Area and Point Mugu Sea Range (overlap area only)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1, MF1K, MF2, MF2K, MF3, MF4, MF5, MF6, ASW2, ASW3, ASW4,) high-frequency sonar (HF1), light and heavyweight torpedoes, (e.g., TORP1, TORP2), high-frequency acoustic modems, vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike, aircraft strike, (birds only) military expended materials, seafloor device strike **Entanglement:** parachutes **Ingestion:** Parachutes, target and munitions fragments, small-caliber gun rounds, chaff
Detailed Military Expended Material Information	Anti-Submarine Warfare target: One MK-39 or MK-30 target (MK-30 is recovered and reused, MK-39 is not) per event. If target is air-dropped, one parachute per target Target remnants, chaff, flares Sonobuoys: (one parachute for each sonobuoy) Large, medium, and small-caliber projectiles, bombs, missiles, rockets, expendable acoustic countermeasures
Assumptions used for Analysis	All Military expended materials, ordnance, explosives, and sonar use is included in individual events

A.1.10.3 Rim of the Pacific Exercise

Activity Name	Activity Description
Major Training Events	
Rim of the Pacific Exercise	A biennial multinational training exercise in which navies from Pacific Rim nations and the United Kingdom assemble in Pearl Harbor, Hawaii to conduct training in a number of warfare areas throughout the Hawaiian Islands. Marine mammal systems may be used during a Rim of the Pacific exercise. Components of Rim of the Pacific such as certain Mine Warfare training may be conducted in the Southern California Range Complex.
Long Description	Rim of the Pacific is the world's largest multinational maritime exercise, typically lasting four to five weeks. Hosted by Commander, Pacific Fleet, the exercise is scheduled in the summer on even years. Rim of the Pacific typically consists of 14 nations, 32 ships, 5 submarines, more than 170 aircraft, and 20,000 personnel. The exercise typically consists of three major phases. Phase I, the Harbor Phase, will consist of operational planning meetings, safety briefings, and sporting events. This phase is designed to make final preparations for the at-sea phases of the exercises, as well as build on professional and personal relationships between the participating countries. Phase II, the Operational Phase, is driven by a structured schedule of events. This portion may include live fire gunnery and missile exercises, maritime interdiction and vessel boarding, anti-surface warfare, undersea warfare, and naval maneuvers, air defense exercises, as well as, explosive ordnance disposal, diving and salvage operations, mine clearance operations, and an amphibious landing. This phase exercises the ability of each nation to conduct robust command and control operations with multinational players and enhances each unit's operational capabilities. Phase III, the Tactical Phase of the exercise, is scenario-driven. The intense training during this phase allows participating nations to further strengthen their maritime skills and capabilities and improve their ability to communicate and operate in simulated hostile scenarios. This phase concludes with the ships' return to Pearl Harbor, where participating nations will reconvene to discuss the exercise and overall accomplishments.
Information Typical to the Event	**Platform:** Surface ships, Aircraft, Submarines **Systems:** Anti-Submarine Warfare systems, Anti-Surface Warfare and Anti-Air Warfare gun and missile systems **Ordnance/Munitions:** Numerous gun rounds, bombs, and missiles, all captured in specific events **Targets:** MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, MK-30 Recoverable Training Target, submarine **Duration:** 30 days **Location:** Hawaii Range Complex: Hawaii Operating Area (including Barking Sands Underwater Range Extension; Barking Sands Tactical Underwater Range; Shallow Water Training Range Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1, MF1K, MF2, MF2K, MF3, MF4, MF5, MF6, ASW2, ASW3, ASW4,) light and heavyweight torpedoes, (e.g., TORP1, TORP2), high-frequency acoustic modems and tracking pingers, vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, vessel and in-water device strike, aircraft strike (birds only) **Entanglement:** Torpedo guidance wires, parachutes **Ingestion:** Parachutes, target and munitions fragments, small-caliber gun rounds, chaff

Detailed Military Expended Material Information	Anti-Submarine Warfare target: One MK-39 or MK-30 target (MK-30 is recovered and reused, MK-39 is not) per event. If target is air-dropped, one parachute per target Target remnants, chaff, flares Sonobuoys: (one parachute for each sonobuoy) Large, medium, and small-caliber projectiles, bombs, missiles, rockets Torpedo guidance wire Expendable acoustic countermeasures
Assumptions used for Analysis	All Military Expended Material, ordnance, explosives, and sonar use is included in individual events

A.1.10.4 Multi-Strike Group Exercise

Activity Name	Activity Description	
Major Training Events		
Multi-Strike Group Exercise	A 10-day exercise in which up to three strike groups would conduct training exercises simultaneously.	
Long Description	Elements of the anti-submarine warfare tracking exercise combine in the exercise of multiple air, surface, and subsurface units, over a period of up to 10 days. No explosive ordnance is used. Sonobuoys, active and passive sonar, and Nixie are used. The AN/SLQ-25 Nixie is a surface ship countermeasure system that includes a towed torpedo decoy device and a shipboard signal generator. The decoy emits signals to draw a torpedo away from its intended target. Up to three Strike Groups would conduct training exercises simultaneously in the Hawaii Range Complex. The Strike Groups would not be homeported in Hawaii, but would stop in Hawaii en route to a final destination. The Strike Groups would be in Hawaii for up to 10 days per exercise. The exercise would involve Navy assets engaging in a “free play” battle scenario, with U.S. forces pitted against a replicated opposition force. The exercise provides realistic in-theater training.	
Information Typical to the Event	**Platform:** Multiple surface combatant vessels, aircraft, and submarines **Systems:** Anti-submarine warfare systems, anti-surface warfare and anti-air warfare gun and missile systems **Ordnance/Munitions:** Numerous gun rounds, bombs, and missiles, all captured in specific events **Targets:** MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, MK-30 recoverable training target, submarine **Duration:** Each multi-strike group exercise lasts for up to 10 days and consists of multiple 12-hour Anti-Submarine Warfare events.	**Location:** Hawaii Operating Area Southern California Operating Area and Point Mugu Range (overlap area only)
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1, MF1K, MF2, MF2K, MF3, MF4, MF5, MF6, ASW2, ASW3, ASW4,) Light and heavyweight torpedoes, (e.g., TORP1, TORP2), high-frequency acoustic modems and tracking pingers, vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, vessel and in-water device strike, aircraft strike (birds only) **Entanglement:** Parachutes **Ingestion:** Parachutes,	
Detailed Military Expended Material Information	Anti-Submarine Warfare target: One MK-39 or MK-30 target (MK-30 is recovered and reused, MK-39 is not) per event. If target is air-dropped, one parachute per target Target remnants, chaff, flares Sonobuoys: (one parachute for each sonobuoy) Large, medium, and small-caliber projectiles, bombs, missiles, rockets Expendable acoustic countermeasures	
Assumptions used for Analysis	All Military Expended Material, ordnance, and sonar use is included in individual events	

A.1.10.5 Integrated Anti-Submarine Warfare Course

Activity Name	Activity Description
Major Training Events	
Integrated Anti-Submarine Warfare Course	Multiple vessels, aircraft, and submarines integrate the use of their sensors, including sonobuoys, to search, detect, and track threat submarines.
Long Description	Integrated Anti-Submarine Warfare Course is a tailored course of instruction designed to improve Sea Combat Commander and Strike Group integrated anti-submarine warfare warfighting skill sets. Integrated Anti-Submarine Warfare Course is a coordinated training scenario that typically involves five surface ships, two to three embarked helicopters, a submarine and one maritime patrol aircraft searching for, locating, and attacking one submarine. The scenario consists of two 12-hour events that occur five times per year. The submarine may practice simulated attacks against the ships while being tracked. Hull mounted, towed array and dipping sonar is employed by ships and helicopters. The submarine also periodically operates its sonar.
Information Typical to the Event	**Platform:** Surface vessels, Fixed and rotary-wing aircraft, Submarines, Unmanned vehicles **Systems:** Hull-mounted, Towed array, and Dipping sonar, Mid-frequency sonar, acoustic countermeasures Sonobuoys **Ordnance/Munitions:** Sonobuoys **Targets:** Expendable mobile anti-submarine warfare training targets **Duration:** 2 to 5 days **Location:** Southern California Operating Area: Southern California Anti-submarine Warfare Range
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Sonar and other active acoustic sources (e.g., MF1, MF1K, MF2, MF2K, MF3, MF4, MF5, MF6, ASW2, ASW3, ASW4), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, vessel and in-water device strike, aircraft strike (birds only) **Entanglement:** Parachutes **Ingestion:** Parachutes, countermeasures, sonobuoy fragments
Detailed Military Expended Material Information	Parachutes, Sonobuoy fragments, Expended countermeasures
Assumptions used for Analysis	Two MK-39 Expendable Mobile Anti-Submarine Warfare Training Target may be used in place of an actual submarine target Air deployed sonobuoy will have a parachute

A.1.10.6 Group Sail

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Major Training Events</td></tr>
<tr><td>Group Sail</td><td colspan="2">Multiple ships and helicopters integrate the use of sensors, including sonobuoys, to search, detect, and track a threat submarine. Group sail exercises are not dedicated Anti-Submarine Warfare events and involve multiple warfare areas.</td></tr>
<tr><td>Long Description</td><td colspan="2">Multiple ships and helicopters integrate the use of sensors, including sonobuoys, to search, detect, classify, localize, and track a threat submarine to launch a torpedo. Group sail exercises are not dedicated ASW events and involve multiple warfare areas.
Group Sail is an intermediate training exercise primarily intended to introduce coordinated operations after Unit Level Training and prior to Composite Training. This event stresses planning, coordination, and communications during multiple warfare training scenarios.
Two or more ships and up to two helicopters searching for, locating, and attacking one submarine. Typically, one ship and helicopter are actively prosecuting while the other ship and helicopter are repositioning. Simultaneously, the submarine may practice simulated attacks against the ships. Multiple acoustic sources may be active at one time.
Typical participants and systems used during a Group Sail include:
• Navy Destroyer (2)
• Navy Frigate (1)
• Submarine (1)
• Maritime Patrol Aircraft (1)
• MH-60 (3)</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Rotary-wing aircraft, surface combatant vessels, submarine
Systems: Mid-frequency hull mounted sonar, towed array and dipping sonar, acoustic countermeasures high-frequency acoustic modems and tracking pingers

<tr><td>Assumptions Used for Analysis</td><td colspan="2">One Destroyer Squadron in Hawaii will conduct two Group Sails per year. These exercises are also known by the Hawaiian name "Koa Kai" (ocean warrior). Koa Kai is a 2 to 3 day event including Anti-Submarine Warfare.
While preference will be to train against an actual submarine, or MK 30 recoverable target, assume only MK 39 expendable targets will be used.</td></tr>
</table>

A.1.10.7 Undersea Warfare Exercise

Activity Name	Activity Description
Major Training Events	
Undersea Warfare Exercise	Elements of Anti-Submarine Warfare Tracking Exercises combine in this exercise of multiple air, surface, and subsurface units, over a period of several days. Sonobuoys released from aircraft. Active and passive sonar used.
Long Description	Elements of the anti-submarine warfare tracking exercise combine in an exercise of multiple air, surface, and subsurface units, over a period of 4 days. No explosive ordnance. Sonobuoys are released from aircraft, and active and passive sonar is used. Undersea Warfare Exercise is conducted up to five times annually. Undersea Warfare Exercise is an assessment based anti-submarine warfare exercise conducted by Expeditionary Strike Groups and Carrier Strike Groups while in transit from the west coast of the United States to the Western Pacific Ocean. Undersea Warfare Exercise can involve more than one Carrier Strike Group or Expeditionary Strike Group formation. Typical systems and participants used during an Undersea Warfare Exercise include: • AN/SQS-53: 64 hours (total = 192 hours) (3 Guided Missile Destroyers (DDGs) x 64 hours each) • Nixie (DDG): 70 hours (total = 210 hours) (3 DDG x 70 hours each) • AN/SSQ-62: 2 buoys (total = 6 buoys) (3 DDG x two buoys each) • AN/SQS-56: 64 hours • Nixie (Fast Frigate): 70 hours • AN/SSQ-62: 02
Information Typical to the Event	**Platform:** Rotary-wing aircraft, Fixed-wing Aircraft, submarines **Systems:** Mid-frequency and high-frequency sonar, dipping sonar high-frequency acoustic modems and sonobuoys **Ordnance/Munitions:** None **Targets:** MK-30, MK-39 Expendable Mobile Anti-submarine Warfare Training Targets, submarine **Duration:** 4 days **Location:** Hawaii Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency, high-frequency sonar, sonobuoys, high-frequency acoustic modems, and dipping sonar (MF1, MF2, MF3, MF4, MF5, MF6, ASW2, ASW4), aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike, aircraft strike, military expended materials **Entanglement:** Parachutes **Ingestion:** Parachutes
Military Expended Detailed Material Information	One MK-39 or MK-30 target (MK-30 is recovered and reused, MK-39 is not) If target is air-dropped, one parachute per target Sonobuoys: (one parachute for each sonobuoy)
Assumptions Used for Analysis	All MEM, ordnance, explosives, and sonar use is included in individual events.

A.1.10.8 Ship Anti-Submarine Warfare Readiness and Evaluation Measuring

Activity Name	Activity Description	
Major Training Events		
Ship Anti-Submarine Warfare Readiness and Evaluation Measuring	This exercise will typically involve multiple ships, submarines, and aircraft in several coordinated events over a period of a week or less. The Navy uses this exercise to collect and analyze high-quality data to quantitatively "assess" surface ship Anti-Submarine Warfare readiness and effectiveness.	
Long Description	Ship Anti-Submarine Warfare Readiness and Evaluation Measuring Exercise is a Chief of Naval Operations chartered program with the overall objective to collect and analyze high-quality data to quantitatively assess surface ship anti-submarine warfare readiness and effectiveness. The exercise will typically involve multiple ships, submarines, and aircraft in several coordinated events over a period of a week or less.	
Information Typical to the Event	**Platform:** Multiple rotary-wing aircraft, fixed-wing aircraft, submarines **Systems:** Mid-frequency and high-frequency sonar, dipping sonar, high frequency acoustic modems and sonobuoys **Ordnance/Munitions:** None **Targets:** MK-30, MK-39 Expendable Mobile Anti-submarine Warfare Training Targets, submarine **Duration:** 5-7 days/1 time per year	**Location:** Southern California Operating Area: Southern California Anti-submarine Warfare Range
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency, high-frequency sonar, high frequency acoustic modem, sonobuoys, and dipping sonar (MF1, MF2, MF3, MF4, MF5, MF6, ASW2, ASW4), aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike, Aircraft strike, Military expended materials **Entanglement:** Parachutes **Ingestion:** Parachutes	
Military Expended Detailed Material Information	• One MK-39 or MK-30 target (MK-30 is recovered and reused, MK-39 is not) • If target is air-dropped, one parachute per target • Sonobuoys: (one parachute for each sonobuoy)	
Assumptions Used for Analysis	All MEM, ordnance, explosives, and sonar use is included in individual events.	

A.2 NAVAL AIR SYSTEMS COMMAND TESTING ACTIVITIES

Naval Air Systems Command events will closely follow Fleet primary mission areas, such as the testing of airborne mine warfare and anti-submarine warfare weapons and systems. Naval Air Systems Command events include, but are not limited to, the testing of new aircraft platforms, weapons, and systems that have not been integrated into Fleet training events, such as directed energy weapons and the Joint Strike Fighter. In addition to testing new platforms, weapons, and systems, Naval Air Systems Command also conducts lot acceptance testing of airborne weapons and sonobuoys in support of the Fleet. These types of events do not fall within one of the Fleet primary mission areas; however, in general, most Naval Air Systems Command testing events in terms of their potential environmental effects are similar to Fleet training events.

While many of these systems will eventually be used by the Fleet during normal training and will be addressed in this EIS/OEIS for those Fleet activities, testing and development activities involving the same or similar systems as will be used by operational Fleet units may be used in different locations and manners than when actually used by operational Fleet units. Hence, the analysis for testing events and training of Fleet units may differ.

A.2.1 ANTI-AIR WARFARE TESTING

A.2.1.1 Air Combat Maneuver Test

Activity Name	Activity Description	
Anti-Air Warfare		
Air Combat Maneuver	Aircrews engage in flight maneuvers designed to gain a tactical advantage during combat.	
Long Description	Air Combat Maneuver is the general term used to describe an air-to-air test event involving two or more aircraft, each engaged in continuous proactive and reactive changes in aircraft attitude, altitude, and airspeed. No weapons are fired during Air Combat Maneuver activities.	
Information Typical to the Event	**Platform:** Fixed-wing aircraft (e.g., F-35; F/A-18, E/A-18G) **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** 1.5 to 2 flight hours/event	**Location:** Hawaii Operating Area Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	Two Chaff Flares per event that are captured under Air Platform/Vehicle Test.	

A.2.1.2 Air Platform Vehicle Test

Activity Name	Activity Description	
Anti-Air Warfare		
Air Platform/Vehicle Test	Testing performed to quantify the flying qualities, handling, airworthiness, stability, controllability, and integrity of an air platform or vehicle, and in-flight refueling capabilities. No weapons are released during an Air Platform/Vehicle Test.	
Long Description	The Air Platform/Vehicle Test describes the testing performed to quantify the flying qualities, handling, airworthiness, stability, controllability, and integrity of an air platform/vehicle. Integration of non-weapons system including-flight refueling tests are also conducted as part of an Air Platform/Vehicle Test. Test results are compared against design and performance specifications for compliance. The test results are also used to define stability and controllability characteristics and limitations and to improve and update existing analytical and predictive models. A wide variety of fixed-wing and rotary-wing aircraft, including unmanned aerial systems would undergo air platform/vehicle testing. No weapons are released during an Air Platform/Vehicle Test. Aircraft may employ laser detection for targeting systems and trailing antenna. Events may involve two or more fighter jet aircrafts and a towed target tractor by a contracted aircraft (e.g., Lear jet for laser targeting tests).	
Information Typical to the Event	**Platform:** Fixed and rotary-wing (e.g. V-22, F-35, E-2/C-2), includes Unmanned Aerial Systems **Systems:** None **Ordnance/Munitions:** Flares **Targets:** None **Duration:** 2 to 8 flight hours/event	**Location:** Hawaii Operating Area Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** In-air low energy lasers **Physical Disturbance and Strike:** Military expended material strike (fuel tanks or similar), Aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Fuel tanks, carriages, flares, dispensers, or similar types of support systems on aircraft may be jettisoned depending on test	
Assumptions used for Analysis	Estimated two to four fuel tanks expended per event; however this can vary based on requirements. fuel tanks may contain water to simulate different fuel levels.	

A.2.1.3 Air Platform Weapons Integration Test

Activity Name	**Activity Description**	
Anti-Air Warfare		
Air Platform Weapons Integration Test	Testing performed to quantify the compatibility of weapons with the aircraft from which they would be launched or released. Mostly non-explosive weapons or shapes are used.	
Long Description	The Air Platform Weapons Integration Test describes the testing performed to quantify the compatibility of weapons with the aircraft from which they would be released. Tests evaluate the compatibility of the weapon and its carriage, suspension, and launch equipment with the performance and handling characteristics of the designated aircraft. Additional tests assess the ability of the weapon to separate or launch safely from the aircraft at combat velocities, including at supersonic speeds. Test results are compared against design specifications for compliance. The test results are also used to define performance characteristics and to improve and update existing analytical and predictive models.	
Information Typical to the Event	**Platform:** Fixed and rotary-wing aircraft (e.g., F/A-18; F-35 ; E/A-18G; MH-60R) **Systems:** Gun systems integration; Air Intercept Missile Series (e.g., AIM-9x); Advanced Medium Range Air-to-Air Missile; AGM-114R, MK46, MK54, 20 mm **Ordnance/Munitions:** Missiles, rockets, small and medium-caliber projectiles, bombs (non-explosive) **Targets:** The use of drones, such as the BQM-74 and 34, may be used as a target for weapon and mission system test events. Surface targets will also be used as needed for proposed test events. **Duration:** 1.5 to 2.5 flight hours/event	**Location:** Hawaii Operating Area Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Weapons firing and aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (projectiles, missiles, rockets, bombs), aircraft strike (birds only) **Entanglement:** None **Ingestion:** Medium-caliber projectiles, casings	
Detailed Military Expended Material Information	Small-caliber projectiles Medium-caliber canon rounds Non-explosive rockets and missiles Non-explosive bombs Weapons carriage, suspension, and launch equipment	
Assumptions used for Analysis	Estimate two to four weapons carriages expended per event	

A.2.1.4 Intelligence, Surveillance, and Reconnaissance Test

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Anti-Air Warfare</td></tr>
<tr><td>Intelligence, Surveillance, and Reconnaissance Test</td><td colspan="2">Aircrews use all available sensors to collect data on threat vessels.</td></tr>
<tr><td>Long Description</td><td colspan="2">An Anti-Air Warfare intelligence, surveillance, and reconnaissance test involves evaluating communications capabilities of fixed-wing and rotary-wing aircraft, including unmanned systems that can carry cameras, sensors, communications equipment, or other payloads. New systems are tested at sea to ensure proper communications between aircraft and vessels.
Several unmanned aerial systems are planned for testing, including the Broad Area Maritime Surveillance system, Fire Scout vertical take-off and landing tactical unmanned air vehicle, and the Unmanned Combat Air System; Aircraft Carrier Demonstration; Unmanned Aerial System. Unmanned Aerial Systems are remotely piloted or self-piloted aircraft.
Tactical Unmanned Aerial Systems are designed to support tactical commanders with near-real-time imagery intelligence at ranges up to 200 kilometers. Most small- to mid-sized unmanned systems, such as Small Tactical Unmanned Aerial System/Tier II, act as eyes in the sky, relaying raw imagery back to military personnel on the ground. The data are then processed, analyzed, and shared up and down the chain of command. New technology systems provide combat identification Friend or Foe and are used for aircraft and ship-based communications.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Fixed-wing aircraft (e.g., E-2 and P-8, P-3); Rotary-wing aircraft; Broad Area Maritime Surveillance system; Fire Scout vertical take-off and landing tactical unmanned air vehicle; Unmanned Combat Air System; Aircraft Carrier Demonstration; Small Tactical Unmanned Aerial System/Tier II

A.2.2 ANTI-SURFACE WARFARE TESTING

A.2.2.1 Air-to-Surface Missile Test

Activity Name	Activity Description
Anti-Surface Warfare	
Air-to-Surface Missile Test	This event is similar to the training event missile exercise air-to-surface. Test may involve both fixed-wing and rotary-wing aircraft launching missiles at surface maritime targets to evaluate the weapons system or as part of another systems integration test.
Long Description	Similar to a missile exercise air-to-surface, an Air to Surface Missile Test may involve both fixed-wing and rotary-wing aircraft launching missiles at surface maritime targets to evaluate the weapons system or as part of another systems integration test. Air-to-Surface Missile Tests can include high explosive, non-explosive, or non-firing (captive air training missile) weapons. Both stationary and mobile targets would be utilized during testing, and some operational tests would use explosive missiles (i.e., high explosive warhead). All developmental testing will use non-explosive missile (i.e., non-explosive warhead) with a live motor. NAVAIR plans to conduct integration testing of the MH-60R/S helicopters and the joint air to ground missile. Both stationary and mobile targets would be using during testing. Approximately 25 percent of some operational tests could use explosive missiles (i.e. high explosive warhead). All developmental testing will use non-explosive (i.e., non-explosive warhead). Similar integration tests would be conducted with the MH-60R/S and the Hellfire air to ground missile. Approximately 25 percent of these tests could involve high-explosive missiles (i.e. high-explosive warhead). P-3 and P-8A fixed-wing aircraft plan to conduct software and weapons verification testing with Harpoon or Joint Stand-off Weapon (or equivalent) missiles. Some explosive missiles are planned for use.
Information Typical to the Event	**Platform:** Fixed and rotary-wing aircraft (e.g., P3, P8; MH 60) **Systems:** Missile systems **Ordnance/Munitions:** Joint air to surface missile; Hellfire air-to-ground missile (high-explosive); Harpoon, Joint Stand-off Weapon (non-explosive); Captive air training missile; SLAM-ER missile **Targets:** Stationary and mobile surface marine targets **Duration:** 2 to 4 flight hours/event **Location:** Hawaii Operating Area Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives, aircraft noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (missiles), aircraft strike (birds only) **Entanglement:** None **Ingestion:** Missile fragments, Target fragments
Detailed Military Expended Material Information	Missile and target fragments
Assumptions used for Analysis	Two air-to-surface missiles per event, 25 percent will be high-explosive

A.2.2.2 Air-to-Surface Gunnery Test

Activity Name	Activity Description
Anti-Surface Warfare	
Air-to-Surface Gunnery Test	This event is similar to the training event gunnery exercise air-to-surface. Strike fighter and helicopter aircrews evaluate new or enhanced aircraft guns against surface maritime targets to test that the gun, gun ammunition, or associated systems meet required specifications or to train aircrew in the operation of a new or enhanced weapons system.
Long Description	Strike fighter and helicopter aircrews evaluate new or enhanced aircraft guns against surface maritime targets to test that the gun, gun ammunition, or associated systems meets required specifications or to train aircrew in the operation of a new or enhanced weapons system. Non-explosive practice munitions are typically used during this type of test; however, a small number of high explosive rounds may be used during final testing. Rounds that may be used include 7.62 mm, 20 mm, 30 mm, 0.30-caliber, and 0.50-caliber gun ammunition.
Information Typical to the Event	**Platform:** Fixed-wing and rotary aircraft (e.g., F-35; F/A-18; and MH 60) **Systems:** Small- and medium-caliber gun systems (GAU-17, GAU-21, M197, M230, M240) **Ordnance/Munitions:** Small- and Medium-caliber projectiles (e.g., 7.62 mm, 20 mm, 30 mm, 30 mm supercavitating, 0.30 caliber, and 0.50 caliber [non-explosive and explosive]) **Targets:** Stationary and mobile surface maritime targets may be used **Duration:** 2 flight hours/event **Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (projectiles), aircraft strike (birds only) **Entanglement:** None **Ingestion:** Projectile fragments, casings, target fragments, medium-caliber projectiles
Detailed Military Expended Material Information	Projectiles Casings Target fragments Projectile fragments
Assumptions used for Analysis	None

A.2.2.3 Rocket Test

Activity Name	Activity Description	
Anti-Surface Warfare		
Rocket Test	Rocket tests are conducted to evaluate the integration, accuracy, performance, and safe separation of laser-guided and unguided 2.75-inch rockets fired from a hovering or forward flying helicopter or from a fixed-wing strike aircraft.	
Long Description	Rocket tests are conducted to evaluate the integration, accuracy, performance, and safe separation of laser-guided and unguided 2.75-inch rockets fired from a hovering or forward flying helicopter or from a fixed-wing strike aircraft. Rocket tests would involve the release of primarily live motor/non-explosive warhead rockets. Some high explosive warhead rockets would be tested, and during a jettison test, rockets with a non-explosive motor and non-explosive warhead would be jettisoned along with the rocket launcher. Rocket tests are also conducted to train aircrew on the use of new or enhanced weapons systems. Rocket types may include variations of the Hydra-70 rocket developed under the Advanced Precision Kill Weapons System program or similar munitions developed under Low-cost Guided Imaging Rocket program as well as MEDUSA rockets. All rockets planned for testing are 2.75-inch rockets. Some rocket tests may be conducted in conjunction with upgrades to or integration of the Forward Looking Infrared targeting system.	
Information Typical to the Event	**Platform:** Fixed-wing or rotary aircraft (e.g., F/A 18; F-35; MH-60) **Systems:** **Ordnance/Munitions:** 2.75 inch rockets (e.g., Hydra-70 or similar [explosive and non-explosive]) **Targets:** Stationary and mobile surface maritime targets may be used **Duration:** 1.5 to 2 hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (rockets), aircraft strike (birds only) **Entanglement:** None **Ingestion:** Rocket fragments, target fragments	
Detailed Military Expended Material Information	Rocket fragments Target fragments Rocket launcher	
Assumptions used for Analysis	Under the No Action Alternative, all rockets are non-explosive Alternatives 1 and 2: Multiple rockets fired per event, 25 percent which will be high-explosive	

A.2.2.4 Laser Targeting Test

Activity Name	Activity Description	
Anti-Surface Warfare		
Laser Targeting Test	Aircrews illuminate enemy targets with lasers.	
Long Description	Aircrew use laser targeting devices integrated into aircraft or weapons systems to evaluate targeting accuracy and precision and to train aircrew in the use of newly developed or enhanced laser targeting devices designed to illuminate designated targets for engagement with laser-guided weapons. No weapons are released during a laser targeting test.	
Information Typical to the Event	**Platform:** Rotary or fixed-wing aircraft (e.g., MH-60; P8) **Systems:** Laser targeting systems, including the Laser Range Designator on the MH-60 helicopters **Ordnance/Munitions:** None **Targets:** None **Duration:** 2.5 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** In-air low energy lasers **Physical Disturbance and Strike:** Aircraft strikes (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	Laser energy for targeting is not carried forward for analysis	

A.2.3 ELECTRONIC WARFARE TESTING

A.2.3.1 Electronic Systems Evaluation

Activity Name	**Activity Description**	
Electronic Warfare		
Electronic Systems Evaluation	Test to evaluate the effectiveness of electronic systems to control, deny, or monitor critical portions of the electromagnetic spectrum. In general, Electronic Warfare testing will assess the performance of three types of Electronic Warfare systems: Electronic Attack, Electronic Protect, and Electronic Support.	
Long Description	Electronic Systems Evaluations are performed to determine the effectiveness of designated Electronic Warfare systems to control, deny, or monitor critical portions of the electromagnetic spectrum. In general, Electronic Warfare testing will assess the performance of three types of Electronic Warfare systems; specifically, Electronic Attack, Electronic Protect, and Electronic Support. Aircraft Electronic Attack systems are designed to confuse the enemy or deny the enemy the use of its electronically-targeted weapons systems. The Suppression of Enemy Air Defenses and active jamming against hostile aircraft and surface combatant radars are examples of the application of Electronic Attack. Aircraft Electronic Protect systems are designed to intercept, identify, categorize, and defeat threat weapons systems that are already targeting that or other friendly aircraft. Aircraft Electronic Support systems employ passive tactics to intercept, exploit, locate (target), collect, collate, and decipher information from the Radio Frequency spectrum for the purpose of determining the intentions of the radiating source. Test results are compared against design specifications to evaluate the performance of the actually Electronic Warfare system. The test results are also used to define performance characteristics and to improve and update existing analytical and predictive models.	
Information Typical to the Event	**Platform:** Fixed or rotary-wing aircraft (e.g., E-2/C-2, P-3C, P-8, F/A-18, E-6B; CH-53K) **Systems:** Electronic warfare systems (electronic attack, electronic protect, and electronic support) **Ordnance/Munitions:** None **Targets:** None **Duration:** 2 to 6 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.2.4 ANTI-SUBMARINE WARFARE TESTING

A.2.4.1 Anti-Submarine Warfare Torpedo Test

Activity Name	Activity Description	
Anti-Submarine Warfare		
Anti-Submarine Warfare Torpedo Test	This event is similar to the training event, Torpedo Exercise. Test evaluates Anti-Submarine Warfare systems onboard rotary-wing and fixed-wing aircraft and the ability to search for, detect, classify, localize, and track a submarine or similar target.	
Long Description	Similar to a Torpedo Exercise, an Anti-Submarine Warfare Torpedo Test evaluates Anti-Submarine Warfare systems onboard rotary-wing (e.g., MH-60R helicopter) and fixed-wing Marine Patrol Aircraft (e.g., P-8, P-3) aircraft and the ability to search for, detect, classify, localize, track, and attack a submarine or similar target (e.g., MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, or MK-30). The focus of the Anti-Submarine Warfare Torpedo test is on the torpedo and torpedoes (e.g., MK-46 or MK-54), but other Anti-Submarine Warfare systems are often used during the test, such as AN/AQS-22 dipping sonar (MH-60R) and sonobuoys (e.g., AN/SSQ-62). MK-39 or MK-30 targets simulate a submarine threat and are deployed at varying depths and speeds. If available, tests may be conducted using a submarine as the target. This activity can be conducted in shallow or deep waters and aircraft can originate from a land base or from a surface ship. The Torpedo Test culminates with the release of an exercise torpedo against the target and is intended to evaluate the targeting, release, and tracking process of deploying torpedoes from aircraft. All exercise torpedoes used in testing are either running (EXTORP) or non-running (REXTORP). Non-explosive torpedoes are recovered. A parachute assembly and guidance wire used for aircraft-launched torpedoes is jettisoned and sinks. Ballast (typically lead weights) may be released from the torpedoes to allow for recovery and sink to the bottom.	
Information Typical to the Event	**Platform:** Fixed and rotary-wing aircraft (e.g., P-3/P-8, MH-60R) **Systems:** Dipping sonar(e.g., AN/AQS-22); sonobuoys (e.g., AN/SSQ-62) **Ordnance/Munitions:** Torpedoes (e.g., MK-46, MK-54, MK-50, and MK-56; non-explosive) **Targets:** MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, MK-30, or submarine **Duration:** 2 to 6 flight hours/event.	**Location:** Hawaii Operating Area Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency Sonar (MF4), sonobuoys (MF5), lightweight torpedoes (TORP1), aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, aircraft strike (birds only) **Entanglement:** Parachutes, guidance wire **Ingestion:** Parachutes	
Detailed Military Expended Material Information	Torpedo accessories (e.g. parachute assembly, guidance wire) Sonobuoys Ballast targets	
Assumptions used for Analysis	Assume one torpedo accessory package (parachute, ballast, guidance wire) per torpedo Assume one target per torpedo Assume 12 sonobuoys per event Assume 15 percent of torpedoes are not recovered	

A.2.4.2 Kilo Dip

Activity Name	**Activity Description**	
Anti-Submarine Warfare		
Kilo dip	Functional check of the AN/AQS-22 dipping sonar prior to conducting full test or training event on the dipping sonar.	
Long Description	A kilo dip is the operational term used to describe a functional check of a helicopter deployed dipping sonar system. During a functional check, a single MH-60R helicopter would transit to an area designated for dipping sonar testing (i.e., a dip point usually close to shore) and would deploy the AN/AQS-22 sonar transducer assembly via a reel mechanism to a predetermined depth or series of depths while the helicopter hovers over the dip point. Once at the desired depth, the AN/AQS-22 sonar transducer would be activated and would transmit a pulsed, acoustic signal (i.e., ping) for approximately two to four minutes (enough time to check that all systems are functioning properly). After the check is completed, the AN/AQS-22 sonar transducer assembly would be reeled in, and in some instances the helicopter would transit to a second dip point before the procedure is repeated. A kilo dip is a precursor to more comprehensive testing.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft (e.g., MH-60R) **Systems:** Mid-frequency dipping sonar (AN/AQS-22) **Ordnance/Munitions:** None **Targets:** None **Duration:** 1.5 flight hours/event	**Location:** Hawaii Operating Area Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (MF4), aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.2.4.3 Sonobuoy Lot Acceptance Test

Activity Name	**Activity Description**	
Anti-Submarine Warfare		
Sonobuoy Lot Acceptance Test	Sonobuoys are deployed from surface vessels and aircraft to verify the integrity and performance of a lot or group of sonobuoys in advance of delivery to the Fleet for operational use.	
Long Description	Sonobuoys are deployed from surface vessels and aircraft to verify the integrity and performance of a lot or group of sonobuoys in advance of delivery to the Fleet for operational use. Lot acceptance testing would occur for the following types of sonobuoys: AN/SSQ-62 DICASS, AN/SSQ-110 Improved Extended Echo Ranging, AN/SSQ-125 MAC, MK-61 SUS, MK-64 SUS, MK-82 SUS, MK-84 SUS, and Mini Source. Some sonobuoys are high explosive.	
Information Typical to the Event	**Platform:** Surface combat vessels, fixed-wing aircraft, rotary-wing aircraft **Systems:** Sonobuoys (AN/SSQ-62x DICASS, AN/SSQ-110x Improved Extended Echo Ranging, AN/SSQ-125 MAC, MK-61 SUS, MK-64 SUS, MK-82 SUS, MK-84 SUS, Mini Source, and high duty cycle sonar **Ordnance/Munitions:** High explosive sonobuoy systems described above **Targets:** None **Duration:** 6 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Sonar and other active acoustic sources (ASW2, MF5, MF6), underwater explosives (E3, E4), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, vessel strike, aircraft strike (birds only) **Entanglement:** Parachutes **Ingestion:** Parachutes, sonobuoy fragments	
Detailed Military Expended Material Information	Parachutes Sonobuoy fragments	
Assumptions used for Analysis	Assume one parachute per sonobuoy Assume an average of 80 non-explosive sonobuoys per event; however the number of sonobuoys used in each event may vary	

A.2.4.4 Anti-Submarine Warfare Tracking Test – Helicopter

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Anti-Submarine Warfare</td></tr>
<tr><td>Anti-Submarine Warfare Tracking Test – Helicopter</td><td colspan="2">This event is similar to the training event, Anti-Submarine Tracking Exercise–Helicopter. The test evaluates the sensors and systems used to detect and track submarines and to ensure that helicopter systems used to deploy the tracking systems perform to specifications.</td></tr>
<tr><td>Long Description</td><td colspan="2">Similar to an Anti-Submarine Tracking Exercise–Helicopter, an Anti-Submarine Tracking Test — Helicopter evaluates the sensors and systems used to detect and track submarines and to ensure that platform systems used to deploy the tracking systems perform to specifications. Typically, one MH-60R helicopter conducts Anti-Submarine testing using the AN/AQS-22 dipping sonar, tonal sonobuoys (e.g., AN/SSQ-62), passive sonobuoys (e.g., AN/SSQ-53D/E), or explosive sonobuoys (e.g., mini sound-source seeker buoys). Targets (e.g., MK-39 Expendable Mobile Anti-Submarine Warfare Training Target or MK-30) may also be employed during an Anti-Submarine event. If available, tests may be conducted using a submarine as the target. This activity would be conducted in shallow or deep waters and could initiate from a land base or from a surface ship. Helicopter Anti-Submarine tests are intended to evaluate the sensors and systems used to detect and track submarines and to ensure that platform systems used to deploy the tracking systems perform to specifications. Some Anti-Submarine Helicopter Tracking Test could be conducted as part of an Anti-Submarine Tracking Coordinated Event with Fleet training activities.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Rotary-wing aircraft (e.g., MH-60R)
Systems: Dipping sonar (e.g., AN/AQS-22), tonal sonobuoys (e.g., AN/SSQ-62), explosive sonobuoys (e.g., mini sound-source seeker buoys), passive sonobuoys (e.g., AN/SSQ-53),and new development of mid-frequency active sonar buoys (follow-on to DICASS)
Ordnance/Munitions: High explosive sonobuoys [mini sound-source seeker buoys (i.e., mini-buoys)]
Targets: MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, MK-30 recoverable target, submarine
Duration: 2 flight hours/event</td><td>Location:
Hawaii Operating Area
Southern California Operating Area</td></tr>

If target air dropped, one parachute/target
24 sonobuoys per event</td></tr>
</table>

A.2.4.5 Anti-Submarine Warfare Tracking Test – Maritime Patrol Aircraft

Activity Name	Activity Description
Anti-Submarine Warfare	
Anti-Submarine Warfare Tracking Test – Maritime Patrol Aircraft	This event is similar to the training event, Anti-Submarine Warfare Tracking Exercise–Maritime Patrol Aircraft. The test evaluates the sensors and systems used by maritime patrol aircraft to detect and track submarines and to ensure that aircraft systems used to deploy the tracking systems perform to specifications and meet operational requirements.
Long Description	Similar to an Anti-Submarine Warfare Tracking Exercise-Maritime Patrol Aircraft. Anti-Submarine Warfare Tracking Test—Maritime Patrol Aircraft evaluates the sensors and systems used to detect and track submarines and to ensure that platform systems used to deploy the tracking systems perform to specifications and meet operational requirements. P-3 or P-8A fixed-wing aircraft conduct Anti-Submarine Warfare testing using tonal sonobuoys (e.g., AN/SSQ-62 DICASS), explosive sonobuoys (e.g., AN/SSQ-110 Improved Extended Echo Ranging), passive sonobuoys (e.g., AN/SSQ-53), torpedoes (e.g., MK-46), smoke devices (e.g., MK-58), SUS devices (e.g., MK-61 SUS), missiles (e.g., harpoons), and chaff. Targets (e.g., MK-39 Expendable Mobile Anti-Submarine Warfare Training Target) may also be employed during an Anti-Submarine Warfare scenario. This activity would be conducted in deep waters and could initiate from a land base or from a surface ship. Some Anti-Submarine Warfare Maritime Patrol Aircraft Tracking Test could be conducted as part of a Coordinated Event with Fleet training activities.
Information Typical to the Event	**Platform:** Fixed-wing Maritime Patrol Aircraft (e.g., P-3, P-8A,) **Systems:** Tonal sonobuoys (e.g., AN/SSQ-62 DICASS); passive sonobuoys (e.g., AN/SSQ-53); Explosive sonobuoys (e.g., AN/SSQ-110 Improved Extended Echo Ranging), **Ordnance/Munitions:** Non-explosive, all recovered; other non-explosive class stores (1000 lbs.) torpedoes, smoke devices, chaff, missiles, SUS devices **Targets:** MK-39 or MK-30 **Duration:** 4 to 6 flight hours/event **Location:** Hawaii Operating Area Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonobuoys (ASW2, MF5, MF6), underwater explosives (E3), aircraft noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike, in-water device strike, aircraft strike (birds only) **Entanglement:** Parachutes **Ingestion:** Parachutes, sonobuoy fragments, torpedo fragments, chaff
Detailed Military Expended Material Information	One MK-39 or MK-30 target (MK-30 is recovered and reused, MK-39 is not) If target air dropped, one parachute per target 20-60 sonobuoys per event (one parachute per sonobuoy) Smoke device
Assumptions used for Analysis	Torpedo, missile, flare, and chaff use will be captured under Anti-submarine warfare Torpedo Test, Anti-Surface Warfare Missile Test, and Chaff Test, respectively: Analysis of these will not be conducted under this activity

A.2.5 MINE WARFARE TESTING

A.2.5.1 Airborne Mine Neutralization System Test

Activity Name	**Activity Description**	
Mine Warfare		
Airborne Mine Neutralization Systems Test-AN/AQS-235	Airborne mine neutralization tests of the AN/ASQ-235 evaluate the system's ability detect and destroy mines off of the MH-60 Airborne Mine Countermeasures capable helicopter. The AN/ASQ-235 uses up to four unmanned underwater vehicles equipped with high frequency sonar, video cameras, and explosive neutralizers.	
Long Description	Mine neutralization tests evaluate aircraft and aircraft systems intended to neutralize or otherwise destroy mines through the use of explosives or other munitions. For most neutralization tests, mine shapes or non-explosive mines are used to evaluate new or enhanced mine neutralization systems. The AN/ASQ-235 uses up to four unmanned underwater vehicles equipped with high frequency sonar and video cameras to detect submerged mines. The unmanned underwater vehicles are also equipped with explosives to neutralize the mines after they are located. Data from unmanned underwater vehicles are relayed to the operator in the helicopter through a fiber-optic cable enabling the operator to position the neutralizing charge onto the most vulnerable area of the mine. The explosive charge is then detonated to neutralize the mine. For most tests, recoverable non-explosive neutralizers are used. A mine shape, rather than a high explosive mine, serves as the target and a range support vessel recovers the non-explosive neutralizer and the mine shape following the test. Testing scenarios include a non-explosive neutralizer against an inert mine shape, or a high explosive neutralizer against an explosive mine.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft (e.g., MH-60S) **Systems:** Airborne Mine Neutralization System (e.g. AN/ASQ-235) **Ordnance/Munitions:** Neutralizers (explosive and non-explosive), Mines (explosive and non-explosive) **Targets:** Floating/moored/bottom mine shapes **Duration:** 2.5 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High frequency sonar (HF4), underwater explosives (E4, E11), aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only), military expended material strike, seafloor device strike (mine shapes) **Entanglement:** Fiber optic cable **Ingestion:** Mine fragments, neutralizer fragments, fiber optic cable fragments	
Detailed Military Expended Material Information	Fiber-optic cable, plus additional expended material, such as the can that holds and deploys the cable Explosive and target residue (during 20 percent of testing and training when an explosive neutralizer is used) One to four neutralizers deployed per high explosive event Mine shapes are typically retrieved and reused, if they are not too badly damaged from neutralization attempt	
Assumptions used for Analysis	None	

A.2.5.2 Airborne Towed Minehunting Sonar System Test

Activity Name	Activity Description	
Mine Warfare		
Airborne Towed Minehunting Sonar System Test	A mine-hunting system that is towed from an MH-60S helicopter with sonar for detection and classification of bottom and moored mines. An electro-optical sensor allows for identification of bottom mines.	
Long Description	Tests of towed mine-hunting sonar systems (e.g., AN/AQS-20A) evaluate the search capabilities of this helicopter-towed, mine hunting, detection, and classification system. The sonar on the Q20 identifies mine-like objects in the deeper parts of the water column, but is not designed to identify near-surface mines.	
Information Typical to the Event	**Platform:** Rotary-wing (e.g., MH-60S) **Systems:** Towed mine-hunting sonar systems (e.g., AN/AQS-20A) **Ordnance/Munitions:** None **Targets:** Floating/moored/near surface mine or mine shape **Duration:** 2.5 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High frequency sonar (HF4), aircraft noise **Energy:** None **Physical Disturbance and Strike:** In-water device strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Anchors (moored mine targets only)	
Assumptions used for Analysis	None	

A.2.5.3 Airborne Towed Minesweeping System Test

Activity Name	Activity Description	
Mine Warfare		
Airborne Towed Minesweeping System Test	Airborne Towed Minesweeping Test (e.g., Organic Airborne and Surface Influence Sweep) would be conducted by a MH-60S helicopter to evaluate the functionality of towed minesweeping devices and the MH-60S at sea. The Organic Airborne and Surface Influence Sweep is towed from a forward flying helicopter and works by emitting an electromagnetic field and mechanically generated underwater sound to simulate the presence of a ship. The sound and electromagnetic signature cause nearby mines to explode.	
Long Description	Airborne Towed Minesweeping Test (e.g., Organic Airborne and Surface Influence Sweep) would be conducted by an Airborne Mine Countermeasures capable MH-60S helicopter to evaluate the functionality of Organic Airborne and Surface Influence Sweep and MH-60S at sea. For most tests, mine sweeping would be simulated using Versatile Exercise Mine System (non-explosive mine shapes that emit a plume of smoke rather than exploding) and high explosive mines at the culmination of testing, approximately one per event. The Organic Airborne and Surface Influence Sweep works by emitting an electromagnetic field and underwater sound generated from a mechanical source to simulate a vessel's sound signature. The Organic Airborne and Surface Influence Sweep serves to "sweep" or cause live mines to detonate when exposed to the electromagnetic field and simulated ship sound signature. The sound generated from the Organic Airborne and Surface Influence Sweep is not sonar, but rather a mechanically-generated sound to simulate a vessel prop.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft (e.g., MH-60S) **Systems:** Towed minesweeping systems (e.g., Organic Airborne and Surface Influence Sweep) **Ordnance/Munitions:** Mines (explosive), Versatile Exercise Mine System **Targets:** Floating/moored/bottom mine shapes (non-explosive and explosive) **Duration:** 2.5 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E11), aircraft noise **Energy:** Electromagnetic **Physical Disturbance and Strike:** In-water device strike, seafloor device strike (mine shapes), aircraft strike (birds only) **Entanglement:** None **Ingestion:** Mine fragments	
Detailed Military Expended Material Information	Mine fragments	
Assumptions used for Analysis	Non-explosive mine shapes will be recovered	

A.2.5.4 Airborne Laser-Based Mine Detection System Test

Activity Name	Activity Description	
Mine Warfare		
Airborne Laser-Based Mine Detection System Test	An airborne mine hunting test of the AN/AES-1 Airborne Laser Mine Detection System, that is operated from the MH-60S helicopter and evaluates the system's ability to detect, classify, and fix the location of floating and near-surface, moored mines. The system uses a laser to locate mines and may operate in conjunction with an airborne projectile-based mine detection system to neutralize mines.	
Long Description	During an Airborne Mine Countermeasures test, a MH-60S helicopter evaluates the search capabilities of the AN/AES-1 Airborne Laser Mine Detection System Airborne Laser Mine Detection System is a mine hunting system designed to detect, classify, and localize floating and near-surface, moored sea mines using a laser system. The Airborne Laser Mine Detection System will be integrated into the MH-60S helicopter to provide a rapid wide-area reconnaissance and assessment of mine threats in littoral zones, confined straits, choke points, and amphibious objective areas for Carrier and Expeditionary Strike Groups. The Airborne Laser Mine Detection System uses pulsed laser light to image the entire near-surface volume potentially containing mines. Airborne Laser Mine Detection System is capable of day or night operations without stopping to deploy or recover equipment and without towing any equipment in the water. With un-tethered operations, it can attain high area search rates. This design uses the forward motion of the aircraft to generate image data negating the requirement for complex scanning mechanisms and ensuring high system reliability. Airborne Laser Mine Detection System also provides accurate target geo-location to support follow on neutralization of the detected mines. Airborne Laser Mine Detection System works in conjunction with the Airborne Projectile-Based Mine Clearance System.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft (e.g., MH-60S) **Systems:** AN/AES-1 Airborne Laser Mine Detection System **Ordnance/Munitions:** None **Targets:** Floating/moored mine shapes **Duration:** 2.5 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** Aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.2.5.5 Airborne Projectile-Based Mine Clearance System

Activity Name	**Activity Description**	
Mine Warfare		
Airborne Projectile-Based Mine Clearance System	An MH-60S helicopter uses a laser-based detection system to search for mines and to fix mine locations for neutralization with an airborne projectile-based mine clearance system. The system neutralizes mines by firing a small- or medium-caliber inert, supercavitating projectile from a hovering helicopter.	
Long Description	During an airborne projectile-based mine clearance system test, an MH-60S helicopter evaluates the search capabilities of an Airborne Projectile-based Mine Clearance System (such as the AN/AWS-2 Rapid Airborne Mine Clearance System) to detect mines and fix mine locations using a laser. The airborne projectile-based mine clearance system can work in tandem with the Airborne Laser Mine Detection System by providing a mine neutralizing (destroying) capability for Airborne Laser Mine Detection System—detected, near-surface mines. The gun (e.g., Bushmaster) fires a medium-caliber (e.g., 30 mm) non-explosive, supercavitating projectile at the target from a hovering MH-60S. The projectile penetrates the target, rendering it non-functional. Mine shapes would almost always be used as the targets during a test. In the event a high explosive mine is used during the final testing phase, an underwater explosion may be generated as the mine is neutralized.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft (e.g., MH-60S) **Systems:** Rapid Airborne Mine Clearance System or similar system **Ordnance/Munitions:** Medium-caliber supercavitating projectile (non-explosive), Mines (non-explosive and explosive) **Targets:** Floating/moored/bottom mine or mine shape **Duration:** 2.5 flight hours/event	**Location:** Southern California Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (E11), aircraft noise **Energy:** In-air low energy laser **Physical Disturbance and Strike:** Military expended material strike (projectiles), seafloor device strike (mine shapes), aircraft strikes (birds only) **Entanglement:** None **Ingestion:** Projectiles (small- and medium-caliber), target fragments	
Detailed Military Expended Material Information	Projectiles (small- and medium-caliber) Target fragments Mine shapes are typically retrieved and reused, if they are not too badly damaged from neutralization attempt	
Assumptions used for Analysis	All mines under the No Action Alternative are non-explosive	

A.2.6 OTHER TESTING

A.2.6.1 Test and Evaluation – Catapult Launch

Activity Name	Activity Description	
Other Testing		
Test and Evaluation – Catapult Launch	Tests evaluate the function of aircraft carrier catapults at sea following enhancements, modifications, or repairs to catapult launch systems, including aircraft catapult launch tests. No weapons or other expendable materials would be released.	
Long Description	Aircraft catapults are systems used to assist aircraft take-off in aircraft carriers. Catapults consist of a track built into the flight deck, below which is a large piston or shuttle that is attached through the track to the nose gear of the aircraft. Navy aircraft launch systems are powered by steam or driven by an electromagnetic motor. Steam-powered catapults draw steam from the ship's boilers to the catapult steam receivers or accumulator, where it is stored at the desired pressure. From the receivers/accumulator, steam is directed to the launching valves, and provides the energy to launch aircraft. The most significant differences between the various types of steam catapults are the length and capacity. An electromagnetic launch system provides higher launch energy capability, reduced weight, volume, and maintenance, increased controllability, availability, reliability, and efficiency. The present electromagnetic aircraft launch system design centers around a linear synchronous motor and supplied power from pulsed disk alternators through a cycloconverter. Average power, obtained from an independent source on the host platform, is stored kinetically in the rotors of the disk alternators. It is then released in a two to three second pulse during a launch. This high-frequency power is fed to the cycloconverter which acts as a rising voltage, rising frequency source to the launch motor. The linear synchronous motor takes the power from the cycloconverter and accelerates the aircraft down the launch stroke, all the while providing "real time" closed loop control. Catapult launch tests would occur on Fleet aircraft carriers during deployment. The specific locations of carriers from 2014-2020 is unknown. No weapons or other expendable materials would be released during catapult tests.	
Information Typical to the Event	**Platform:** Aircraft Carrier (e.g., CVN 68-78), Fixed-wing aircraft (e.g., E-2/C-2) **Systems:** Catapult, Electromagnetic aircraft launch system **Ordnance/Munitions:** None **Targets:** None **Duration:** Fixed-wing aircraft 2 to 6 flight hours/event	**Location:** Throughout HSTT Study Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.2.6.2 Air Platform Shipboard Integration Test

Activity Name	Activity Description	
Other Testing		
Air Platform Shipboard Integration Test	Tests evaluate the compatibility of aircraft and aircraft systems with ships and shipboard systems. Tests involve physical operations and verify and evaluate communications and tactical data links. This test function also includes an assessment of carrier-shipboard suitability, such as Hazards of Electromagnetic Radiation to Ordnance, Hazard of Electromagnetic Radiation to Personnel, and High Energy Radio Frequency.	
Long Description	The Air Platform Shipboard Integration Test is performed to evaluate the compatibility of an aircraft to operate from designated shipboard platforms, perform shipboard physical operations, and to verify and evaluate communications and tactical data links. This test function also includes an assessment of carrier-shipboard suitability, such as Hazards of Electromagnetic Radiation to Ordnance, Hazard of Electromagnetic Radiation to Personnel, and High Energy Radio Frequency.	
Information Typical to the Event	**Platform:** Aircraft carrier (e.g., CVN 68-78), Fixed-wing aircraft (e.g., E-2/C-2) **Systems:** Data link and communication systems, Hazards of Electromagnetic Radiation to Ordnance, Hazard of Electromagnetic Radiation to Personnel, High Energy Radio Frequency **Ordnance/Munitions:** None **Targets:** None **Duration:** 2 to 6 flight hours/event	**Location:** Throughout HSTT Study Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Aircraft noise **Energy:** None **Physical Disturbance and Strike:** vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions used for Analysis	None	

A.2.6.3 Shipboard Electronic Systems Evaluation

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Other Testing</td></tr>
<tr><td>Shipboard Electronic Systems Evaluation</td><td colspan="2">Tests measure ship antenna radiation patterns and test communication systems with a variety of aircraft.</td></tr>
<tr><td>Long Description</td><td colspan="2">Shipboard electronic systems evaluation tests measure ship antenna radiation patterns and evaluate communication systems linking vessels and aircraft. Aircraft capable of landing on a vessel (e.g. aircraft carrier or Littoral Combat Ship) temporarily deploy to a nearshore vessel and conduct a variety of tests over a period of days to test newly installed or modified systems onboard the aircraft for compatibility with shipboard electronic systems. Follow-on test and evaluation of unmanned aerial systems would consist of dynamic interface testing, shipboard electromagnetic testing, and envelope expansion tests intended to evaluate capability of the unmanned aerial system to conduct launch and recovery operations from a vessel at sea as well as perform missions in a maritime environment. Altitudes would range from mean seal level to 15,000 ft. above mean seal level with the majority of flights occurring between mean seal level and 3,000 ft. Unmanned aerial systems would include Small Tactical Unmanned Aerial System/Tier II tactical unmanned aerial system, Broad Area Maritime Surveillance System, Fire Scout vertical take-off and landing tactical unmanned air vehicle, and Unmanned Combat Air System; and Aircraft Carrier Demonstration testing.

Shipboard testing of the Joint Precision Approach and Landing System, test new technology systems to provide precision guidance to aircraft landing on air capable vessels. At-sea flight test of the CH-53K helicopter would consist of shipboard compatibility (dynamic interface/envelope expansion) and, during Operational Evaluation, amphibious assault scenarios. Shipboard electronic systems evaluation tests of the V-22 helicopter would involve flight and wind envelope expansion interface testing with Amphibious Assault Ships, Amphibious Transport Dock, and Dock Landing Ship class vessels.</td></tr>

A.3 Naval Sea Systems Command Testing Activities

Naval Sea Systems Command testing activities are aligned with its mission of new ship construction, life cycle support, and weapon systems development. Each major category of Naval Sea Systems Command activities is described below.

A.3.1 New Ship Construction

Ship construction activities include pierside testing events, a series of sea trials, and developmental and operational test and evaluation programs. Pierside and at-sea testing of systems aboard a ship may include activation of acoustic sources, acoustic countermeasures, radars, and radio equipment. Pierside events also consist of light-off and operational checks of the vessel's propulsion, weapons, and other combat systems prior to at-sea operations. However, for purposes of this EIS/OEIS, pierside testing at Navy contractor shipyards will consist only of tactical sonar systems. At sea, each new ship is operated at full power and subjected to high-speed runs and steering tests. At-sea test firing of shipboard weapons systems, including guns, are also conducted.

A.3.1.1 Surface Combatant Sea Trials – Pierside Sonar Testing

Activity Name	Activity Description	
New Ship Construction		
Surface Combatant Sea Trials – Pierside Sonar Testing	Tests vessel's sonar systems pierside to ensure proper operation.	
Long Description	Pierside sonar testing is one part of the total surface combatant sea trial activity. Surface combatant sonar is tested pierside to ensure proper operation prior to conducting the at-sea portion of the sea trial. Surface combatants included in this activity are the ARLEIGH BURKE class (DDG 51) and the ZUMWALT class (DDG 1000) destroyers.	
Information Typical to the Event	**Platform:** Surface combatant vessel (e.g., DDG 51 and DDG 1000) **Systems:** Mid-frequency sonar **Ordnance/Munitions:** None **Targets:** None **Duration:** Event duration is 3 weeks accumulative per ship, with each source run independently and not continuously during this time	**Location:** Pierside: Pearl Harbor, HI Pierside: San Diego, CA
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1, MF1K, MF10), underwater communications (e.g., MF9) **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None

A.3.1.3 Surface Combatant Sea Trials – Gun Testing

Activity Name	Activity Description	
New Ship Construction		
Surface Combatant Sea Trials – Gun Testing	Gun systems are tested using non-explosive rounds.	
Long Description	Gun testing is one part of the total surface combatant sea trial activity. Tests currently include firing of 5-inch, 0.62-caliber guns, and will potentially include a 155 mm gun for future DDG 1000 platforms.	
Information Typical to the Event	**Platform:** Surface combatant vessel (e.g., DDG 51 and DDG 1000) **Systems:** Large-caliber guns (5 inch, 155 mm), medium caliber guns (close-in weapons system) **Ordnance/Munitions:** Large- and medium-caliber projectiles (e.g., 5 inch, 155 mm, 20 mm cannon [non-explosive]) **Targets:** None **Duration:** The entire sea trial duration is 4 days, within which gun testing would occur.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, military expended materials strike (non-explosive projectiles) **Entanglement:** None **Ingestion:** Projectiles, casings	
Detailed Military Expended Material Information	26 large-caliber non-explosive practice munitions per event; 700 medium-caliber non-explosive practice munitions per event Projectiles Casings	
Assumptions Used for Analysis	Vessels will not be conducting test constantly for the entire duration 26 large-caliber non-explosive practice munitions per event, 700 medium-caliber non-explosive practice munitions per event	

A.3.1.4 Surface Combatant Sea Trials – Missile Testing

Activity Name	Activity Description	
New Ship Construction		
Surface Combatant Sea Trials – Missile Testing	Non-explosive or explosive missiles are fired at target drones to test the launching system.	
Long Description	Missile testing is one part of the total surface combatant sea trial activity. During the event, support craft launch target drones, upon which two explosive or non-explosive missiles are fired.	
Information Typical to the Event	**Platform:** Surface combatant vessel (e.g., DDG 51 and DDG 1000) **Systems:** Missile launch system **Ordnance/Munitions:** Missiles (explosive and non-explosive) **Targets:** Retrievable mobile targets (e.g., drones) **Duration:** The entire sea trial duration is 4 days, within which missile testing would occur.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise, in-air explosives **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive practice munitions), vessel strike, munitions fragments **Entanglement:** None **Ingestion:** Munitions fragments	
Detailed Military Expended Material Information	Two missiles (explosive or non-explosive)/event	
Assumptions Used for Analysis	Vessels will not be conducting test constantly for the entire duration Two Missiles per event (explosive or non-explosive) Target drones are recovered by supporting craft	

A.3.1.5 Surface Combatant Sea Trials – Decoy Testing

Activity Name	Activity Description	
New Ship Construction		
Surface Combatant Sea Trials – Decoy Testing	Includes testing of the MK-36 Decoy Launching system	
Long Description	Testing of the MK-36 Decoy Launching system is one part of the total surface combatant sea trial activity. During the event, chaff cartridges are launched to ensure proper operation of the system.	
Information Typical to the Event	**Platform:** Surface combatant vessel (e.g., DDG 51 and DDG 1000) **Systems:** MK-36 Decoy Launching system **Ordnance/Munitions:** None **Targets:** None **Duration:** The entire sea trial duration is 4 days, within which decoy launching testing would occur.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel Noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, expended material other than munitions (concrete slugs) **Entanglement:** None **Ingestion:** End caps, pistons, chaff	
Detailed Military Expended Material Information	36 chaff cartridges (end caps, pistons, and chaff) or concrete slugs/event	
Assumptions Used for Analysis	Vessels will not be conducting test constantly for the entire duration 36 chaff cartridges or concrete slugs per event	

A.3.1.6 Surface Combatant Sea Trials – Surface Warfare Testing

Activity Name	Activity Description	
New Ship Construction		
Surface Combatant Sea Trials – Surface Warfare Testing – Large Caliber	Vessels defend against surface targets with large-caliber guns.	
Long Description	Surface warfare testing is one part of the total surface combatant sea trial activity. During this event, a high speed maneuverable surface target would run a weaving pattern towards the vessel at speeds in excess of 20 knots. The surface combatant would fire non-explosive large-caliber rounds at the incoming target.	
Information Typical to the Event	**Platform:** Surface combatant vessel (e.g., DDG 51 and DDG 1000) **Systems:** Large-caliber weapons systems **Ordnance/Munitions:** Large-caliber projectiles (e.g., 5 inch, 155 mm [non-explosive]) **Targets:** Surface targets (e.g., High Speed Maneuverable Surface Target) **Duration:** The entire sea trial duration is 4 days, within which surface warfare testing would occur.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike, military expended material strike (non-explosive practice munitions) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Large-caliber projectiles, target fragments	
Assumptions Used for Analysis	Vessels will not be conducting test constantly for the entire duration 48 rounds/event

A.3.1.8 Other Ship Class Sea Trials – Propulsion Testing

Activity Name	Activity Description	
New Ship Construction		
Other Class Ship Sea Trials – Propulsion Testing	Vessel is run at high speeds in various formations (e.g., straight-line and reciprocal paths).	
Long Description	Propulsion testing is one part of the total sea trial activity. During this event, the vessel is tested for maneuverability, including full power and endurance runs.	
Information Typical to the Event	**Platform:** Amphibious warfare vessels, surface combatant vessels (e.g., Littoral Combat Ship), support craft/other – specialized high speed vessels **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** Propulsion testing occurs during one day of a 5-day sea trial.	**Location:** Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Vessels will not be conducting test constantly for the entire duration Vessels may not be traveling in a straight line Vessels will operate across the full spectrum of capable speeds	

A.3.1.9 Other Ship Class Sea Trials – Gun Testing – Small Caliber

Activity Name	Activity Description	
New Ship Construction		
Other Class Ship Sea Trials – Gun Testing – Small Caliber	Vessels defend against surface targets with small-caliber guns.	
Long Description	Small-caliber gun testing is included as part of the total sea trial activity. Small-caliber gun testing includes 0.50-caliber guns.	
Information Typical to the Event	**Platform:** Amphibious warfare vessels, surface combatant vessel (e.g., Littoral Combat Ship), support craft/other – specialized high speed, **Systems:** Small-caliber weapon systems **Ordnance/Munitions:** Small-caliber projectiles (e.g., 0.50 caliber [non-explosive]) **Targets:** None **Duration:** Small-caliber gun testing would occur within the 5-day sea trials	**Location:** Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive projectiles), vessel strike **Entanglement:** None **Ingestion:** Small-caliber projectiles, casings	
Detailed Military Expended Material Information	Small-caliber projectiles Casings	
Assumptions Used for Analysis	Vessels will not be conducting test constantly for the entire duration	

A.3.1.10 Anti-Submarine Warfare Mission Package Testing

Activity Name	Activity Description	
New Ship Construction		
Anti-Submarine Warfare Mission Package Testing	Ships and their supporting platforms (e.g., helicopters, unmanned aerial vehicles) detect, localize, and prosecute submarines.	
Long Description	Vessels conduct detect-to-engage operations against modern diesel-electric and nuclear submarines using airborne and surface assets (both manned and unmanned). Active and passive acoustic systems are used to detect and track submarine targets, culminating in the deployment of lightweight torpedoes to engage the threat.	
Information Typical to the Event	**Platform:** Surface Combatant Vessels (e.g., Littoral Combat Ship); Rotary-wing aircraft, Submarines **Systems:** Surface ship sonar, helicopter-deployed sonar, active sonobuoys, torpedo sonar **Ordnance/Munitions:** Non-explosive torpedoes **Targets:** Motorized Autonomous Targets (e.g., Expendable Mobile Anti-Submarine Warfare Training Target) **Duration:** Event duration is approximately 1 to 2 weeks, with 4 to 8 hours of active sonar use with intervals of non-activity in between.	**Location:** Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF12), helicopter-deployed sonar (e.g., MF4), active sonobuoys (e.g., MF5), torpedo sonar (e.g., TORP1); Anti-submarine sonar (e.g., ASW1); acoustic countermeasures (e.g., ASW3), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel and in-water device strike, military expended material strike (sonobuoys), towed device strike, aircraft strike (birds only) **Entanglement:** Parachutes **Ingestion:** Parachutes	
Detailed Military Expended Material Information	Torpedo launch accessories Sonobuoys and parachutes	
Assumptions Used for Analysis	One target per event Two sonobuoys expended per event; all sonobuoys have a parachute unless otherwise noted	

A.3.1.11 Surface Warfare Mission Package – Gun Testing – Small Caliber

Activity Name	Activity Description	
New Ship Construction		
Surface Warfare Mission Package Testing – Gun Testing – Small Caliber	Vessels defend against surface targets with small-caliber guns.	
Long Description	Vessels conduct surface warfare by detecting, tracking, and prosecuting small-boat threats. The Surface Warfare Mission Package provides a layered strike/defensive capability by use of its embarked support aircraft, medium range surface-to-surface missiles, and 30 mm gun weapon system.	
Information Typical to the Event	**Platform:** Surface combatant vessels (e.g., Littoral Combat Ship) **Systems:** Small-caliber gun systems **Ordnance/Munitions:** Small-caliber projectiles (e.g., 0.50 caliber) (non-explosive) **Targets:** None **Duration:** Event duration is approximately 1 to 2 weeks, with intervals of surface warfare mission package use during this time.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive projectiles), vessel strike **Entanglement:** None **Ingestion:** Small projectile, casing	
Detailed Military Expended Material Information	Small projectiles Casings	
Assumptions Used for Analysis	500 rounds per event	

A.3.1.12 Surface Warfare Mission Package – Gun Testing – Medium Caliber

Activity Name	Activity Description	
New Ship Construction		
Surface Warfare Mission Package Testing – Gun Testing Medium Caliber	Vessels defend against surface targets with medium-caliber guns.	
Long Description	Vessels conduct surface warfare by detecting, tracking, and prosecuting small-boat threats. The surface warfare Mission Package provides a layered strike/defensive capability by use of its embarked support aircraft, medium range surface-to-surface missiles, and 30 mm gun weapon system.	
Information Typical to the Event	**Platform:** Surface Combatant Vessels **Systems:** Medium-caliber gun systems **Ordnance/Munitions:** Medium-caliber projectiles (explosive and non-explosive) **Targets:** None **Duration:** Event duration is approximately 1 to 2 weeks, with intervals of surface warfare mission package use during this time.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Weapons firing noise, vessel noise, underwater explosives (E1), **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive projectiles), vessel strike **Entanglement:** None **Ingestion:** Projectiles, casings, fragments	
Detailed Military Expended Material Information	Projectiles Casings, Fragments	
Assumptions Used for Analysis	700 explosive and 700 non-explosive rounds per event

A.3.1.14 Surface Warfare Mission Package Testing – Missile/Rocket Testing

Activity Name	Activity Description
New Ship Construction	
Surface Warfare Mission Package Testing – Missile/Rocket Testing	Vessels defend against surface targets with medium range missiles or rockets.
Long Description	Vessels conduct surface warfare by detecting, tracking, and prosecuting small-boat threats. The surface warfare Mission Package provides a layered strike/defensive capability by use of its embarked support aircraft, medium range missiles or rockets, and gun weapon system.
Information Typical to the Event	**Platform:** Surface Combatant Vessels, rotary-wing aircraft, unmanned aircraft **Systems:** None **Ordnance/Munitions:** Missiles (e.g., anti-surface) or rockets (non-explosive and explosive) **Targets:** None **Duration:** Event duration is approximately 1 to 2 weeks, with intervals of surface warfare mission package use during this time. **Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Underwater explosives (e.g., E6), weapons firing noise, aircraft noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive projectiles and explosive fragments), aircraft strike (birds only), vessel strike **Entanglement:** None **Ingestion:** Missile or rocket fragments
Detailed Military Expended Material Information	Missile or rocket fragments
Assumptions Used for Analysis	Two missiles or rockets per event

A.3.1.15 Mine Countermeasure Mission Package Testing

Activity Name	Activity Description	
New Ship Construction		
Mine Countermeasure Mission Package Testing	Vessels and associated aircraft conduct mine countermeasure operations.	
Long Description	Littoral Combat Ships conduct mine detection using unmanned submersible and aerial vehicles, magnetic and acoustic sensor systems deployed by vessel or support helicopters, and laser systems. Mines are then neutralized using magnetic, acoustic, and supercavitating systems.	
Information Typical to the Event	**Platform:** Littoral Combat Ship, Unmanned Underwater Vehicles, Rotary aircraft **Systems:** Towed sonar system **Ordnance/Munitions:** Mine neutralization systems (e.g., Airborne Mine Neutralization System) **Targets:** Floating/moored/bottom non-explosive, mines or passive mine simulation systems **Duration:** 1 to 2 weeks with intervals of mine countermeasure mission package use during this time.	**Location:** Hawaii Range Complex, Southern California Range Complex: Camp Pendleton Amphibious Assault Area; Pyramid Cove; Tanner Bank Minefield
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Towed sonar systems (e.g., HF4), underwater explosives (e.g., E4), aircraft noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike; aircraft strike (birds only) **Entanglement:** None **Ingestion:** Fragments	
Detailed Military Expended Material Information	Fragments	
Assumptions Used for Analysis	For Alternative 1: 9 events using 96 neutralizers (48 HE) For Alternative 2: 12 events using 128 neutralizers (64 HE)	

A.3.1.16 Post-Homeporting Test (All Classes)

Activity Name	Activity Description	
New Ship Construction		
Post-Homeporting Testing (All classes)	Tests electronic, navigation, and refueling capabilities.	
Long Description	Post-Homeporting testing includes Shipboard Electronic Systems Evaluation Facility measurements of antenna radiation patterns, Tactical Air Navigation certification, Identification Friend of Foe Verification, Dynamic Interface test (to validate helicopter operations), and underway replenishments.	
Information Typical to the Event	**Platform:** All classes of surface vessels **Systems:** Electronic and navigation systems **Ordnance/Munitions:** None **Targets:** None **Duration:** 1 to 5 days, depending upon the test being conducted (e.g., Shipboard Electronic Systems Evaluation Facility testing is 1 day; dynamic interface testing is 5 days).	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None	

A.3.2 Lifecycle Activities

Testing activities are conducted throughout the lifecycle of a Navy ship to verify performance and mission capabilities. Tactical sonar system testing occurs pierside during maintenance, repair and overhaul availabilities, and at sea immediately following most major industrial periods. A Combat System Ship Qualification Trial is conducted for new ships and for ships that have undergone modification or overhaul of their combat systems.

Radar cross signature testing of surface ships is accomplished on new vessels and periodically throughout a ship's life cycle to measure how detectable the ship is to radar. Additionally, new construction, post availability, and lifecycle electromagnetic measurements of off-board electromagnetic signature are conducted for submarines.

A.3.2.1 Ship Signature Testing

Activity Name	Activity Description
Lifecycle Activities	
Ship Signature Testing	Tests vessel and submarine radar signatures and electromagnetic countermeasures.
Long Description	Radar cross signature testing of surface vessels is accomplished on new vessels and periodically throughout a vessel's lifecycle to measure how detectable the vessel is to radar. For example, Assessment Identification of Mine Susceptibility measurements are specific electromagnetic and passive acoustical tests performed on mine countermeasure vessels and on the Littoral Combat Ship mine countermeasure modules to determine their mine susceptibility. Additionally, measurements of deployed electromagnetic countermeasures are conducted during the new construction, post-delivery, and lifecycle phases of the acquisition process for submarines. Signature testing of all surface vessels and submarines verifies that each vessel's signature is within specifications, and may include the use of helicopter-deployed instrumentation, ship-mounted safety and navigation systems, fathometers, tracking devices, radar systems, and underwater communications equipment. Event duration includes all systems checks, including those that do not have active sonar.
Information Typical to the Event	**Platform:** All surface vessel and submarine classes **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** Up to 20 days **Location:** Hawaii Range Complex Pierside: Pearl Harbor, HI Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None
Detailed Military Expended Material Information	None
Assumptions Used for Analysis	None

A.3.2.2 Surface Ship Sonar Testing/Maintenance (in Operating Areas and Ports)

Activity Name	Activity Description	
Lifecycle Activities		
Surface Ship Sonar Testing/Maintenance (in Operating Areas and Ports)	Pierside and at-sea testing of surface vessel systems occurs periodically following major maintenance periods and for routine maintenance.	
Long Description	Following major and routine maintenance periods, pierside and at-sea testing and maintenance is required. Multiple systems with active and passive acoustic sources such as tactical sonar, navigation systems, fathometers, underwater communications systems, underwater distress beacons, range finders, and other similar systems, would be tested.	
Information Typical to the Event	**Platform:** All surface vessel classes **Systems:** Surface ship sonar, underwater communications **Ordnance/Munitions:** None **Targets:** None **Duration:** Event duration for each test can be up to 3 weeks, with intermittent use of active sonar.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1, MF1K), underwater communications (e.g., MF9, MF10), acoustic countermeasures (e.g., ASW3), vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Sonar would not be continuously active for the duration of the test	

A.3.2.3 Submarine Sonar Testing/Maintenance (in Operating Areas and Ports)

Activity Name	Activity Description	
Lifecycle Activities		
Submarine Sonar Testing/Maintenance (in Operating Areas and Ports)	Pierside and at-sea testing of submarine systems occurs periodically following major maintenance periods and for routine maintenance.	
Long Description	Following major and routine maintenance periods, pierside and at-sea testing and maintenance is required. Multiple systems with active and passive acoustic sources such as navigation systems, fathometers, underwater communications systems, underwater distress beacons, range finders, and other similar systems, would be tested.	
Information Typical to the Event	**Platform:** Submarine **Systems:** Submarine sonar, underwater communications, tracking pingers **Ordnance/Munitions:** None **Targets:** None **Duration:** Event duration for each test can be up to 3 weeks, with intermittent use of active sonar.	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High-frequency sonar (e.g. , HF1, HF3), mid-frequency sonar (e.g., MF3) underwater communications (e.g., M3), vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Sonar would not be used continuously throughout duration of test	

A.3.2.4 Combat System Ship Qualification Trial – In-Port Maintenance Period

Activity Name	Activity Description	
Lifecycle Activities		
Combat System Ship Qualification Trial – In-Port Maintenance Period	Each combat system is tested to ensure they are functioning in a technically acceptable manner and are operationally ready to support at-sea Combat System Ship Qualification Trial events.	
Long Description	Each combat system is tested to ensure they are functioning in a technically acceptable manner and are operationally ready to support at-sea Combat System Ship Qualification Trial events. The ship's test plans and procedures, Maintenance Repair/Requirements Cards, and computerized planned maintenance system are used in establishing testing standards for each system and pieces of equipment. Vessel's crew, under supervision of subject matter experts, complete all actions and receive remedial training where required. Trouble Observation Reports are written on noted discrepancies.	
Information Typical to the Event	**Platform:** Surface combatant vessel, amphibious warfare vessel **Systems:** All combat systems **Ordnance/Munitions:** None **Targets:** None **Duration:** 3 weeks	**Location:** Pierside: Pearl Harbor, HI Pierside: San Diego, CA
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1) **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Sonar would not be continuously active for the duration of the test.	

A.3.2.5 Combat System Ship Qualification Trial – Air Defense

Activity Name	**Activity Description**	
Lifecycle Activities		
Combat System Ship Qualification Trial – Air Defense	Tests the vessel's capability to detect, identify, track, and successfully engage live and simulated targets.	
Long Description	Air Defense events are conducted in clear and varied electronic attack environments, using a mix of missile firings to verify the vessel's capability to detect, identify, track, and successfully engage live and simulated targets. The tests include testing the radar's track load in the presence of debris, long range engagement processing, low-elevation detection and tracking, track load in the presence of electronic attack and chaff, and missile performance.	
Information Typical to the Event	**Platform:** Surface combatant vessel, Amphibious warfare vessel **Systems:** All combat systems **Ordnance/Munitions:** Missiles (e.g., anti-air) (non-explosive and explosive), medium-caliber projectiles (non-explosive), large-caliber projectiles (explosive and non-explosive) **Targets:** Retrievable mobile targets (e.g., drones) and towed targets **Duration:** 1 week	**Location:** Hawaii Range Complex: Pacific Missile Range Facility. Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** In-air explosions, weapons firing noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive practice munitions, munition fragments), aircraft strike (birds only), vessel strike **Entanglement:** None **Ingestion:** Chaff, target fragments, medium-caliber projectiles, end caps, pistons, casings	
Detailed Military Expended Material Information	Projectiles Munition fragments Target fragments Chaff, end caps, pistons Targets Surface-to-air missiles	
Assumptions Used for Analysis	2,000 medium-caliber projectiles/event non-explosive; 20 large-caliber projectiles/event (explosive and non-explosive) 14 missiles/event (7 high-explosive) 24 canisters per event	

A.3.2.6 Combat System Ship Qualification Trial – Surface Warfare

Activity Name	Activity Description	
Lifecycle Activities		
Combat System Ship Qualification Trial – Surface Warfare	Tests shipboard sensors capabilities to detect and track surface targets, relay the data to the gun weapon system, and engage targets.	
Long Description	Surface warfare events are gun weapons system tests conducted in a clear environment to demonstrate shipboard sensors capabilities to detect and track surface targets, relay the data to the gun weapon system, and engage targets. The event qualified the vessel's surface warfare gun capability to receive track data from the sensors, filter it, calculate ballistics, recommend aim-point corrections (spots), generate gun orders, select ammunition properly for targets at differing ranges, and deliver surface direct fire on the surface targets.	
Information Typical to the Event	**Platform:** Surface combatant vessel, Amphibious warfare vessel **Systems:** Gun weapons system, Missile systems **Ordnance/Munitions:** Large-caliber projectiles (e.g., 155 mm, 5 inch) (non-explosive and explosive), medium-caliber projectiles (non-explosive), missiles (non-explosive) **Targets:** Mobile surface targets (e.g., High-Speed Maneuvering Surface Target), towed surface targets (e.g., low cost modular target) **Duration:** 1 week	**Location:** Hawaii Range Complex: Pacific Missile Range Facility Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** In-air explosives (E5), weapons firing noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive practice munitions, projectile fragments), vessel strike, in-water device strike **Entanglement:** None **Ingestion:** Medium-caliber projectiles, fragments	
Detailed Military Expended Material Information	Projectiles, munition fragments	
Assumptions Used for Analysis	Up to 300 large-caliber gun rounds/event (113 high-explosive) One surface-to-surface missile/event Up to 2,000 medium-caliber rounds/event Explosive large-caliber rounds are air-burst	

A.3.2.7 Combat System Ship Qualification Trial – Undersea Warfare

Activity Name	Activity Description	
Lifecycle Activities		
Combat System Ship Qualification Trial – Undersea Warfare	Tests vessel's ability to track and engage undersea targets.	
Long Description	Undersea warfare events are comprised of a series of tracking and firing exercises. The events ensure the operability of the undersea warfare suite and its interface with the Light Airborne Multi-Purpose System helicopter. Approximately one week of in-port training precedes exercises on an instrumented underwater range, where vessel's force becomes familiar with operation and maintenance of the undersea warfare system. Personnel then demonstrate the capability to establish the data link between the helicopter and vessel's undersea warfare system.	
Information Typical to the Event	**Platform:** Surface combatant vessel, rotary-wing aircraft **Systems:** Surface ship sonar, underwater communication systems, sonobuoys, missile systems **Ordnance/Munitions:** Non-explosive torpedoes **Targets:** Motorized autonomous targets (e.g., Expendable Mobile Anti-Submarine Warfare Training Target) **Duration:** 1 week	**Location:** Hawaii Range Complex: Pacific Missile Range Facility Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1, MF2), high-frequency sonar (e.g., HF4), helicopter-deployed dipping sonar (e.g., MF4), active sonobuoys (e.g., MF5), torpedo sonar (e.g., TORP1), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, In-water device strike, aircraft strike (birds only), military expended material strike (sonobuoys, torpedo launch accessories) **Entanglement:** Parachutes **Ingestion:** Parachutes and torpedo launch accessories	
Detailed Military Expended Material Information	Torpedo launch accessories (nose cap, suspension bands, air stabilizer, sway brace pad, arming wire, fahnstock clip, parachute) Sonobuoys Expendable targets Parachutes	
Assumptions Used for Analysis	Five targets per event All sonobuoys have a parachute unless otherwise noted Lightweight torpedoes only; no guidance wires Sonobuoys: 8 DICASS + 75 DIFAR/event	

A.3.3 SURFACE WARFARE/ANTI-SUBMARINE WARFARE TESTING

A.3.3.1 Missile Testing

Activity Name	Activity Description	
Surface Warfare/Anti-Submarine Warfare Testing		
Missile Testing	Missile testing includes various missiles fired from submarines and surface combatants.	
Long Description	Missile testing includes various missiles (e.g., standard missiles, Water Piercing Missile Launch) fired from submarines and surface combatants.	
Information Typical to the Event	**Platform:** Surface combatant vessels, submarines **Systems:** None **Ordnance/Munitions:** Missiles (e.g. anti-surface[non-explosive]) **Targets:** Unmanned surface vehicles, drones **Duration:** 1 to 2 hours	**Location:** Hawaii Range Complex: Pacific Missile Range Facility Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Weapons firing noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive practice munition), vessel strike, in-water device strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Missiles	
Assumptions Used for Analysis	All targets will be recovered One surface-to-surface missile/event	

A.3.3.2 Kinetic Energy Weapon Testing

Activity Name	Activity Description	
Anti-Surface Warfare/Anti-Submarine Warfare Testing		
Kinetic Energy Weapon Testing	A kinetic energy weapon uses stored energy released in a burst to accelerate a non-explosive projectile.	
Long Description	A kinetic energy weapon uses stored energy released in a burst to accelerate a non-explosive projectile to more than seven times the speed of sound to a range of up to 200 miles.	
Information Typical to the Event	**Platform:** Surface combatant vessel **Systems:** Kinetic energy weapon **Ordnance/Munitions:** Large-caliber projectile (non-explosive) **Targets:** Recoverable or expendable floating target **Duration:** 1 day	**Location:** Hawaii Range Complex: Pacific Missile Range Facility
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Weapons firing noise, vessel noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive projectile), vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Expended targets and target fragments	
Assumptions Used for Analysis	40 large-caliber projectile per event Assume one expendable target/per event One event with 5,000 projectiles would occur only once before 2019.	

A.3.3.3 Electronic Warfare Testing

Activity Name	Activity Description	
Surface Warfare/Anti-Submarine Warfare Testing		
Electronic Warfare Testing	Testing will include radiation of military and commercial radar and communication systems (or simulators).	
Long Description	Testing will include radiation of military and commercial radar and communication systems (or simulators). No subsurface transmission would occur during this testing.	
Information Typical to the Event	**Platform:** Submarines **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** 3 hours per day over 7 days	**Location:** Pierside: Pearl Harbor, HI Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None	

A.3.3.4 Torpedo (Non-Explosive) Testing

Activity Name	Activity Description
Surface Warfare/Anti-Submarine Warfare Testing	
Torpedo (Non-explosive) Testing	Air, surface, or submarine crews employ non-explosive torpedoes against submarines or surface vessels.
Long Description	Aerial, surface, and subsurface assets fire exercise torpedoes against surface or subsurface targets. Torpedo testing evaluates the performance and the effectiveness of hardware and software upgrades of heavyweight or lightweight torpedoes.
Information Typical to the Event	**Platform:** Submarines, Surface combatant vessels, Fixed-wing aircraft, Rotary-wing aircraft, Support Craft/Other **Systems:** Surface vessel and submarine sonar, sonobuoys, dipping sonar **Ordnance/Munitions:** Non-explosive lightweight torpedoes, heavyweight explosive torpedoes **Targets:** Submarines, surface vessels, motorized autonomous targets (e.g., Expendable Mobile Anti-Submarine Warfare Training Target), stationary artificial targets (e.g., fleet training target) **Duration:** Up to 2 weeks **Location:** Hawaii Range Complex: Hawaii Area Tracking System; Test area north of Maui or Penguin Bank Hawaii Range Complex: Pacific Missile Range Facility Hawaii Range Complex: Shallow Water Training Range Southern California Range Complex: Tanner/Cortes, or Southern California Anti-Submarine Warfare Range; Shore Bombardment Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High-frequency sonar (e.g., HF1), mid-frequency sonar (e.g., MF1, MF3), helicopter-deployed sonar (e.g., MF4), active sonobuoy (e.g., MF5), torpedo sonar (e.g., TORP1, TORP2), acoustic countermeasure (e.g., ASW3, ASW4), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike, aircraft strike (birds only), military expended material strike **Entanglement:** Parachutes (sonobuoy and torpedo), guidance wire **Ingestion:** Parachutes (sonobuoy and torpedo), torpedo launch accessories
Detailed Military Expended Material Information	Sonobuoys Parachutes Expendable targets Acoustic countermeasures Torpedo launch accessories o Lightweight/heavyweight torpedo launch accessories ▪ Nose cap, suspension bands, air stabilizer, sway brace pad, arming wire,Fahnstock clip, wing kit, rocket booster, parachute, lead weights o Expended material is dependent upon torpedo fired and firing platform. o Heavyweight torpedo launch accessories ▪ Guidance wire, flex hose
Assumptions Used for Analysis	Sonobuoys – 384 sonobuoys per year Expendable targets – one target per event Acoustic countermeasures – 356 countermeasures per year All torpedoes are recovered Assume all lightweight torpedo launch accessories have all listed material All sonobuoys have a parachute unless otherwise noted Typically, no more than eight torpedoes are fired per day during daylight hours.

A.3.3.5 Torpedo (Explosive) Testing

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>
<tr><td colspan="3">Surface Warfare/Anti-Submarine Warfare Testing</td></tr>
<tr><td>Torpedo (Explosive) Testing</td><td colspan="2">Air, surface, or submarine crews employ explosive torpedoes against artificial targets.</td></tr>
<tr><td>Long Description</td><td colspan="2">Non-explosive and explosive torpedoes (carrying a warhead) would be launched at a suspended target by a submarine and fixed- or rotary-winged aircraft or surface combatants. Torpedoes would detonate on an artificial target located at a depth between 200 and 700 ft. below the water’s surface.</td></tr>
<tr><td>Information Typical to the Event</td><td>Platform: Submarine, Surface combatant vessel, fixed-wing aircraft, rotary-wing aircraft, support craft/other
Systems: None
Ordnance/Munitions: Torpedoes (heavyweight and lightweight) (explosive and non-explosive)
Targets: Stationary artificial targets (e.g., MK-28)
Duration: 1 to 2 days during daylight hours. Only one heavyweight torpedo test could occur in 1 day; two heavyweight torpedo tests could occur on consecutive days. Two lightweight torpedo tests could occur in a single day.</td><td>Location:
Hawaii Range Complex
Southern California Range Complex</td></tr>
<tr><td>Potential Impact Concerns

<tr><td>Assumptions Used for Analysis</td><td colspan="2">All sonobuoys have a parachute unless otherwise noted
28 torpedoes per year (Alternatives 1 and 2)
8 high-explosive torpedoes/year
210 passive sonobuoys per event</td></tr>
</table>

A.3.3.6 Countermeasure Testing

Activity Name	**Activity Description**	
Anti-Surface Warfare/Anti-Submarine Warfare Testing		
Countermeasure Testing	Various acoustic systems (e.g., towed arrays and surface ship torpedo defense systems) are employed to detect, localize, track, and neutralize incoming weapons.	
Long Description	Countermeasure testing involves the testing of systems that would detect, localize, and track incoming weapons. At-sea testing of the Surface Ship Torpedo Defense systems include towed acoustic systems, torpedo warning systems, and countermeasure subsystems. Some countermeasure scenarios would employ non-explosive or explosive torpedoes against targets released by secondary platforms (e.g., helicopter or submarine). While surface vessels are in transit, countermeasure systems will be used to identify false alert rates.	
Information Typical to the Event	**Platform:** Aircraft Carrier, surface combatant, submarine, fixed-wing aircraft **Systems:** Countermeasure systems **Ordnance/Munitions:** Lightweight torpedoes (non-explosive and explosive) **Targets:** Torpedo test vehicle **Duration:** Up to 7 days	**Location:** Transit Corridor Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF1), high-frequency sonar (e.g., HF5), acoustic countermeasure (e.g., ASW3), torpedo sonar (e.g., TORP1, TORP2), underwater explosives (E7), vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, In-water device strike, aircraft strike (birds only) **Entanglement:** Parachute (torpedo) **Ingestion:** Torpedo launch accessories/fragments, parachutes, sonobuoys	
Detailed Military Expended Material Information	Light-weight torpedo launch accessories (nose covers, parachutes, ram plates)/fragments	
Assumptions Used for Analysis	None	

A.3.3.7 Pierside Sonar Testing

Activity Name	Activity Description	
Anti-Surface Warfare (ASUW)/Anti-Submarine Warfare (ASW) Testing		
Pierside Sonar Testing	Pierside testing to ensure systems are fully functional in a controlled pierside environment prior to at-sea test activities.	
Long Description	Ships and submarines would activate mid- and high-frequency tactical sonars, underwater communications systems, and navigational devices to ensure they are fully functional prior to at-sea test events. Event duration is 2 weeks with active sonar used intermittently over 2 days during the total event duration.	
Information Typical to the Event	**Platform:** Submarine, surface combatant **Systems:** Mid- and high-frequency sonars, underwater communications systems, countermeasure systems **Ordnance/Munitions:** None **Targets:** None **Duration:** Event duration is up to 2 weeks.	**Location:** Pearl Harbor, Hawaii San Diego, CA
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF3), high-frequency sonar (e.g., HF1, HF3), acoustic countermeasure (e.g., ASW3) **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Materials Information	None	
Assumptions Used for Analysis	Event duration is 2 weeks with active sonar used intermittently over 2 days during the total event duration.	

A.3.3.8 At-Sea Sonar Testing

Activity Name	Activity Description	
Surface Warfare/Anti-Submarine Warfare Testing		
At-sea Sonar Testing	At-sea testing to ensure systems are fully functional in an open ocean environment.	
Long Description	At-sea sonar testing is required to calibrate sonar systems while the vessel or submarine is in an open ocean environment. Tests consist of electronic support measurement, photonics, and sonar sensor accuracy testing. In some instances, a submarine's passive detection capability is tested when a second submarine utilizes its active sonar or is equipped with a noise augmentation system in order to replicate acoustic or electromagnetic signatures of other vessel types or classes.	
Information Typical to the Event	**Platform:** Surface combatant vessels, Submarines **Systems:** Tactical sonar **Ordnance/Munitions:** None **Targets:** None **Duration:** 4 hours to 11 days	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency sonar (e.g., MF3), high-frequency sonar (e.g., HF1, HF3), acoustic countermeasure (e.g., ASW4), vessel noise, acoustic modem (e.g., M3) **Energy:** None **Physical Disturbance and Strike:** Vessel strike, military expended material strike (acoustic countermeasures) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Acoustic countermeasures	
Assumptions Used for Analysis	Active sonar use is intermittent throughout the duration of the event Acoustic countermeasures – 10 per event	

A.3.4 Mine Warfare Testing

A.3.4.1 Mine Detection and Classification

Activity Name	Activity Description	
Mine Warfare Testing		
Mine Detection and Classification Testing	Air, surface, and subsurface vessels detect and classify mines and mine-like objects.	
Long Description	Mine detection and classification systems require testing to evaluate the capability of generating underwater magnetic and acoustic signature fields capable of sweeping a wide range of threat mines at tactically significant water depths, ranging from the surf zone to deep water. In order to develop better and safer methods of minesweeping, the Navy is currently testing new systems to detect, locate, and identify mines including a laser airborne mine detection system that uses laser illumination coupled with sensitive electro-optic receivers to find mines in the upper part of the water column. This type of equipment is currently designed for operation from a manned helicopter; however, the next generation of such equipment is expected to operate from unmanned aerial vehicles.	
Information Typical to the Event	**Platform:** Rotary-wing aircraft, unmanned aerial systems, surface combatant vessels, amphibious warfare vessels, remotely operated vehicles **Systems:** Mine detection and classification systems **Ordnance/Munitions:** None **Targets:** Floating/moored/bottom non-explosive mines or passive mine simulation systems **Duration:** Up to 10 days	**Location:** Hawaii Range Complex Hawaii Range Complex: Kahoolawe Training Minefield Southern California Range Complex Southern California Range Complex: Mission Bay Training Minefield
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High-frequency sonar (e.g., HF1), vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Laser systems also used during testing	

A.3.4.2 Mine Countermeasure/Neutralization Testing

Activity Name	Activity Description	
Mine Warfare (MIW) Testing		
Mine Countermeasure/ Neutralization Testing	Air, surface, and subsurface vessels neutralize threat mines that would otherwise restrict passage through an area.	
Long Description	Mine countermeasure/neutralization testing is required to ensure systems can effectively neutralize threat mines that would otherwise restrict passage through an area. Countermeasure systems are deployed from surface ships and helicopters to neutralize mines a number of ways: cutting mooring cables of buoyant mines, producing medium- to high-frequency acoustic energy that fires acoustic-influence mines, producing electrical energy to replicate the magnetic signatures of surface ships in order to detonate threat mines, detonation of mines using remotely-operated vehicles such as the Archerfish Common Neutralizer, and using explosive charges or supercavitating projectiles to destroy threat mines.	
Information Typical to the Event	**Platform:** Surface combatant ship, rotary-wing aircraft, remotely operated vehicles **Systems:** Mine neutralization systems **Ordnance/Munitions:** Mine neutralization systems; explosive mines **Targets:** Floating/moored/bottom non-explosive and explosive mines and mine simulation systems **Duration:** Event duration ranges from 1 to 10 days, with intermittent use of countermeasure/neutralization systems during this period.	**Location:** Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mine countermeasure systems (e.g., HF4, M3), underwater explosives (e.g., E4, E8), vessel noise, aircraft noise **Energy:** Electromagnetic minesweeping systems **Physical Disturbance and Strike:** Vessel strike, aircraft strike (birds only), seafloor device strike (mine shapes) **Entanglement:** Fiber-optic cable **Ingestion:** Target fragments	
Detailed Military Expended Material Information	Target fragments, fiber-optic cable	
Assumptions Used for Analysis	**Other Sensors:** Mine countermeasures systems (e.g., AN/AWS-2 Rapid Airborne Mine Clearance System, AN/ALQ-220 Organic Airborne and Surface Influence Sweep)	

A.3.4.3 Pierside Systems Health Checks

Activity Name	Activity Description	
Mine Warfare Testing		
Pierside Systems Health Checks	Mine warfare systems are tested in pierside locations to ensure acoustic and electromagnetic sensors are fully functional prior to at-sea test activities.	
Long Description	Mine warfare systems are tested in pierside locations to ensure acoustic and electromagnetic sensors are fully functional prior to at-sea test activities. Systems that are tested pierside include mine hunting and localization sonar, electromagnetic mine neutralization systems, and navigation systems.	
Information Typical to the Event	**Platform:** Surface combatant vessel **Systems:** Mine detection systems **Ordnance/Munitions:** None **Targets:** None **Duration:** Event duration is up to 5 days, with systems being tested independently and periodically (not continuously) during the total event duration.	**Location:** Pierside: San Diego, CA
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None	

A.3.5 Shipboard Protection Systems and Swimmer Defense Testing

A.3.5.1 Pierside Integrated Swimmer Defense

Activity Name	Activity Description	
Shipboard Protection Systems and Swimmer Defense Testing		
Pierside Integrated Swimmer Defense	Swimmer defense testing ensures that systems can effectively detect, characterize, verify, and engage swimmer/diver threats in harbor environments.	
Long Description	Swimmer defense testing includes testing of systems to determine if they can effectively detect, characterize, verify, and engage swimmer/diver threats in harbor environments. Swimmer and diver threats are detected with high frequency sonar. The threats are then warned to exit the water through the use of underwater voice communications. If the threat does not comply, non-lethal diver deterrent air guns are used against the threat. Surface loudhailers are also used during the test.	
Information Typical to the Event	**Platform:** Support Craft/Other **Systems:** High-frequency sonar; airguns surface loudhailers **Ordnance/Munitions:** None **Targets:** None **Duration:** 14 days with intermittent periods of use for each system during this time.	**Location:** Pierside: San Diego, CA
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Low-frequency sonar (e.g., LF4), mid-frequency sonar (e.g., MF8), swimmer defense sonar (e.g., SD1), airguns (e.g., AG) **Energy:** None **Physical Disturbance and Strike:** Seafloor device strike (swimmer defense tripod) **Entanglement:** None **Ingestion:** None	
Military Expended Material	None	
Assumptions Used for Analysis	**Other Sensors:** Surface ship protection systems (e.g., communications systems, loudhailers, swimmer deterrents)	

A.3.5.2 Shipboard Protection Systems Testing

Activity Name	Activity Description	
Shipboard Protection Systems and Swimmer Defense Testing		
Shipboard Protection Systems Testing	Various systems are used to protect surface combatants from various threats.	
Long Description	Surface vessels engage small boat threats through the use of spotlights and loudhailers (pierside) but can also include the use of 0.50 cal guns (at-sea).	
Information Typical to the Event	**Platform:** Surface combatant vessels **Systems:** None **Ordnance/Munitions:** Small-caliber projectiles (e.g., 0.50 caliber [non-explosive]) **Targets:** Floating target, rigid-hull inflatable boat **Duration:** 10 days	**Location:** Pierside: San Diego, CA Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, weapons firing noise **Energy:** None **Physical Disturbance and Strike:** Military expended material strike (non-explosive projectiles), vessel strike **Entanglement:** None **Ingestion:** Small-caliber projectiles, casings	
Detailed Military Expended Material Information	Casings Projectiles Target fragments	
Assumptions Used for Analysis	Small-caliber rounds will not be used pierside	

A.3.5.3 Chemical/Biological Simulant Testing

Activity Name	Activity Description	
Shipboard Protection Systems and Swimmer Defense Testing		
Chemical/Biological Simulant Testing	Chemical/biological agent simulants are deployed against surface ships.	
Long Description	Chemical or biological agent simulants are deployed against surface vessels to verify the integrity of the vessel's defense system including installed detection, protection, and decontamination systems. Methods of simulant delivery include aerial dispersal and by hand-held spray.	
Information Typical to the Event	**Platform:** Surface combatant vessels, fixed-wing aircraft **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** 3 days	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Vessel noise, aircraft noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike, aircraft strike (birds only) **Entanglement:** None **Ingestion:** Simulants	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Examples of Chemical Simulants: glacial acetic acid, triethyl phosphate Examples of Biological Simulants: spore-forming bacteria, non-spore-forming bacteria, the protein ovalbumin, MS2 bacteriophages, and the fungus *Aspergillus niger*	

A.3.6 Unmanned Vehicle Testing

A.3.6.1 Underwater Deployed Unmanned Aerial Vehicle Testing

Activity Name	Activity Description	
Unmanned Vehicle Testing		
Underwater Deployed Unmanned Aerial Vehicle Testing	Submarines launch unmanned aerial vehicles while submerged.	
Long Description	During testing, a negatively buoyant capsule is deployed underwater and descends to a programmed depth. The capsule then drops a weight, inflates a flotation collar, rises to the surface, and launches an unmanned aerial system. Personnel use radio frequency communications to control and communicate with the unmanned aerial system during its flight.	
Information Typical to the Event	**Platform:** Submarine **Systems:** Unmanned aerial systems **Ordnance/Munitions:** None **Targets:** None **Duration:** 8 hours (4 hours/day over 2 days)	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** None **Energy:** None **Physical Disturbance and Strike:** Vessel strike, in-water device strike (unmanned aerial system launch), aircraft strike (birds only) **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Expandable capsule (with flotation collar) Ballast weights	
Assumptions Used for Analysis	None	

A.3.6.2 Unmanned Vehicle Development and Payload Testing

<table>

A.3.7 OTHER TESTING

A.3.7.1 Special Warfare

Activity Name	Activity Description	
Other Testing		
Special Warfare	Special warfare includes testing of submersibles capable of inserting and extracting personnel and payloads into denied areas from strategic distances.	
Long Description	Special warfare includes testing of submersibles capable of inserting and extracting personnel and payloads into denied areas from strategic distances. Testing could include the use of special operations forces deployed from submerged submarines while at sea.	
Information Typical to the Event	**Platform:** Surface craft/other, submarines **Systems:** Submarine sonar, Doppler sonar, side scan sonar, underwater communications **Ordnance/Munitions:** None **Targets:** None **Duration:** Up to 30 days	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High-frequency sonar (e.g., HF1), acoustic modem (M3), underwater communications (e.g., MF9), vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Test will not occur constantly throughout duration	

A.3.7.2 Acoustic Communications Testing

Activity Name	Activity Description	
Other Testing		
Acoustic Communications Testing	Acoustic modems, submarines, and surface vessels transmit signals to communicate.	
Long Description	Acoustic communications testing can include transmission of low-, mid-, and high-frequency signals between acoustic modems, submarines, sub and surface vessels, vessels and shore, and between surface vessels and mines.	
Information Typical to the Event	**Platform:** Surface ships, submarines **Systems:** None **Ordnance/Munitions:** None **Targets:** None **Duration:** 12 hours	**Location:** Hawaii Range Complex Southern California Range Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** High-frequency sonar (e.g., HF1), acoustic communication (e.g., M3), vessel noise **Energy:** None **Physical Disturbance and Strike:** Vessel strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None	

A.4 SPACE AND NAVAL WARFARE SYSTEMS COMMAND TESTING EVENTS

The mission of Space and Naval Warfare Systems Command is to acquire, develop, deliver, and sustain decision superiority for the warfighter at the right time and for the right cost. Space and Naval Warfare Systems Center Pacific is the research and development part of Space and Naval Warfare Systems Command focused on developing and transitioning technologies in the area of command, control, communications, computers, intelligence, surveillance, and reconnaissance for the Navy. Space and Naval Warfare Systems Command and Space and Naval Warfare Systems Center Pacific conduct research, development, test, and evaluation projects to support emerging technologies for intelligence, surveillance, and reconnaissance, anti-terrorism and force protection, mine countermeasures, anti-submarine warfare, oceanographic research, remote sensing, and communications. These activities include, but are not limited to, the testing of unmanned undersea and surface vehicles, a wide variety of sensor systems, underwater surveillance technologies, and underwater communications.

A.4.1 RESEARCH, DEVELOPMENT, TEST, AND EVALUATION

A.4.1.1 Autonomous Undersea Vehicle Anti-Terrorism/Force Protection Mine Countermeasures

<table>
<tr><th>Activity Name</th><th colspan="2">Activity Description</th></tr>

</table>

A.4.1.2 Autonomous Undersea Vehicle Underwater Communications

Activity Name	Activity Description	
Underwater Communications		
Autonomous Undersea Vehicle Underwater Communications	This testing is focused on providing two-way networked communications below the ocean surface while maintaining mission profile.	
Long Description	This testing is focused on providing two-way networked communications below the ocean surface while maintaining mission profile. The goal of this testing is to enable two-way communications during missions that require Autonomous Underwater Vehicles to remain submerged to minimize counter-detection and maximize tactical positioning.	
Information Typical to the Event	**Platform:** Autonomous Underwater Vehicle **Systems:** Acoustic modems (e.g., M3) **Ordnance/Munitions:** None **Targets:** Mine Shapes **Duration:** Typically 5 days of daily operations for 6 hours per day	**Location:** Hawaii Range Complex: Oahu, Hawaii Southern California Range Complex: San Diego Bay, Camp Pendleton Amphibious Assault Area, San Clemente Island Operating Areas Silver Strand Training Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Acoustic modems (e.g., M3) **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	San Diego Bay vehicle depth shallow and slow moving. All other areas are deeper water with the vehicle moving approximately 3 to 4 knots near the sea floor. It may also include glider operations in the San Clemente Island Operating Area and open ocean. Conducted in multiple marine environments within HSTT study to include San Clemente Island Operating Area, Silver Strand Training Complex, and in and around rocky outcroppings and between Naval piers, pilings, and ships.	

A.4.1.3 Fixed System Underwater Communications

Activity Name	Activity Description	
Underwater Communications		
Fixed System Underwater Communications	Fixed underwater communications systems testing is focused on testing stationary or free floating equipment that provides two-way networked communications below the ocean surface while maintaining mission profile.	
Long Description	Fixed underwater communications systems testing is focused on testing stationary or free floating equipment that provides two-way networked communications below the ocean surface while maintaining mission profile. The goal of this testing is to enable two-way communications during missions that require the fixed sensor to remain submerged to minimize counter-detection and maximize tactical positioning. Typical tests last 5 days of 8 hours testing per day.	
Information Typical to the Event	**Platform:** Fixed systems **Systems:** Acoustic modem (e.g., M3) **Ordnance/Munitions:** None **Targets:** None **Duration:** Typically 5 days of daily operations for 6–8 hours per day	**Location:** SOCAL Range Complex: San Diego Bay, San Clemente Island Operating Areas Silver Strand Training Complex
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Acoustic modem (e.g., M3) **Energy:** None **Physical Disturbance and Strike:** Military expended material strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Clump anchors and/or sand bags Expendable communications buoys	
Assumptions Used for Analysis	Fixed or free floating, stationary source

A.4.1.6 Passive Mobile Intelligence, Surveillance, and Reconnaissance Sensor Systems

Activity Name	Activity Description	
Intelligence, Surveillance, and Reconnaissance (ISR) Sensor Systems		
Passive Mobile Intelligence, Surveillance, and Reconnaissance Sensor Systems	These systems use passive arrays hosted by surface and subsurface vehicles and vessels for conducting submarine detection and tracking experiments and demonstrations.	
Long Description	These systems use passive arrays hosted by surface and subsurface vehicles and vessels for conducting submarine detection and tracking experiments and demonstrations. The arrays, which are composed of hydrophones to receive acoustic energy radiated by targets of interest, are deployed by surface ships. The unmanned undersea vehicles and associated systems are monitored and controlled by operators stationed aboard another vessel or at a land-based remote host station. The arrays are tested to evaluate various system performance parameters and requirements. Surrogate quiet submarine threats are provided by low-frequency towed projectors as well as existing Fleet assets such as underwater autonomous mobile acoustic sources.	
Information Typical to the Event	**Platform:** Surface or subsurface vehicle **Systems:** Towed sound projector with passive towed arrays **Ordnance/Munitions:** None **Targets:** sub-surface vessels **Duration:** Typically 5 days of daily operations for 8 hours per day	**Location:** Silver Strand Training Complex/Imperial Beach/Point Loma San Clemente Island Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Towed sound projector (e.g., LF5) **Energy:** None **Physical Disturbance and Strike:** In-water device strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Towed moving source in the water column	

A.4.1.7 Fixed Intelligence, Surveillance, and Reconnaissance Sensor Systems

Activity Name	Activity Description	
Intelligence, Surveillance, and Reconnaissance (ISR) Sensor Systems		
Fixed Intelligence, Surveillance, and Reconnaissance Sensor Systems	These systems use stationary fixed arrays for conducting submarine detection and tracking experiments and demonstrations.	
Long Description	These systems use stationary fixed passive arrays for conducting submarine detection and tracking experiments and demonstrations. The arrays are composed of passive hydrophones to receive acoustic energy radiated by targets of interest. Surrogate threats are provided by low frequency towed projectors. This type of testing may also include free floating sensor systems such as buoys, sonobuoys, and other types of sensors floating on the surface or suspended in the water column.	
Information Typical to the Event	**Platform:** Fixed and free floating arrays **Systems:** Towed sound source and free floating buoys **Ordnance/Munitions:** None **Targets:** sub-surface vessels **Duration:** Typically 5 days of daily operations for 6–8 hours per day	**Location:** Hawaii Operating Area Silver Strand Training Complex/Imperial Beach/Point Loma San Clemente Island Operating Area
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Towed sound source and free floating buoys (e.g., MF9, HF6, LF4, LF5, LF6 **Energy:** None **Physical Disturbance and Strike:** In-water device strike **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	Steel framework in deep water only (one per every 5 years)	
Assumptions Used for Analysis	Towed moving and free floating source in the water column	

A.4.1.8 Anti-Terrorism/Force Protection Fixed Sensor Systems

Activity Name	**Activity Description**	
Anti-Terrorism/Force Protection		
Fixed Sensor Systems	These systems are for Anti-Terrorism/Force Protection operations in navy ports and bays	
Long Description		
Information Typical to the Event	**Platform:** Fixed system **Systems:** Mid-frequency active source **Ordnance/Munitions:** None **Targets:** Sub-surface objects of interest **Duration:** Typically 5 days of daily operations for 8 hours per day	**Location:** San Diego Bay
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Mid-frequency active source (e.g., MF 9) **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	Fixed stationary source above sea bottom	

A.5 OFFICE OF NAVAL RESEARCH AND NAVAL RESEARCH LABORATORY TESTING ACTIVITIES

As the Department of the Navy's Science and Technology provider, the Office of Naval Research and the Naval Research Laboratory provide technology solutions for Navy and Marine Corps needs. The Office of Naval Research's mission, as defined by law, is to plan, foster, and encourage scientific research in recognition of its paramount importance as related to the maintenance of future naval power, and the preservation of national security. Further, the Office of Naval Research manages the Navy's basic, applied, and advanced research to foster transition from science and technology to higher levels of research, development, test and evaluation.

The Ocean Battlespace Sensing Department explores science and technology in the areas of oceanographic and meteorological observations, modeling and prediction in the battlespace environment; submarine detection and classification (anti-submarine warfare); and mine warfare applications for detecting and neutralizing mines in both the ocean and littoral environment. Office of Naval Research events include: research, development, test and evaluation activities; surface processes acoustic communications experiments; shallow water acoustic communications experiments; sediment acoustics experiments; shallow water acoustic propagation experiments; and long range acoustic propagation experiments.

A.5.1 RESEARCH, DEVELOPMENT, TEST, AND EVALUATION

A.5.1.1 Kauai Acoustic Communications Experiment (Coastal)

Activity Name	Activity Description	
RDT&E Testing		
Kauai Acoustic Communications Experiment (Coastal)	The primary purpose of the Kauai Acoustic Communications Experiment is to collect acoustic and environmental data appropriate for studying the coupling of oceanography, acoustics, and underwater communications.	
Long Description	The primary purpose of the Kauai acoustic communications experiment is to collect acoustic and environmental data appropriate for studying the coupling of oceanography, acoustics, and underwater communications. A specific experimental interest is obtaining data that would relate the impact of a fluctuating oceanographic environment and source/receiver motion to fluctuations in the waveguide acoustic impulse response between multiple sources and receivers. These data would ultimately provide insight into the design and performance of shallow underwater systems for acoustic digital data communications. The focus is on fluctuations over scales of a few seconds to a few tens of seconds that directly affect the reception of a data packet and the variability of packet-to-packet reception. These experiments involve the use of underwater acoustic sources to collect acoustic and environmental data appropriate for studying the coupling of oceanography, acoustics, and underwater communications.	
Information Typical to the Event	**Platform:** UNOLS ship R/V Kilo Moana **Systems:** Research and Enviro Sensing **Ordnance/Munitions:** None **Targets:** None **Duration:** 1-2 weeks	**Location:** Hawaii Range Complex: Pacific Missile Range Facility (Warning Areas -72B, and 386 [Air D, G, H, and K])
Potential Impact Concerns *(Information regarding deconstruct categories and stressors)*	**Acoustic:** Acoustic Doppler Current Profiler (ADCP [DS1]) Upward-looking RDI Workhorse Sentinel 300 kHz ADCP. ITC-1001 transducers, ITC-1032 transducers, ITC-1007 transducers **Energy:** None **Physical Disturbance and Strike:** None **Entanglement:** None **Ingestion:** None	
Detailed Military Expended Material Information	None	
Assumptions Used for Analysis	None

41162 Federal Register / Vol. 75, No. 135 / Thursday, July 15, 2010 / Notices

proposed information collection; (c) ways to enhance the quality, utility, and clarity of the information to be collected; and (d) ways to minimize the burden of the information collection on respondents, including the use of automated collection techniques or other forms of information technology. The Office of Management and Budget (OMB) has approved this information collection requirement for use through November 30, 2010. DoD proposes that OMB extend its approval for these collections to expire three years after the approval date.

DATES: DoD will consider all comments received by September 13, 2010.

ADDRESSES: You may submit comments, identified by OMB Control Number 0704–0252, using any of the following methods:

○ *Federal eRulemaking Portal: http://www.regulations.gov.* Follow the instructions for submitting comments.

○ *E-mail: dfars@acq.osd.mil.* Include OMB Control Number 0704–0252 in the subject line of the message.

○ *Fax:* (703) 602–0350.

○ *Mail:* Defense Acquisition Regulations System, Attn: Ms. Meredith Murphy, OUSD(AT&L)DPAP(DARS), 3060 Defense Pentagon, Room 3B855, Washington, DC 20301–3060.

Comments received generally will be posted without change to *http://www.regulations.gov*, including any personal information provided.

FOR FURTHER INFORMATION CONTACT: Ms. Meredith Murphy, 703–602–1302. The information collection requirements addressed in this notice are available electronically via the Internet at: *http://www.acq.osd.mil/dp/dars/dfars.html.*

Paper copies are available from Ms. Meredith Murphy, OUSD(AT&L)DPAP(DARS), 3060 Defense Pentagon, Room 3B855, Washington, DC 20301–3060.

SUPPLEMENTARY INFORMATION:

Title, Associated Form, and OMB Number: Defense Federal Acquisition Regulation Supplement (DFARS) Part 251, Contractor Use of Government Supply Sources, and the associated clauses at DFARS 252.251–7000, Ordering from Government Supply Sources; and 252.251–7001, Use of Interagency Fleet Management System (IFMS) Vehicles and Related Services; OMB Control Number 0704–0252.

Needs and Uses: This information collection permits contractors to—

• Place orders under Federal Supply Schedule contracts and requirements contracts or for Government stock. The information enables DoD to evaluate whether a contractor is authorized to place such orders.

• Submit requests for use of Government vehicles under the Interagency Fleet Management System (IFMS) and obtain related services. The information submitted enables DoD to evaluate whether the contractor is authorized such use.

Affected Public: Businesses or other for-profit and not-for-profit institutions.

Annual Burden Hours: 5,250.

Number of Respondents: 3,500.

Responses per Respondent: approximately 3.

Annual Responses: 10,500.

Average Burden per Response: approximately 30 minutes.

Frequency: On occasion.

Summary of Information Collection

The clause at DFARS 252.251–7000, Ordering from Government Supply Sources, requires a contractor to provide a copy of an authorization when placing an order under a Federal Supply Schedule, a Personal Property Rehabilitation Price Schedule, or an Enterprise Software Agreement.

The clause at DFARS 252.251–7001, Use of Interagency Fleet Management System Vehicles and Related Services, requires a contractor to submit a request for use of Government vehicles when the contractor is authorized to use such vehicles in the performance of Government contracts.

Ynette R. Shelkin,

Editor, Defense Acquisition Regulations System.

BILLING CODE 5001–08–P

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Intent To Prepare an Environmental Impact Statement and Overseas Environmental Impact Statement for Navy Hawaii-Southern California Training and Testing and To Announce Public Scoping Meetings

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: Pursuant to section 102 of the National Environmental Policy Act (NEPA) of 1969, as implemented by the Council on Environmental Quality Regulations (40 Code of Federal Regulations [CFR] Parts 1500–1508), and Executive Order 12114, the Department of the Navy (DON) announces its intent to prepare an Environmental Impact Statement (EIS) and Overseas EIS (OEIS) to evaluate the potential environmental effects associated with military readiness training and research, development, testing, and evaluation (RDT&E) activities (hereinafter referred to as "training and testing" activities) conducted within the Hawaii-Southern California Training and Testing (HSTT) study area. The HSTT study area combines the at-sea portions of the Hawaii Range Complex, the Southern California Range Complex (including the San Diego Bay); the Silver Strand Training Complex; areas where vessels transit between the Hawaii Range Complex and the Southern California Range Complex; and select Navy pierside locations. This EIS and OEIS is being prepared to renew and combine current regulatory permits and authorizations; address current training and testing not covered under existing permits and authorizations; and to obtain those permits and authorizations necessary to support force structure changes and emerging and future training and testing requirements.

The DON will invite the National Marine Fisheries Service to be a cooperating agency in preparation of this EIS and OEIS.

DATES AND ADDRESSES: Six public scoping meetings will be held between 4 p.m. and 8 p.m., unless otherwise stated, on the following dates and at the following locations:

1. Wednesday, August 4, 2010, 3:30 p.m. to 7:30 p.m., Point Loma/Hervey Branch Library, Community Room, 3701 Voltaire Street, San Diego, CA.
2. Thursday, August 5, 2010, Lakewood High School, Room 922/924, 4400 Briercrest Avenue, Lakewood, CA.
3. Tuesday, August 24, 2010, Kauai Community College Cafeteria, 3–1901 Kaumuali'i Highway, Lihue, HI.
4. Wednesday, August 25, 2010, Disabled American Veterans Hall, Weinberg Hall, 2685 North Nimitz Highway, Honolulu, HI.
5. Thursday, August 26, 2010, Hilo High School Cafeteria, 556 Waianuenue Avenue, Hilo, HI.
6. Friday, August 27, 2010, Maui Waena Intermediate School Cafeteria, 795 Onehee Avenue, Kahului, HI.

Each of the six scoping meetings will consist of an informal, open house session with informational stations staffed by DON representatives. Meeting details will be announced in local newspapers. Additional information concerning meeting times is available on the EIS and OEIS Web page located at: *http://www.HawaiiSOCALEIS.com.*

FOR FURTHER INFORMATION CONTACT: Kent Randall, Naval Facilities Engineering Command, Southwest. Attention: HSTT EIS/OEIS, 1220 Pacific Highway, Building 1, Floor 5, San Diego, CA

Federal Register / Vol. 75, No. 135 / Thursday, July 15, 2010 / Notices **41163**

92132, or Meghan Byrne, Naval Facilities Engineering Command, Pacific. Attention: HSTT EIS/OEIS, 258 Makalapa Dr, Ste 100, Building 258, Floor 3, Room 258C210, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The DON's proposed action is to conduct training and testing activities that include the use of active sonar and explosives within the at-sea portions of existing DON training range complexes around the Hawaiian Islands and off the coast of Southern California (known as the HSTT study area). While the majority of these training and testing activities take place in operating and warning areas and/or on training and testing ranges, some training activities, such as sonar maintenance and gunnery exercises, are conducted concurrent with normal transits and may occur outside of DON operating and warning areas.

The HSTT study area combines the at-sea portions of the following range complexes: Hawaii Range Complex, Southern California Range Complex, and Silver Strand Training Complex. The existing western boundary of the Hawaii Range Complex is being expanded 60 miles to the west to the International Dateline. The HSTT study area also includes the transit route between Hawaii and Southern California as well as DON and commercial piers at Pearl Harbor, HI and San Diego, CA where sonar may be tested.

The proposed action is to conduct military training and testing activities in the HSTT study area. The purpose of the proposed action is to achieve and maintain Fleet Readiness to meet the requirements of Title 10 of the U.S. Code, which requires DON to "maintain, train, and equip combat-ready naval forces capable of winning wars, deterring aggression, and maintaining freedom of the seas." The proposed action would also allow DON to attain compliance with applicable environmental authorizations, consultations, and other associated environmental requirements, including those associated with new platforms and weapons systems, for example, the Low Frequency Anti-Submarine Warfare capability associated with the Littoral Combat Ship.

The alternatives that will be analyzed in the HSTT EIS and OEIS meet the purpose and need of the proposed action by providing the level of training that meets the requirements of Title 10, thereby ensuring that Sailors and Marines are properly prepared for operational success. Similarly, the level of RDT&E proposed for the HSTT study area is necessary to ensure that Sailors and Marines deployed overseas have the latest proven military equipment. Accordingly, the alternatives to be addressed in the HSTT EIS and OEIS are:

1. No Action—The No Action Alternative continues baseline training and testing activities and force structure requirements as defined by existing DON environmental planning documents. This documentation includes the Records of Decision for the Hawaii and Southern California range complexes and the Preferred Alternative for the Silver Strand Training Complex Draft EIS and OEIS.

2. Alternative 1—This alternative consists of the No Action alternative, plus expansion of the overall study area boundaries, and updates and/or adjustments to locations and tempo of training and testing activities. This alternative also includes changes to training and testing requirements necessary to accommodate force structure changes, and the development and introduction of new vessels, aircraft, and weapons systems.

3. Alternative 2—Alternative 2 consists of Alternative 1 with an increased tempo of training and testing activities. This alternative also allows for additional range enhancements and infrastructure requirements.

Resource areas that will be addressed because of the potential effects from the proposed action include, but are not limited to: Ocean and biological resources (including marine mammals and threatened and endangered species); air quality; airborne soundscape; cultural resources; transportation; regional economy; recreation; and public health and safety.

The scoping process will be used to identify community concerns and local issues to be addressed in the EIS and OEIS. Federal agencies, state agencies, local agencies, Native American Indian Tribes and Nations, the public, and interested persons are encouraged to provide comments to the DON to identify specific issues or topics of environmental concern that the commenter believes the DON should consider. All comments provided orally or in writing at the scoping meetings, will receive the same consideration during EIS and OEIS preparation. Written comments must be postmarked no later than September 14, 2010, and should be mailed to: Naval Facilities Engineering Command, Southwest, 2730 McKean Street, Building 291, San Diego, CA 92136–5198, Attention: Mr. Kent Randall—HSTT EIS/OEIS.

Dated: July 9, 2010.

D.J. Werner

Lieutenant Commander, Office of the Judge Advocate General, U.S. Navy, Federal Register Liaison Officer.

[FR Doc. 2010–17234 Filed 7–14–10; 8:45 am]

BILLING CODE 3810–FF–P

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Intent To Prepare an Environmental Impact Statement and Overseas Environmental Impact Statement for Navy Atlantic Fleet Training and Testing and To Announce Public Scoping Meetings

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: Pursuant to section 102 of the National Environmental Policy Act (NEPA) of 1969, as implemented by the Council on Environmental Quality Regulations (40 Code of Federal Regulations [CFR] Parts 1500–1508), and Executive Order 12114, the Department of the Navy (DON) announces its intent to prepare an Environmental Impact Statement (EIS) and Overseas EIS (OEIS) to evaluate the potential environmental effects associated with military readiness training and research, development, testing, and evaluation (RDT&E) activities (hereinafter referred to as "training and testing" activities) conducted within the Atlantic Fleet Training and Testing (AFTT) study area. The AFTT study area includes the western North Atlantic Ocean along the east coast of North America (including the area where the Undersea Warfare Training Range will be used), the Chesapeake Bay, and the Gulf of Mexico. Also included are select Navy pierside locations and channels. The AFTT study area does not include the Arctic. This EIS and OEIS is being prepared to renew and combine current regulatory permits and authorizations; address current training and testing not covered under existing permits and authorizations; and to obtain those permits and authorizations necessary to support force structure changes and emerging and future training and testing requirements.

The DON will invite the National Marine Fisheries Service to be a cooperating agency in preparation of this EIS and OEIS.

DATES AND ADDRESSES: Five public scoping meetings will be held between 4 p.m. and 8 p.m. on the following dates and at the following locations:

Federal Register / Vol. 77, No. 92 / Friday, May 11, 2012 / Notices 27771

waters, states are required to establish TMDLs according to a priority ranking.

EPA's Water Quality Planning and Management regulations include requirements related to the implementation of Section 303(d) of the CWA (40 CFR 130.7). The regulations require states to identify water-quality-limited waters still requiring TMDLs every two years. The lists of waters still needing TMDLs must also include priority rankings, identify the pollutants causing the impairment, and must identify the waters targeted for TMDL development during the next two years (40 CFR 130.7).

Consistent with EPA's regulations, Utah submitted to EPA its listing decisions under Section 303(d)(2) in correspondence dated March 31, 2011 and April 21, 2011. On February 10, 2012, EPA partially approved with further review pending for Kanab Creek and tributaries, Utah's 2008 and 2010 listings of waters and associated priority rankings. On April 11, 2012, EPA disapproved Utah's decision to not include Kanab Creek and tributaries, from state line to irrigation diversion at confluence with Reservoir Canyon on the 2008 and 2010 lists. EPA solicits public comment on the addition of these waters to the State's list, as required by 40 CFR 130.7(d)(2).

Authority: Clean Water Act, 33 U.S.C. 1251 *et seq.*

Dated: April 26, 2012.

Martin Hestmark,

Acting Assistant Regional Administrator, Office of Ecosystems Protection and Remediation.

FEDERAL COMMUNICATIONS COMMISSION

Information Collection Being Reviewed by the Federal Communications Commission

AGENCY: Federal Communications Commission.

ACTION: Notice and request for comments.

SUMMARY: As part of its continuing effort to reduce paperwork burden and as required by the Paperwork Reduction Act (PRA) of 1995 (44 U.S.C. 3501–3520), the Federal Communications Commission invites the general public and other Federal agencies to take this opportunity to comment on the following information collection(s). Comments are requested concerning: (a) Whether the proposed collection of information is necessary for the proper performance of the functions of the Commission, including whether the information shall have practical utility; (b) the accuracy of the Commission's burden estimate; (c) ways to enhance the quality, utility, and clarity of the information collected; (d) ways to

Federal Register / Vol. 77, No. 92 / Friday, May 11, 2012 / Notices 27743

Alternatives 1 and 2 analyze adjustments to Study Area boundaries and the location, type, and level of training and testing activities necessary to support current and planned DoN training and testing requirements through 2019. The analysis addresses force structure changes, including those resulting from the development, testing, and ultimate introduction of new vessels, aircraft and weapons systems into the fleet.

No significant adverse impacts are identified for any resource area in any geographic location within the Study Area that cannot be mitigated. Additionally, due to the exposure of marine mammals to underwater sound, NMFS has received an application from DoN for a Marine Mammal Protection Act Letter of Authorization and governing regulations to authorize incidental take of marine mammals that may result from the implementation of the activities analyzed in the Draft EIS/OEIS. In accordance with Section 7 of the Endangered Species Act, the DoN is consulting with NMFS and U.S. Fish and Wildlife Service, as appropriate, for potential impacts to federally listed species. In accordance with the Magnuson-Stevens Fishery Conservation and Management Act, the DoN is consulting with NMFS on federally managed species and their essential fish habitat. The DoN will initiate consultation under the National Historic Preservation Act regarding impacts to historic properties, and will comply with other applicable laws and regulations.

The Draft EIS/OEIS was distributed to Federal, State, and local agencies, elected officials, and other interested individuals and organizations. Copies of the Draft EIS/OEIS are available for public review at the following libraries:

1. Anne Arundel County Public Library, Annapolis Area Branch, 1410 West Street, Annapolis, MD 21401.
2. Bay County Public Library, 898 West 11th Street, Panama City, FL 32401.

BILLING CODE 3810–FF–P

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Public Meetings for the Draft Environmental Impact Statement/Overseas Environmental Impact Statement for Navy Hawaii-Southern California Training and Testing

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: Pursuant to section 102(2)(c) of the National Environmental Policy Act of 1969, and regulations implemented by the Council on Environmental Quality regulations (40 Code of Federal Regulations parts 1500–1508), and Presidential Executive Order 12114, the Department of the Navy (DoN) has prepared and filed with the U.S. Environmental Protection Agency a Draft Environmental Impact Statement (EIS)/Overseas EIS (OEIS). The Draft EIS/OEIS evaluates the potential environmental effects associated with military readiness training and research, development, test and evaluation activities (training and testing) conducted within the Hawaii-Southern California Training and Testing (HSTT) Study Area. The National Marine Fisheries Service (NMFS) is a Cooperating Agency for the EIS/OEIS.

The HSTT Study Area is comprised of established operating and warning areas across the north-central Pacific Ocean, from Southern California west to Hawaii and the International Date Line. The Study Area combines the at-sea portions of the Hawaii Range Complex; the Southern California Range Complex; the Silver Strand Training Complex; transit corridors on the high seas that are not part of the range complexes where training and sonar testing may occur during vessel transit between the Hawaii Range Complex and the Southern California Range Complex; and Navy pierside locations where sonar maintenance and testing activities occurs. The HSTT Study Area includes only the at-sea components of the range complexes and testing ranges. The land-based portions of the range complexes are not a part of the Study Area and will be or already have been addressed under separate DoN environmental planning documentation.

With the filing of the Draft EIS/OEIS, the DoN is initiating a 60-day public comment period, beginning on May 11, 2012 and ending on July 10, 2012. During this period the DoN will conduct five public meetings to receive oral and written comments on the Draft EIS/OEIS. This notice announces the dates and locations of the public meetings and provides supplementary information about the environmental planning effort.

DATES AND ADDRESSES: Public information and comment meetings will be held at each of the locations listed below between 5:00 p.m. and 8:00 p.m. The meetings will provide individuals with information on the Draft EIS/OEIS in an open house format. DoN and NMFS representatives at informational poster stations will be available during the public meetings to clarify information related to the Draft EIS/OEIS.

The public meetings will be held between 5:00 p.m. and 8:00 p.m. on the following dates and at the following locations:

1. June 12, 2012 (Tuesday) at the Wilcox Elementary School Cafeteria, 4319 Hardy Street, Lihue, HI.
2. June 13, 2012 (Wednesday at Maui Waena Intermediate School Cafeteria, 795 Onehee Avenue, Kahului, HI.
3. June 14, 2012 (Thursday) at East Hawaii Cultural Center, 141 Kalakaua Street, Hilo, HI.
4. June 15, 2012 (Friday) at McKinley High School Cafeteria, 1039 South King Street, Honolulu, HI.
5. June 20, 2012 (Wednesday) at Marina Village Conference Center, Starboard Room, 1936 Quivira Way, San Diego, CA.

Federal, State and local agencies and officials, interested groups and individuals are encouraged to provide oral comments in person at any of the public meetings or in writing anytime during the public comment period. Oral testimony from the public will be recorded by a court reporter. In the interest of available time, and to ensure all who wish to give an oral statement to the court reporter have the opportunity to do so, each speaker's comments will be limited to three (3) minutes, which may be extended if meeting attendance permits. Comments may also be submitted via the U.S. Postal Service to Naval Facilities Engineering Command, Southwest, Attention: HSTT EIS/OEIS Project Manager—EV21.CS; 1220 Pacific Highway, Building 1, Floor 3, San Diego, CA 92132–5190 or electronically via the project Web site (*http://www.HSTTEIS.com*). All statements, oral or written, submitted during the public review period will become part of the public record on the Draft EIS/OEIS and will be responded to in the Final EIS/OEIS. Equal weight will be given to oral and written statements. All public comments must be postmarked or received by July 10, 2012 to ensure they become part of the official record.

FOR FURTHER INFORMATION CONTACT: Naval Facilities Engineering Command, Southwest, Attention: HSTT EIS/OEIS Project Manager—EV21.CS; 1220 Pacific Highway, Building 1, Floor 3, San Diego, CA 92132–5190.

SUPPLEMENTARY INFORMATION: A Notice of Intent to prepare this Draft EIS/OEIS was published in the **Federal Register** on July 15, 2010 (75 FR 41162).

The DoN's Proposed Action is to conduct training and testing activities—which may include the use of active Sound Navigation and Ranging (sonar) and explosives—primarily within existing range complexes and testing ranges throughout the in-water areas around the Hawaiian Islands and off the coast of Southern California, Navy pierside locations, and the ocean transit corridor between Hawaii and Southern California. The purpose of the Proposed Action is to conduct training and testing activities to ensure that the DoN accomplishes its mission to maintain, train, and equip combat-ready U.S. naval forces capable of winning wars, deterring aggression, and maintaining freedom of the seas. This Draft EIS/OEIS will also support the renewal of federal regulatory permits and authorizations for current training and testing activities and to propose future training and testing activities requiring environmental analysis.

The Draft EIS/OEIS evaluates the potential environmental impacts of three alternatives, including the No Action Alternative and two action alternatives. The No Action Alternative continues baseline training and testing activities, as defined by existing DoN environmental planning documents. Alternatives 1 and 2 analyze adjustments to Study Area boundaries and the location, type, and level of training and testing activities necessary to support current and planned DoN training and testing requirements through 2019. The analysis addresses force structure changes, including those resulting from the development, testing, and ultimate introduction of new vessels, aircraft and weapons systems into the fleet.

No significant adverse impacts are identified for any resource area in any geographic location within the Study Area that cannot be mitigated. Additionally, due to the exposure of marine mammals to underwater sound, NMFS has received an application from DoN for a Marine Mammal Protection Act Letter of Authorization and governing regulations to authorize incidental take of marine mammals that may result from the implementation of the activities analyzed in the Draft EIS/OEIS. In accordance with Section 7 of the Endangered Species Act, the DoN is consulting with NMFS and U.S. Fish and Wildlife Service, as appropriate, for potential impacts to federally listed species. In accordance with the Magnuson-Stevens Fishery Conservation and Management Act, the DoN is consulting with NMFS on Federally managed species and their essential fish habitat.

The Draft EIS/OEIS was distributed to Federal, State and local agencies, elected officials, as well as other interested individuals and organizations. Copies of the Draft EIS/OEIS are also available for public review at the following libraries:

1. Lihue Public Library, 4344 Hardy Street, Lihue, HI 96766.
2. Wailuku Public Library, 251 High Street, Wailuku, HI 96793.
3. Hilo Public Library, 300 Waianuenue Avenue, Hilo, HI 96720.
4. Kailua-Kona Public Library, 75–138 Hualalai Road, Kailua-Kona, HI 96740.
5. Hawaii State Library, Hawaii and Pacific Section Document Unit, 478 South King Street, Honolulu, HI 96813.
6. San Diego Central Library, 820 E Street, San Diego, CA 92101.
7. Long Beach Main Library, 101 Pacific Avenue, Long Beach, CA 90822.

In addition, copies of the HSTT Draft EIS/OEIS are available for electronic viewing or download at *http://www.HSTTEIS.com.* A paper copy of the Executive Summary or a single compact disc of the Draft EIS/OEIS will be made available upon written request by contacting: Naval Facilities Engineering Command, Southwest, Attention: HSTT EIS/OEIS Project Manager—EV21.CS; 1220 Pacific Highway, Building 1, Floor 3, San Diego, CA 92132–5190.

ENVIRONMENTAL PROTECTION AGENCY

[EPA–HQ–OPP–2012–0003; FRL–9348–6]

SFIREG Full Committee; Notice of Public Meeting

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice.

SUMMARY: The Association of American Pesticide Control Officials (AAPCO)/State FIFRA Issues Research and Evaluation Group (SFIREG), Full Committee will hold a 2-day meeting, beginning on June 18, 2012 and ending June 19, 2012. This notice announces the location and times for the meeting and sets forth the tentative agenda topics.

DATES: The meeting will be held on Monday, June 18, 2012 from 8:30 a.m. to 5:00 p.m. and 8:30 a.m. to 12 noon on Tuesday June 19, 2012.

To request accommodation of a disability, please contact the person listed under **FOR FURTHER INFORMATON CONTACT**, preferably at least 10 days prior to the meeting, to give EPA as much time as possible to process your request.

ADDRESSES: The meeting will be held at EPA. One Potomac Yard (South Bldg.), 2777 S. Crystal Dr., Arlington, VA, 22202, 1st Floor South Conference Room.

FOR FURTHER INFORMATION CONTACT: Ron Kendall, Field External Affairs Division, Office of Pesticide Programs, Environmental Protection Agency, 1200 Pennsylvania Ave. NW., Washington, DC 20460–0001; telephone number: (703) 305–5561; fax number: (703) 305–1850; email address: *kendall.ron@epa.gov.* or Grier Stayton, SFIREG Executive Secretary, P.O. Box 466, Milford, DE 19963; telephone number (302) 422–8152; fax (302) 422–2435; email address: *stayton.grier@aapco-sfireg@comcast.net.*

SUPPLEMENTARY INFORMATION:

I. General Information

A. Does this action apply to me?

You may be potentially affected by this action if you are interested in pesticide regulation issues affecting States and any discussion between EPA and SFIREG on FIFRA field implementation issues related to human health, environmental exposure to pesticides, and insight into EPA's decision-making process. You are invited and encouraged to attend the meetings and participate as appropriate. Potentially affected entities may include, but are not limited to:

Those persons who are or may be required to conduct testing of chemical substances under the Federal Food, Drug and Cosmetics Act (FFDCA), or the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and those who sell, distribute or use pesticides, as well as any Non Government Organization.

This listing is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be affected by this action. Other types of entities not listed in this unit could also be affected. The North American Industrial Classification System (NAICS) codes have been provided to assist you and others in determining whether this action might apply to certain entities. If you have any questions regarding the applicability of this action to a particular entity, consult the person listed under **FOR FURTHER INFORMATION CONTACT.**

B. How can I get copies of this document and other related information?

EPA has established a docket for this action under docket ID number EPA–HQ–OPP–2012–0003. Publicly available docket materials are available either in the electronic docket at *http://www.regulations.gov,* or, if only available in hard copy, at the Office of Pesticide Programs (OPP) Regulatory Public Docket in Rm. S–4400, One Potomac Yard (South Bldg.), 2777 S. Crystal Dr., Arlington, VA. The hours of operation of this Docket Facility are from 8:30 a.m. to 4 p.m., Monday through Friday, excluding legal holidays. The Docket Facility telephone number is (703) 305–5805.

II. Tentative Agenda Topics

1. Office of Pesticide Programs update
2. Office of Compliance and Enforcement update
3. Responses to SFIREG Bed Bug and Endangered Species Act Consultation letters
4. Pollinator Protection issues
5. Methomyl fly bait restricted use classification
6. Pyrethroid Label Changes
7. Regional issues/responses to pre-SFIREG questionnaire
8. Report on "State Regulator in Residence" program—issues and opportunities
9. Tribal certification policy implementation—Issues and information exchange
10. Performance Measures Development
11. Imprelis update/discussion on "down stream" effects of pesticides outside control of applicator (e.g. hot compost, treated irrigation water)
12. Interactions of EPA Regions and State Lead Agencies on:
    a. Support for/involvement with
    b. Enforcement/compliance efforts
    c. Certification/training efforts
    d. Environmental programs
    e. Registration issues
13. Grant Negotiation Procedures
14. Distributor Label Enforcement coordination
15. Update on progress of referred cases

III. How can I request to participate in this meeting?

This meeting is open for the public to attend. You may attend the meeting without further notification.

List of Subjects Environmental protection.

Dated: May 5, 2012.

Ser N01CE1/0715
14 Jul 10

Dear Sir or Madam:

SUBJECT: ENVIRONMENTAL IMPACT STATEMENT/OVERSEAS ENVIRONMENTAL IMPACT STATEMENT (EIS/OEIS) FOR NAVY MILITARY READINESS ACTIVITIES IN THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

This letter is to inform you that the U.S. Navy is preparing an EIS/OEIS for Navy training and testing activities in the HSTT study area. The study area combines the at-sea portions of the Hawaii Range Complex (HRC); the Southern California (SOCAL) Range Complex (including the San Diego Bay); the Silver Strand Training Complex (SSTC); areas where vessels transit between the HRC and the SOCAL Range Complex; and select Navy pierside location (see Enclosure 1). The Navy is requesting your comments on the scope, content and issues to be considered during the development of the HSTT EIS/OEIS.

The Navy's mission is to organize, train, equip and maintain combat-ready naval forces capable of winning wars, deterring aggression and maintaining freedom of the seas. This mission is mandated by federal law (Title 10 U.S. Code (U.S.C.) § 5062), which charges the Chief of Naval Operations (CNO) with the responsibility for ensuring the readiness of the nation's naval forces. The CNO meets that directive, in part, by establishing and executing training programs and ensuring naval forces have access to the ranges, operating areas and airspace needed to develop and maintain skills for the conduct of operations.

The Navy proposes to conduct military readiness training activities and research, development, testing and evaluation (RDT&E) activities (hereinafter referred to as "training and testing") in areas currently used by the Navy in the HSTT study area. To both achieve and maintain Fleet readiness, the Navy proposes to:

- Adjust baseline training and testing activities from current levels to match levels required to support Navy training and testing requirements beginning in 2014.
- Accommodate evolving mission requirements associated with force structure changes, including those resulting from the development, testing and ultimate introduction of new platforms (vessels, aircraft and weapons systems) into the Fleet.

SUBJECT: ENVIRONMENTAL IMPACT STATEMENT/OVERSEAS ENVIRONMENTAL IMPACT STATEMENT (EIS/OEIS) FOR NAVY MILITARY READINESS ACTIVITIES IN THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

The HSTT EIS/OEIS will address Navy activities that occur in the air, under the ocean surface and on the ocean surface for the following range complexes: HRC, SOCAL Range Complex, and SSTC. Land activities occurring at SOCAL installations and within the HRC have been analyzed in other EIS documents and will be incorporated by reference in this EIS/OEIS.

Environmental issues that will be addressed in the EIS/OEIS include, but are not limited to, the following resource areas: oceanography; air quality; airborne soundscape; biological resources, including threatened and endangered species; cultural resources; transportation; regional economy; recreation; and public health and safety. Your input in identifying specific issues and concerns that should be assessed, in these areas and any additional areas, is important to the process.

In compliance with the National Environmental Policy Act (NEPA) of 1969, the Navy is holding open house public scoping meetings to support an early and open process for determining the scope of issues to be addressed and for identifying significant issues related to the proposed action. Scoping meetings will inform the public of the Navy's proposed action and give community members an opportunity to make comments. Input from scoping meetings will be used to help identify potentially significant issues to be analyzed in the Draft EIS/OEIS.

Six public open house scoping meetings will be held in SOCAL and Hawaii. Members of the public can arrive anytime during the scoping meetings. Representatives from the Navy will be available to provide information and answer questions about the proposed action. There will be no formal presentation. The public scoping meeting schedule is as follows:

Wednesday, August 4, 2010
3:30 to 7:30 p.m.
Point Loma/Hervey Branch Library
Community Room
3701 Voltaire St.
San Diego, Calif.

Thursday, August 5, 2010
4:00 to 8:00 p.m.
Lakewood High School
Room 922/924
4400 Briercrest Ave.
Lakewood, Calif.

2000 NAVY PENTAGON
WASHINGTON, DC 20350-2000

IN REPLY REFER TO

5090
Ser N456D/10U158198
21 July 2010

Mr. Eric C. Schwaab
Assistant Administrator
National Marine Fisheries Service
1315 East West Highway
Silver Spring, MD 20910

Dear Mr. Schwaab: Eric

In accordance with the National Environmental Policy Act (NEPA), the Department of the Navy (Navy) is initiating the preparation of an Environmental Impact Statement (EIS)/Overseas Environmental Impact Statement(OEIS) to evaluate the potential environmental effects associated with military readiness training and research, development, testing, and evaluation (RDT&E) activities that include the use of active sonar and explosives around the Hawaiian Islands and off the coast of Southern California (Hawaii-Southern California Training and Testing [HSTT] study area). The HSTT study area specifically combines the at-sea portions of existing Navy range complexes: Hawaii Range Complex (HRC), Southern California Range Complex (SOCAL), and Silver Strand Training Complex (SSTC). The study area also includes those areas where vessels transit between the Hawaii Range Complex and the Southern California Range Complex and select Navy pier-side locations. As a result, the separate analyses contained in the HRC, SOCAL, and SSTC EIS/OEISs will be consolidated into a single EIS/OEIS.

An important aspect of the HSTT EIS/OEIS will be the analysis of the acoustic effects to marine species protected under the Marine Mammal Protection Act (MMPA) and the Endangered Species Act (ESA). The HSTT EIS/OEIS is also intended to serve as a basis for the renewal of current regulatory permits and authorizations; address current training and testing not covered under the existing permits and authorizations; and obtain those permits and authorizations necessary to support force structure changes and emerging and future training and testing requirements. MMPA Final Rules and ESA Section 7 Programmatic Biological Opinions for HRC and SOCAL will expire in January 2014. The Navy anticipates receiving an Incidental Harassment Authorization (IHA) for the Silver Strand Training Complex in October 2010 and combining that IHA into the permitting and consultation effort for the HSTT study area.

To complete the analysis required by the permitting and consultation processes, the Navy and the National Marine Fisheries Service (NMFS) will need to work together. Therefore, in accordance with the Council on Environmental Quality's (CEQ) NEPA guidelines (specifically, 40 CFR Part 1501) and CEQ's 2002 guidance on cooperating agencies, Navy requests NMFS serve as a cooperating agency for the development of the HSTT EIS/OEIS.

As the lead agency, the Navy will be responsible for overseeing preparation of the EIS/OEIS that will include, but not be limited to, the following:

- Gathering all necessary background information and preparing the EIS/OEIS and all necessary permit applications associated with acoustic issues.
- Working with NMFS personnel to determine the method of estimating potential effects to protected marine species, including threatened and endangered species.
- Determining the scope of the EIS/OEIS, including the alternatives evaluated.
- Circulating the appropriate NEPA documentation to the general public and any other interested parties.
- Scheduling and supervising meetings held in support of the NEPA process, and compiling any comments received.
- Maintaining an administrative record and responding to any Freedom of Information Act requests relating to the EIS/OEIS.

Navy respectfully requests that NMFS, in its role as a cooperating agency, provide support as follows:

- Providing timely comments after the Agency Information Meeting (which will be held at the onset of the EIS/OEIS process) and on working drafts of the EIS/OEIS documents. The Navy requests that comments on draft EIS/OEIS documents (Version 2) be provided within 30 working days.
- Responding to Navy requests for information, in particular related to review of the acoustic effects analysis and evaluation of the effectiveness of protection and mitigation measures.
- Coordinating, to the maximum extent practicable, any public comment periods required in the MMPA permitting process with the Navy's NEPA public comment periods.
- Participating, as necessary, in meetings hosted by the Navy for discussion of issues related to the EIS/OEIS, including public hearings and meetings.

2

- Adhering to the overall schedule as set forth by the Navy.
- Providing a formal, written response to this request.

The Navy views this agreement as important to the successful completion of the environmental planning process for the HSTT EIS/OEIS. NMFS assistance will be invaluable in this endeavor.

My point of contact for this action is Ms. Dawn Roderique, (703) 604-1268, email: Dawn.Roderique@navy.mil.

Sincerely,

John Quinn

THE DIRECTOR

JUL 11 2013

Mr. John P. Quinn
Deputy Director, Energy and
Environmental Readiness Division
Department of the Navy
2000 Navy Pentagon
Washington, DC 20350-2000

Dear Mr. Quinn:

Thank you for your letter requesting that NOAA's National Marine Fisheries Service (NMFS) participate as a cooperating agency in the preparation of an Environmental Impact Statement (EIS)/Overseas Environmental Impact Statement (OEIS) to evaluate potential environmental effects of military readiness training and research, development, testing, and evaluation (RDT&E) activities conducted within the Hawaii-Southern California Training and Testing (HSTT) Study Area. We reaffirm our support of the Navy's decision to prepare an EIS/OEIS and agree to be a cooperating agency, due, in part, to our responsibilities under section 101(a)(5)(A) of the Marine Mammal Protection Act (MMPA) and section 7 of the Endangered Species Act.

In response to your letter, NMFS staff will continue to, to the extent possible,

- Provide timely review and comments, within 30 working days, after the Agency Information Meeting and on working drafts of the EIS/OEIS documents;
- Respond to Navy requests for information, in particular those related to the acoustic effects analysis and the evaluation of the effectiveness of protection and mitigation measures, in a timely manner;
- Participate in meetings, as necessary, hosted by the Navy to discuss issues related to the EIS/OEIS, including public hearings on the draft EIS/OEIS; and
- Adhere to the overall schedule as agreed upon by NMFS and the Navy.

If you need any additional information, please contact Ms. Jolie Harrison, NMFS Office of Protected Resources, at (301) 427-8401.

Sincerely,

Samuel D. Rauch, III

SUBJECT: REQUEST FOR MARINE MAMMAL PROTECTION ACT (MMPA) INCIDENTAL TAKE AUTHORIZATION AND REGULATIONS FOR U.S. HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) ACTIVITIES

Dear Ms. Golde:

In accordance with MMPA, as amended and 50 C.F.R. Part 216, the U.S. Navy requests 5-year incidental take authorization and regulations for the incidental taking of marine mammals associated with HSTT activities occurring within the Pacific Ocean.

The Proposed Action may incidentally expose marine mammals that reside within the HSTT study area to sound and other environmental stressors associated with training and testing activities. The enclosed request further describes the HSTT activities and study area and provides the specific information required by National Marine Fisheries Service (NMFS) for consideration of an incidental take request.

The U.S. Navy requests the above regulations authorize, and the NMFS issue, two 5-year Letter of Authorizations; one issued to Commander, U.S. Pacific Fleet for training activities and one issued to Commander, Naval Sea Systems Command for testing activities. Addresses for these commands are provided below:

Silver Spring, MD 20910-3282

SUBJECT: REVISED REQUEST FOR MARINE MAMMAL PROTECTION ACT INCIDENTAL TAKE AUTHORIZATION AND REGULATIONS FOR U.S. NAVY HAWAII AND SOUTHERN CALIFORNIA TRAINING AND TESTING ACTIVITIES

On April 4, 2012 the U.S. Navy submitted an application for a five-year incidental take authorization and regulations under the Marine Mammal Protection Act (MMPA) for the incidental taking of marine mammals associated with Hawaii and Southern California and Testing (HSTT) activities occurring within the Pacific Ocean. Since our submittal of the application we have continued to refine our proposed activities and the associated analysis of potential impacts on marine mammals. We have also discussed the initial application with your staff and incorporated additional information based on those discussions. In light of the above refinements and discussions, the U.S. Navy is submitting the enclosed revised application in accordance with the MMPA, as amended, and 50 C.F.R. Part 216, for a five-year incidental take authorization and regulations for HSTT activities.

The primary revisions to the initial application include: 1) corrections to errors, typos, and transcription mistakes; 2) addition of training and testing requirements that were not identified in time to incorporate into the initial application; 3) clarification of how events were modeled; and 4) the addition of post-model quantification to supplement the analysis of acoustic effects to include animal avoidance of sound sources, animal avoidance of areas of activity before use of a sound source or explosive, and implementation of mitigation.

As stated in our April 4, 2012 letter, the U.S. Navy requests the above regulations authorize, and National Marine Fisheries Service (NMFS) issue two five-year Letters of Authorization; one issued to Commander, United States Pacific Fleet for training activities, and one issued to Commander, Naval Sea Systems Command for testing activities.

SUBJECT: REQUEST FOR INITIATION OF ENDANGERED SPECIES ACT SECTION 7 FORMAL CONSULTATION FOR COMMANDER, UNITED STATES PACIFIC FLEET TRAINING AND TESTING ACTIVITIES

Dear Ms. Golde:

In accordance with section 7 of the Endangered Species Act, the U.S. Navy requests initiation of formal consultation on Hawaii-Southern California Training and Testing (HSTT) activities occurring within the Pacific Ocean off the coast of Southern California and in the surrounding waters of the Hawaiian Islands.

The proposed action may affect listed species that reside within the HSTT Study Area by exposing them to sound and other environmental stressors associated with training and testing activities. The enclosed HSTT Draft Environmental Impact Statement (DEIS)/Draft Overseas Environmental Impact Statement (DOEIS) is the Navy's primary document that provides the required information pursuant to 50 C.F.R. §402.12(f). The U.S. Navy is requesting formal consultation on Alternative 2 within the EIS/OEIS. In addition, the enclosed Supplemental Information document serves as a roadmap for identifying the required information within the EIS/OEIS, and provides additional, supporting information not found within the EIS/OEIS.

5090
Ser N01CE1/1251
24 Sept 2012

The Navy is requesting formal consultation on ESA-listed species addressed in this consultation package including the humpback whale, (*Megaptera novaeangliae*), sei whale (*Balaenoptera borealis*), fin whale (*Balaenoptera physalus*), blue whale (*Balaenoptera musculus*), sperm whale (*Physeter macrocephalus*), Hawaiian monk seal (*Monachus schauinslandi*), green turtle (*Chelonia mydas)*, hawksbill turtle *(Eretmochelys imbricata*), olive ridley turtle (*Lepidochelys olivacea*), loggerhead turtle (*Caretta caretta*), and leatherback turtle (*Dermochelys coriacea*), as well as designated critical habitat for Hawaiian monk seal. The Navy is also requesting concurrence on our Not Likely to Adversely Affect determinations for black abalone (*Haliotis cracherodii*), white abalone (*Haliotis sorenseni*), and steelhead trout (*Oncorhynchus mykiss*) as well as designated critical habitat for steelhead trout and black abalone. In addition, the Navy is requesting a conference opinion on the Hawaiian insular stock of false killer whale (*Pseudorca crassidens*).

We appreciate your continued support in helping the U.S. Navy to meet its environmental responsibilities.

Sincerely,

L. M. FOSTER

Loyal Mehrhoff, PhD
Field Supervisor
Pacific Islands Fish and Wildlife Office
300 Ala Moana Blvd., Suite 3-122
Honolulu, Hawaii 96850

SUBJECT: REQUEST FOR INFORMAL CONSULTATION UNDER SECTION 7 OF THE ENDANGERED SPECIES ACT (ESA) FOR SPECIES UNDER U.S. FISH AND WILDLIFE SERVICE (USFWS) JURISDICTION WITHIN THE HAWAII PORTION OF THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

Dear Dr. Mehrhoff:

In accordance with section 7 of the ESA, the U.S. Navy requests informal consultation on HSTT activities occurring within the Pacific Ocean in the surrounding waters of the Hawaiian Islands.

The Proposed Action may affect listed species that reside within the HSTT Study Area by exposing them to sound and other environmental stressors associated with training and testing activities. The enclosed HSTT Draft Environmental Impact Statement (DEIS)/Overseas Environmental Impact Statement (OEIS) (Enclosure 1) is the Navy's primary document that provides the required information pursuant to 50 C.F.R. §402.12(f). Chapter 5 was revised after the DEIS release so the revised Chapter is provided as Enclosure 3.

The U.S. Navy is requesting informal consultation on Alternative 2 within the EIS/OEIS for species that occur within the Hawaii portion of the HSTT Study Area and are under the jurisdiction of the USFWS. Sea turtles are not included in this consultation as land-based activities are not being covered in the HSTT EIS. Those activities were covered in the Hawaii Range Complex (HRC) EIS and are not changing. Also, the Navy is consulting with National

SUBJECT: REQUEST FOR INFORMAL CONSULTATION UNDER SECTION 7 OF THE ENDANGERED SPECIES ACT (ESA) FOR SPECIES UNDER U.S. FISH AND WILDLIFE SERVICE (USFWS) JURISDICTION WITHIN THE HAWAII PORTION OF THE HAWAII-SOTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

Marine Fisheries Service under ESA for proposed at-sea training and testing activities that may affect listed species under their jurisdiction. Therefore, ESA-listed seabirds are the only species being covered in this informal consultation. In addition, the enclosed Supplemental Information (Enclosure 3) serves as a roadmap for identifying the required information within the EIS/OEIS.

The Navy requests concurrence that the described actions may affect, but are not likely to adversely affect the Hawaiian petrel (*Pterodroma sandwichensis*), short-tailed albatross (*Phoebastria albatrus*), and Newell's shearwater (*Puffinus auricularis newelli*).

Thank you for your assistance. Please contact Mr. Frans Juola at Naval Facilities Engineering Command, Pacific at email: frans.juola@navy.mil, (808)472-1433 or Ms. Julie Rivers at email julie.rivers@navy.mil, (808)474-6391 regarding this informal consultation request.

Sincerely,

L. M. FOSTER

Subject: Informal Consultation on the Hawaii Portion of the Proposed U.S. Navy Hawaii-Southern California Training and Testing Study Area within the Pacific Ocean

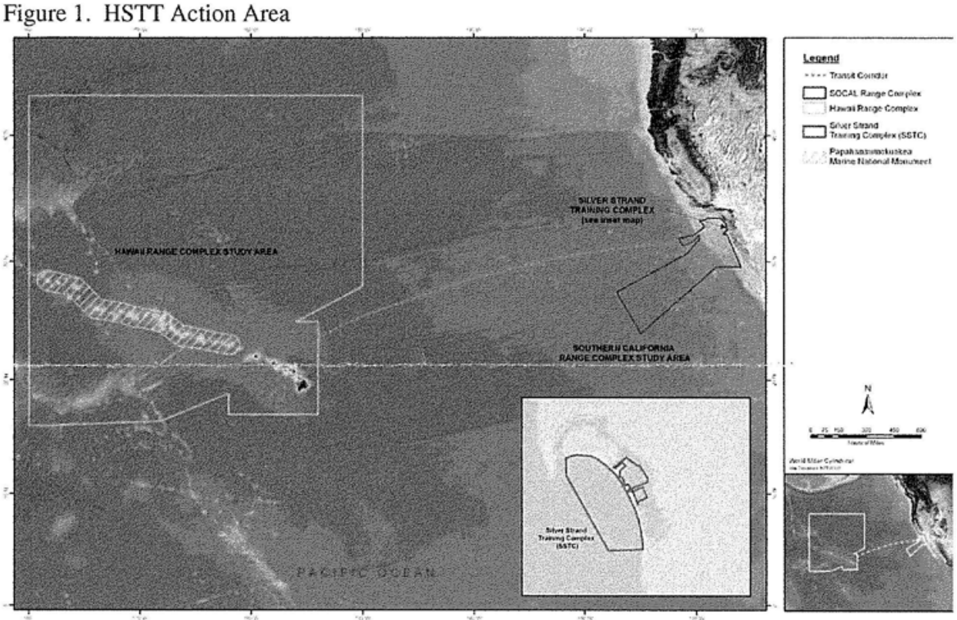
Dear Mr. Foster:

This letter is in response to your November 15, 2012, request for informal consultation for the proposed U.S. Navy Hawaii-Southern California Training and Testing (HSTT) activities occurring in waters off of the Hawaiian Islands. We received the letter on November 21, 2012. You determined the proposed action is not likely to adversely affect federally endangered short-tailed albatross (*Phoebastria albatrus*), Hawaiian petrel (*Pterodroma sandwichensis*), and the threatened Newell's shearwater (*Puffinus auricularis newelli*).

HSTT activities will be implemented as described in Alternative 2 of the HSTT Draft Environmental Impact Statement/Overseas Environmental Impact Statement (DEIS/OEIS). The HSTT action area includes established U.S. Navy (Navy) operating and warning areas across the north-central Pacific Ocean, from Southern California west to Hawaii and the International Date Line. The Study Area includes three existing Navy range complexes: the Hawaii Range Complex, SOCAL Range Complex and Silver Strand Training Complex (SSTC) (Figure 1). The HSTT action area also includes Navy vessel transit corridors and piers outside of the range complexes. HSTT will include: use of active sonar and explosives in the existing range complexes; sonar maintenance and gunnery exercises during ship transits between the range complexes; and sonar testing at Navy piers in Pearl Harbor, Hawaii and San Diego Bay, California. HSTT training and testing activities may occur year round.

HSTT will occur in areas under the jurisdiction of the U.S. Fish and Wildlife Service's Pacific Islands Field Office (PIFWO) and Carlsbad Field Office. This letter addresses only the portions of HSTT under the PIFWO's jurisdiction.

Figure 1. HSTT Action Area



It is likely that few seabirds would be affected by sonar and other underwater active acoustic sources because sources are used intermittently during a training event, training events are dispersed in space and time, most seabirds spend little time submerged, and exposures sufficiently intense (i.e., of a certain duration or within a close proximity) to cause physiological impacts are unlikely. Hawaiian petrels and short-tailed albatrosses do not submerge while foraging; therefore, they would not be exposed to underwater sound from sonar and other active acoustic sources. Newell's shearwater may briefly submerge while foraging, pursuit diving, so there is a remote chance that these species could be exposed to underwater sound sonar and other active acoustic sources.

The short-tailed albatross, Hawaiian petrel, and Newell's shearwater occur in oceanic and off shore waters within the HSTT action area at low frequencies (Navy 2012). HSTT activities could result in adverse effects to these species. Due to the widely dispersed, temporary and intermittent nature of the HSTT activities, and the low frequencies of these species within the HSTT action area, we consider such effects to short-tailed albatross, Hawaiian petrel, and Newell's shearwater possible, but unlikely.

Based on the above and implementation of mitigation measures outlined in detail within DEIS/OEIS, we concur with the Navy's determination that HSTT is not likely to adversely affect endangered short-tailed albatross, Hawaiian petrel, and the threatened Newell's shearwater. Unless the project description changes, or new information reveals that the effects of the proposed action may affect listed species in a manner or to an extent not considered, or a new species or critical habitat is designated that may be affected by the proposed action, no further action pursuant to the Act is necessary.

Mr. Larry M. Foster 3

We appreciate your continued efforts to address the conservation needs of wildlife that may be affected by military training activities. If you have questions regarding this consultation, please contact Aaron Nadig, Fish and Wildlife Biologist, at 808-792-9400.

Sincerely,

Crystal Leonetti

SUBJECT: REQUEST FOR INFORMAL CONSULTATION UNDER SECTION 7 OF THE ENDANGERED SPECIES ACT (ESA) FOR SPECIES UNDER U.S. FISH AND WILDLIFE SERVICE (USFWS) JURISDICTION WITHIN THE SOUTHERN CALIFORNIA (SOCAL) PORTION OF THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

Dear Mrs. Goebel:

In accordance with section 7 of the ESA, the U.S. Navy requests informal consultation on HSTT activities occurring within the Pacific Ocean off the coast of Southern California.

The Proposed Action may affect listed species that reside within the HSTT Study Area by exposing them to sound and other environmental stressors associated with training and testing activities. The enclosed HSTT Draft Environmental Impact Statement (DEIS)/Overseas Environmental Impact Statement (OEIS) (Enclosure 1) is the Navy's primary document that provides the required information pursuant to 50 C.F.R. §402.12(f). Chapter 5 was revised after the DEIS release so the revised Chapter is provided as Enclosure 2.

The U.S. Navy is requesting informal consultation on Alternative 2 within the EIS/OEIS for species that occur within the SOCAL portion of the HSTT Study Area and are under the jurisdiction of the USFWS. Land-based activities are not part of the HSTT EIS proposed activities. Those activities were addressed in the SOCAL and Silver Strand Training Complex (SSTC)

SUBJECT: REQUEST FOR INFORMAL CONSULTATION UNDER SECTION 7 OF THE ENDANGERED SPECIES ACT (ESA) FOR SPECIES UNDER U.S. FISH AND WILDLIFE SERVICE (USFWS) JURISDICTION WITHIN THE SOUTHERN CALIFORNIA (SOCAL) PORTION OF THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

EISs, and associated Biological Opinions and are not proposed to change under the HSTT EIS Proposed Action. Also, the Navy is consulting with National Marine Fisheries Service under ESA for proposed at-sea training and testing activities that may affect listed species under their jurisdiction. Therefore, ESA-listed seabirds are the only species being covered in this informal consultation. In addition, the enclosed Supplemental Information (Enclosure 3) serves as a roadmap for identifying the required information within the EIS/OEIS.

The Navy requests concurrence that the described actions may affect, but are not likely to adversely affect the California least tern (*Sterna antillarum browni*), short-tailed albatross (*Phoebastria albatrus*), and marbled murrelet (*Brachyramphus marmoratus*).

Thank you for your assistance. Please contact Jacqueline Rice (jacqueline.rice@navy.mil, (619) 545-9339) regarding this informal consultation request.

Sincerely,

L. M. FOSTER

Pearl Harbor, Hawaii 96860-3131

Subject: Informal Section 7 Consultation on the U.S. Navy's Hawaii-Southern California Training and Testing

Dear Mr. Foster:

This is in response to your letter dated November 26, 2012, requesting informal consultation on Hawaii-Southern California Training and Testing (HSTT), and its effects on the federally endangered California least tern (*Sterna antillarum browni*, least tern), short-tailed albatross (*Phoebastria albatrus*), and marbled murrelet (*Brachyramphus marmoratus*), in accordance with section 7 of the Endangered Species Act (Act) of 1973, as amended (16 U.S.C. 1531 *et seq*.). We received your letter on January 4, 2013.

HSTT activities will be implemented as described in Alternative 2 of the HSTT Draft Environmental Impact Statement/Overseas Environmental Impact Statement (DEIS/OEIS). The HSTT action area includes established U.S. Navy (Navy) operating and warning areas across the north-central Pacific Ocean, from southern California to Hawaii and the International Date Line. The action area includes three existing Navy complexes: the Hawaii Range Complex, SOCAL Range Complex, and Silver Strand Training Complex (SSTC) (Figure 1). The HSTT action area also includes Navy vessel transit corridors and piers outside of the complexes. HSTT will include: use of active sonar and explosives in the existing complexes; sonar maintenance and gunnery exercises during ship transits between the complexes; and sonar testing at Navy piers in Pearl Harbor, Hawaii, and San Diego Bay, California. HSTT activities may occur year round.

HSTT will occur in areas under the jurisdiction of the U.S. Fish and Wildlife Service's Pacific Islands Fish and Wildlife Office and Carlsbad Fish and Wildlife Office (CFWO). This letter addresses only the portions of HSTT under the CWFO's jurisdiction.

Based on your letter, HSTT will not include land training and testing activities, nor result in a change to land or in-water training and testing activities identified in the biological opinion on the SSTC Operations (FWS-SDG-8B0503-09F0517), and the San Clemente Island Military

Operations and Fire Management Plan (FWS-LA-09B0027-09F0040). These previous biological opinions addressed potential adverse effects of some HSTT activities to the least tern and western snowy plover (*Charadrius alexandrinus nivosus*), and exempted take associated with the activities. Although the HSTT DEIS/OEIS includes tables that reflect an increase in training frequency for some significant training activities that were previously consulted on (e.g., Battalion sized landings; Table A-1 of HSTT DEI/OEIS, page 2-78), the Navy provided corrected tables that confirm no increase in training will occur on San Clemente Island or the SSTC as part of HSTT (Rice 2013). It is our understanding that these corrected tables will be incorporated into the final HSTT EIS/OEIS.

Figure 1. HSTT Action Area

The Navy will implement the conservation measures identified in biological opinion FWS-SDG-8B0503-09F0517 to avoid and minimize potential adverse effects to the least tern associated with HSTT activities conducted at the SSTC. Therefore, no further consultation on potential impacts to the least tern is necessary for activities already addressed in biological opinion FWS-SDG-8B0503-09F0517.

Additional training and testing activities included in HSTT and not previously addressed in biological opinion FWS-SDG-8B0503-09F0517 include gunnery exercises during ship transits between the range complexes, mine countermeasure exercises, and sonar testing/maintenance. These activities may affect least terns by exposing them to strikes or collisions with vessels, aircraft, or munitions; physical disturbance; and electromagnetic stressors (Navy 2012). Due to the low density of least terns anticipated within ship transit and at-sea training areas, the mobility of least terns that will allow them to depart from areas of disturbance, and the foraging strategy of least terns that results in little time spent under water, we expect potential effects to least tern to be discountable.

The marbled murrelet and short-tailed albatross occur in oceanic and/or near shore waters off the coast of California, and have been recorded within the HSTT action area at low frequencies (Navy 2012). HSTT activities could result in adverse effects to these species. Due to the widely dispersed, temporary and intermittent nature of the HSTT activities, and the low frequencies of these species within the HSTT action area, we expect potential effects to marbled murrelet and short-tailed albatross to also be discountable.

Based on the above, we concur with the Navy's determination that HSTT is not likely to adversely affect the least tern, marbled murrelet, and short-tailed albatross. Therefore, the interagency consultation requirements of section 7 of the Act have been satisfied. Should project plans change or if additional information on the distribution of listed or proposed species becomes available, this determination may be reconsidered and further section 7 consultation may be required.

We appreciate your continued efforts to address the conservation needs of wildlife that may be affected by military training activities. If you have any questions or concerns with regard to this consultation, please contact Sandy Vissman at 760-431-9440.

Sincerely,

Karen A. Goebel
Assistant Field Supervisor

Honolulu, HI 96804

Dear Mr. Souki:

In accordance with 15 CFR §930, the U.S. Navy, Commander, U.S. Pacific Fleet is submitting the enclosed Consistency Determination (CD) for operations within the Hawaii-Southern California Training and Testing (HSTT) Study Area, which includes the Hawaii Range Complex (HRC). The CD addresses ongoing and future military training and testing within the HRC. The CD is being submitted for consideration by the Office of Planning. A separate CD was prepared and submitted to the California Coastal Commission for their consideration under the CZM Program for operations within the Southern California portion of the Study Area.

In addition to the CZMA Federal Consistency requirements addressed by the submission of the enclosed CD, the Navy is addressing compliance with other environmental laws as follows:

- National Environmental Policy Act and Executive Order 12114. Navy released a Draft Environmental Impact Statement for the HSTT in May, 2012.

- Marine Mammal Protection Act. Navy is seeking an Incidental Harassment Authorization request from the National Marine Fisheries Service (NMFS).

- Endangered Species Act (ESA). Navy is consulting with NMFS and U.S. Fish and Wildlife Service under Section 7 of the ESA.

Mr. Larry M. Foster, Director
Environmental Readiness
Department of the Navy
Commander
United States Pacific Fleet
250 Makalapa Drive
Pearl Harbor, Hawaii 96860-3131

Dear Mr. Foster:

Subject: Hawaii Coastal Zone Management (CZM) Program Federal Consistency Review for U.S. Navy Hawaii-Southern California Training and Testing (HSTT) Activities

The Office of Planning, CZM Program, State of Hawaii, has completed its review of the Navy's CZM Act federal consistency determination dated January 13, 2013 (received January 18, 2013), for operations and activities within the HSTT area. The Office of Planning conditionally concurs with the Navy's determination that the conduct of U.S. Navy HSTT activities is consistent to the maximum extent practicable with the enforceable policies of the Hawaii CZM Program.[1] The following condition shall apply to all HSTT operations and activities:

> Pursuant to Hawaii CZM Program enforceable policies Hawaii Revised Statutes (HRS) Chapter 195D, and Hawaii Administrative Rules (HAR) Chapter 13-124, HSTT operations or activities within the State of Hawaii CZM management area shall not harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect endangered or threatened species of aquatic life or wildlife, or cut, collect, uproot, destroy, injure, or possess endangered or threatened species of aquatic life or land plants, or attempt to engage in any such conduct. Endangered or threatened species referred to in this condition are those listed in HAR Chapter 13-124. This condition shall not apply to marine mammals.[2]

---

[1] Pursuant to 15 CFR 930.32(a)(1), "[t]he term 'consistent to the maximum extent practicable' means fully consistent with the enforceable policies of management programs unless full consistency is prohibited by existing law applicable to the Federal agency."

[2] *See* Letter from Jane C. Luxtion, NOAA General Counsel, to Frank R. Jimenez, General Counsel of the Navy, June 20, 2008.

Mr. Larry M. Foster
Page 2
March 20, 2013

The subject condition is based on two federally-approved enforceable policies of the Hawaii CZM Program: (1) HRS Chapter 195D, *Conservation of Aquatic Life, Wildlife, and Land Plants*, and (2) HAR Chapter 13-124, *Indigenous Wildlife, Endangered and Threatened Wildlife, and Introduced Wild Birds*. HRS §195D-4(e)(2) and HAR §13-124-3(b), prohibit the "take" of any threatened or endangered species within the State of Hawaii. Pursuant to HRS §195D-2, "take" is defined as "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect endangered or threatened species of aquatic life or wildlife, or to cut, collect, uproot, destroy, injure, or possess endangered or threatened species of aquatic life or land plants, or to attempt to engage in any such conduct." The State of Hawaii listing of threatened and endangered species is contained in HAR Chapter 13-124.

According to the Navy's "Coastal Zone Management Act Consistency Determination for Hawaii," dated January 2013 ("Consistency Determination"), impacts to threatened sea turtles are predicted to result from explosions during both training activities and testing activities. Table 3-4, page 35, shows that HSTT activities will cause 21 occurrences of permanent threshold shift (i.e., permanent hearing damage), 13 occurrences of lung injury, and 4 mortalities annually. Table 3-5, page 35, shows that HSTT activities will cause 5 permanent threshold shifts annually. Consequently, HSTT training and testing activities will "take" threatened sea turtles, contravening enforceable policies of the Hawaii CZM Program.

In addition, HSTT activities involving explosive detonations will likely "take" endangered or threatened seabirds. Page 44 of the Consistency Determination predicts that

> [w]hile the impacts of explosive detonations on seabirds under the Proposed Action cannot be quantified due to limited data on seabird density, lethal injury to some seabirds could occur. Lethal injuries would likely be associated with detonations of bombs with larger net explosive weights, although any event employing static targets may attract seabirds to the detonation site.

According to page 43 of the Consistency Determination, "[a] seabird close to an explosive detonation could be killed or injured." Based on this information, it is reasonably foreseeable that HSTT explosive detonations will cause the "take" of endangered or threatened seabirds, contravening enforceable policies of the Hawaii CZM Program.

If the requirements for conditional concurrences specified in 15 CFR §§930.4(a)(1) through (3) are not met, then all parties shall treat this conditional concurrence letter as an objection pursuant to 15 CFR Part 930, Subpart C. Furthermore, you are hereby notified that, pursuant to 15 CFR §930.63(e), you have an opportunity to appeal an objection resulting from not meeting the requirements of 15 CFR §§930.4(a)(1) through (3) to the Secretary of Commerce within 30 days after receiving this conditional concurrence letter.

Mr. Larry M. Foster
Page 3
March 20, 2013

CZM consistency concurrence does not represent an endorsement or favorable consideration of any of the Navy's HSTT operations and activities, nor does it convey approval with any regulations administered by any state or county agency. If you have any questions, please contact me at (808) 587-2846.

Sincerely,

Jesse K. Souki
Director

Mr. Jesse K. Souki
Director
Hawaii Department of Business, Economic
Development & Tourism, Office of Planning
P.O. Box 2359
Honolulu, HI 96804

Dear Mr. Souki:

The Navy is in receipt of the State of Hawaii's Office of Planning (OP) letter (dated 18 April 2013) regarding the Hawaii-Southern California Training and Testing Consistency Determination, and the OP's request for clarification regarding our intentions.

The OP specifically asked if the Navy was suggesting that it would engage in consultation with the endangered species recovery committee and apply for a temporary license as part of a habitat conservation plan with the State Board of Land and Natural Resources.

The Navy wishes to make clear that it does not intend to engage in consultation with State offices. Rather, the Navy has initiated consultation with the National Marine Fisheries Service and the Fish and Wildlife Service to ensure that the population and future of endangered species are not put into jeopardy. Additionally, the Navy will minimize and mitigate to the maximum extent practicable the impacts to species of concern in order to ensure that the potential taking of the species are not "likely" to occur.

The Endangered Species Act, and the Navy's consultation under Section 7 of the act serves as the functional equivalent of the State programs and will ensure that Navy activities remain consistent with the enforceable policies of the Hawaii CZM Program.

5090
N01CE1/xxxx
April 23, 2013

The Navy thanks the Office of Planning for allowing us this opportunity to provide clarification and we look forward to continuing our professional relationship with you and your staff.

Sincerely,

L. M. FOSTER

Ref. No. P-13956

April 18, 2013

Mr. John Coronado
Department of the Navy
Commander
United States Pacific Fleet
250 Makalapa Drive
Pearl Harbor, Hawaii 96860-3131

Dear Mr. Coronado:

Subject: Hawaii-Southern California Training and Testing (HSTT) Consistency Determination

The Office of Planning (OP) has reviewed the Department of the Navy's letter, dated April 12, 2013, regarding its response to OP's Coastal Zone Management Act conditional concurrence regarding the subject activities.

OP seeks to better understand the Navy's position on this matter. According to the Navy's letter, "the proposed conditions [in OP's conditional concurrence letter dated March 20, 2013] are not necessary for the Navy's training and testing activities to be fully consistent with HRS 195-4(e) and (g) because any take would be incidental to, and not the purpose of, an otherwise lawful activity." Is the Navy suggesting that it will engage in consultation with the endangered species recovery committee and apply for a temporary license as a part of a habitat conservation plan with the State Board of Land and Natural Resources (BLNR)?

According to HRS §195-4(e), it is unlawful to take any threatened or endangered species of aquatic life. With regard to subsection (g), which the Navy cites in its letter, an exception to this general rule against taking may be allowed, but only as follows:

> **After consultation with the endangered species recovery committee, the [BLNR] may issue a temporary license as a part of a habitat conservation plan** to allow a take otherwise prohibited by subsection (e) if the take is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity[.]

See HRS §195-4(g) (emphasis added).

Mr. John Coronado
Page 2
April 18, 2013

Thank you for the Navy's willingness to address any remaining concerns using the remaining portion of the 90-day notice period. If you have any questions, please contact me at (808) 587-2846.

Sincerely,

Jesse K. Souki

San Francisco, California 94105-2219

Dear Mr. Lester:

In accordance with 15 CFR §930, the U.S. Navy, Commander, U.S. Pacific Fleet is submitting the enclosed Consistency Determination (CD) for operations within the Hawaii-Southern California Training and Testing (HSTT) Study Area, which includes the Southern California (SOCAL) Range Complex and the Silver Strand Training Complex (SSTC). The CD addresses ongoing and future military training and testing within the SOCAL Range Complex and SSTC. The CD is being submitted for consideration by the Coastal Commission at the March 6-8, 2013 hearing in San Diego. A separate CD was prepared and submitted to the Hawaii Department of Business, Economic Development & Tourism, Office of Planning for their consideration under the CZM Program for operations within the Hawaii Range Complex portion of the Study Area.

In addition to the CZMA Federal Consistency requirements addressed by the submission of the enclosed CD, the Navy is addressing compliance with other environmental laws as follows:

- National Environmental Policy Act and Executive Order 12114. Navy released a Draft Environmental Impact Statement for the HSTT in May, 2012.
- Marine Mammal Protection Act. Navy is seeking an Incidental Harassment Authorization request from the National Marine Fisheries Service (NMFS).
- Endangered Species Act (ESA). Navy is consulting with NMFS and U.S. Fish and Wildlife Service under Section 7 of the ESA.

Re: **CD-008-13,** Department of the Navy, Consistency Determination, Southern California portion of the Hawaii-Southern California Training and Testing (HSTT) Program

Dear L.M. Foster:

On March 8, 2013, by a unanimous vote, the California Coastal Commission objected to the above-referenced consistency determination submitted by the Navy for the California portion of its Hawaii-Southern California Training and Testing Program (Program). The Commission's objection was based on lack of sufficient information to determine the Program's consistency to the maximum extent practicable with the marine resource protection policy (Section 30230) and the commercial fishing policies (Sections 30230, 30234, and 30234.5) of the California Coastal Act, all of which are enforceable policies under the California Coastal Management Program (CCMP).

In its deliberations the Commission determined that the consistency determination lacked sufficient information to enable it to determine consistency with the marine resource policy (Section 30230) for the following reasons:

1) The Navy's analysis relied on an incomplete analysis of the requirements of Section 30230, in that it only looked at one of the three tests (population-level effects), ignoring requirements of Section 30230 for the maintenance, enhancement, and, where feasible, restoration, of the overall marine environment, as well as for providing special protection for areas and species of special biological or economic significance.

2) The Navy arbitrarily limited its analysis to only 10 of the 34 marine mammals present in the southern California study area, when the preponderance of the evidence is that 32 of the 34 species are present in the coastal zone.

-2-

3) Even the Navy's population level effects analysis was questionable, as it was not supported by substantial evidence. Moreover, it did not include the type of analysis typically supplied in current-day marine mammal population analyses to estimate whether a proposed activity could result in marine mammal stocks falling below their optimal sustainable population levels, which was included in the analysis the Commission relied on in its recent review of the Pacific Gas and Electric Company's high energy seismic survey, and which compared "Level A takes" (under the Marine Mammal Protection Act) against residual "Potential Biological Removal" rates, and "Level B takes" for listed species against minimum population estimates.

4) The Navy provided no explanation as to why significant intensification of use of mid-frequency sonar was needed for military training and testing (e.g., an increase in "MF-1" sonar use (the loudest of the sonars) from 4,454 to 11,534 hours per year).

5) The Navy failed to analyze and consider alternatives such as implementing "time-area" closures, as well as other mitigation measures previously adopted by the Commission in reviewing past Navy consistency determinations for Southern California Training and Testing (CD-086-06 and CD-049-08), measures which the Commission staff requested the Navy to analyze in its July 10, 2012, comments on the HSTT DEIS.

The Commission determined that, without the above information, it was unable to determine whether feasible less damaging alternatives are available that would lessen adverse effects on marine resources, and whether the Program would be carried out: (a) in a manner that maintains, enhances, and, where feasible, restores marine resources; and (b) in a manner that provides special protection to areas of special biological or economic significance.

The Commission also:

1) noted that the Navy's refusal to consider avoiding state- and federally-designated Marine Protected Areas (MPAs) would undermine significant state and federal efforts establishing Marine Protected Areas, by potentially compromising the collection of accurate MPA baseline studies;

2) determined that the consistency determination lacked sufficient information to enable the Commission to determine consistency with the commercial fishing policies (Sections 30230, 30234, and 30234.5) of the Coastal Act, in the Navy's refusal to consider implementing its own 2009 commercial fishing survey recommendations to improve communications with the commercial fishing industry;

3) noted that the Navy had not raised any "practicability" issues in its consistency determination or its testimony before the Commission; and

4) noted and included in the record the attached letter from former NOAA Administrator Jane Lubchenco (sent to Council on Environmental Quality Chair Nancy Sutley) urging consideration of "time-area closures" and "new approaches" by the Navy.

Finally, the Commission urged the Navy to provide the above-requested information and bring back a modified consistency determination for the Program, with a more comprehensive analysis and consideration of alternatives, at a future Commission meeting.

We anticipate the Commission's formal findings in support of its action to be adopted at the April 10-12, 2013, Commission meeting in Santa Barbara.

The federal consistency regulations provide:

§ 930.43 State agency objection.

(b) If the State agency's objection is based upon a finding that the Federal agency has failed to supply sufficient information, the State agency's response must describe the nature of the information requested and the necessity of having such information to determine the consistency of the Federal agency activity with the enforceable policies of the management program.

(c) State agencies shall send to the Director a copy of objections to Federal agency consistency determinations.

(d) In the event of an objection, Federal and State agencies should use the remaining portion of the 90-day notice period (see § 930.36(b)) to attempt to resolve their differences. If resolution has not been reached at the end of the 90-day period, Federal agencies should consider using the dispute resolution mechanisms of this part and postponing final federal action until the problems have been resolved. At the end of the 90-day period the Federal agency shall not proceed with the activity over a State agency's objection unless:

(1) the Federal agency has concluded that under the "consistent to the maximum extent practicable" standard described in section 930.32 consistency with the enforceable policies of the management program is prohibited by existing law applicable to the Federal agency and the Federal agency has clearly described, in writing, to the State agency the legal impediments to full consistency (See §§ 930.32(a) and 930.39(a)), or

(2) the Federal agency has concluded that its proposed action is fully consistent with the enforceable policies of the management program, though the State agency objects.

(e) If a Federal agency decides to proceed with a Federal agency activity that is objected to by a State agency, or to follow an alternative suggested by the State agency, the Federal agency shall notify the State agency of its decision to proceed before the project commences.

UNITED STATES DEPARTMENT OF COMMERCE
The Under Secretary of Commerce
for Oceans and Atmosphere
Washington, D.C. 20230

JAN 19 2010

Ms. Nancy Sutley
Chair, Council on Environmental Quality
730 Jackson Place, NW
Washington, DC 20503

Dear Nancy,

I write to report to you on the National Oceanic and Atmospheric Administration's (NOAA) review of mitigation measures in rules authorizing take of marine mammals incidental to Navy training exercises, and to inform you of the plan with respect to future work with the Navy on possible additional mitigation measures.

As you recall, on January 20, 2009, as the Obama Administration was taking office, NOAA's National Marine Fisheries Service (NMFS) was in the process of publishing a regulation that would establish a framework to authorize the take of marine mammals incidental to the Navy training exercises involving use of mid-frequency active sonar on its ranges along the Atlantic Coast and in the Gulf of Mexico. Earlier in January, NMFS had published similar rules related to the take of marine mammals incidental to Navy training on Navy training ranges in Hawaii and Southern California. This issue has a history of being controversial, and you requested that NOAA conduct a comprehensive review of all mitigation measures applicable to the use of sonar.

NMFS intended the comprehensive review to give the new Administration an opportunity to understand the process used to develop the rules, and also to evaluate the adequacy of the mitigation measures required by the rule. Each rule took months to develop jointly by the Navy and NOAA scientists, with input from the public during a comment process on the proposed rules. For each rule, an Environmental Impact Statement (EIS) was prepared by the Navy and adopted by NOAA regarding Navy training exercises. In addition to the EISs, for each rule, NMFS prepared an Environmental Assessment in which it specifically considered a suite of mitigation measures, many of which had been recommended by members of the public during the public comment process. In those assessments, NMFS evaluated the potential effectiveness and benefit of each possible mitigation measure. Also, as required by the Marine Mammal Protection Act, NMFS reviewed the practicability of each of the mitigation measures in light of the impact on personnel safety, the practicality of implementation, and the impacts on the Navy's ability to achieve its training goals.

In the Environmental Assessments, NMFS also identified the relevant uncertainties regarding the impacts of the proposed training on marine mammals. Two are worth highlighting. One involves lack of knowledge about the mechanisms whereby some species of marine mammals, particularly beaked whales, are adversely affected by mid-frequency active sonar. The other concerns the difficulties of limiting the impact of active sonar where the mitigation efforts depend on visual sighting of whales. The ongoing mitigation efforts, in our view, must do more

THE ADMINISTRATOR

Printed on Recycled Paper

to address both of these uncertainties. NMFS included adaptive management provisions in the rules as a mechanism for improving the effectiveness of mitigation, as appropriate. NMFS also required the Navy to provide after-action reports following each exercise, which NMFS will monitor and use to modify mitigation measures, as appropriate. Thus, there are some mechanisms already in place to improve mitigation measures in the long run as new information becomes available.

In the short run, as a result of our findings in this review, NOAA will undertake three specific activities to address the issue of whether there are areas of biological significance impacted by these permitted activities and others undertaken under permits from NMFS (such as oil and gas exploration). First, NMFS, in concert with other civilian agencies (e.g., Minerals Management Service), would like to reinitiate comprehensive aerial cetacean and sea turtle surveys (i.e., multipurpose surveys). I will encourage the Navy to be part of the planning process for these new surveys, and to support their implementation. These surveys will provide not only fine-scale density estimates of whales in particularly sensitive or otherwise important areas (e.g., the ranges), but also provide improved population estimates supporting listing decisions and activities of take reduction teams.

Second, NMFS will conduct a workshop to develop a plan for estimating a comprehensive sound budget for the oceans. We will invite the Navy and other agencies to take part. There is currently a great deal of concern that a variety of human sources of marine sound (e.g., vessel traffic, seismic activity, sonar, and construction activities) are acting in a cumulative way to degrade the environment in which sound-sensitive animals communicate. There are no comprehensive baselines with which to measure the cumulative sound impacts such as increased military vessel traffic and emitted sound, e.g., in the ranges.

Third, NMFS will organize another workshop this year to learn more about marine mammal "hot spots." The Navy and NMFS have made substantial investments in models of existing whale distribution and environmental data to predict abundance and distribution of whales and other mammals in specific locations. As part of this focus, the workshop will evaluate these models, developed primarily for the Northwest Atlantic and the California Current and eastern tropical Pacific, and assess their general applicability. Such models, if verified, have great potential to assist in the design of appropriate mitigation measures that are effective and efficient. Protecting important marine mammal habitat is generally recognized to be the most effective mitigation measure currently available.

In addition, there are ongoing activities that NMFS will be conducting with the Navy because they are required by the permits that have been issued. For example, NMFS has required that the Navy convene a workshop to review and modify, as appropriate, the monitoring measures included in the regulations. This workshop is scheduled for 2011 to give agencies time to gain experience with the rules, to collect information for analysis at the workshop, and to identify any needed changes to improve the monitoring program. NMFS and the Navy have agreed to conduct a pre-workshop in 2010 to allow the public an opportunity to provide input and prepare for the 2011 workshop.

All of the planned workshops should lead to substantial new information related to improved mitigation strategies for military activities that would be implemented through the adaptive management provisions of the permits. Based on the information developed in these workshops, I will encourage NMFS and the Navy and other permittees to address the uncertainties identified above and to evaluate additional methods to reduce further any adverse effects on marine mammals resulting from the Navy's training exercises or other activities that may impact marine mammals or other protected resources.

In addition, NMFS included in various final rules, a requirement that the Navy develop an integrated comprehensive monitoring program, which it recently completed and will go into effect immediately. Any changes to the monitoring program will be made during workshops with NMFS and Navy. NMFS will also continue to work with the Navy to develop and implement new tools to characterize and predict areas that are important to marine mammals in the context of developing associated measures, as appropriate, to reduce impacts to marine mammals in these important areas while allowing the Navy to meet its training goals. In several rules, NMFS required the Navy to enter into a Memorandum of Agreement requiring the Navy to assist NMFS with investigations of strandings of marine mammals. NMFS is working with the Navy to complete this Agreement as soon as possible. NMFS will recommend that the Navy further focus on, develop, and implement technologies that enhance marine mammal detection capabilities (such as passive acoustic detection on instrumented ranges) to allow for both a better understanding of marine mammal activities in the presence of military training as well as, potentially, more effective implementation of mitigation measures.

Moreover, consistent with our legal and scientific mandates, I have directed NMFS to ensure thorough reviews of the Navy's after-action reports are conducted to identify opportunities for strengthening mitigation measures; to process and integrate new information from population assessments, interagency biological response studies, and other sources into its decision making framework; and to take advantage of the adaptive mechanisms in the regulations and annual authorizations to optimize the mitigation measures that are in place for protection of marine mammal species or stocks.

Finally, as part of a settlement agreement in litigation regarding the effects of sonar training on marine mammals, the Navy and the Natural Resources Defense Council (NRDC) have begun to meet and confer to resolve outstanding differences concerning marine mammal mitigation measures. NOAA participated in the first discussion, and is committed to playing an active role in future meetings. I have met with both the Navy and NRDC over the past several months, and I have developed an understanding of the issues and of their respective positions. I believe NOAA's participation will enhance these discussions, and can help to resolve the differing views among the parties. My expectation is that the parties will identify areas of scientific disagreement and uncertainty, and will engage in a healthy debate concerning how to ensure the Navy's training activities minimize, to the least practicable impact, adverse effects on marine mammal species or stocks. I also expect the Navy to be open to new ideas and approaches to mitigation that are supported by the best available science.

At this point, NOAA's review has concluded, but our work on these issues will continue. In addition to the actions outlined above, NMFS will continue to work with the Navy, and in the event specific problems are identified, NMFS will aggressively seek appropriate solutions.

Sincerely,

Jane Lubchenco, Ph.D.
Under Secretary of Commerce
for Oceans and Atmosphere

DEPARTMENT OF THE NAVY
COMMANDER
UNITED STATES PACIFIC FLEET
250 MAKALAPA DRIVE
PEARL HARBOR, HAWAII 96860-3131

IN REPLY REFER TO:
5090
Ser N01CE1/0390
March 26, 2013

Mr. Mark Delaplaine
Manager, Energy, Ocean Resources, and Federal Consistency Division
California Coastal Commission
45 Fremont Street, Suite 2000
San Francisco, California 94105-2219

Dear Mr. Delaplaine:

SUBJECT: HAWAII-SOCAL TESTING AND TRAINING (HSTT) CONSISTENCY DETERMINATION

This letter provides the Navy's response to your letter of March 14, 2013, notifying the Navy of the decision by the California Coastal Commission on March 8, 2013 regarding the Navy's HSTT activities Consistency Determination (CD), CD-008-13.

The decision made by the Commission was to object to the Navy's CD based on a lack of sufficient information. The letter contains five areas where the Commission believes that the CD is lacking in sufficient information. It also addresses other issues noted by the Commission and requests the Navy to return with an updated CD.

The Navy believes that CD-008-13 provides sufficient information to support the Commission's determination as detailed below. The Navy's CD was prepared in accordance with, and meets all the requirements of 15 C.F.R. §930.39. In addition, throughout the HSTT project, the Navy has coordinated with the Commission staff extensively and has provided, or made available, various associated HSTT environmental analysis documents such as: the Draft Environmental Impact Statement (DEIS), Marine Mammal Protection Act (MMPA) Letter of Authorization (LOA) application, and National Marine Fisheries Service (NMFS) proposed rule.

All of these documents, consistent with the analysis in the CD, provide detailed analysis and information regarding the Navy activities. Furthermore, during the time between the submission of the Navy's CD in January 2013 and the hearing, our staff worked closely with the Commission staff by answering questions and providing requested supplemental information.

SUBJECT: CONSISTENCY DETERMINATION (CD-008-13) ADDITIONAL INFORMATION

While the Navy disagrees with the Commission's decision that the CD lacks in sufficient information, we value our relationship with the Commission and fully support using the remainder of the 90-day notice period to attempt to resolve our differences.

To facilitate this process we provide additional information in enclosure (1) that addresses the issues raised by the Commission in your letter. We believe this information will foster further discussions which we are hopeful can lead to resolving our differences. The Navy views its relationship with the State of California as essential to meeting its national security mandate and looks forward to continuing our professional relationship with the Commission and your Staff.

S. A. WEIKERT
Fleet Civil Engineer

Enclosure: Consistency Determination (CD-008-13) Additional Information

Copy to:
Chief of Naval Operations (N45)
Commander, Navy Region Southwest (N00, N40)
Commander, Third Fleet (N7)

2

SUBJECT: CONSISTENCY DETERMINATION (CD-008-13) ADDITIONAL INFORMATION

1) The Navy's analysis relied on an incomplete analysis of the requirements of Section 30230, in that it only looked at one of the three tests (population-level effects), ignoring requirements of Section 30230 for the maintenance, enhancement, and, where feasible, restoration, of the overall marine environment, as well as for providing special protection for areas and species of special biological or economic significance.

NAVY RESPONSE: The Navy's analysis properly accounts for all aspects of the California Coastal Act's marine resource policy found in Section 30230. Section 30230 provides:

> Marine resources shall be maintained, enhanced, and where feasible, restored. Special protection shall be given to areas and species of special biological or economic significance. Uses of the marine environment shall be carried out in a manner that will sustain the biological productivity of coastal waters and that will maintain healthy populations of all species of marine organisms adequate for long-term commercial, recreational, scientific, and educational purposes.

The Navy does not interpret this policy as containing three separate tests with which a federal entity must comply. The Navy interprets the first sentence of Section 30230 as providing the general purpose driving the marine resource policy. While the Navy's section 30230 analysis focuses on population-level effects and sustaining biological productivity, the analysis also addresses special protection for areas and species of special biological or economic significance. Specifically, the Navy has an extensive suite of event-specific mitigation measures described in detail in the CD that provide protection for all areas and all marine mammals. In addition, the CD analysis contains a detailed description of the Navy's process for considering geographic mitigation measures and the rationale that those measures were not carried forward. Because the Navy's action sustains biological productivity and healthy populations of all species of marine organisms and provides necessary special protections, the general policy of maintaining, enhancing and where feasible, restoring, is also met.

Enclosure (1)

SUBJECT: CONSISTENCY DETERMINATION (CD-008-13) ADDITIONAL INFORMATION

2) The Navy arbitrarily limited its analysis to only 10 of the 34 marine mammals present in the southern California study area, when the preponderance of the evidence is that 32 of the 34 species are present in the coastal zone.

NAVY RESPONSE: The analysis in the CD addresses those species the Navy considers coastal resources subject to federal consistency review. Coastal resources are those found in a state's coastal zone on a regular or cyclical basis. The species not addressed in the CD are either not regularly or cyclically found in the coastal zone or do not rely on coastal zone habitat. However, the Navy's associated EIS and the NMFS proposed rule fully address all marine mammals.

The determination on which species were included in the CD was based on a review of NMFS stock assessment reports, scientific literature, results from five years of Navy funded research and compliance monitoring within the SOCAL Range Complex (over $6M and 75,000 miles surveyed), and personal communication with NMFS Southwest Fisheries scientists as well as other non-government marine experts.

While acknowledging there can be scientific uncertainty and even differences in opinion as to movement patterns for some marine mammal species, the Navy's assessment factored in that degree of uncertainty in specifying the list of coastal zone species for inclusion in the CD. The Navy considered and included those species with a known, documented potential for coastal occurrence in terms of foraging and long-term occupancy. Conversely, the CD did not include species having a scientifically documented habitat beyond any reasonable coastal zone consideration (e.g., beaked whales), or infrequent occurrence mostly offshore within the SOCAL Range Complex portion of California (e.g., killer whales). The HSTT DEIS, LOA application, and NMFS proposed rule contain life history information and a full impact analysis and assessment for all marine mammal species thought to occur within the study area.

3) Even the Navy's population level effects analysis was questionable, as it was not supported by substantial evidence. Moreover, it did not include the type of analysis typically supplied in current-day marine mammal population analyses to estimate whether a proposed activity could result in marine mammal stocks falling below their optimal sustainable population levels, which was included in the analysis the Commission relied

2

SUBJECT: CONSISTENCY DETERMINATION (CD-008-13) ADDITIONAL INFORMATION

on in its recent review of the Pacific Gas and Electric Company's high energy seismic survey, and which compared "Level A takes" (under the Marine Mammal Protection Act) against residual "Potential Biological Removal" rates, and "Level B takes" for listed species against minimum population estimates.

NAVY RESPONSE: The analysis in the CD and associated DEIS use the best available analysis methodology for assessing impacts on marine mammals developed in cooperation with NMFS, the federal agency with expertise and jurisdiction for marine mammals. In the proposed rule, NMFS found, regarding the analysis in the Navy's HSTT documents, that: "Based on the analysis contained herein of the likely effects of the specified activity on marine mammals and their habitat and dependent upon the implementation of the mitigation and monitoring measures, NMFS preliminarily finds that the total taking from Navy training and testing exercises in the HSTT Study Area will have a negligible impact on the affected species or stocks. NMFS has proposed regulations for these exercises that prescribe the means of effecting the least practicable adverse impact on marine mammals and their habitat and set forth requirements pertaining to the monitoring and reporting of that taking."

4) The Navy provided no explanation as to why significant intensification of use of mid-frequency sonar was needed for military training and testing (e.g., an increase in "MF-1" sonar use (the loudest of the sonars) from 4,454 to 11,534 hours per year).

NAVY RESPONSE: Section 2.2 of the CD as well as Chapters 1 and 2 of the Navy's DEIS fully document the purpose and need for the proposed activities. The Navy also spoke about the additional requirements at the Commission hearing, explaining that the HSTT document addresses the 2014-2019 Navy requirements, which include flexibility for years during which there may be a significant surge in training based on real-world Navy deployment requirements.

Also, HSTT covers significantly more sources than prior documents, includes more areas, and adds research, development and testing activities. Previous documents only focused on training activities.

3

SUBJECT: CONSISTENCY DETERMINATION (CD-008-13) ADDITIONAL INFORMATION

Finally, anti-submarine warfare continues to be a training priority for the Navy, and with the Navy and U.S. military's increasing focus on the Asia-Pacific region, the waters off Southern California will remain the focus of such training and testing.

5) The Navy failed to analyze and consider alternatives such as implementing "timearea" closures, as well as other mitigation measures previously adopted by the Commission in reviewing past Navy consistency determinations for Southern California Training and Testing (CD-086-06 and CD-049-08), measures which the Commission staff requested the Navy to analyze in its July 10, 2012, comments on the HSTT DEIS.

NAVY RESPONSE: The Navy fully considered spatial and temporal based mitigation measures, as well as all the Commission's previously adopted mitigation measures. Please see the Appendix C of CD 008-13 for further discussion where the Navy details the process used in developing and considering mitigation measures as well as the rationale for why candidate measures, after careful consideration, were eliminated.

The analysis within Navy's CD 008-13 addresses all mitigation measures identified as conditions by the Commission in prior CDs (CD-86-06 and CD049-08). As demonstrated by that analysis, the Navy's decision to eliminate measures is based on a finding that the measures either lacked a scientific basis for reducing impacts or had too great an impact on Navy training and testing. The analysis is particularly relevant to the Commission's proposed geographic restrictions. In addition, as the Navy described at the Commission hearing, the geographic areas addressed within the CD are the same areas the Navy has conducted sonar and explosive testing and training for decades without any significant impacts to the marine environment.

Finally, as stated at the hearing, the Navy's proposed mitigation measures are effective and appropriate for avoiding and minimizing impacts for all areas in the HSTT study area.

OTHER ITEMS NOTED BY THE COMMISSION

The Commission noted the Navy's refusal to avoid state and Federal MPAs. The establishment of all of the MPAs in the study area

4

SUBJECT: CONSISTENCY DETERMINATION (CD-008-13) ADDITIONAL INFORMATION

included recognition of the Navy ongoing activities within those MPAs, and a finding that those activities are compatible with the MPAs. For the State MPAs, from California Title 14, Section 632 states: "Nothing in this section expressly or implicitly precludes, restricts or requires modification of current or future uses of the waters identified as marine protected areas, special closures, or the lands or waters adjacent to these designated areas by the Department of Defense, its allies or agents." For the Channel Islands National Marine Sanctuary, the sanctuary's regulation, EIS, and Management Plan, all include and recognize the need for Navy to conduct its continuing training and testing activities in sanctuary waters.

The Commission noted a lack of sufficient information on fishing because the Navy has not implemented all the recommendations from a study conducted by the Navy in 2009. In that study, the Navy conducted interviews with members of the fishing community who made a number of recommendations. Since that time the Navy has addressed most all the recommendations and overall has significantly improved communication with the fishing community mostly through a significantly improved real-time website. Also, the Navy has established new safety zones around San Clemente Island that further reduce impacts on fishing access. The remaining recommendations, such as new cell towers, have largely been overcome by the improved website and communications, but are still being considered as part of the Navy's long-standing relationship with the fishing community. The Navy does not agree that this constitutes a lack of sufficient information.

Subj: ESSENTIAL FISH HABITAT (EFH) ASSESSMENT FOR THE HAWAII-SOUTHERN CALIFORNIA TRAIING AND TESTING (HSTT)

Dear Mr. Davis:

In accordance with the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the U.S. Navy has prepared the EFH Assessment for the HSTT activities conducted in the Pacific Ocean within the Southern California Range Complex, Silver Strand Training Complex, Hawaii Range Complex and a transit corridor on the high seas. The U.S. Navy's assessment concludes that EFH within the HSTT Study Area may be adversely affected by training and testing activities and requests initiation of the MSA's EFH consultation process.

Additional information on HSTT may be found at the project website, including the EFH Assessment and the Draft Environmental Impact Statement /Overseas Environmental Impact Statement prepared by the U.S. Navy to analyze potential environmental impacts that could result from activities under the Proposed Action. The website is located at: http://hstteis.com. The U.S. Navy's preferred alternative in the Draft EIS and analyzed in the EFH Assessment is Alternative 2.

We appreciate your continued support in helping the U.S. Navy to meet its environmental responsibilities. Please note that due to the large HSTT Study Area, a similar letter is concurrently being sent to the National Marine Fisheries Service's Southwest Regional Office, Habitat Conservation Division.

Our point of contact for the HSTT EFH Assessment is Ms. Julie Rivers, at 808-474-6391 or julie.rivers@navy.mil.

Sincerely,

L. M. FOSTER
By direction

Pearl Harbor, Hawaii 96860-3131

April 8, 2013

Dear Mr. Foster:

The Habitat Conservation Division of the NOAA Fisheries Service Pacific Islands Regional Office (NMFS PIRO) has reviewed the February 12, 2013 U.S. Department of the Navy's (Navy) Hawaii-Southern California Training and Testing (HSTT) Essential Fish Habitat (EFH) Assessment (5090 Ser N01CE1/0198). We appreciate the opportunity to offer the following comments pursuant to the EFH provision (§305(b)) of the Magnuson Stevens Fishery Conservation and Management Act (MSA;16 U.S.C. 1855(b)).

The proposed action is to conduct a variety of military training activities throughout the HSST study area, which includes the existing Navy Hawaii Range Complex (HRC), Southern California (SOCAL) Range Complex, Silver Strand Training Complex (SSTC), also Navy pierside locations outside of the range complexes, and transit corridors between Hawaii and California on the high seas. The proposed activities for these in-water areas include the detonation of underwater explosives, weapons firing, the use of active sonar, acoustics and electromagnetic devices, pile driving, deployment of seafloor devices and other in-water devices (e.g., remotely operated vehicles), vessel movement, and ship to shore transport of personnel, equipment and supplies. Sonar maintenance and gunnery exercises may also be conducted concurrently with ship transits that may occur outside the geographic boundaries of Navy range complexes.

NMFS PIRO has focused on evaluating the proposed activities as relevant to the HRC as the NMFS South West Regional Office has reviewed and commented on the activities occurring within the SOCAL Range Complex and SSTC. The HRC geographically encompasses an approximately 1200 nautical miles (nm) by 1600 nm ocean area bounded by 16 degrees (°) North to 43° North latitude and from 150° West longitude to the International Date Line. A subset of the water column (surface down to 1000 m depth from shore out to the outer Exclusive Economic Zone 200 mile boundary) and seafloor (shoreline down to 400m depth) within the HRC around the Hawaiians Islands chain has been designated as Essential Fish Habitat (EFH) and may support various life stages for the management unit species (MUS) identified under the Western Pacific Regional Fishery Management Council's Pelagic and Hawaii Archipelago Fishery Ecosystem Plans (FEPs). The MUS and life stages found within the area include: eggs, larvae, juveniles and adults of Coral Reef Ecosystem MUS (CRE-MUS); eggs, larvae, juveniles and adults of Bottomfish MUS (BMUS); eggs, larvae, juveniles and adults of Crustacean MUS

(CMUS); eggs, larvae, juveniles and adults of Precious Coral MUS (PCMUS); and juveniles and adults of Pelagic MUS (PMUS).

The proposed action would adversely affect EFH as a result of acoustic stressors (e.g., sonar, explosives, pile driving), electromagnetic devices, direct physical disturbance (e.g., vessels, seafloor devices, expended materials, pile driving), and contaminants (explosives and byproducts, metals, other chemicals and materials). Impacts associated with these activities would range in intensity and extent and would include increased turbidity, potential habitat loss or conversion, modifications in fish behavior, and physical injury or mortality. The duration of these impacts would be expected to range over spatial scales from temporary to permanent.

NMFS PIRO is concerned about the land-based portions of the HRC having been excluded from analysis within the EFH Assessment. Without an understanding of these connected land based activities, we are unable to evaluate the effect of these activities on EFH, and hence unable to provide conservation recommendations for these activities as required. We are also concerned that Navy's definition of impact as presented on page 4-2 of the EFH assessment may not appropriately capture what we consider to be adverse effects to EFH. For example, a "stressor" duration of a few hours, days or weeks can result in adverse effect to EFH that is more than temporary or minimal in nature. Navy has also determined throughout the document that adverse effect to EFH will be minimal due to calculation that the impact area from an individual stressor only represents a small proportion of the entire range complex/es. For example on p. 4-21 the Navy's calculated impact area from bottom detonations in HRC is 23,2388 square meters. This area may represent a small proportion of the entire HSST, but may on a local scale be considered a substantial adverse effect to EFH if it involves impact to coral reef or CREMUS EFH. We are also concerned that there will be unavoidable impacts from all the activities over time, which the EFH assessment does not address.

In taking into consideration the range of activities in HRC, the large local spatial scale of the project, and the potential for cumulative impacts, NMFS considers that the proposed activities in HRC may have more than minimal adverse effect to EFH. We recommend that the Navy avoid, minimize and offset adverse effect to EFH as per following:

1) Evaluate the impacts to EFH from the land-based portions of the HRC such as any activities occurring on the Pacific Missile Range Facility (PMRF), Naval Station Pearl Harbor, Marine Corp Base Hawaii (MCBH), and Marine Corps Training Area- Bellows, and work together with NMFS to implement measures to mitigate any identified adverse effects to EFH.

2) Avoid, to the greatest extent practicable, conducting all training and testing activities in HRC for EFH that has been designated as a Habitat Area of Concern (HAPC) for CREMUS (e.g. Kaneohe Bay). Also avoid conducting activities that have impact to seafloor in areas designated as bottom EFH for PCMUS, and in HAPC for BMUS. Avoidance of these areas will eliminate risk of impact to these important habitats. (Please refer to the Western Pacific Regional Fishery Management Council's Hawaii Archipelago FEP for these EFH designations).

2

3) Increase the distance between activities resulting in acoustic non-impulsive stressors and importantly explosive impulsive stressors and coral reefs to greater than the currently proposed 0-320 yards (0-293 m). This will provide a greater protection/buffer zone around coral reefs hence minimize impact to these sensitive systems. Navy may wish to consider mirroring the distances proposed for the floating vegetation and kelp paddies in southern California for each of the stressors as listed on page 5-2.

4) Develop and implement a protocol for immediate clean-up of unexploded ordinance also for floating debris such as parachutes in areas designated as EFH for juvenile and adult life stages for CREMUS (all bottom around the Hawaiian Islands shallower than 100 m depth). Unexploded ordinance may cause direct impacts to EFH if triggered after use, and parachutes become marine debris that may move with currents, tides and waves and trap fish and abrade corals in their path.

5) Operate amphibious vessels such that they, in transitioning between land and sea, minimize turbidity and sedimentation and avoid abrasion impact to corals and dense seagrass beds present in and near operational paths at all locations including at the MCBH, Marine Corps Training Area- Bellows, and the Kawaihae Pier.

6) Ensure that any expected also unexpected unavoidable adverse effects to EFH be identified, and fully offset. For example, if damage to coral reef resources occurs from unexploded ordinance being blown in place during removal, or from a vessel grounding on top of a reef, the lost coral reef resources should be replaced. NMFS PIRO can offer guidance and technical assistance where needed and wherever possible to help Navy during this process.

We appreciate the opportunity to comment on this HSTT project and wish to continue engaging and working with the Navy where needed to support this important mission, while ensuring the appropriate level of protection of NOAA trust resources. If you have any questions regarding this determination, contact Danielle Jayewardene at 808 944-2162 (danielle.jayewardene@noaa.gov).

Sincerely,

Gerry Davis

Honolulu, HI 96814-4700

Dear Mr. Davis:

SUBJECT: ESSENTIAL FISH HABITAT (EFH) ASSESSMENT FOR THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

Thank you for the comments you provided in your letter dated April, 8 2013. Your letter correctly acknowledges that the scope of the HSTT Proposed Action is limited to the Navy's various in-water training and testing activities throughout the HSTT Study Area. You also indicated that because land-based activities are not included in the analysis in the EFH assessment, that you are unable to provide conservation recommendations pursuant to Section 305(b).

Although HSTT analysis is limited to in-water activities, land-based activities and associated mitigation measures have been previously analyzed and evaluated by the Navy and NMFS PIRO as part of the Hawaii Range Complex (HRC) EIS. The Navy did not re-analyze the land portions of the HRC because land-based activities will not be altered by the HSTT Proposed Action. Likewise, ballistic missile defense activities at the Pacific Missile Range Facility (PMRF) were not re-analyzed.

For reference, please see NMFS PIRO letter dated April 7, 2008, in which NMFS concluded that if the proposed mitigation measures are implemented, "[n]o further conservation recommendations are necessary at this time."

Notwithstanding the conclusion that you cannot offer conservation recommendations, I would like to address the enumerated comments/recommendations provided in your letter.

Recommendations 1 and 5 relate to evaluation of land-based activities at various locations in Hawaii and the development of mitigation measures for certain activities that transition from sea to land, such as amphibious landings. As noted above, these activities have been thoroughly analyzed and evaluated by the Navy and NMFS and

SUBJECT: ESSENTIAL FISH HABITAT (EFH) ASSESSMENT FOR THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

mitigation measures have been put in place to minimize or avoid any adverse impacts to EFH. For example, amphibious landings are restricted to specific areas of designated beaches through mapped sandy beaches at PMRF, Marine Corp Base Hawaii and Marine Corp Training Area Bellows, therefore avoiding areas of Habitat Area of Particular Concern (HAPC) and other EFH.

Recommendation 2 requests avoiding, to the greatest extent practicable, all training and testing activities in EFH that has been designated HAPC for Coral Reef Ecosystem Management Unit Species (MUS), as well as to avoid conducting activities that have impact to the seafloor in EFH for Precious Coral MUS and HAPC for Bottom Fish MUS. Although it is impracticable to avoid all designated areas for all activities, the Navy is in fact proposing to implement the following measures to avoid adverse impacts to EFH:

- The Navy avoids and minimizes impacts to coral by conducting underwater detonations primarily in locations where these activities have historically occurred, for example, Puuloa Underwater Range, Barbers Point Underwater Range, Lima Landing and Ewa Training Minefield;
- Most training and testing activities are conducted in open ocean areas away from sensitive EFH, HAPC, or special aquatic sites;
- The Navy will not conduct precision anchoring or explosive mine countermeasure and neutralization activities within 350 yd.(320 m)of surveyed shallow coral reefs, live hardbottom, artificial reefs, or shipwrecks (EFHA at Section 5.2; EIS at Chapter 5)

Recommendation 3 appears to request a greater activity buffer around coral reefs; however, a specific range is not specified. The recommendation does state that the current proposed buffer extends to 320 yds, which is incorrect. The current proposal includes a mitigation zone up to 350 yds (320 m), which the Navy believes is adequate to minimize any adverse impacts to coral reefs. The mitigation zone of 350 yd. (320 m) is based on the estimated maximum seafloor impact zone for explosives (EIS at Section 5.3.3.2.1.1, Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks; Section 3.3, Marine Habitats). The mitigation zones for floating vegetation are specifically for marine mammal and turtle mitigations as indicators of the potential presence of marine mammals or sea turtles and do not have a scientific relevance to coral.

Finally, recommendations 4 and 6 appear to be related to emergency actions and accidents associated with unexploded ordnance which are outside the scope of this Proposed Action. An emergency real world

2

SUBJECT: ESSENTIAL FISH HABITAT (EFH) ASSESSMENT FOR THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT) STUDY AREA

operation is not considered a training or testing activity, and operating procedures are in place depending on the type of emergency. In developing an appropriate response for these types of incidents, the Navy considers numerous factors including safety of personnel and equipment, as well as, minimizing impacts to the environment.

To the extent that recommendation 4 refers to debris as a result of a training activity, the Navy will remove associated debris to the extent practicable. For example, wherever blanks/pyrotechnics or plastics for wrapping C4 charges are used, they are collected at the conclusion of the exercise when practicable. Some targets, torpedoes and other non-expendable materials are recovered to the extent practicable.

Furthermore, the majority of military training items would be expended in the open ocean, where substrates would primarily be clays and silts with few benthic invertebrates. Military expended material in the coastal portions of the Study Area would be limited to small-caliber projectiles, flares, and target fragments (EIS at Section 3.3, Marine Habitats; EFH at Section 4.1.3.4, Military Expended Materials).

We again thank you for your support of this critical project and appreciate your timely response. We also would like to reaffirm the Navy's commitment to working with your agency in support of our mutual goals. My point of contact for this matter is Ms. Julie Rivers (808) 474-6391, or e-mail: julie.rivers@navy.mil.

Subj: ESSENTIAL FISH HABITAT (EFH) ASSESSMENT FOR THE HAWAII-SOUTHERN CALIFORNIA TRAINING AND TESTING (HSTT)

Dear Mr. Chavez:

In accordance with the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the U.S. Navy has prepared the EFH Assessment for the HSTT activities conducted in the Pacific Ocean within the Southern California Range Complex, Silver Strand Training Complex, Hawaii Range Complex and a transit corridor on the high seas. The U.S. Navy's assessment concludes that EFH within the HSTT Study Area may be adversely affected by training and testing activities and requests initiation of the MSA's EFH consultation process.

Additional information on HSTT may be found at the project website, including the EFH Assessment and the Draft Environmental Impact Statement/Overseas Environmental Impact Statement prepared by the U.S. Navy to analyze potential environmental impacts that could result from activities under the Proposed Action. The website is located at: http://hstteis.com. The U.S. Navy's preferred alternative in the Draft EIS and analyzed in the EFH Assessment is Alternative 2.

We appreciate your continued support in helping the U.S. Navy to meet its environmental responsibilities. Please note that due to the large HSTT Study Area, a similar letter is concurrently being sent to the National Marine Fisheries Service's Pacific Islands Regional Office, Habitat Conservation Division.

Our point of contact for the HSTT EFH Assessment is Mr. Alex Stone, at 619-545-8128 or alexander.stone@navy.mil.

Sincerely,

L. M. FOSTER
By direction

Subject: Re: EFH Assessment for HSTT
Date: Wednesday, April 03, 2013 6:21:45

Alex,

NOAA's National Marine Fisheries Service (NMFS) has reviewed the U.S. Department of the Navy's (Navy) Hawaii-Southern California Training and Testing (HSTT) Essential Fish Habitat (EFH) Assessment and offers the following comments pursuant to section 305(b)(4)(A) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA).

The proposed project is to conduct a variety of military training activities throughout the in-water areas off the coast of Southern California, at Navy pierside locations, in the transit corridor between Hawaii and Southern California, and around the Hawaiian Islands. As agreed to previously with the Navy, NMFS Southwest Regional Office will focus this consultation primarily on those activities occurring within the Southern California region, including the Southern California (SOCAL) Range Complex Study Area and Silver Strand Training Complex (SSTC), and to some extent, the transit corridor. Situated between Dana Point and San Diego, the SOCAL Range Complex Study Area extends more than 600 nautical miles (nm) southwest into the Pacific Ocean and covers approximately 120,000 nm2 of sea space. The SSTC is an integrated set of training areas located on and adjacent to the Silver Strand, a narrow isthmus separating San Diego Bay from the Pacific Ocean. Although not part of any defined range complex, the transit corridor provides adequate air, sea, and undersea space to conduct training and some sonar maintenance and testing while en route between Southern California and Hawaii. Those activities that occur within the Hawaii Range Complex Study Area will be addressed in a separate EFH consultation between the Navy and NMFS Pacific Islands Regional Office. The proposed project includes the detonation of underwater explosives, weapons firing, the use of active sonar, acoustics and electromagnetic devices, pile driving, deployment of seafloor devices and other in-water devices (e.g., remotely operated vehicles), vessel movement, and ship to shore transport of personnel, equipment and supplies. Sonar maintenance and gunnery exercises may also be conducted concurrently with ship transits that may occur outside the geographic boundaries of Navy range complexes.

The proposed project occurs within EFH for various federally managed fish species within the Coastal Pelagic Species, Pacific Coast Groundfish, and Highly Migratory Species Fishery Management Plans (FMPs). In addition, the proposed project occurs within estuarine habitat and in the vicinity of seagrass (e.g., eelgrass, surfgrass), rocky reef, and kelp habitat, which have been identified as habitat areas of particular concern (HAPC) under the Pacific Coast Groundfish FMP. Designated HAPC are not afforded any additional regulatory protection under MSA; however, Federal projects with potential adverse impacts to HAPC will be more carefully scrutinized during the consultation process.

The proposed project would adversely affect EFH as a result of acoustic stressors (e.g., sonar, explosives, pile driving), electromagnetic devices, direct physical disturbance (e.g., vessels, seafloor devices, expended materials, pile driving), and contaminants (explosives and byproducts, metals, other chemicals and materials). Impacts associated with these activities would range substantially and would include increased turbidity, potential habitat loss or conversion, modifications in fish behavior, and physical injury or mortality. The duration of these impacts would also be expected to range from temporary to permanent. However, many of the activities associated with the HSTT project have been addressed through extensive coordination between NMFS and the Navy during previous EFH consultations for the SOCAL Range Complex and SSTC, and the assessment of impacts to EFH from those consultations is consolidated into this EFH Assessment. Based on information within the HSTT EFH Assessment and recent communications with Navy staff members, Alexander Stone and Chip Johnson, the Navy will implement conservation measures developed during those previous EFH consultations to avoid or minimize impacts to EFH from this project. For instance, the Navy performed benthic habitat mapping surveys throughout much of the SSTC as a result of that EFH consultation, and is also in the process of collecting similar benthic habitat data for the San Clemente Island region. Data collected from these surveys will be used by the Navy to avoid impacts to sensitive habitats (e.g., seagrass, understory algal communities, kelp, rocky reefs, sea fans or sea palms, etc.) to the greatest extent practicable when conducting underwater demolition exercises or other activities that may impact bottom habitat. The Navy has also agreed to use benthic habitat information collected during the EFH five-year review for Pacific Coast Groundfish, once it is provided by NMFS, to assist their efforts to avoid impacts to sensitive habitats. In addition, the detonation of any explosives larger than 0.033 pounds net explosive weight will occur outside of San Diego Bay in the nearshore environment over sandy bottom. During the SSTC EFH consultation, the Navy also agreed to provide general location data for underwater explosives, mitigate for 1.13 acres of eelgrass impacts using credits from their San Diego Bay mitigation bank, and implement protective measures to minimize impacts to California grunion (Leuresthes tenuis). Therefore, NMFS believes the proposed conservation measures are sufficient to avoid, minimize or offset impacts to EFH and has no additional EFH Conservation Recommendations to provide at this time. Thank you for consulting with NMFS.

Regards,
Eric

> Hi - hope all is well. We have completed the EFH Assessment associated with the Hawaii-SOCAL Testing and Training (HSTT) EIS. Attached is the transmittal letter submitting to NMFS. The hard copy of the letter and EFHA (with a CD-ROM) are coming to you in the mail. I'd email it, but it's too large of a file.
>
> As I think you know the EIS (and EFHA) address the in-water only testing and training we do in SOCAL and Hawaii. It consolidates the in-water activities from the SSTC and SOCAL EISs. It also adds some new area (transit lanes between SOCAL and Hawaii) and is more comprehensive in terms of acoustic and explosive sources. That said, in general the activities are the same as SSTC and SOCAL. The real driver behind the EIS is the need for new MMPA authorization as the five-year permits we have will be expiring.
>
> We look forward to working with you on this consultation. Chip Johnson and I are the primary pocs but we will also involve other Navy SMEs. Also, we are submitting this EFHA also to the Hawaii NMFS office for EFH under their jurisdiction.

Hawaii State Historic Preservation Officer
Department of Land and Natural Resources
State Historic Preservation Division
Kakuhihewa Building, Room 555
601 Kamokila Boulevard
Kapolei, HI 96707

Dear Mr. Aila Jr.:

In accordance with implementation of regulations for Section 106 of the National Historic Preservation Act, the subject project has been evaluated and determined to be an undertaking as defined in 36 CFR 800.16(y).

Project Description

The Hawaii-Southern California Training and Testing (HSTT) Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) Proposed Action encompasses the ocean areas located around the Hawaiian Islands; however, activities would be mainly restricted to the Hawaii Operating Area (OPAREA), see enclosures (1 and 2). Activities specific to the Proposed Action include gunnery and explosive exercises as well as the use and maintenance of sonar equipment. The Study Area also includes select pierside locations within Pearl Harbor where Navy surface ship and submarine sonar maintenance testing occur.

National Environmental Policy Act

In addition to requesting your Section 106 review, the Navy is also providing the HSTT Draft EIS/OEIS (Enclosure 3) for your review and comment. In compliance with the National Environmental Policy Act (NEPA) of 1969, the Navy will be holding five open house meetings to inform the public and allow those concerned an opportunity to comment on the Proposed Action, alternatives under consideration, and the adequacy and accuracy of the analysis in the Draft EIS/OEIS. All comments

5090
Ser N01CE1/0621
3 May 12

(oral or written) submitted during the 60-day public review period (May 11, 2012, to July 10, 2012) will become part of the public record on the Draft EIS/OEIS and will be responded to in the Final EIS/OEIS.

There will be no formal presentation; however, Navy representatives will be available to provide information and answer questions about the proposed action and Draft EIS/OEIS. The open house public meetings will be held from **5 to 8 p.m.** at the following locations:

In Hawaii

Tuesday, June 12, 2012
Wilcox Elementary School Cafeteria
4319 Hardy St., Lihue

Wednesday, June 13, 2012
Maui Waena Intermediate School Cafeteria
795 Onehee Ave., Kahului

Thursday, June 14, 2012
East Hawaii Cultural Center
141 Kalakaua St., Hilo

Friday, June 15, 2012
McKinley High School Cafeteria
1039 S. King St., Honolulu

In California

Wednesday, June 20, 2012
Marina Village Conference Center Starboard Room
1936 Quivira Way, San Diego

The Draft EIS/OEIS is also available in electronic form on the project website at www.HSTTEIS.com.

Area of Potential Effect

The Area of Potential Effect (APE) would encompass areas in the open ocean area within the Hawaii OPAREA, as detailed on the enclosures (1 and 2).

5090
Ser N01CE1/0621
3 May 12

Identification of Historic Properties

A majority of the training activities for the HSTT are to take place within open ocean portions of the Hawaii OPAREA. The Papahānaumokuākea Marine National Monument, an area having both cultural and ecological significance, is located just northwest of the Hawaii OPAREA but within the Hawaii portion of the HSTT Study Area. It was placed on the United Nations Educational, Scientific, and Cultural Organization (UNESCO) World Heritage List in 2010.

Near-shore activities would take place within Pearl Harbor, which in itself is a National Historic Landmark listed on both the National Register of Historic Places (NRHP) and the Hawaiʻi State Register of Historic Places (Site 50-80-13-9992). There are also several known culturally significant and historic sites located within the Pearl Harbor area.

Determination of Effect

Training and testing activities would continue in existing localities, as specified in the Hawaii Range Complex (HRC) EIS. These activities have been historically conducted or are similar to those historically conducted for some time with no cultural resources being affected throughout the years. For example, all artillery and explosive exercises are to take place within the open ocean, away from where there are any known cultural or historical resources, and the only pierside activities would be those associated with Navy surface ship and submarine sonar maintenance testing. While sonar maintenance testing would take place within the Pearl Harbor National Historic Landmark, the proposed activities would not impact any of the cultural and historic sites in the vicinity. The Navy is not proposing any new activities in the Papahanaumokuakea Marine National Monument or activities that are different from those currently conducted in this area. Therefore, proposed activities are consistent with those activities currently conducted in this area, are consistent with those described in the sanctuary's designation document, and are not being changed or modified in a way that would require consultation with the National Marine Fisheries Service.

5090
Ser N01CE1/0621
3 May 12

Based on the above, the proposed activities within the HSTT EIS/OEIS would result in a "no historic properties affected" determination in accordance with Section 106 implementing regulations under 36 CFR 800.4(d)(1). Additionally, the Navy surface ship and submarine sonar maintenance testing would not affect the significant historic qualities of the Pearl Harbor National Historic Landmark. The Navy requests your concurrence with our determination of effect. As defined in 36 CFR 800.5(c), we will assume your concurrence if no objection is received from your office within 30 days of receipt of this letter.

Should you have any questions regarding the undertaking, please contact Jeffrey Fong at 808-472-1383 or at Jeffrey.fong@navy.mil. You may send written comments to:
Naval Facilities Engineering Command, Southwest
Attention: HSTT EIS/OEIS Project Manager - EV21.CS
1220 Pacific Highway, Building 1, Floor 3
San Diego, CA 92132-5190.

Comments may also be submitted on-line at the website (www.HSTTEIS.com). All comments must be postmarked or received online by **July 10, 2012**, to be considered in the Final EIS/OEIS.

Sincerely,

Larry M. Foster

5090
Ser N01CE1/0622
3 May 12

The Draft EIS/OEIS is also available in electronic form on the project website at www.HSTTEIS.com.

Area of Potential Effect

The Area of Potential Effect (APE) would encompass open ocean areas in the SOCAL Range Complex within the OPAREA, and boat lanes and anchorages offshore of the SSTC including the bayside training areas within San Diego Bay, as detailed on the enclosures (1 through 5).

Identification of Historic Properties

A majority of the training activities for the HSTT are to take place within the open ocean areas within the SOCAL Range Complex and OPAREA, and boat lanes and anchorages offshore of the SSTC including the bayside training areas within San Diego Bay. The Study Area contains no identified National Register-listed or eligible sites.

Submerged cultural resources in the waters around San Clemente Island include pleasure craft, sport and commercial fishers, and cargo and military vessels. Of these 68 submerged cultural resources, 22 are within 12 nm of San Clemente Island and seven are beyond the territorial limit. Submerged aircraft are also reported off San Clemente Island. Submerged cultural resources identified include 35 shipwrecks, 14 unknown or unidentified vessels, 17 aircraft, an anchor, and the abandoned Sea Lab.

On the bay side of Silver Strand peninsula, three shipwrecks are in or near the training beaches. Unnamed wrecks are recorded in shallow water at the northern end of Delta South beach, in the middle of San Diego Bay, and at the mouth of Fiddler's Cove. The ages and cultural value of these wrecks are not known.

On the ocean side of the peninsula, three shipwrecks are located near SSTC training areas: the bark Narwhale (sank in 1934); the submarine S-142: and the Subchaser YC689(sank in

5090
Ser N01CE1/0622
3 May 12

1943). The destroyer *USS Hogan* (DD178), a military aircraft (S2F Tracker), and a sunken sailboat are located offshore, south of SSTC and west of the City of Imperial Beach.

Known cultural resources in San Diego Bay have not been inventoried. However, cultural resources were reviewed for the San Diego Deepening at Tenth Avenue Marine Terminal project (EDAW 2005). This review identified three known submerged cultural features: a shipwreck (the *Della*), an 1887 marine utility cable, and a sunken Ford Model T. The EDAW study identified 24 cultural resources with unknown location, but known to be lost in the San Diego area, including schooners, barges, a submarine, clippers, gas and oil screws, a yacht, a bark, a ferry, a ship, and a steamer

Determination of Effect

Training and testing activities would continue in existing localities, as specified in the SOCAL EIS/OEIS and the SSTC EIS. These activities have been historically conducted or are similar to those historically conducted for some time with no cultural resources being affected throughout the years. For example, artillery and explosive exercises are to take place within the open ocean or near-shore areas, away from where there are any known cultural or historical resources, and the only pierside activities would be those associated with Navy surface ship and submarine sonar maintenance testing within San Diego Bay. Pile-driving for Elevated Causeway training at SSTC would subject nearshore sediments to vibration, disruption, and compaction at SSTC and would occur only in the Oceanside Boat Lanes 1-10 and in the bayside Bravo training area. Proposed activities are consistent with those activities currently conducted in these areas.

Based on the above, the proposed activities within the HSTT EIS/OEIS would result in a "no historic properties affected" determination in accordance with Section 106 implementing regulations under 36 CFR 800.4(d)(1). The Navy requests your concurrence with our determination of effect. As defined in 36 CFR 800.5(c), we will assume your concurrence if no objection is received from your office within 30 days of receipt of this letter.

RE: Hawaii-Southern California Training and Testing Activities, Various Ocean Areas, Southern California

Dear Mr. Yatsko:

Thank you for requesting my comments on the above-referenced undertaking. Pursuant to 36 CFR Part 800, the regulations implementing Section 106 of the National Historic Preservation Act, the United States Navy (Navy) is requesting my concurrence with a finding of No Historic Properties Affected.

The Navy plans to renew training and testing activities in the waters off of Southern California, Hawaii, and the Open Ocean Transit corridor between these two regions. The majority of activities off of California will occur within the Southern California Operating Area (OPAREA), including the waters surrounding San Clemente Island, boat lanes and anchorages offshore of the Silver Strand Training Complex (SSTC), and the bayside training areas within San Diego Bay. Activities specific to this undertaking include gunnery and explosive exercises as well as the use and maintenance of sonar equipment. The project area also includes select pier side locations within San Diego Bay where Navy surface ship and sonar maintenance testing occurs.

The Navy defines the Area of Potential Effects (APE) for this activity as the open ocean areas in the Southern California Range Complex with the OPAREA, and boat lanes and anchorages offshore of the SSTC, including the bayside training areas within San Diego Bay. In addition to your letter, you have provided maps and a CDR containing environmental studies undertaken in the project area.

Submerged cultural resources in the waters around San Clemente Island include pleasure craft, sport and commercial fishers, cargo ships, and military vessels. Of these resources, twenty-two are sited within twelve nautical miles of San Clemente Island and seven are beyond the territorial limit.

On the bay side of Silver Strand peninsula, three shipwrecks are in or near the training beaches. Unnamed wrecks are sited in shallow water at the northern end of Delta

Mr. Andy Yatsko USN120509B
June 5, 2012
Page 2 of 2

South Beach, in the middle of San Diego Bay, and at the mouth of Fiddler's Cove. The ages and cultural value of these wrecks are unknown.

On the ocean side of the peninsula, three shipwrecks are located near SSTC training areas: the bark Narwhale (sank in 1934); the submarine S-142; and the Subchaser YC689 (sank in 1943). The destroyer USS Hogan, a military aircraft, and a sunken sailboat are located offshore, south of SSTC and west of the City of Imperial Beach.

Known cultural resources in San Diego Bay have not been comprehensively inventoried. However, cultural resources were reviewed for the San Diego Deepening at Tenth Avenue Marine Terminal Project (EDAW 2005). This review identified three known submerged cultural features: a shipwreck (identified as the *Della*), an 1887 marine utility cable, and a sunken Ford Model T. The EDAW study identified an additional twenty-four resources known to have been lost in the San Diego area, including schooners, barges, a submarine, clippers, gas and oil screws, a yacht, a bark, a ferry, a ship, and a steamer.

Training and testing activities are consistent with actions currently conducted in the above-referenced areas. For example, artillery and explosive exercises will take place within the Open Ocean or near-shore areas, away from where there are any known cultural or historical resources. Pile driving for elevated causeway training at STC will subject near shore sediments to vibration, disruption, and compaction at SSTC and will occur only in the Oceanside Boat Lanes 1-10 and in the Bayside Bravo Training Area. Proposed activities area consistent with activities currently conducted in these areas.

Having reviewed your submittal, I concur with your Finding of Effect. I also agree that you have adequately determined the undertaking's APE. Please be advised that in the event of a change in project description or an inadvertent discovery, you may have additional responsibilities under 36 CFR Part 800.

Thank you for considering historic properties during project planning. If you have any questions or comments, please contact Tristan Tozer of my staff at (916) 445-7027 or by email at ttozer@parks.ca.gov.

Sincerely,

Jenan Saunders
(for) Milford Wayne Donaldson, FAIA
State Historic Preservation Officer

APPENDIX D AIR QUALITY EXAMPLE EMISSIONS CALCULATIONS AND EXAMPLE RONA

This appendix discusses emission factor development, calculations, and assumptions used in the air quality analyses presented in the Air Quality section of Chapter 3 (see Section 3.2).

D.1 SURFACE OPERATIONS EMISSIONS

Surface operations are activities associated with vessel movements. Fleet training activities use a variety of marine vessels, including cruisers, destroyers, frigates, carriers, submarines, amphibious vessels, and small boats. Testing activities use a variety of marine vessels, including various testing support vessels, work boats, torpedo recovery vessels, unmanned surface vehicles, and small boats. These vessels use a variety of propulsion methods, including marine outboard engines, diesel engines, and gas turbines.

Marine Outboard Engines:

The United States (U.S.) Environmental Protection Agency (USEPA) has published emissions factors for air pollutants produced by several types of two-stroke and four-stroke outboard engines. The most conservative emission factors for two-stroke engines of various horsepower are presented in Table D.1-1.

Table D.1-1: Emission Factors for Two Stroke Engines

USEPA Outboard Engine Emissions Factors (grams/hp-hr.)			
NO_x	CO	VOC	SO_x
0.018	0.63	0.25	0.00108

Notes: USEPA = United States Environmental Protection Agency, hp = horsepower, hr. = hour; NO_x = nitrogen oxides, CO = carbon monoxide, VOC = volatile organic compounds, SO_x = sulfur oxides

Source: USEPA, 1999, Exhaust Emissions Factors for Non-Road Engine Modeling-Spark Ignition. Report No. NR-010b; Office of Mobile Sources, Assessment and Modeling Division, EPA-R-99-009

Emissions for surface craft using outboard engines were calculated using USEPA AP-42 factors, and multiplied by the engine horsepower and hours of operation.

$$Emissions = HP \times HR/YR \times EF \times ENG$$

Where:

Emissions = surface craft emissions
HP = horsepower (reflective of a particular load factor/engine power setting)
HR/YR = hours per year
EF = emission factor for specific engine type
ENG = number of engines

To obtain the total criteria pollutant emissions for the Proposed Action, emissions were calculated for each training or testing activity, type of surface vessel, and criteria pollutant. These individual estimates of emissions, in units of tons per year, were then summed by criteria pollutant to obtain the aggregate emissions for surface vessel emissions activities.

Diesel Engines:

Limited data were available for large marine diesel engines. Therefore, USEPA AP-42 emissions factors for industrial reciprocating engines were used to calculate diesel engine emissions. Other sources of vessel emissions factors were previous U.S. Department of the Navy (Navy) Environmental Impact Statement (EIS)/Overseas EIS (OEIS) documents (citing JJMA 2001). Diesel was assumed to be the primary fuel to ensure a conservative estimate. Calculation methods similar to those described for Marine Outboard Engines were used to obtain emissions estimates for diesel engines.

$$Emissions = HP \times HR/YR \times EF \times ENG$$

Where:

Emissions = surface craft emissions
HP = horsepower (reflective of a particular load factor/engine power setting)
HR/YR = hours per year
EF = emission factor for specific engine type
ENG = number of engines

Diesel engine emission factors were multiplied by the engine horsepower and annual hours of operation to calculate the pollutant emissions per year.

D.2 AIR OPERATIONS EMISSIONS

Fleet training and Naval Air Systems Command testing consists of the activities of various aircraft, including the F/A-18, P-3, SH-60B, MH-53, MH-60S, and Lear jet. RDT&E air operations consist of the activities of various aircraft, including the 1UH-1N, SH-60B, MH-53, MH-60S, and Cessna-172. Aircraft operations of concern are those that occur from ground level up to 3,000 feet (ft.) (914 meters [m]) above ground level (AGL). The 3,000 ft. (914 m) AGL ceiling was assumed to be the atmospheric mixing height above which any pollutant generated would not contribute to increased pollutant concentrations at ground level (known as the mixing zone). All criteria pollutant emissions from aircraft generated above 3,000 ft. (914 m) AGL are excluded from analysis of compliance with National Ambient Air Quality Standards. The pollutant emission rate is a function of the aircraft engine's fuel flow rate and efficiency. Emissions for one complete training activity for a particular aircraft are calculated by knowing the specific engine pollutant emission factors for each mode of operation.

For this EIS/OEIS, emission factors for most military engines were obtained from Navy's Aircraft Environmental Support Office (AESO) memoranda and previous Navy EIS/OEIS documentation (primarily citing the Federal Aviation Administration's EDMS model). For those aircraft for which engine data were unavailable, an applicable surrogate was used. Table D-2 is an example of emission factors for the aircraft engines. The table lists the various engine power modes, time in each mode, fuel flow, and corresponding pollutant emission factors. Using these data, as well as information on activity levels (i.e., number of sorties), pollutant emissions for each aircraft/organization were calculated by applying the equation below.

$$Emissions = TIM \times FF \times EF \times ENG \times CF$$

Where:

Emissions = aircraft emissions (pounds [lb.]) (for EF in lb./1,000 gallons [gal.] fuel)
TIM = time-in-mode at a specified power setting (hours [hr.]/operation).

FF = fuel flow at a specified power setting (gal./hr./engine)
EF = emission factor for specific engine type and power setting (lb./1,000 gal. of fuel used)
ENG = number of engines on aircraft
CF = conversion factor (0.001)

D.3 ORDNANCE AND MUNITIONS EMISSIONS

Available emissions factors (AP-42, *Compilation of Air Pollutant Emission Factors*) were used. These factors were then multiplied by the net weight of the explosive and the number of items that were used per year. This calculation provides estimates of annual emissions.

$$Emissions = EXP/YR \times EF \times Net\ Wt$$

Where:

Emissions = ordnance emissions
EXP/YR = explosives, propellants, and pyrotechnics used per year
EF = emissions factor
Net Wt = net weight of explosive

D.4 EMISSIONS ESTIMATES SPREADSHEETS

The following spreadsheets are examples of the emissions calculations for aircraft, vessels, and munitions. The examples provided for aircraft are for baseline training within the Southern California Range Complex. These examples are representative of calculation spreadsheets developed for each range complex or testing area. They are also representative of calculation spreadsheets developed for testing events. Moreover, they are representative of the calculations developed for each alternative analyzed in this EIS/OEIS. The example ordnance emissions calculation is for baseline ordnance emissions. The full set of calculation spreadsheets is available on the Hawaii-Southern California Training and Testing (HSTT) EIS project website.

D.5 DRAFT RECORD OF NON-APPLICABILITY

This appendix provides a Record of Non-Applicability (RONA) Memorandum (Figure D.5-1) and draft Records of Non-Applicability and Conformity Analyses (Figures D.5-2 through D.5-5) for each California Air Basin potentially impacted by the Proposed Action (South Coast Air Basin and San Diego Air Basin).

MEMORANDUM FOR THE RECORD

From: __________

Subj: Applicability Analyses for Hawaii-Southern California Training and Testing (HSTT) Environmental Impact Statement/Overseas Environmental Impact Statement – Operations in State of California Waters

Ref: (a) 40 C.F.R., 51.853(b)

Encl: (1) Record of Non-Applicability (RONA) for Hawaii-Southern Training and Testing in State of California Waters, South Coast Air Basin; and

(2) Record of Non-Applicability (RONA) for Hawaii-Southern Training and Testing in State of California Waters, San Diego Air Basin.

1. Enclosure (1) is a RONA for those Pacific Fleet training and testing activities that are expected to occur annually in State of California waters in South Coast Air Basin (SCAB). The Preferred Alternative (Alternative 2) emissions of carbon monoxide (CO), nitrogen oxides (NO_x), volatile organic compounds (VOC), and particulates under 10 microns (PM_{10}) and under 2.5 microns ($PM_{2.5}$), in SCAB are provided in Enclosure 1. A comparison of the relevant criteria air pollutant emissions of the Proposed Action with Reference (a) shows that the anticipated emissions are *de minimis*.

2. Enclosure (2) is a RONA for those Pacific Fleet training and testing activities that are expected to occur annually in State of California waters in San Diego Air Basin (SDAB). The Preferred Alternative (Alternative 2) emissions of CO, NO_x, and VOC in SDAB are provided in Enclosure 2. A comparison of the relevant criteria air pollutant emissions of the Proposed Action with Reference (a) shows that the anticipated emissions are *de minimis*.

2. If there are any questions or if additional information is needed, please call ________ at ______.

Attainment Area Status and Emissions Evaluation Conclusion:

To the best of my knowledge and belief, the information contained within this General Conformity Applicability Analysis is correct and accurate. By signing this statement, I am in agreement with the finding that the total of all reasonably foreseeable direct and indirect emissions that will result from this action is below the *de minimis* threshold set forth in 40 C.F.R. 51.853(b). Accordingly, it is my determination that this action conforms to the applicable State Implementation Plan (SIP).

Figure D.5-2: Record of Non-Applicability Form, South Coast Air Basin

Subject: Conformity Analysis for Navy Training and Testing, South Coast Air Basin

INTRODUCTION

The Proposed Action falls under the Record of Non-Applicability (RONA) category pursuant to 40 Code of Federal Regulations (CFR) Parts 52 and 93, and the basis for exemption from conformity requirements is documented with this RONA.

The United States (U.S.) Environmental Protection Agency (USEPA) published *Determining Conformity of General Federal Actions to State or Federal Implementation Plans; Final Rule*, in the Federal Register (40 CFR Parts 6, 51, and 93) on November 30, 1993. The U.S. Navy published *Clean Air Act General Conformity Guidance* in Chief of Naval Operations Instruction (OPNAVINST) 5090.1C CH-1 (18 July 2011). These publications provide guidance to document Clean Air Act Conformity requirements. Federal regulations state that no department, agency, or instrumentality of the federal government shall engage in, support in any way, or provide financial assistance for, license or permit, or approve any activity that does not conform to an applicable implementation plan. The federal agency that is the action proponent is responsible for determining whether a federal action conforms to the applicable implementation plan before the Proposed Action is taken (40 CFR Part 1, Section 51.850[a]).

Federal actions may be exempt from conformity determinations if they do not exceed designated *de minimis* levels for criteria pollutants as set forth in 40 CFR § 93.153(c) (Table 1). These standards are reflected in Appendix F of OPNAVINST 5090.1C CH-1.

Table 1: *De Minimis* Thresholds for Conformity Determinations

Pollutant	Nonattainment or Maintenance Area Type	*De Minimis* Threshold (TPY)
Ozone (VOC or NO_x)	Serious nonattainment	50
	Severe nonattainment	25
	Extreme nonattainment	10
	Other areas outside an ozone transport region	100
Ozone (NO_x)	Marginal and moderate nonattainment inside an ozone transport region	100
	Maintenance	100
Ozone (VOC)	Marginal and moderate nonattainment inside an ozone transport region	50
	Maintenance within an ozone transport region	50
	Maintenance outside an ozone transport region	100
CO, SO_2 and NO_2	All nonattainment & maintenance	100
PM_{10}	Serious nonattainment	70
	Moderate nonattainment and maintenance	100
$PM_{2.5}$	All nonattainment & maintenance	100
Lead (Pb)	All nonattainment & maintenance	25

Notes: NO_X = nitrogen oxides; Pb = lead; PM_{10} = particulate matter under 10 microns; SO_x = sulfur oxides; TPY = tons per year; VOC = volatile organic compounds

Figure D.5-3: Conformity Analysis, South Coast Air Basin

PROPOSED ACTION

Proposed Action Summary

The Proposed Action consists of increases in training and testing activities on the at-sea portions of the Southern California (SOCAL) Range Complex required to address a training shortfall, and to accommodate expected force-structure changes and range enhancements. The assessment of air quality impacts includes all military training activities in the SOCAL Range Complex involving vessels, aircraft, and weapons systems in State of California waters.

Proposed Action Emissions

Aircraft

To estimate aircraft emissions, the operating modes (e.g., “cruise” mode), number of hours of operation, and types of engine for each type of aircraft were evaluated. All aircraft are assumed to travel to and from training ranges at or above 3,000 ft. (914 m) above ground level and, therefore, their transits to and from the ranges do not affect surface air quality. Air combat maneuvers and air-to-air missile exercises are primarily conducted at altitudes well in excess of 3,000 ft. (914 m) above ground level and, therefore, are not included in the estimated emissions of criteria air pollutants. Activities or portions of those training or testing activities occurring below 3,000 ft. (914 m) are included in emissions estimates. Examples of activities typically occurring below 3,000 ft. (914 m) include those involving helicopter platforms such as mine warfare, anti-surface warfare, and anti-submarine warfare training and testing activities.

The types of aircraft used and the numbers of flights flown under the No Action Alternative are derived from historical data. The types of aircraft identified include the typical aircraft platforms that conduct a particular training or testing exercise (or the closest surrogate when information is not available), including range support aircraft (e.g., non-Navy commercial air services). For the Preferred Alternative, estimates of future aircraft sorties are based on evolutionary changes in the Navy’s force structure and mission assignments. Where there are no major changes in types of aircraft, future activity levels are estimated from the distribution of baseline activities.

Time on range (activity duration) under the No Action Alternative was calculated from average times derived from range records and Navy subject matter experts. To estimate time on range for each aircraft activity under the Preferred Alternative, the average flight duration approximated in the baseline data was used in the calculations. Estimated altitudes of activities for all aircraft were obtained from aircrew members in operational squadrons. Several testing activities are similar to training activities, and therefore similar assumptions were made for such activities in terms of aircraft type, altitude, and flight duration. Where aircraft testing activities were dissimilar to training activities, assumptions for time on range were derived from Navy subject matter experts.

Air pollutant emissions were estimated based on the Navy’s Aircraft Environmental Support Office Memorandum Reports for individual aircraft categories (Aircraft Emission Estimates: Mission Operations). For aircraft for which Aircraft Environmental Support Office emission factors were not available, emission factors were obtained from other published sources.

Figure D.5-3: Conformity Analysis, South Coast Air Basin (continued)

The emissions calculations for each alternative conservatively assume that each aircraft activity is separately conducted. In practice, a testing activity may be conducted during a training flight. Two or more training activities also may be conducted during one flight (e.g., chaff or flare exercises may occur during electronic warfare operations; or air-to-surface gunnery and air-to-surface bombing activities may occur during a single flight operation). Using conservative assumptions may produce elevated aircraft emissions estimates, but accounts for the possibility (however remote) that each aircraft training and testing activity is separately conducted.

Vessels

The methods of estimating marine vessel emissions involve evaluating the type of activity, the number of hours of operation, the type of propulsion, and the type of onboard generator for each vessel type. The types of surface ships and numbers of activities for the No Action Alternative are derived from range records and Navy subject matter experts regarding vessel participant data. For the Preferred Alternative, estimates of future ship activities are based on anticipated evolutionary changes in the Navy's force structure and mission assignments. Where there are no major changes in types of ships, estimates of future activities are based on the historical distribution of ship use. Navy aircraft carriers and submarines are nuclear-powered, and have no air pollutant emissions associated with propulsion.

For surface ships, the durations of activities were estimated by taking an average over the total number of activities for each type of training and testing. Emissions for baseline activities and for future activities were estimated based on discussions with exercise participants. In addition, information provided by subject-matter experts was used to develop a breakdown of time spent at each operational mode (i.e., power level) used during activities in which marine vessels participated. Several testing activities are similar to training activities, and therefore similar assumptions were made for such activities in terms of vessel type, power level, and activity duration.

Emission factors for marine vessels were obtained from the database developed for Naval Sea Systems Command by John J. McMullen Associates, Inc. (John J. McMullen Associates 2001). Emission factors were provided for each marine vessel type and power level. The resulting calculations provided information on the time spent at each power level in each part of the Study Area, emission factors for that power level (in pounds of pollutant per hour), and total emissions for each marine vessel for each operational type and mode.

The pollutants for which calculations are made include exhaust total hydrocarbons, CO, NO_x, PM, CO_2, and SO_2. For non-road engines, all particulate matter emissions are assumed to be smaller than PM_{10}, and 92 percent of the particulate matter from gasoline and diesel-fueled engines is assumed to be smaller than $PM_{2.5}$. For gaseous-fueled engines (liquefied petroleum gas/compressed natural gas), 100 percent of the particulate matter emissions are assumed to be smaller than $PM_{2.5}$.

The emissions calculations for each alternative conservatively assume that each vessel activity is separately conducted and separately produces vessel emissions. In practice, one or more testing activities may take advantage of an opportunity to travel at sea aboard and test from a vessel conducting a related or unrelated training activity. It is also probable that two or more training activities may be conducted during one training vessel movement (e.g., a ship may conduct large-, medium-, and small-caliber surface-to-surface gunnery exercises during one vessel movement). Furthermore, multiple unit level training activities may be conducted during a larger composite training unit exercise. Using conservative assumptions may produce elevated vessel emissions estimates, but accounts for the possibility (however remote) that each training or testing activity is separately conducted.

Figure D.5-3: Conformity Analysis, South Coast Air Basin (continued)

Naval Gunfire, Missiles, Bombs, Other Munitions and Military Expended Material

Naval gunfire, missiles, bombs, and other types of munitions used in training and testing activities emit air pollutants. To estimate the amounts of air pollutants emitted by ordnance during their use, the numbers and types of munitions used during training or testing activities are first totaled. Then generally accepted emissions factors (AP-42, Compilation of Air Pollutant Emission Factors, Chapter 15: Ordnance Detonation [USEPA 1995]) for criteria air pollutants are applied to the total amounts. Finally, the total amounts of air pollutants emitted by each munition type are summed to produce total amounts of each criteria air pollutant under each alternative.

The estimated annual operational emissions for the No Action Alternative and Preferred Alternative are presented in Table 2. Annual emissions are expected to increase from the No Action Alternative levels to the Preferred Alternative levels over several years. All annual Preferred Alternative emissions would be below General Conformity *de minimis* levels.

Table 2: Estimated Air Pollutant Emissions Under the Proposed Action

Parameter	Emissions by Air Pollutant (TPY)				
	CO	NO_X	VOC	PM_{10}	$PM_{2.5}$
No Action Alternative	229	540	285	42	39
Preferred Alternative	252	540	284	42	39
Net Change	**23**	**0**	**-1**	**0**	**0**
De Minimis Threshold	100	10	10	70	100
Exceeds Threshold?	No	No	No	No	No

Notes: Table includes criteria pollutant precursors (e.g., VOC). Individual values may not add exactly to total values due to rounding. CO = carbon monoxide; NO_X = nitrogen oxides; PM_{10} = particulates under 10 microns; $PM_{2.5}$ = particulates under 2.5 microns; TPY = tons per year; VOC = volatile organic compounds

EMISSIONS EVALUATION CONCLUSION

The U.S. Navy concludes that the *de minimis* thresholds for applicable criteria pollutants would not be exceeded by implementation of the Proposed Action. The emissions data supporting that conclusion are shown in Table 2, which summarizes the calculated estimates and *de minimis* limits. Therefore, the U.S. Navy concludes that further formal Conformity Determination procedures are not required, resulting in this record of Non-Applicability.

INTRODUCTION

The Proposed Action falls under the Record of Non-Applicability (RONA) category pursuant to 40 Code of Federal Regulations (CFR) Parts 52 and 93, and the basis for exemption from conformity requirements is documented with this RONA.

The United States (U.S.) Environmental Protection Agency (USEPA) published *Determining Conformity of General Federal Actions to State or Federal Implementation Plans; Final Rule*, in the Federal Register (40 CFR Parts 6, 51, and 93) on November 30, 1993. The U.S. Navy published *Clean Air Act General Conformity Guidance* in Chief of Naval Operations Instruction (OPNAVINST) 5090.1C CH-1 (18 July 2011). These publications provide guidance to document Clean Air Act Conformity requirements. Federal regulations state that no department, agency, or instrumentality of the federal government shall engage in, support in any way, or provide financial assistance for, license or permit, or approve any activity that does not conform to an applicable implementation plan. The federal agency that is the action proponent is responsible for determining whether a federal action conforms to the applicable implementation plan before the Proposed Action is taken (40 CFR Part 1, Section 51.850[a]).

Federal actions may be exempt from conformity determinations if they do not exceed designated *de minimis* levels for criteria pollutants as set forth in 40 CFR § 93.153(c) (Table 1). These standards are reflected in Appendix F of OPNAVINST 5090.1C CH-1.

Table 1: *De Minimis* Thresholds for Conformity Determinations

Pollutant	Nonattainment or Maintenance Area Type	*De Minimis* Threshold (TPY)

PROPOSED ACTION

Proposed Action Summary

The Proposed Action consists of increases in training and testing activities on the at-sea portions of the Southern California (SOCAL) Range Complex required to address a training shortfall, and to accommodate expected force-structure changes and range enhancements. The assessment of air quality impacts includes all military training activities in the SOCAL Range Complex involving vessels, aircraft, and weapons systems in State of California waters.

Proposed Action Emissions

Aircraft

To estimate aircraft emissions, the operating modes (e.g., “cruise” mode), number of hours of operation, and types of engine for each type of aircraft were evaluated. All aircraft are assumed to travel to and from training ranges at or above 3,000 ft. (914 m) above ground level and, therefore, their transits to and from the ranges do not affect surface air quality. Air combat maneuvers and air-to-air missile exercises are primarily conducted at altitudes well in excess of 3,000 ft. (914 m) above ground level and, therefore, are not included in the estimated emissions of criteria air pollutants. Activities or portions of those training or testing activities occurring below 3,000 ft. (914 m) are included in emissions estimates. Examples of activities typically occurring below 3,000 ft. (914 m) include those involving helicopter platforms such as mine warfare, anti-surface warfare, and anti-submarine warfare training and testing activities.

The types of aircraft used and the numbers of flights flown under the No Action Alternative are derived from historical data. The types of aircraft identified include the typical aircraft platforms that conduct a particular training or testing exercise (or the closest surrogate when information is not available), including range support aircraft (e.g., non-Navy commercial air services). For the Preferred Alternative, estimates of future aircraft sorties are based on evolutionary changes in the Navy’s force structure and mission assignments. Where there are no major changes in types of aircraft, future activity levels are estimated from the distribution of baseline activities.

Time on range (activity duration) under the No Action Alternative was calculated from average times derived from range records and Navy subject matter experts. To estimate time on range for each aircraft activity under the Preferred Alternative, the average flight duration approximated in the baseline data was used in the calculations. Estimated altitudes of activities for all aircraft were obtained from aircrew members in operational squadrons. Several testing activities are similar to training activities, and therefore similar assumptions were made for such activities in terms of aircraft type, altitude, and flight duration. Where aircraft testing activities were dissimilar to training activities, assumptions for time on range were derived from Navy subject matter experts.

Air pollutant emissions were estimated based on the Navy’s Aircraft Environmental Support Office Memorandum Reports for individual aircraft categories (Aircraft Emission Estimates: Mission Operations). For aircraft for which Aircraft Environmental Support Office emission factors were not available, emission factors were obtained from other published sources.

Figure D.5-5: Conformity Analysis, San Diego Air Basin (continued)

The emissions calculations for each alternative conservatively assume that each aircraft activity is separately conducted. In practice, a testing activity may be conducted during a training flight. Two or more training activities also may be conducted during one flight (e.g., chaff or flare exercises may occur during electronic warfare operations; or air-to-surface gunnery and air-to-surface bombing activities may occur during a single flight operation). Using conservative assumptions may produce elevated aircraft emissions estimates, but accounts for the possibility (however remote) that each aircraft training and testing activity is separately conducted.

Vessels

The methods of estimating marine vessel emissions involve evaluating the type of activity, the number of hours of operation, the type of propulsion, and the type of onboard generator for each vessel type. The types of surface ships and numbers of activities for the No Action Alternative are derived from range records and Navy subject matter experts regarding vessel participant data. For the Preferred Alternative, estimates of future ship activities are based on anticipated evolutionary changes in the Navy's force structure and mission assignments. Where there are no major changes in types of ships, estimates of future activities are based on the historical distribution of ship use. Navy aircraft carriers and submarines are nuclear-powered, and have no air pollutant emissions associated with propulsion.

For surface ships, the durations of activities were estimated by taking an average over the total number of activities for each type of training and testing. Emissions for baseline activities and for future activities were estimated based on discussions with exercise participants. In addition, information provided by subject-matter experts was used to develop a breakdown of time spent at each operational mode (i.e., power level) used during activities in which marine vessels participated. Several testing activities are similar to training activities, and therefore similar assumptions were made for such activities in terms of vessel type, power level, and activity duration.

Emission factors for marine vessels were obtained from the database developed for Naval Sea Systems Command by John J. McMullen Associates, Inc. (John J. McMullen Associates 2001). Emission factors were provided for each marine vessel type and power level. The resulting calculations provided information on the time spent at each power level in each part of the Study Area, emission factors for that power level (in pounds of pollutant per hour), and total emissions for each marine vessel for each operational type and mode.

The pollutants for which calculations are made include exhaust total hydrocarbons, CO, NO_x, PM, CO_2, and SO_2. For non-road engines, all particulate matter emissions are assumed to be smaller than PM_{10}, and 92 percent of the particulate matter from gasoline and diesel-fueled engines is assumed to be smaller than $PM_{2.5}$. For gaseous-fueled engines (liquefied petroleum gas/compressed natural gas), 100 percent of the particulate matter emissions are assumed to be smaller than $PM_{2.5}$.

The emissions calculations for each alternative conservatively assume that each vessel activity is separately conducted and separately produces vessel emissions. In practice, one or more testing activities may take advantage of an opportunity to travel at sea aboard and test from a vessel conducting a related or unrelated training activity. It is also probable that two or more training activities may be conducted during one training vessel movement (e.g., a ship may conduct large-, medium-, and small-caliber surface-to-surface gunnery exercises during one vessel movement). Furthermore, multiple unit level training activities may be conducted during a larger composite training unit exercise. Using conservative assumptions may produce elevated vessel emissions estimates, but accounts for the possibility (however remote) that each training or testing activity is separately conducted.

Figure D.5-5: Conformity Analysis, San Diego Air Basin (continued)

Naval Gunfire, Missiles, Bombs, Other Munitions and Military Expended Material

Naval gunfire, missiles, bombs, and other types of munitions used in training and testing activities emit air pollutants. To estimate the amounts of air pollutants emitted by ordnance during their use, the numbers and types of munitions used during training or testing activities are first totaled. Then generally accepted emissions factors (AP-42, Compilation of Air Pollutant Emission Factors, Chapter 15: Ordnance Detonation [USEPA 1995]) for criteria air pollutants are applied to the total amounts. Finally, the total amounts of air pollutants emitted by each munition type are summed to produce total amounts of each criteria air pollutant under each alternative.

The estimated annual operational emissions for the No Action Alternative and Preferred Alternative are presented in Table 2. Annual emissions are expected to increase from the No Action Alternative levels to the Preferred Alternative levels over several years. All annual Preferred Alternative emissions would be below General Conformity *de minimis* levels.

Table 2: Estimated Air Pollutant Emissions Under the Proposed Action

Parameter	Emissions by Air Pollutant (TPY)		
	CO	NO_X	VOC
No Action Alternative	176	546	175
Preferred Alternative	243	592	184
Net Change	**67**	**46**	**9**
De Minimis Threshold	100	100	100
Exceeds Threshold?	No	No	No

Notes: Table includes criteria pollutant precursors (e.g., VOC). Individual values may not add exactly to total values due to rounding. CO = carbon monoxide; NO_X = nitrogen oxides; TPY = tons per year; VOC = volatile organic compounds

EMISSIONS EVALUATION CONCLUSION

The U.S. Navy concludes that the *de minimis* thresholds for applicable criteria pollutants would not be exceeded by implementation of the Proposed Action. The emissions data supporting that conclusion are shown in Table 2, which summarizes the calculated estimates and *de minimis* limits. Therefore, the U.S. Navy concludes that further formal Conformity Determination procedures are not required, resulting in this record of Non-Applicability.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

There are no figures in this section.

APPENDIX E PUBLIC PARTICIPATION

This appendix includes information about the public's participation in the development of the Hawaii-Southern California Training and Testing Activities (HSTT) Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS).

E.1 PROJECT WEB SITE

A public web site was established specifically for this project, http://www.HSTTEIS.com/. The web site address (originally http://www.HawaiiSOCALEIS.com) was published in the *Notice of Intent to Prepare an Environmental Impact Statement and Overseas Impact Statement* (Appendix B; Federal Register Notices). It was subsequently re-printed in newspaper advertisements, agency letters, and postcards for the Notice of Intent, Notices of Availability, and Notice of Public Meetings. The scoping meeting fact sheets, public meeting fact sheets, technical reports, and various other materials are available on the project web site and will be made available throughout the course of the project.

E.2 SCOPING PERIOD

The public scoping period began with the issuance of the Notice of Intent in the *Federal Register* on 15 July 2010 (Appendix B; Federal Register Notices). This notice included a project description and scoping meeting dates and locations. The scoping period lasted 60 days, concluding on 14 September 2010. The scoping period allowed a variety of opportunities for the public to comment on the scope of the EIS/OEIS. The Navy made significant efforts to notify the public to ensure maximum public participation during the scoping process, including using stakeholder notification letters, postcard mailers, press releases, and newspaper display advertisements. The meetings were structured in an open house format, presenting informational posters and written information, with Navy staff and project experts available to answer participants' questions. Section E.2.1 describes the United States (U.S.) Department of the Navy's (Navy's) notification efforts during scoping. The scoping period allowed a variety of opportunities for the public to comment on the scope of the EIS/OEIS.

E.2.1 PUBLIC SCOPING NOTIFICATION

The Navy made significant efforts at notifying the public to ensure maximum public participation during the scoping process. A summary of these efforts follows.

E.2.1.1 Scoping Notification Letters

Notice of Intent/Notice of Scoping Meeting Letters were distributed on 14 July 2010, to 230 federal, state, and local elected officials and government agencies. Recipients included:

<u>Federal</u>
U.S. Senators (Hawaii, California)
U.S. Representatives (California Districts 35, 36, 37, 44, 46, 48, 49, 50, 52, and Hawaii Districts 1 and 2)

E.2.2 Scoping Meetings

Six scoping meetings were held on August 4, 5, 24, 25, 26, and 27 in the cities of San Diego, CA; Lakewood, CA; Lihue, HI; Honolulu, HI; Hilo, HI; and Kahului, HI, respectively. At each scoping meeting, staffers at the welcome station greeted guests and encouraged them to sign in to be added to the project mailing list to receive future notifications. In total, 131 people signed in at the welcome table. The meetings were held in an open house format, presenting informational posters and written information, with Navy staff and project experts available to answer participants' questions. Additionally, a digital voice recorder was available to record participants' oral comments. The interaction during the information sessions was productive and helpful to the Navy.

What is a scoping meeting?

The scoping period determines the extent of the EIS in terms of significant issues. Scoping meetings allow the face-to-face exchange of information and ideas to ensure relevant topics are identified and properly studied and that the Draft EIS is thorough and balanced.

E.2.3 PUBLIC SCOPING COMMENTS

Scoping participants submitted comments in five ways:

- Oral statements at the public meetings (as recorded by the tape recorder)
- Written comments at the public meetings
- Written letters (received any time during the public comment period)
- Electronic mail (received any time during the public comment period)
- Comments submitted directly on the project web site (received any time during the public comment period)

In total, the Navy received comments from 72 individuals and groups during the scoping comment period. Because many of the comments addressed more than one issue, 228 total comments resulted. Table E-1 provides a breakdown of areas of concern based on comments received during scoping. The summary following Table E-1 provides an overview of comments and is organized by area of concern.

Table E.2-1: Public Scoping Comment Summary

Area of Concern	Count	Percent of Total
Sonar/Underwater Detonations	44	19.3%
Marine Mammals	43	18.9%
Other	30	13.2%
Fish/Marine Habitat	29	12.7%
Meeting/NEPA Process	11	4.8%
Alternatives	10	4.4%
Regional Economy	9	3.9%
Noise	9	3.9%
Threatened and Endangered Species	8	3.5%
Proposed Action	7	3.1%
Water Quality	6	2.6%
Air Quality	5	2.2%
Depleted Uranium	5	2.2%
Public Health and Safety	4	1.8%
Cumulative Impacts	4	1.8%
Terrestrial/Birds	3	1.3%
Recreation	1	0.4%
TOTAL	**228**	

E.2.3.1 Sonar and Underwater Detonations

Many comments mentioned concerns about the effect of Navy sonar on marine life, such as marine mammals, fish, sea turtles, and sea invertebrates. Participants frequently requested that the EIS/OEIS consider alternative technologies to mid-frequency active sonar.

E.2.3.2 Biological Resources-Marine Mammals

A significant number of participants expressed concerns about impacts to marine mammals, primarily from the use of Navy sonar. It was frequently requested that the EIS/OEIS consider alternative technologies to mid-frequency active sonar.

E.2.3.3 Other

This category of comments expressed the desire to close all military bases, that all military activities should cease, and the land be returned to the native Hawaiian people. There were several comments expressing that activities be performed elsewhere.

E.2.3.4 Biological Resources-Fish and Marine Habitat

A significant number of participants expressed concerns about impacts to fish and marine habitat.

E.2.3.5 Meetings/National Environmental Policy Act Process

Comments on the National Environmental Policy Act (NEPA) process included several that felt the information available during the scoping process was inadequate to provide informed comments. There was one comment stating that the Navy HSTT informational video was too basic. There were also comments received indicating a desire for more active public participation at scoping meetings via public speaking at the scoping meetings.

E.2.3.6 Alternatives

Most comments regarding alternatives were in opposition to the current training and testing activities of the Navy in general. Many expressed concerns about the perceived expansion of the training and testing activities area that now includes an adjusted Study Area and a transit corridor between Hawaii and California.

E.2.3.7 Regional Economy

There were several comments regarding regional economic concerns, including questions about the effects on commercial shipping and commercial fishing.

E.2.3.8 Noise

Many participants in the commenting process wanted to know what the noise impacts would be to marine mammals and how they would be protected from acoustic trauma.

E.2.3.9 Threatened and Endangered Species

Concerns in this area were about ensuring that endangered marine mammals and other species would not be harmed during Navy activities.

E.2.3.10 Proposed Action

The comments pertaining to the Proposed Action requested more details on the web site regarding the planned activities and request for a timeline to be presented for the use of the HSTT area.

E.2.3.11 Biological Resources-Onshore

Terrestrial issues mentioned were concerns about habitat fragmentation and potential damage to intertidal, inland, or upland resources.

E.2.3.12 Water Quality

Water quality comments included general concerns about the potential contaminants in the water.

E.2.3.13 Air Quality

Comments in this category expressed concern about the effects of military activities on air quality, including off-shore emissions.

E.2.3.14 Depleted Uranium

The concern with depleted uranium was the effect of its use on the environment in general.

E.2.3.15 Public Health and Safety

One comment was made regarding the safety challenge of military ship transits through San Diego Bay. Another participant expressed concern over the effect on people of sonar testing.

E.2.3.16 Cumulative Impacts

Comments in this category expressed concern about the overall impact of military activity in the HSTT Study Area.

E.2.3.17 Terrestrial/Birds

Comments in this area addressed the impact of training activities on birds and the land.

E.2.3.18 Recreation

One comment regarding recreation was concerned about how all levels of Navy sonar use would impact recreational activities.

E.3 PUBLIC COMMENT PERIOD FOR THE DRAFT ENVIRONMENTAL IMPACT STATEMENT/OVERSEAS ENVIRONMENTAL IMPACT STATEMENT

The 60-day public comment period on the Draft EIS/OEIS began with the issuance of the Notice of Availability and a Notice of Public Meetings in the Federal Register on 11 May 2012 (Appendix B; Federal Register Notices). The public comment period began on 11 May 2012 and concluded on 10 July 2012. The Navy made significant efforts to notify the public to ensure maximum public participation during the public comment period, including using postcards, press releases, and newspaper display advertisements.

The Notice of Public Meetings included a project description and dates and locations of the five public meetings. The public comment period allowed a variety of opportunities for the public to comment on the Draft EIS/OEIS (Appendix B; Federal Register Notices). Copies of the Draft EIS/OEIS were provided to seven libraries in California and Hawaii, and the document was available on the project web site for review. Navy representatives were available during the open house public meetings to provide information and answer questions one-on-one. Comment sheets were made available to attendees.

Commenters provided their input on the Draft EIS/OEIS in letters submitted through mail, written or oral comments received at the public meetings, and via the project web site. The Navy also received form letters from one non-governmental organization and a petition from another non-governmental organization. Approximately 76,000 copies of one form letter were received, and there was an online petition that generated approximately 477,000 signatures (See Sections E.3.2.1 and E.3.2.2, respectively).

Additionally, during the 60-day public comment period, comments were received from 5 federal agencies, 10 state/local/regional agencies, 2 Native-American Tribes, 18 non-governmental organizations, and approximately 850 private individuals (approximation due to duplicate comments received).

Tables E.3-1, E.3-2, E.3-3, and E.3-4 provide a listing of all comments received on the Draft EIS/OEIS and the Navy's response. Each row in these tables presents the identification of the commenter, the comment, and the Navy's response to the comment. Because many commenters touched on more than one topic, the commenter's topics were separated into individual comments, assigned a number, and responded to separately. The commenter's name is abbreviated when the comment is broken into more than one topic. The comment numbering system also captures whether the comment was received electronically via HSTTEIS.com or a computer at one of the public meetings, in written form by mail or during a public meeting, or orally during public testimony at a public meeting. For example, the first of the agency comments is by the U.S. Environmental Protection Agency, Region IX. Since their comments cover several topics, these are separated into subsequent comments named USEPA-02, USEPA-03, etc.

Responses to all comments were prepared and reviewed for scientific and technical accuracy and completeness. Comments appear as they were submitted and have not been altered with the exception that expletives and personal information were removed, as necessary.

Table E.3.2-1 contains comments from federal, state, and local agencies received during the public comment period and the Navy's response.

Table E.3-1: Responses to Comments from Agencies

Commenter	Comment	Navy Response
U.S. Environmental Protection Agency – Region IX-01 (Written)	We have rated the DEIS as Environmental Concerns- Insufficient Information (EC-2) (see enclosed "Summary of Rating Definitions"), based on the adverse impacts to marine resources described in the DEIS, and our concern that the information provided in the document does not sufficiently assess such impacts. While we defer to the National Marine Fisheries Service's expertise regarding the likely adverse affect of proposed project on marine mammals and sea turtles, we believe that the FEIS would benefit from improved and corrected disclosure of impacts. Please see the enclosed detailed comments for more information regarding our concerns. EPA appreciates the opportunity to review this DEIS. When the Final EIS is released for public review, please send one copy to the address above (mail code: CED-2). If you have any questions, please contact me at (415) 972-3521 or Tom Kelly, the lead reviewer for this project, at 415-972-3856 or kelly.thomasp@epa.gov.	Navy responses are provided to the specific comments below. A copy of the Final EIS/OEIS will be delivered to U.S. EPA Region IX per the request.
USEPA-02	Acoustic Impacts The DEIS frequently mentions the Navy Acoustic Effects Model as the source of the estimates of impacts on marine mammals and sea turtles. The Navy's website contains a supporting technical document that discusses the model and its results. While the supporting technical document appears consistent in many respects with the DEIS, the hours of sonar operation modeled in the technical report (Table 14) differ from the hours of sonar use in the DEIS (Table 3.0-8) for some source classes. For example, the technical report indicates the hours of operation for Sonar Source Class LF-4 (Low-frequency sources equal to 180 dB and up to 200 dB) for the preferred alternative is 87 hours, while the DEIS indicates that number is 2,157. Similarly, the number of mammal species experiencing permanent threshold shift (i.e., permanent noise-induced hearing damage) differs between the reports. For example, the technical report indicates that annual testing events would result in permanent threshold shift for nearly 5,850 Short-Beaked Common Dolphins (Table 19), while the DEIS indicates that number would be 309 (Table 3.4-14). Recommendation: The FEIS should correct any discrepancies between the technical report and the FEIS.	Late changes to the technical document were not included in the Draft EIS/OEIS, but have been corrected in the Final EIS/OEIS. The Technical Report itself has been revised also, and can be found on the HSTTEIS.com website.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
USEPA-03	Mitigation Measures Ramp-Up The DEIS clarifies the distinction between training and testing in Section 1.4, emphasizing the need for training to "be as realistic as possible to provide the experiences so important to success and survival" (p. 1-5). It separates testing into several categories: scientific research and testing, private contractor testing, developmental testing, operational testing, fleet training support, follow-on test evaluation and maintenance and repair testing (1-7). We note that, under the preferred alternative, sonar testing results in more level A harassment to marine mammals than does sonar training. Mitigation considered but rejected from the DEIS discusses the concept of sonar "[r]ampup procedures, (slowly increasing the sound in the water to necessary levels)" (p. 5-55), which appears to be a process that greatly reduces the effects of sonar for many testing processes. Ramp up procedures are dismissed for training because they would not allow the Navy to "train as they fight," but the DEIS also states, "ramp-up procedures have been used in testing." Recommendation: The FEIS should include a more thorough discussion of ramp-up, either as a mitigation measure or an operational procedure, for testing (not training) activities listed in Chapter 2. We recognize that ramp-up would not be appropriate in many sonar testing procedures (e.g. where testing is concurrent with training), but the FEIS should disclose the circumstances under which it would be compatible with testing.	The Navy has considered ramp-up of sound sources during testing, and very rarely practices this procedure (only as needed). For a description of those rare circumstances when a ramp-up is necessary, see Section 5.3.4.2.1 (Implementing Active Sonar Ramp-Up Procedures During Testing) of Chapter 5 in the Draft EIS/OEIS. However, in most cases a ramp-up is either ineffective or would impact the purpose of the test event. Regarding the effectiveness and practicality of ramp-up for testing, the following points are provided for explanation: 1. Most testing must be performed "realistically" as in training, either as the stated goal of the particular test, or because the test is "piggy-backing" on a training event, where ramp-up would be counter to the training objectives. 2. Some tested systems are either "on" or "off" and can't be ramped up. 3. Nearly all of the potential effects to marine mammals result from sound sources that have significant intervals between "pings," and are on moving platforms, typically ships. Because the ship is moving, the ramp up of a signal would begin in one location, but the increased, or "ramped up" signal would be generated in a different location, nullifying the effect of the lower energy ramp-up signal. For example, the ASW sonar used on a DDG will nominally transmit at 50 second intervals. A ship traveling at 15 nautical miles per hour (a typical speed) would move approximately 400 yards in the time between pings. 4. Finally, the summation of energy is what contributes to most effects, and a ramp up before actual training or testing could begin would require putting more total sound energy into the water and result in more exposure to marine species.
USEPA-04	Identification of Cautionary Areas and Coral Reef Resources The DEIS discusses the designation of a humpback whale cautionary area, "which consists of a 5 km (3 .1 miles) buffer zone that has been identified as having one of the highest concentrations of humpback whales during the critical winter months" (p. 5-45). From December 15 to April 15, the cautionary area will only be used for training if approval is granted by the commander of the U.S. Pacific Fleet, taking into account "the Navy's commitment to fully consider and balance mission requirements with environmental stewardship" (p. 5.45-46). It is not clear whether the area identified in the DEIS as a cautionary area is within or consistent with the boundaries of the Hawaiian	A figure depicting the Navy Humpback Whale Cautionary Area (Figure 5.3-1) has been added to Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS. Maps showing coral locations are located in the Marine Habitats section, Figures 3.3-3 through 3.3-6. The Navy Humpback Whale Cautionary Area is not intended to prevent Navy activities from taking place in the Cautionary Area, nor is it intended to provide protection for coral. The Protective Measures Assessment Protocol is not merely a

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	Islands Humpback Whale National Sanctuary managed by NMFS. The DEIS also includes a mitigation measure to limit training and testing within 350 yards of coral reefs (p. 5-46). While it discusses the inclusion of coral reefs and other protected areas in the Navy's mapping program, known as the Protective Measures Protocol Assessment, the DEIS does not include a map of these areas. Recommendation: The FEIS should clarify the relationship, if any, of the Humpback Whale Cautionary Area to the Hawaiian Islands Humpback Whale National Sanctuary, and include a map of the Area, as well as a map of coral reefs that will be avoided. By including these maps in the FEIS, or making them available through a link similar to DEIS technical reports, the Navy and NMFS could invite comments on the accuracy or thoroughness of the maps from researchers and ocean protection groups.	"mapping program." As described in Section 5.2.2.2 (Protective Measures Assessment Protocol), the protocol is a decision support and situational awareness tool that provides information about required mitigation, a visual display of the exercise area, the unit's position relative to the target area, and any relevant environmental data.
International Boundary and Water Commission (Written)	During our review of the EIS it appears that the operations conducted under this EIS do not impact any of the property or interests of the USIBWC, however, the USIBWC would like to note the location of the South Bay Ocean Outfall located off shore of Imperial Beach. The South Bay Ocean Outfall extends 23,600 feet in a westerly direction from near the mouth of the Tijuana River. The South Bay Ocean Outfall is a treated wastewater effluent pipe containing a vertical drop shaft located on the land that descends 190 feet to a horizontal tunnel that extends 18,970 feet under the ocean floor to a riser assembly that ascends 160 feet to the seafloor. At the seafloor the outfall extends 4,670 feet west along the seafloor to a wye diffuser. From this wye diffuser, two diffuser legs extend 1,974 feet north and south and terminate at a depth of approximately 93 feet below sea level. The terminus of the diffuser is located at Latitude 32° 32' 15" North and Longitude 117° 11' 00" West. The outfall, based on the maps provided in the EIS, lies slightly to the east of the HSTT in this area, however, any operations in the area of the outfall should use caution as any unmanned and manned vehicles, munitions, and divers could present a hazard to the outfall. Thank you again for the opportunity to review and comment on the subject document for the proposed project. Should you or your staff have questions, please contact me at (915) 832-4749 or Mr. Wayne Belzer at (915) 832-4703.	The Navy appreciates this information.
Marine Mammal Commission-01 (Written)	The Marine Mammal Commission recommends that the Navy- • revise the DEIS by expanding the range of alternatives under consideration to include at least one with lower levels of training and testing activities. Doing so is particularly important at this time when decision-makers may be faced with the choice of reducing the Navy's budget and, if they do so, they should be well informed about the environmental consequences of the various decisions that they might make;	The Navy developed the alternatives considered in this EIS/OEIS after careful assessment of the Navy's training and testing requirements by subject matter experts, including military units and commands that utilize the ranges, military range management professionals, and Navy environmental managers and scientists. The environmental consequences of individual activities (e.g., torpedo exercises, mine countermeasures exercises, tracking exercises, etc.) have been analyzed in the EIS/OEIS with sufficient detail to inform the decision maker of the environmental consequences of making a budget-related

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		reduction in training or testing activity if needed.
MMC-02	• revise the discussion of North Pacific right whales by (1) moving it from the section on species unlikely to be found in the study area (i.e., 3.4.1.1) to the section discussing other marine mammals in the study area (i.e. section 3.4.2) and (2) expanding it to provide a more complete review of their status and threats; • undertake research to determine if North Pacific right whales use or regularly migrate through Navy training and testing areas in the Pacific during fall and winter months-that research should include satellite telemetry studies to identify the migratory routes and overwintering areas of whales using summer feeding grounds in the Southeast Bering Sea and passive acoustic monitoring to detect right whale vocalizations in the Hawaii and southern California training and testing areas;	Applying the best scientific information available, and as described in the Draft EIS/OEIS, there is ample evidence to support the Navy's conclusion that North Pacific right whales are unlikely to be present in the Study Area. Further, with no density information on this species for the Study Area, no quantitative impact analysis could be conducted. While new research that goes beyond existing studies are not required for an EIS, the Navy will continue to work with its Scientific Advisory Group to determine new opportunities for coherent and synergistic research.
MMC-03	• adjust all acoustic and explosive thresholds for low-, mid-, and high-frequency cetaceans by the appropriate amplitude factor (e.g., 16.5 or 19.4 dB), if it intends to use the type II weighting functions as depicted in Figure 6 of Finneran arid Jenkins (2012);	The thresholds were adjusted based on weighting the exposures from the original research from which the thresholds were derived with the Type II weighing functions. The weighted threshold is not derived by a simple amplitude shift.
MMC-04	• explain why Kastak et al. (2005) data were used as the basis for explosive thresholds in pinnipeds and specify the extrapolation process and factors used as the basis for associated TTS thresholds;	The same offset between impulsive and non-impulsive temporary threshold shift found for the only species where both types of sound were tested (beluga) was used to convert the Kastak data (which used non-impulsive tones) to an impulsive threshold. This method is explained in Finneran and Jenkins (2012) and Southall et al. (2007).
MMC-05	• provide detailed information regarding how it determined marine mammal takes that occur when multiple types (i.e., acoustic, explosive, and non-explosive impulsive) of sound producing sources of varying frequencies (i.e., low, mid, and high) are used simultaneously;	Events involving multiple source types (e.g., acoustic vs. explosive) are treated as separate events, and the sound exposure levels are not summed. Furthermore, in most cases, explosives and sonar are not used within the same activities and therefore are unlikely to affect the same animals over the same time period. Energy is summed for multiple exposures of similar source types. For sonars, including use of multiple systems within any scenario, energy is accumulated within the following four frequency bands: low-frequency, mid-frequency, high-frequency, and very-high-frequency. After the energy has been summed within each frequency band, the band with the greatest amount of energy is used to evaluate the onset of PTS or TTS. For explosives, including use of multiple explosives in a single scenario, energy is summed across the entire frequency band. Please see *Determination of Acoustic Effects on Marine Mammals and Sea Turtles for the Phase II Hawaii-Southern California Fleet Training and Testing EIS/OEIS* (Naval Undersea Warfare Center 2012) on the HSTTEIS.com website for additional explanation.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
MMC-06	• use its spatially and temporally dynamic simulation models to estimate strike probabilities for specific activities (i.e., movements of vessels, torpedoes, unmanned underwater vehicles and expended munitions, ordnance, and other devices) rather than using simple probability calculations;	The recommendation of the Marine Mammal Commission to use a dynamic simulation model to estimate strike probability was considered, but the Navy found that use of historical data was more appropriate for the analysis. The strike probability analysis completed in this EIS/OEIS is based upon actual data collected from historical use of vessels, in-water devices, and military expended materials and the likelihood that these items may even have the potential to strike an animal. These data account for real world variables over the course of many years, and any model would be expected to be less accurate than the use of actual data.
MMC-07	• provide the predicted average and maximum ranges for all criteria (i.e., behavioral response, ITS, PTS, onset slight lung injury, onset slight gastrointestinal injury, and onset mortality), for all activities (i.e., based on the activity category and representative source bins), and all functional hearing groups of marine mammals;	Ranges to effects for all criteria and functional hearing groups are provided for representative active sonars (Section 3.4.3.2.1.1, Range to Effects) and explosives (Section 3.4.3.2.2.1, Range to Effects). The representative sources include the most powerful active sonar source and the largest proposed charge weight analyzed. The Navy needs to conduct testing and training in a variety of environments having variable acoustic propagation conditions. These variations in acoustic propagation conditions are considered in the Navy's acoustic modeling and the quantitative analysis of acoustic impacts; average ranges to effect are provided in the EIS to show the reader typical zones of impact around representative sources.
MMC-08	• use passive and active acoustics, whenever practicable, to supplement visual monitoring during the implementation of its mitigation measures for all activities that generate sound;	Passive acoustic monitoring is already and will continue to be implemented with several activities (e.g., Improved Extended Echo Ranging sonobuoys and torpedo [explosive] testing). I As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		ship and aircraft and then provide “a crude estimate” of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, “(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching.” When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal surveys, are generally available to Navy Lookouts on board vessels over 60’. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in “calm sea conditions” is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier’s and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the “one or two personnel” described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy’s reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
MMC-09	• cease the use of its sound sources (including explosive activities that do not use time-delay firing devices) and not reinitiate them for periods at least as long as the maximum dive times of the species observed (if identified to species) or likely to be encountered (if species identification is uncertain), after the sighting of one or more marine mammals within or about to enter a mitigation zone;	As described in the Final EIS/OEIS in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring), a 30 min. wait period more than covers the average dive times of most marine mammal species but may not be sufficient for some deep-diving marine mammal species or for sea turtles. However, the analysis in Section 3.4.3.1.1 (Non-Impulsive and Impulsive Sound Sources) shows that injury to deep-diving marine mammals (e.g., sperm whales and beaked whales) is not expected to occur. Furthermore, any wait period greater than 30 min. would result in an unacceptable operational impact on readiness.
MMC-10	• adjust the size of the mitigation zone for mine neutralization events using the average swim speed of the fastest swimming marine mammal occurring in the area where time-delay firing devices would be used to detonate explosives;	The principles of HSTT time-delay firing device mitigation are similar to those contained within the 2011 VACAPES Letter of Authorization. For time delay activities, the mitigation zone is 1,000 yd. for all charge sizes (5, 10, and 20 lb. charges) and for a maximum time-delay of 10 min. The mitigation zone takes into account a portion of the distance that a marine mammal could potentially travel during the time delay. However, the mitigation zone was set at 1,000 yd. because that is the maximum distance that Lookouts in two small boats can realistically observe. The use of more than two boats for observation during this activity presents an unacceptable impact to readiness due to limited personnel resources. If a swim speed of 3 knots (101 yd./min.) (A nominal average for a delphinid in this area) is considered, the 1,000-yd. mitigation zone results in coverage of the potential range to mortality for all charges, including up to a 9 min. time delay. Furthermore, the mitigation zone covers the potential range to injury for 5 lb. charges, including up to a 6 min. time delay, and for 10 lb. and 20 lb. charges, including up to a 5 min. time delay. The 3 knot swim speed, therefore, was a consideration, but not the only determining factor in development of the time delay mitigation zones; therefore, considering different swim speeds would not result in a change to or expansion of the mitigation zone size for time delay activities. The Navy asserts that the 1,000 yd. time delay zone is both practical and protective. The proposed AFTT mitigation zone covers the entire predicted maximum range to PTS as well as a portion of the estimated swim speed distance. Due to practicality of implementation and impact on the effectiveness of the military readiness activity, the proposed mitigation zone represents the maximum distance that Lookouts on small boats can adequately observe given the number of personnel who will be involved. The use of more than two boats for observation

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		during this activity presents an unacceptable impact on readiness due to limited personnel and equipment resources. Takes that cannot be avoided through mitigation are considered in the MMPA permitting process. Species-specific identification of marine mammals is not a Lookout requirement; therefore, a single activity-specific waiting time is needed between species.
MMC-11	• revise its DEIS by (1) including in its cumulative impacts analysis all potential risk factors, whether they are deemed individually significant or negligible and (2) describing the specific details needed for 'the reader to evaluate the utility of the Navy's conceptual framework for its cumulative impacts analysis.	As stated in Section 4.4.1 (Resource Areas Dismissed from Current Impact Analysis) of the Draft EIS/OEIS, in accordance with Council on Environmental Quality guidance, the cumulative impacts analysis focused on impacts that are “truly meaningful.” This was accomplished by reviewing the direct and indirect impacts that would occur on each resource under each of the alternatives. Key factors considered were the current status and sensitivity of the resource and the intensity, duration, and spatial extent of the impacts of each potential stressor. In general, long-term rather than short-term impacts and widespread rather than localized impacts were considered more likely to contribute to cumulative impacts. Those impacts to a resource that were considered to be negligible were not considered further in the analysis. The level of analysis for each resource was commensurate with the intensity of the impacts identified in Chapter 3 (Affected Environment and Environmental Consequences).
MMC-12	The no action alternative In this and several prior environmental impact statements for various range complexes, the Navy uses the term "no action" to mean continued use at the current level. The Navy cites guidance from the Council on Environmental Quality as the basis of its selection of this baseline as the no action alternative against which other alternatives are compared. The Council on Environmental Quality has published guidance (http://ceq.hss.doe.gov/nepa/regs/40/1-10.HTM) that posits two alternative interpretations of what constitutes no action. The first is that the action would not take place at all. Under this alternative, the impacts of the other alternatives would be assessed against not conducting any training or testing activities. As characterized by the Navy (page 2-62), the second interpretation "allows the No Action Alternative to be thought of in terms of continuing with the present course of action until that action is changed." The referenced guidance states that- The first situation might involve an action such as updating a land management plan where ongoing management programs initiated under existing legislation and regulations will continue, even as new plans are developed. In these cases "no action" is "no change" from current management direction or level of management intensity. To construct an alternative that is based on no management at	The Navy developed the alternatives considered in this EIS/OEIS after careful assessment by subject matter experts, including military units and commands that utilize the ranges, military range management professionals, and Navy environmental managers and scientists. A reduction in training and testing activities would fail to meet the Purpose and Need and would not allow the Navy to meet its obligations under Title 10. Refer to Section 2.5 (Alternatives Development) of the Draft EIS/OEIS for an explanation of the alternatives development. The Navy has analyzed individual activities within the document with sufficient detail to inform a decision-maker of the environmental consequences of a making a future budget-related reduction in training or testing activities.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	all would be a useless academic exercise. Therefore, the "no action" alternative may be thought of in terms of continuing with the present course of action until that action is changed. Consequently, projected impacts of alternative management schemes would be compared in the EIS to those impacts projected for the existing plan. In this case, alternatives would include management plans if both greater and lesser intensity, especially greater and lesser levels of resource development. (Emphasis added) The Navy has chosen to use a continuation of current activities as the no action alternative. The Commission understands that choice and considers it reasonable as long as the environmental impacts of all major current activities have been assessed appropriately. However, the Commission must question the selection of the other alternatives because, as a set, they do not satisfy the requirement under the applicable guidance that the DEIS consider management of both greater and lesser intensity. Therefore, the Marine Mammal Commission recommends that the Navy revise the DEIS by expanding the range of alternatives under consideration to include at least one with lower levels of training and testing activities. Doing so is particularly important at this time when decision makers may be faced with the choice of reducing the Navy's budget and, if they do so, they should be well informed about the environmental consequences of the various decisions that they might make.	
MMC-13	Marine mammal occurrence Sections 3.4.1 and 3.4.2 in the DEIS are very well drafted generally. Those sections include relevant, up-to-date, and accurate information on most species of marine mammals. However, the Navy assumed that North Pacific right whales would be unlikely to occur in either the Hawaii or Southern California study areas. It stated that the presence of North Pacific right whales in the study area is extremely low, as they have been sighted only rarely in the Bering Sea and Gulf of Alaska in recent years. Although sightings of right whales in the study area are rare, this may be due to the small size the North Pacific right whale population rather than a lack of importance of the area as habitat for the species. In recent years, a few North Pacific whales have been seen in the southeast Bering Sea every summer since 1997 when regular efforts to look for them began (Wade et al. 2011). Those sightings indicate that the southeast Bering Sea is an important summer feeding area for the small number of remaining whales. The whales' winter habitat, however, remains unknown and requires further research to identify. All other right whale populations whose winter habitats are known make annual migrations between summer high-latitude feeding grounds and lower-latitude calving grounds. That being the case, right whales feeding in the summer in the southeastern Bering Sea and along the Kurile Islands are likely to migrate to lower latitudes in the winter. Rare as they may be, sightings of right whales in Hawaiian waters indicate that	Applying the best scientific information available, and as described in the Draft EIS/OEIS, there is ample evidence to support the Navy's conclusion that North Pacific right whales are unlikely to be present in the Study Area. Further, with no density information on this species for the Study Area, no quantitative impact analysis could be conducted. [Same as MMC-2. Awaiting validation from EAB.]

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	this area may be important for reproductive purposes or at least as part of a migratory corridor. Such habitat use patterns are supported by photographs matching an individual right whale in Hawaii and the southeast Bering Sea in 1996 (Kennedy et al. 2011). Therefore, the DEIS should be revised to note that although their occurrence around Hawaii is uncertain, waters off Hawaii could provide important migratory and winter habitats for North Pacific right whales. Accordingly, the Marine Mammal Commission recommends that the Navy revise the discussion of North Pacific right whales by (1) moving it from the section on species unlikely to be found in the study area (i.e., 3.4.1.1) to the section discussing other marine mammals in the study area (i.e. section 3.4.2) and (2) expanding it to provide a more complete review of their status and threats. Given the extremely endangered status of the North Pacific right whale and the possibility that the Pacific study area may include vital habitat for the species, the Marine Mammal Commission also recommends that the Navy undertake research to determine if North Pacific right whales use or regularly migrate through Navy training and testing areas in the Pacific during fall and winter months-that research should include satellite telemetry studies to identify the migratory routes and overwintering areas of whales using summer feeding grounds in the Southeast Bering Sea and passive acoustic monitoring to detect right whale vocalizations in the Hawaii and southern California training and testing areas.	
MMC-14	Criteria and thresholds The Navy proposes to estimate takes resulting from its activities by adjusting received sound levels at different frequencies based on the hearing sensitivity of various groups of marine mammals at those frequencies. The adjustments are based on "weighting" functions derived by Southall et al. (2007) and Finneran and Jenkins (2012; type I and type II weighting functions, respectively). Type I weighting functions (see Figure 1 in Southall et al. 2007) are flat over a wide range of frequencies and then decline at the extremes of the animal's hearing range. Type II weighting functions (Finneran and Jenkins 2012) are used only for cetaceans and combine the precautionary type I curves developed by Southall et al. (2007) with equal loudness weighting functions derived from empirical studies with bottlenose dolphins (Finneran and Schlundt 2011). The Commission considers the theory behind those weighting functions to be sound. However, the amplitudes of the final type II weighting functions appear to have been shifted, lowering the sensitivity at all frequencies by roughly 16-20 dB (compare Figures 2 and 6 of Finneran and Jenkins (2012)). For sonar-related activities Finneran and Jenkins (2012) reduced the acoustic thresholds for low- and mid-frequency cetaceans by 16.5 dB (presumably to account for the amplitude decrease in the type II weighting functions), but it appears that they did not apply a similar adjustment of 19.4 dB for high-frequency cetaceans. Because data are lacking for TTS thresholds for high-frequency cetaceans exposed to acoustic (i.e., tonal) signals, they appear to add a 6-dB correction factor to the TTS threshold derived from non-explosive impulsive sources (i.e., airguns)	The same offset between impulsive and non-impulsive TTS found for the only species where both types of sound were tested (beluga) was used to convert the Kastak data (which used non-impulsive tones) to an impulsive threshold. This method is explained in Finneran and Jenkins (2012) and Southall et al. (2007).

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	based on the method outlined in Southall et al. (2007). However, the Commission's understanding is that Southall et al. (2007) did not use the 6-dB factor to extrapolate between impulsive and acoustic thresholds, but rather to estimate PTS thresholds from TTS thresholds based on peak pressure levels. In addition, it is unclear how the explosive thresholds (i.e., for underwater detonations) were adjusted downward to account for the amplitude decrease in the type II weighting functions. If those thresholds were not adjusted by the appropriate amplitude factor, the Navy may have underestimated takes of marine mammals. To address these concerns, the Marine Mammal Commission recommends that the Navy adjust all acoustic and explosive thresholds for low-, mid-, and high-frequency cetaceans by the appropriate amplitude factor (e.g., 16.5 or 19.4 dB), if it intends to use the type II weighting functions as depicted in Figure 6 of Finneran and Jenkins (2012). For determining TTS thresholds for pinnipeds for underwater detonations, the Navy used data from Kastak et al. (2005) and extrapolation factors from Southall et al. (2007). Kastak et al. (2005) estimated the average sound exposure level for onset-TTS for pinnipeds exposed to octave band underwater sound centered at 2.5 kHz (i.e., mid-frequency sound). However, underwater detonations produce broadband sound in the low-frequency range. The Commission recognizes that Kastak et al. (2005) may be the only available data, but those data may not provide an appropriate basis for estimating those thresholds. Furthermore, the extrapolation factors from Southall et al. (2007) were not stated specifically in the Navy's analysis for underwater detonations, but it appears that they used 6 dB. As noted in the previous paragraph, Southall et al. (2007) seem to use 6 dB as the extrapolation factor for determining PTS thresholds from TTS thresholds based on peak sound pressure levels, not for extrapolating from acoustic to explosive thresholds. Thus, the Commission is unsure why thresholds based on octave-band mid-frequency sound were used for underwater detonations and what extrapolation factors were used and why. Therefore, the Marine Mammal Commission recommends that the Navy explain why Kastak et al. (2005) data were used as the basis for explosive thresholds in pinnipeds and specify the extrapolation process and factors used as the basis for associated TTS thresholds.	
MMC-15	Modeling methods Some of the Navy's activities involve the simultaneous use of multiple source types (i.e., acoustic, explosive, non-explosive impulsive) that generate sound within various frequency bands (i.e., low, mid, and high). To account for activities involving those sources, the Navy has proposed to sum all sound exposure levels received by an animal in each frequency band. However, the DEIS did not describe how the Navy would sum the sound exposure levels from multiple source types (e.g., acoustic vs. explosive). It also did not explain how the various thresholds for those different source types would be	Events involving multiple source types (e.g., acoustic vs. explosive) are treated as separate events and the sound exposure levels are not summed. Furthermore, in most cases, explosives and sonar are not used within the same activities and therefore are unlikely to affect the same animals over the same time period. Energy is summed for multiple exposures of similar source types. For sonars, including use of multiple systems within any scenario, energy is accumulated within the following four frequency bands: low-frequency, mid-frequency, high-frequency, and very high frequency. After the energy has been

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	prioritized and applied. In such cases with multiple source types, a simple summation of sound exposure levels may not necessarily estimate takes accurately. In addition, the Navy used three different types of propagation models: the Comprehensive Acoustic System Simulation/ Gaussian Ray Bundle model for acoustic sources, Reflection and Refraction in Multilayered Ocean/Ocean Bottoms with Shear Wave Effects model for explosive sources, and the Range-Dependent Acoustic Model for non-explosive impulsive sources. The DEIS and supporting technical documents did not provide (1) information regarding how the Navy integrated propagation of sound from those three models into its effects model and (2) details regarding how sound exposure levels would be summed. Again, it is not clear whether a basic summation of those sound exposure levels is appropriate. If the Navy used some other algorithm for this summation, it should explain that algorithm. For all of these reasons, the Marine Mammal Commission recommends that the Navy provide detailed information regarding how it determined marine mammal takes that occur when multiple types (i.e., acoustic, explosive, and non-explosive impulsive) of sound-producing sources of varying frequencies (i.e., low, mid, and high) are used simultaneously.	summed within each frequency band, the band with the greatest amount of energy is used to evaluate the onset of PTS or TTS. For explosives, including use of multiple explosives in a single scenario, energy is summed across the entire frequency band. Please see *Determination of Acoustic Effects on Marine Mammals and Sea Turtles for the Phase II Hawaii-Southern California Fleet Training and Testing EIS/OEIS* (Naval Undersea Warfare Center 2012) on the HSTTEIS.com website for additional explanation.
MMC-16	The Navy also estimated the probability of vessels, expended munitions, and non-explosive materials (e.g. sonobuoys) striking a marine mammal. The Navy's method for determining those strike probabilities was based on simple probability calculations. For example, it used a Poisson model to estimate the probability of ship strikes based on the historical rate of ship strikes. Although the use of the Poisson model is not unreasonable for modeling the occurrence of rare events, such as a ship striking a marine mammal, the assumption that the encounter rate will remain the same is questionable if the Navy increases the number of training and testing activities or if the abundance and distribution of marine mammals change. Such an approach may be appropriate for the no action alternative but is clearly deficient for assessing impacts of alternatives 1 and 2. To estimate the probability of spent munitions or non-explosive materials striking marine mammals, the Navy simply compared the aggregated footprint of some specific marine mammal species with the footprint of all objects that might strike them (DEIS Appendix G). Both of those were based only on densities of marine mammals in the action area and expected amount of materials to be expended within a year in those areas. By combining marine mammal densities and those activities over space and time into a single calculation sequence, the Navy provided only a crude estimate of strike probabilities for the "average" condition. Unfortunately, neither marine mammals nor Navy activities are distributed homogeneously in space or time. The Commission does not understand why the Navy did not incorporate spatial and temporal considerations to make its take estimation procedure more realistic biologically. The Navy's model for determining takes of marine mammals from sound-producing activities can account for moving sound sources and marine mammals. In that model, the Navy could adjust the data collected by the animat dosimeters from received sound level to a close approach	The recommendation of the Marine Mammal Commission to use a dynamic simulation model to estimate strike probability was considered, but the Navy found that use of historical data was more appropriate for the analysis. The strike probability analysis completed in this EIS/OEIS is based upon actual data collected from historical use of vessels, in-water devices, and military expended materials and the likelihood that these items may even have the potential to strike an animal. These data account for real world variables over the course of many years, and any model would be expected to be less accurate than the use of actual data.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	distance and estimate strike probabilities more realistically. The Marine Mammal Commission recommends that the Navy use its spatially and temporally dynamic simulation models to estimate strike probabilities for specific activities (i.e., movements of vessels, torpedoes, unmanned underwater vehicles and expended munitions, ordnance, and other devices) rather than using simple probability calculations.	
MMC-17	Table 5.3-2 in the DEIS lists the Navy's predicted distances or ranges over which PTS might occur and recommended mitigation zones. The table categorizes sound sources by type (e.g., MF1:SQS-53 mid-frequency active hull-mounted sonar) and does not include all sources, but rather includes for each category (or bin) the average and maximum distances from the sound source at which PTS could be expected to occur. Chapter 3 of the DEIS also includes tables listing such ranges. However, in Chapter 3, the tables include only a subset of the proposed activities (6 of the 13 explosive activities analyzed) and the average rather than maximum ranges (see Tables 3.4-15). In addition, the DEIS does not provide the ranges to PTS for acoustic sources for more than one ping (Table 3.4-9), as it does for TTS (i.e., 1, 5, and 10 pings; Tables 3.4-10). Instead, the DEIS simply assumes that marine mammals would not maintain a nominal speed of 10 knots parallel to a ship and thereby receive sound from more than a single ping. Absent this kind of information, the DEIS process is not fully transparent and the Commission and public cannot comment on the appropriateness of the proposed mitigation zones. To address those shortcomings in the DEIS, the Marine Mammal Commission recommends that the Navy provide the predicted average and maximum ranges for all criteria (i.e., behavioral response, TTS, PTS, onset slight lung injury, onset slight gastrointestinal injury, and onset mortality), for all activities (i.e., based on the activity category and representative source bins), and all functional hearing groups of marine mammals.	Ranges to effects for all criteria and functional hearing groups are provided for representative active sonars (Section 3.4.3.2.1.1, Range to Effects) and explosives (Section 3.4.3.2.2.1, Range to Effects). The representative sources include the most powerful active sonar source and the largest proposed charge weight analyzed. The Navy needs to conduct testing and training in a variety of environments having variable acoustic propagation conditions. These variations in acoustic propagation conditions are considered in the Navy's acoustic modeling and the quantitative analysis of acoustic impacts; average ranges to effect are provided in the Environmental Impact Statement to show the reader typical zones of impact around representative sources. The range to effects from various acoustic sources are highly dependent on both operating characteristics and environmental variables. The grouping by bin takes into account operating characteristics of the sources and sources within a bin are by definition equal to or lesser in output than the source which represents the bin. It is therefore unnecessary and contrary to the binning approach to provide information for all sources individually. For explosives, it is reasonable to assume that the range for a bin not provided would fall between the next lowest and next highest bins. For these reasons, it is not necessary to provide all average and maximum ranges for all criteria and all sources or bins. With regard to ranges to PTS and as explained in Section 3.4 (Marine Mammals), because the ranges are so short for even the most powerful acoustic source of concern (hull mounted mid-frequency anti-submarine warfare sonar), the ship is moving, and the pings occur approximately every 50 seconds, there is not sufficient overlapping energy from one ping to the next to make presentation of multiple pings useful (each subsequent ping has the same approximate range to PTS from the bow of the ship as the first ping). As noted in the comment and presented in the Draft EIS/OEIS, an animal would have to be exposed to a TTS level first ping and then parallel the ship within close proximity for 50 seconds to receive a second ping potentially resulting in PTS. Given all the science detailed in the EIS/OEIS indicating that marine mammals will behaviorally avoid high levels of

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		sound, the assumption that a marine mammal would not remain along-side a pinging vessel is a simple but reasonable assumption. As presented in the Draft EIS/OEIS, while 10 knots was the speed used in modeling the ship's speed of advance, a ship engaged in anti-submarine warfare training or testing would be moving at between 10 and 15 knots. In addition and as discussed in the Draft EIS/OEIS in Section 3.4.3.1.6.1 (Model Assumptions and Limitations), there are many other conservative inputs made with regard to the modeling that will tend to overestimate impacts such as assuming marine mammals are always facing the source and therefore hearing the maximum sound predicted for a location.
MMC-18	The DEIS notes that the use of observers (lookouts) would increase the likelihood of detecting marine mammals at the surface, but it also notes that the value of visual monitoring is limited and could not be relied on to avoid all impacts to all species. The Commission agrees and has made numerous recommendations to the Navy to characterize the effectiveness of visual observation. Importantly, the Navy is now working with collaborators at the University of St. Andrews to study observer effectiveness. The Commission believes those studies will be very useful once completed. However, until the results are available, the Commission also believes that the Navy should supplement its visual monitoring efforts with other measures rather than simply reducing the size of the zones it plans to monitor. The DEIS does propose to supplement visual monitoring using passive acoustics during activities that generate impulsive sounds (i.e., primarily for explosives), but does not propose the same during the use of (non-impulsive) low-, mid-, and high-frequency active sonar. In contrast, the Navy uses visual, passive acoustic, and active acoustic monitoring during Surveillance Towed Array Sensor System Low Frequency Active (SURTASS LFA) sonar activities to augment its mitigation efforts over large areas. It is not clear why the Navy is not proposing to use those same monitoring methods for the other activities described in the DEIS. To ensure effective monitoring, the Marine Mammal Commission recommends that, whenever practicable, the Navy use passive and active acoustics to supplement visual monitoring during the implementation of its mitigation measures for all activities that generate sound.	Mitigation measures were developed on a case-by-case basis based on predicted potential impacts; therefore, the use of acoustic monitoring is not always warranted, nor practicable from an operational standpoint (Section 5.3.2.1, Acoustic Stressors). Some events do use passive acoustic monitoring as part of the mitigation when practicable, including improved extended echo ranging sonobuoys, explosive sonobuoys using 0.6–2.5 pound net explosive weight, explosive torpedo testing, and sinking exercises. The active sonar system used by SURTASS LFA is built into the system's vertical array and can only be employed in this fashion from a slow-moving platform. It is not possible to employ this system on the types of platforms analyzed in the HSTT EIS/OEIS because it cannot be installed on other ship classes. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal surveys, are generally available to Navy Lookouts on board vessels over 60'. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the "one or two personnel" described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website. .

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
MMC-19	In addition, the Navy proposes that, if feasible, it will cease acoustic activities (i.e., active sonar transmissions) and explosive activities (i.e., detonations that do not use time-delay firing devices) when a marine mammal is detected within the mitigation zone. Those activities would resume when the animal is "thought to have exited" the mitigation zone. The meaning of "thought to have exited" is not clear, and a more definitive criterion is needed to clarify when activities might be resumed. The current mitigation measures allow the Navy to resume mid-frequency active sonar activities only when a sighted marine mammal has not been resighted for 30 minutes or the vessel has transited more than 2,000 yards beyond the location of the last detection. Those measures also stipulate that explosives cannot be detonated unless a sighted marine mammal has not been resighted for 30 minutes, but those measures do not stipulate a distance because those detonations occur at a fixed location. In any case, the Commission must question all of those approaches if the position of the marine mammal is unknown. That is, the key considerations driving those measures are the relative positions of the marine mammal and the sound source. Their relative positions over time are best estimated as a function of their positions when the marine mammal was first sighted, the speed and heading of the vessel, and the speed and heading of the marine mammal. If the vessel and marine mammal are moving in opposite directions, then the marine mammal may leave the mitigation zone relatively quickly. However, if they are moving in the same direction, then the marine mammal may remain in the mitigation zone for a prolonged period. Unless a sighted marine mammal is resighted leaving or outside the safety zone, the Navy should not resume its activity until it has had a reasonable chance of verifying that it can do so safely. The delay should take into account that (1) a marine mammal may remain underwater where it is not visible, (2) it may change its heading and speed in response to the vessel, and (3) using visual observation alone it is not possible to determine a marine mammal's position relative to the vessel or sound source after the initial sighting, unless the marine mammal surfaces again and is observed.	Clarification of what is meant by "thought to have exited" (based on animal course and speed) as well as additional information on additional post-sighting activity recommencement criteria has been added to Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) for each activity. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." 		mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the "one or two personnel" described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website.
MMC-20	The dive time of a sighted marine mammal is a central consideration whenever mitigation measures depend on visual observation. For small cetaceans, the Commission has recommended a delay of at least 15 minutes because their dive times are shorter and generally occur within that timeframe. For some mysticetes and large cetaceans, the proposed 30-minute pause may be inadequate, sometimes markedly so. Sperm whales and beaked whales, in particular, may remain submerged for periods far exceeding 30 minutes. Blainville's beaked whales dive to considerable depths (> 1,400 m) and can remain submerged for nearly an hour (Baird et al. 2006, Tyack et al. 2006). In addition, observers may not detect marine mammals each time they return to the surface. Even under ideal conditions detection can be a problem, particularly for cryptic species such as beaked whales. Barlow (1999) found that "accounting for both submerged animals and animals that are otherwise missed by the observers in excellent survey conditions, only 23 percent of Cuvier's beaked whales and 45 percent of Mesoplodon beaked whales are estimated to be seen on ship surveys if they are located directly on the survey trackline." Thus, depending on the species involved, short-term visual monitoring may not be adequate to confirm that a sighted marine mammal has left the mitigation zone. To address this problem, the Marine Mammal Commission again recommends that, after the sighting of one or more marine mammals within or about to	Dive behavior varies amongst species. As described in *the Dive Distribution and Group Size Parameters for Marine Species Occurring in Navy Training and Testing Areas in the North Atlantic and North Pacific Oceans* technical report, a 30 min. waiting period accounts for the dive capabilities typical of most species. Post-sighting activity recommencement wait periods longer than 30 min. would be impracticable to implement and would decrease realism of activities. For activities involving platforms restricted by fuel or other constraints (e.g., helicopters), the wait times have been adjusted based on operational need and practicability of implementation. A discussion of the effectiveness of each wait time is provided in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) for each activity. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	enter a mitigation zone, the Navy cease the use of its sound sources (including explosive activities that do not use time-delay fusing devices) and not reinitiate them for periods at least as long as the maximum dive times of the species observed (if identified to species) or likely to be encountered (if species identification is uncertain).	detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal surveys, are generally available to Navy Lookouts on board vessels over 60'. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the "one or two personnel"

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website. Lastly, species-specific identification of marine mammals is not a Lookout requirement. Therefore, a single activity-specific waiting time is needed between species.
MMC-21	For explosive activities that do involve time-delay fusing devices, the Navy proposes to use a 915-m mitigation zone, which is smaller than the 1,326-m zone currently used. The current zone was based on a 20-lb net explosive weight charge, a time delay to detonation of 10 minutes, an average swim speed for dolphins of 3 knots, and an added buffer to account for marine mammals that may be transiting at speeds faster than the average. The Commission has commented on this matter in numerous letters and continues to believe that the use of 3 knots as an average swim speed is inaccurate and inadequate, even with an added buffer to account for animals swimming faster than 3 knots. A simple calculation indicates that if a marine mammal swims at just 4 knots for the duration of the time-delay (10 minutes), the size of the mitigation zone would be inadequate, whether at 1,326 or 915 m. Importantly, many marine mammals are capable of swimming, and regularly do swim, much faster than 4 knots, especially for short periods. The average swim speed for bottlenose dolphins, for example, ranges from 2.6 to 8 knots (Lockyer and Morris 1987, Mate et al. 1995, Ridoux et al. 1997). In addition, pelagic dolphins swim faster than coastal species. The average swim speed for captive Pacific white-sided dolphins is 12.4 knots (Rohr and Fish 2004). Wild long-beaked common dolphins have been observed swimming at an average of 8.1 knots and captive individuals of that species have been observed swimming at an average of 13.0 knots (Rohr et al. 1998). In addition, the average swim speed for wild pantropical spotted dolphins is 6.9 knots (Au and Perryman 1982). Because many of the marine mammal species in the study area can and generally do swim faster than 3 knots, the mitigation zone proposed by the Navy is simply inadequate and poses a risk of additional injury and mortality, as was recently observed at the Silver Strand Training Complex. To address this concern, the Marine Mammal Commission recommends that the Navy adjust the size of the mitigation zone for mine neutralization events using the average swim speed of the fastest swimming marine mammal occurring in the area where time-delay firing devices would be used to detonate explosives.	The principles of HSTT time-delay firing device mitigation are similar to those contained within the 2011 VACAPES Letter of Authorization. For time delay activities, the mitigation zone is 1,000 yd. for all charge sizes (5, 10, and 20 lb. charges) and for a maximum time delay of 10 min. The mitigation zone takes into account a portion of the distance that a marine mammal could potentially travel during the time delay. However, the mitigation zone was set at 1,000 yd. because that is the maximum distance that Lookouts in two small boats can realistically observe. The use of more than two boats for observation during this activity presents an unacceptable impact to readiness due to limited personnel resources. If a swim speed of 3 knots (101 yd./min.) (a nominal average for a delphinid in this area) is considered, the 1,000 yd. mitigation zone results in coverage of the potential range to mortality for all charges, including up to a 9 min. time delay. Furthermore, the mitigation zone covers the potential range to injury for 5 lb. charges, including up to a 6 min. time delay, and for 10 lb. and 20 lb. charges, including up to a 5 min. time delay. The 3 knot swim speed, therefore, was a consideration, but not the only determining factor in development of the time delay mitigation zones; therefore, considering different swim speeds would not result in a change to or expansion of the mitigation zone size for time delay activities. The Navy asserts that the 1,000-yard time delay zone is both practical and protective. The proposed AFTT mitigation zone covers the entire predicted maximum range to PTS as well as a portion of the estimated swim speed distance. Due to practicality of implementation and impact on the effectiveness of the military readiness activity, the proposed mitigation zone represents the maximum distance that Lookouts on small boats can adequately observe given the number of personnel who will be involved. The use of more than two boats for observation during this activity presents an unacceptable impact on readiness due

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		to limited personnel and equipment resources. Takes that cannot be avoided through mitigation are considered in the MMPA permitting process. Species-specific identification of marine mammals is not a Lookout requirement; therefore, a single activity-specific waiting time is needed between species.
U.S. Department of the Interior-01 (Written)	The EIS/OEIS should note that military operations and oil and gas operations have been conducted concurrently offshore in southern and south-central California for more than 50 years. During that period there have been no major incidents or accidents involving military and OCS oil and gas operations.	Thank you for providing this information. This information has been included in Section 4.3.2.1 (Proposed Outer Continental Shelf Oil and Gas Leasing Program 2012-2017) of the Final EIS/OEIS.
USDOI-02	Section 4.3.2 Oil and Natural Gas Exploration, Extraction, and Production The EIS/OEIS should note that BOEM and DOD have been working in a collaborative manner at both the planning and operational stages for OCS oil and gas activities to ensure that each organization can carry out its mission requirements in an effective and efficient manner. This collaboration has been ongoing for more than 30 years and is guided by the policies and procedures set forth in a 1983 Memorandum of Agreement (MOA) between DOI and DOD, and a 1987 DOD Directive (see attachment). BOEM recommends that the EIS/OEIS briefly describe the MOA and Directive, and that a copy of the MOA and Directive be included in an appendix of the document.	The Navy agrees that operations between the Bureau of Ocean Energy Management and the Navy have been conducted in a collaborative manner. The 1983 Memorandum of Agreement between DOI and DOD and the 1987 Directive outlines the policies and procedures for joint use of offshore areas for military activities and mineral exploration or other development purposes. The MOA serves to avoid potential conflicting activities and major incidents that could result in environmentally damaging incidents. Thank you for highlighting the collaborative manner in which the planning and operational stages for Off Continental Shelf oil and gas activities ensures that each organization may carry out its mission requirements in an effective and efficient manner. The Memorandum of Agreement (MOA) between DOI and DOD, and a 1987 DOD Directive are available on the HSTT EIS/OEIS public website.
USDOI-03	Section 4.3.2.1 Proposed Outer Continental Shelf Oil and Gas Leasing Program 2012-2017 The Draft EIS/OEIS states "Areas off the Pacific coast are not included in the 2012-2017 Outer Continental Shelf Oil and Gas Leasing Program proposed by the U.S. Department of the Interior Bureau of Ocean Energy Management based upon an agreement signed by the governors of California, Washington, and Oregon in 2006 (Bureau of Ocean Energy Management 2011)." The second part of that sentence -- "based upon an agreement signed by the governors of California, Washington, and Oregon in 2006" -- is inaccurate and should be deleted because the states' agreement (documenting shared opposition to oil and gas development off their coasts) had no legal bearing or influence on the leasing program or on the Secretary's decision about which areas to exclude from the program.	The text in Section 4.3.2.1 (Proposed Outer Continental Shelf Oil and Gas Leasing Program 2012-2017) of the Final EIS/OEIS has been revised in accordance with this recommendation.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
USDOI-04	In addition, the states' opposition was only one of many factors that the Secretary considered. Table 4.3-1 indicates that the Proposed OCS Oil and Gas Leasing Program 2012-2017 is to be "retained" for further consideration in the Cumulative Impacts Analysis. However, since the leasing program does not include any Pacific Region areas and it therefore poses no potential impact to the areas addressed in the EIS/OEIS, BOEM recommends that the table be revised to indicate that the leasing program has been "dismissed" from further analysis. BOEM also advises that the Final OCS Oil and Gas Leasing Program 2012-2017 is scheduled to become effective on July 1, 2012, and that references to the "Proposed" program in the Draft EIS/OEIS should be changed to "Final".	These changes have been incorporated in the Final EIS/OEIS.
USDOI-05	Section 4.3.3 Offshore Power Generation This section of the EIS/OEIS should include a sub-section describing the OCS Renewable Energy Program, and the text in Section 4.3.3.1 (Marine Hydrokinetic Projects) should be revised to ensure consistency between the two sub-sections.	A new section describing the OCS Renewable Energy Program has been added to the Final EIS/OEIS, now Section 4.3.3.1 (Outer Continental Shelf Renewable Energy Program).
USDOI-06	The EIS/OEIS should also note that the Energy Policy Act of 2005 amended the Outer Continental Shelf Lands Act, authorizing the Secretary of the Interior to issue leases on the OCS for activities that produce or support production, transportation, or transmission of energy from sources other than oil and gas. The Secretary delegated these responsibilities to BOEM, which issued regulations for OCS renewable energy activities in April 2009. Those regulations, which were updated in 2011 to address reorganizational changes, establish a program to grant leases, easements, and rights-of-way for orderly, safe, and environmentally responsible renewable energy development activities, such as the siting and construction of offshore wind-generating facilities on the OCS, as well as other forms of renewable energy, such as wave, current, and solar. The Energy Policy Act of 2005 mandated that the Secretary of the Interior coordinate with affected State and local governments and federal agencies in developing the program and issuing leases for the development of renewable energy resources. BOEM has met this statutory requirement by establishing task forces with coastal states that have expressed interest in commercial development of OCS renewable energy resources.	This information does not contribute to the analysis of cumulative impacts and has not been added.
USDOI-07	1. The US Fish and Wildlife Service (Service) recommends that the following language be clarified or corrected in the final EIS/OEIS where it is found though-out the document: Under the ESA, [a specific activity] occurring at [location] under the No Action Alternative, Alternative 1, or Alternative 2 may affect, but are not likely to adversely affect, ESA-listed [specific species]. An assessment of effects is not made in the ESA (Endangered Species Act) per se, and while this is likely not the intent of these statements, as written they imply that the ESA is the reference document in which such determinations were made.	Changed throughout to "pursuant to the ESA…"

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
USDOI-08	2. Effects Determinations pursuant to section 7 of the Endangered Species Act of 1973 (Act), as amended (16 U.S.C. 1531 et seq.) The document concludes that all proposed training activities under all three alternatives (No Action, Alternative 1 and Alternative 2) may affect, but are not likely to adversely affect, any federally-listed species considered in the document. We recommend that an effects determination not be made solely on the basis of the information provided in the draft EIS/OEIS. Impacts to federally-listed species from training activities considered under the No Action Alternative in this document have been the subject of previous formal consultations with the US Fish and Wildlife Service (e.g., Biological Opinion on the U.S. Navy's Silver Strand Training Complex Operations, Naval Base, Coronado, San Diego, California; issued July 10, 2010) and some of the actions proposed under Alternatives 1 and/or 2 may have been, or will be, the subject of consultation as well. Hence, the statement is incorrect in some cases. The question of whether a proposed action has been sufficiently addressed under NEPA differs from an "effects determination" pursuant to section 7 of the Act.	The Navy has concluded formal consultation with the U.S. Fish and Wildlife Service (USFWS) and NMFS, in which previous formal consultations were also considered.
USDOI-09	3. Sediment Quality - Chapter 3.1-14 We recommend that the final EIS/OEIS provide more detailed information regarding sediment quality in San Diego Bay, and if possible, more current information (e.g., the reference documents for section 3.1.2.2.2 were dated 2002 and 2003). For example, could a figure analogous to the figure provided for the Hawaiian Islands (Figure 3.1-1) and a table similar to Tables 3.1-3 and 3.1-4, which provide information on sediment quality within the Hawaiian Islands and San Clemente Island, be provided for San Diego Bay? If there is more current, site-specific information regarding sediment quality, it would be helpful to have it available in the final EIS/OEIS. We recognize the scale and scope of the activities discussed in the draft EIS/OEIS may be such that more fine-scale information about sediment quality is not relevant to the proposed actions. Although we agree with the general conclusion that sediments in San Diego Bay are substantially free of chemical contamination, the broad conclusion seems counter to recent efforts to clean sediments at specific sites; e.g., La Playa Cove, 10th Street Marine Terminal. Does this EIS cover changes to berthing or hull maintenance? If so, the number of ships berthed within the Bay, and estimated contribution of these ships to contaminant load within different areas of the Bay, needs discussion. If a separate EIS evaluates the environmental impacts of ship berthing in San Diego Bay, reference to the document should be provided.	The information presented in the Draft and Final EIS/OEIS regarding sediment quality in San Diego Bay is the most current and relevant information. The Proposed Action does not include hull maintenance.
USDOI-10	4. Inclusion of Other Species We are providing you with a link to the Listing Workplan, a multi-year listing work plan describing the process to review and address more than 250 species listed on the 2010 Candidate Notice of Review to determine if they should be added to the Federal Lists of Endangered and Threatened Wildlife and Plants. We recommend you review this	Thank you for providing this information. These species were all considered in the development of the Draft EIS/OEIS.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	information to determine whether any candidate species within the Study Area warrant further review in the final EIS/OEIS. http://www.fws.gov/endangered/improving_ESA/listing_workplan.html	
USDOI-11	Page 3.6.63: The document addresses the issue of plastic ingestion by seabirds, and discusses the significance of plastic ingestion and seabird survival. However, the full impact of plastic ingestion on the population may be more important in the young rather than mature birds. Fry et al. (1987) showed that ingestion of plastic debris by Laysan albatrosses and wedge-tailed shearwaters chicks in the Hawaiian Islands resulted in a significant percentage of chicks with proventricular impactions or ulcerative lesions. The U.S. Geological Survey suggests that the Final EIS/OEIS include the Fry et al. (1987) description of the potential impact of plastic ingestion on chicks. The reference is: Fry, D. M.; Fefer, S. I.; Sileo, L. 1987. Ingestion of plastic debris by Laysan albatrosses and wedge-tailed shearwaters in the Hawaiian Islands. Marine Pollution Bulletin 18(6):339-343.	The information collected by Fry et al. (1987) has been included in the overall description of potential consequences of plastics ingestion. However, the overall risk to birds, and non-fledging chicks, remains low, as the distribution of plastics associated with training activities is less than 1 piece per square nautical mile. Further, the highest density of ingestible materials would be within the SOCAL Range Portion of the Study area, which does not overlap the areas utilized by foraging adults during the pre-fledging period of chicks.
U.S. Geological Survey (Written)	Thank you for forwarding the subject Draft EIS/OEIS for review and comment by the staff of the U.S. Geological Survey Pacific Islands Water Science Center. We regret however, that due to prior commitments and lack of available staff time, we are unable to review this document. We appreciate the opportunity to participate in the review process.	No response required.
Comments by State and Local Agencies and Elected Officials		
California Coastal Commission-01 (Written)	Thank you for the opportunity to comment on this DEIS/OEIS ("DEIS"). We will focus our comments on the implications for California's coastal species and populations of marine species which spend portions or all of their life cycle within the California coastal zone, impacts to either of which we believe clearly trigger the requirements of Section 307 of the federal Coastal Zone Management Act. We appreciate that the DEIS indicates the Navy's intent to comply with the Coastal Zone Management Act (CZMA), although the document could be clearer on this subject. The procedural discussion on pages 6-4 and 6-5 of the DEIS correctly spells out the applicable CZMA requirements; however the document does not clearly indicate whether the Navy intends to submit a consistency determination to the California Coastal Commission for the activities proposed in California's offshore waters. During the Commission's most recent two reviews of Navy SOCAL testing and training, Consistency Determinations CD-086-06 and CD-049-08, several differences of opinion between the Navy and the Commission arose concerning which activities were considered to involve effects on coastal zone resources, what thresholds should be relied upon in the determination of effects to marine mammals, and, most importantly, what minimization and mitigation measures should be employed to reduce such impacts. Modifications the Commission requested the Navy to consider during the most recent of these reviews (CD-049-08), are attached as Appendix A. Given	The Navy submitted a consistency determination to the California Coastal Commission for the entirety of the Southern California Training and Testing activities. Subsequent correspondence between the California Coastal Commission and the Navy is included in Appendix C (Agency Correspondence).

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	our past disagreements involving the extent to which activities affecting marine mammals in California ocean waters conducted outside the coastal zone (but affecting coastal zone resources, in our opinion), we would appreciate a clear statement that the Navy will be submitting a consistency determination for the entirety of the Southern California Training and Testing activities. We believe the DEIS only underscores the need for such a complete submittal, in that it contains far more expansive estimates (than contained in previous Navy analyses) of the potential for existing levels of training and testing activities to result in harassment of marine mammals (because the previous Navy analyses relied on higher decibel received levels for impact thresholds). Under the Navy's new analysis, harassment (as defined under the Marine Mammal Protection Act (MMPA) of marine mammals under existing, or "baseline," conditions, would be on the order of 10 times more extensive than previously acknowledged, with potentially up to 650,000 California marine mammals affected annually for baseline conditions (with the understanding that these numbers represent "pre-mitigation measure" estimates). In the DEIS the Navy further proposes significant increases to levels of training that would approximately triple the numbers of potential MMPA -defined harassments offshore California. While the harassment numbers have been based on impact definitions contained in the MMPA and Endangered Species Act, the extremely large numbers estimated provide indisputable evidence that the proposed activities can reasonably be considered to be resulting in effects on California's coastal zone resources, and, therefore, that the activities must be conducted in a manner consistent to the maximum extent practicable with the marine resource protection policy of the Coastal Act. This policy provides that: Marine resources shall be maintained, enhanced, and where feasible, restored. Special protection shall be given to areas and species of special biological or economic significance. Uses of the marine environment shall be carried out in a manner that will sustain the biological productivity of coastal waters and that will maintain healthy populations of all species of marine organisms adequate for long-term commercial, recreational, scientific, and educational purposes. To assist us in our analysis of the Navy's consistency determination for these activities, we request that the Navy provide the following information:	
CCC-02	1) A breakdown between California and Hawaii totals for numbers of estimated behavioral and Levels A and B harassments, and mortality, that separates the totals for California from those for Hawaii for the totals presented in the "boxed" discussions such as the one on page 3.4-169, which reads: Impact of sonar and other acoustic sources during training activities under Alternative 1: • May expose marine mammals up to 2,524,784 times annually to sound levels that would be considered Level 8 harassment, as defined by the MMPA • May expose marine mammals up to 441 times annually to sound levels that would be considered Level A harassment, as defined by the MMPA • May expose up to 2 beaked whales annually to sound levels that may elicit stranding	The consistency determination submitted to the California Coastal Commission included the breakdown as requested. Within the Draft and Final EIS/OEIS, the stock of each species indicates if the harassment was predicted for activities in the Hawaii or Southern California portion of the Study Area. For example, any Hawaii stock indicates a potential harassment from activities in Hawaii. All others are attributable to Southern California.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	and subsequent serious injury or mortality Under the ESA, the use of sonar and other acoustic sources during training activities as described in Alternative 1: • May affect, and is likely to adversely affect the humpback whale, sei whale, fin whale, blue whale, sperm whale, Hawaiian monk seal, Guadalupe fur seal, and the Hawaii insular stock of false killer whale • Would have no effect on Hawaiian monk seal critical habitat	
CCC-03	2) A summary of the conclusions the Navy has drawn from its "After-Action Reports" compiled for the past 5 years of Navy SOCAL testing and training.	"The Navy does not produce "After-Action Reports" since the beginning of NMFS' MMPA authorization in January 2009. Instead, the Navy provides NMFS Office of Protected Resources an annual summary of all SOCAL monitoring by 1 October of each year. Publically available copies of reports from 2009, 2010, 2011, and 2012 are available on NMFS's website: http://www.nmfs.noaa.gov/pr/permits/incidental.htm#applications Alternatively, the Navy has also sponsored establishment of a new public monitoring website at: http://www.navymarinespeciesmonitoring.us/ SOCAL specific reports can be downloaded at: http://www.navymarinespeciesmonitoring.us/reading-room/ (under "Southern California Range Complex") As required by the 2009 NMFS Final Rule for U.S. Navy Training in the Southern California Range Complex, the Navy submits an annual SOCAL Range Complex Monitoring Plan Report. The Navy's 2012 annual monitoring report to NMFS has just been delivered to NMFS for their internal review. Finally, a cumulative summary of annual report data acquisition and conclusions will be provided to NMFS in a pending report due at the end of November 2012. NMFS will conduct a 90-day review of that report before the Navy can make it public."
CCC-04	3) A follow-up to the discussion on page 3.4-136 which indicates that, while distress or unusual marine mammal behavior was not observed during past exercises: "Results of monitoring in HSTT are preliminary and data analysis is underway to determine if there is evidence of more subtle behavioral effects present in the data collected to date." [Emphasis added]	The latest information available on behavioral effects can be found on NMFS's website: http://www.nmfs.noaa.gov/pr/permits/incidental.htm#applications.
CCC-05	4) Any relevant data and findings from NOAA's Marine Mammal Underwater Sound Research program, in particular where this research looked into effects occurring during Navy SOCAL testing and training activities, and a discussion of the degree to which NOAA's research program intends to continue to coordinate with the Navy and monitor	The California Coastal Commission would have to ask NOAA for this information, but the Navy's monitoring information can be found at http://www.navymarinespeciesmonitoring.us/reading-room/

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	marine mammal reactions during future Navy training and testing activities.	
CCC-06	5) A clear explanation as to the reasons the Navy is proposing to increase its activities to the degree that would represent an approximately three-fold increase in California marine mammal harassment levels over current training (this increase is based on a cursory study of Tables 3.4-13 and 3.4-14, which provide individual species breakdown of effects between California and Hawaii). In looking at Tables 3.8-1 through 3.8-4, which list baseline and proposed Alternative 1 and 2 levels of activities, we are unable to discern why, or during which activities, such extensive increased levels of harassment would be expected to occur at the levels depicted in Tables 3.4-13 and 3.4-14.	The increase in harassment levels is due to several contributing factors that make it inappropriate to compare takes from the 2008 SOCAL EIS/OEIS: • An increase in training and testing activities and the inclusion of more activities and sources, such as pierside sonar testing, to meet emerging requirements • The 2008 EIS/OEIS included very little of the existing testing that is now included in this EIS/OEIS, much of which was covered under other environmental analyses. • This EIS/OEIS now includes a number of previously unanalyzed sound sources • Combined geographical areas (inclusion of both SOCAL and Silver Strand Training Complexes, and areas not previously analyzed such as San Diego Bay) • Included activities conducted along a transit corridor between SOCAL and Hawaii that account for additional potential harassments • Updated marine mammal density information that reflects current species abundance • New acoustic effects model that provides a more accurate prediction of animal movement and therefore, potential exposures • New acoustic threshold criteria based on the best available science that is more protective of marine mammals, extends the ranges to effects of sound sources, and results in higher numbers of predicted level A takes.
CCC-07	6) Information on the feasibility of debris removal. Tables 3.3-5 through 3.3-7 depict extremely large quantities of heavy metals, materials from munitions and explosives, and other debris that have been and will continue to be expended annually from the existing and proposed testing and training activities, about 85% of which appear to be in California offshore waters. As we have requested from the Navy in numerous past reviews of various proposals, we would appreciate an analysis of whether any of these materials could be retrieved and removed from the marine environment. For example, we note that over 20,000 parachutes are currently being expended in California waters each year (and this number is proposed to increase by over 50%, to approximately 37,000 under Alternative 2). Has the Navy studied how long it takes for these parachutes to break down in deep ocean conditions? Is it possible to retrieve some of these parachutes? We would appreciate a discussion of the feasibility of removal of these and other debris materials listed in these tables, as well as an analysis of their persistence in the marine environment if they cannot be removed.	While the Navy has not conducted specific studies on the time required for expended materials such as parachutes to decompose in the ocean, the information regarding potential effects of these materials to marine resources is included in Chapter 3 (e.g. for entanglement with Sea Turtles in Section 3.5.3.4.2, Impacts from Parachutes) of the EIS/OEIS. Of note, the Navy continues to look for ways to lessen its environmental impacts, including research into biodegradable parachutes, for example.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
CCC-08	Finally, we wish to commend the Navy for its current analytical framework, which we believe is more realistic than previous Navy analyses have acknowledged, and which accepts the possibility that greater numbers of marine mammals and other species may be occurring during Navy training and testing activities, in particular those activities involving mid-frequency sonar use. However we are disappointed that the proposed avoidance, minimization, and mitigation measures have, for the most part, remain relatively unchanged compared to those included in previous years' training and testing activities. As we pointed out that during our above-cited reviews of past Navy SOCAL training and testing activities, clearly any efforts the Navy adopts to further avoid or minimize loud mid-frequency sonar use in areas or seasons where significant concentrations of marine mammals are present, would also inherently benefit the Navy's testing and training itself, by reducing delays and stoppages necessitated by the presence of marine species in the mitigation zones. Accordingly, we again urge the Navy to consider incorporating measures such as those listed in Appendix A, including, to the maximum extent feasible, avoiding testing and training involving loud underwater noise generation in areas (and/or seasons) with significant concentrations of marine mammals, adoption of larger mitigation safety zones, reduced power during periods of reduced visibility and when surface ducting is present, increased monitoring during choke point exercises, and expanded baseline monitoring. Thank you for this opportunity to comment on this important military program EIS/OEIS. If you have any questions about these information requests, or about preparation of a consistency determination, please feel free to contact me at (415) 904-5289.	Through careful exploration of all mitigation measures to determine which were the most effective, the Navy has chosen the measures that will mitigate potential impacts to marine mammals while still being able to meet its operational needs to train for real world conditions. Specific mitigation measures are outlined in the following sections: Section 5.3.1 (Lookout Procedural Measures), Section 5.3.2 (Mitigation Zone Procedural Measures), and Section 5.3.3 (Mitigation Areas). Specifically, Section 5.3.3.1 (Marine Mammal Habitats) addresses important habitat areas. The Navy used the best available data (including data on animal density, distribution, and occurrence) to support its impact analyses in the DEIS/OEIS. Variability in animal presence within relatively small ocean sub-areas is often strongly correlated with daily, weekly, seasonal, and even decadal changes in prey availability, with prey availability being driven by changes in both local and basin-wide oceanographic conditions. Any specific area of high animal density at a given time may have low animal density the following day, week, or year, depending on the biotic and abiotic factors affecting the prey distribution. Blue whales, for example, "integrate food resources (i.e., search for food) over a large area due to the dietary needs of such a large animal" (D. Crull, UCSC, personal communication 2007). Operationally, there is some variability in where Navy major exercises may occur within the SOCAL Range Complex. Location is determined by individual strike group needs. Furthermore, exercises are relatively short in duration (hours to days) and separated in time, so no ocean area within SOCAL OPAREAs is subject to continuous sonar use. Finally, it must be acknowledged that ASW activities have been conducted without incident for decades in SOCAL OPAREAs. In fact, many populations of Endangered Species Act (ESA) species and non-ESA species alike have been increasing in SOCAL OPAREAs over the last several decades. Given the natural variation of marine mammal location over time within the SOCAL OPAREAs, operational variability of Navy ASW operations, and the absence of scientific information demonstrating broad-scale impacts that are either injurious or of significant biological impact to marine mammals, there is little relative risk to marine mammal populations from ASW training exercises.

Commenter	Comment	Navy Response
California Office of Historic Preservation (Written)	Pursuant to 36 CFR Part 800, the regulations implementing Section 106 of the National Historic Preservation Act, the United States Navy (Navy) is requesting my concurrence with a finding of No Historic Properties Affected. The Navy plans to renew training and testing activities in the waters off of Southern California, Hawaii, and the Open Ocean Transit corridor between these two regions. The majority of activities off of California will occur within the Southern California Operating Area (OPAREA), including the waters surrounding San Clemente Island, boat lanes and anchorages offshore of the Silver Strand Training Complex (SSTC), and the bayside training areas within San Diego Bay. Activities specific to this undertaking include gunnery and explosive exercises as well as the use and maintenance of sonar equipment. The project area also includes select pier side locations within San Diego Bay where Navy surface ship and sonar maintenance testing occurs. The Navy defines the Area of Potential Effects (APE) for this activity as the open ocean areas in the Southern California Range Complex with the OPAREA, and boat lanes and anchorages offshore of the SSTC, including the bayside training areas within San Diego Bay. In addition to your letter, you have provided maps and a CDR containing environmental studies undertaken in the project area. Training and testing activities are consistent with actions currently conducted in the above-referenced areas. For example, artillery and explosive exercises will take place within the Open Ocean or near-shore areas, away from where there are any known cultural or historical resources. Pile driving for elevated causeway training at SSTC will subject near shore sediments to vibration, disruption, and compaction at SSTC and will occur only in the Oceanside Boat Lanes 1-10 and in the Bayside Bravo Training Area. Proposed activities area consistent with activities currently conducted in these areas. Having reviewed your submittal, I concur with your Finding of Effect. I also agree that you have adequately determined the undertaking's APE. Please be advised that in the event of a change in project description or an inadvertent discovery, you may have additional responsibilities under 36 CFR Part 800.	Thank you for participating in the NEPA process.
California State Lands Commission-01 (Written)	After review of the information provided and in-house records, CSLC staff has determined that the proposed project will be located within: • Ungranted sovereign lands of the Pacific Ocean and under the leasing jurisdiction of the CSLC. • Lands granted to Orange County pursuant to Chapter 321, Statutes of 1961, with minerals reserved to the State. • Lands granted to the city of Oceanside pursuant to Chapter 846, Statutes of 1979, with minerals reserved to the State. • Lands granted to the city of San Diego pursuant to Chapter 937, Statutes of 1931, with minerals reserved to the State. • Lands granted to the city of San Diego pursuant to Chapter 688, Statutes of 1933, with mineral reserved to the State.	No dredging activities are part of the Proposed Action.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	• Lands granted to the city of San Diego pursuant to Chapter 2139, Statutes of 1963, with minerals reserved to the State. • Lands granted to the city of San Diego pursuant to Chapter 2140, Statutes of 1963, with minerals reserved to the State. • Lands granted to the U.S.A. pursuant to Chapter 89, Statutes of 1937, with minerals reserved to the State. • Lands granted to the city of Avalon pursuant to Chapter 303, Statutes of 1943, with minerals reserved to the State HSTT activities proposed in areas of ungranted sovereign lands under the leasing jurisdiction of the CSLC may require a lease from the CSLC. Additionally, any dredging activities on ungranted sovereign lands, or granted lands for which minerals were reserved for the State, would require a dredging lease from the CSLC. The CSLC's surface lease application can be found at www.slc.ca.qov. Please contact Michelle Andersen, Public Land Manager, at the number listed at the end of this letter regarding any questions regarding leasing.	
CSLC-02	Additionally, the EIS/OEIS indicates on page 2-40 that training and testing activities may include Synthetic Aperture Sonar, "in which active acoustic signals are post-processed to form high-resolution images of the seafloor." Please be aware that geophysical and geological surveys conducted in State waters require a geophysical survey permit from the CSLC pursuant to California Public Resources Code section 6826. For more information on these survey permits, please contact Richard Greenwood at the contact information listed at the end of this letter.	The Navy is not proposing to conduct geophysical or geological surveys under the Proposed Action of this EIS/OEIS.
CSLC-03	Although the EIS/OEIS specifies that certain activities, such as anti-submarine warfare training events, would occur further offshore and outside of State jurisdictional waters, and that certain activities, such as mine-detection sonar, would generally occur in shallower waters, the EIS/OEIS lacks an overall, broader discussion or table, separately identifying the training and testing activities that might occur in state waters and, therefore, potentially affect California's public trust resources. Although CSLC staff understands that the particular location and frequency of the various Project activities at any given time change according to the Navy's needs, CSLC staff requests that the EIS/OEIS provide further information on activities that may occur in California state waters and, if available, an estimate of the frequency of particular activities in State waters. Such a discussion would help CSLC staff with leasing and management activities in the Study Area, both with the Navy and other lease applicants or lessees, and would be useful in determining potential use conflicts with other ocean users in the Study Area in the future.	The flexibility required by the Navy in conducting realistic training means that some activities' locations require broad definitions. To the level of detail that the activities can be predicted, they are described in Chapter 2 of the EIS/OEIS, and specifically in Tables 2.8-1 through 2.8-5. Further, the activities described in this EIS/OEIS are similar in type, frequency, and location as those conducted for decades in the Southern California area.
CSLC-04	The EIS/OEIS should also mention that the title to all abandoned shipwrecks, archaeological sites, and historic or cultural resources on or in the tide and submerged lands of California is vested in the State and under the jurisdiction of the CSLC. The	The Draft EIS/OEIS included language regarding the Abandoned Shipwreck Act in Section 3.0.1.1 (Federal Statutes). This text has been revised in the Final EIS/OEIS to include language that the Act

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	recovery of objects from any submerged archaeological site or shipwreck may require a salvage permit under Public Resources Code section 6309. On statutorily granted tide and submerged lands, a permit may be issued only after consultation with the local grantee and a determination by the CSLC that the proposed salvage operation is not inconsistent with the purposes of the legislative grant. CSLC staff requests that the Navy consult with Senior Staff Counsel Pam Griggs at the contact information noted at the end of this letter, should any cultural resources be discovered during Project activities.	stipulates title to shipwrecks that meet the criteria for inclusion in the National Register of Historic Places will be transferred to the appropriate State.
CSLC-05	Thank you for the opportunity to comment on the EIS/OEIS for the Project. Because part of the proposed Project involves use of State sovereign lands and may require issuance of a lease or permit, the CSLC would need to rely on an environmental document that meets CEQA requirements. The CSLC will review the final document and determine whether it has met the requirements identified in this letter for use in lieu of a separate EIR. If it does not, the CSLC would be required to prepare and circulate a separate environmental document that complies with CEQA prior to taking action on approval of a lease or permit.	Thank you for your comment. The Navy looks forward to continuing the good relationship and communication with the California State Lands Commission.
City of Coronado, Community Development-01	Section 2.7.1 Proposed Adjustments to Baseline Training Activities p. 2-64: This section describes the various adjustments but with the exception of two activities, does not indicate where these adjusted training activities will occur. What training activities of those listed will occur within the SSTC?	Section 2.7.1 (Proposed Adjustments to Baseline Training Activities) is a summary of changes that are more fully described in Table 2.8-1, where the location for each activity is listed. As shown in Table 2.8-1, the changes from current activity (the No Action Alternative) to proposed activities (Alternatives 1 and 2) within SSTC would be 1) the increase in underwater detonations in the SSTC Boat Lanes from 408 annually to 414 (p. 2-92), 2) an increase in the annual number of airborne mine countermeasure – mine detection activities—in the Boat Lanes from 248 to 372 (p. 2-93), 3) an increase in the number of mine neutralization – remotely operated vehicle activities from 208 annually to 312 (p. 2-04), and 4) a decrease in the number of annual marine mammal system activities from 208 to 175 (p. 2-94).
Coronado-02	Section 2.7.2 Proposed Adjustments to Baseline Testing Activities p. 2-67: Similar comment as above. This section describes the adjustments to the baseline testing activities; however does not identify the areas where this would occur. What components of the SSTC testing activities would be adjusted? Please clarify the acronym OPAREA that is referenced several times in Section 2.7.2 above. Does it stand for Ocean Operating Areas Outside the Bounds of Existing Range Complexes?	Section 2.7.2 (Proposed Adjustments to Baseline Testing Activities) is a summary of changes that are more fully described in Tables 2.8-2 through 2.8-5, where the location for each testing activity is listed. No testing activities are proposed to be conducted at SSTC. As described on p. 2-3 of the EIS/OEIS, an OPAREA stands for "Operating Area." The full definition and two examples are included on p. 2-3.
Coronado-03	Proposed Platforms and Systems p. 2-68. Aircraft F-35 Joint Strike Fighter: The document notes that the F-35 Joint Strike Fighter Lightning II will complement the Navy's F/A-18E/F and the F-35 is expected to make up about one-third of Navy's strike inventory by 2020. It notes the F-35 will operate similarly to the	The purpose of the HSTT EIS/OEIS is to analyze only the training and testing activities associated with the F-35 aircraft and other new systems and platforms. Homebasing actions for the F-35C are addressed in the EIS for U.S. Navy F-35C West Coast Homebasing.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	aircraft it replaces or complements, and that no new activities will result from the introduction of the F-35. Where will the F-35 be home-based? Will it be at NASNI? What type of supportive facilities will be required for general maintenance/service/housing of the replacement F-35's? What about personnel changes associated with the F-35? How do the noise levels generated by the aircraft compare? EA-18G Airborne Electronic Attack Aircraft: This aircraft will replace the EA-6Bs and operate in similar training areas and capacities. The same question as noted for the strike fighter applies to the EA-18G. Where will these be home-based? What types of new supportive facilities will be required, personnel, etc? How much noise does this aircraft generate in comparison to existing?	The draft EIS was released for public review in February 2013 and is available for review at: http://www.navyf35cwestcoasteis.com. Navy prepared an EA in November 2005 addressing the replacement of the EA-6B by the EA18-G in 2005 and signed a Finding of No Significant Impact on July 19, 2005. The decision was to homebase all EA-18G aircraft at NAS Whidbey Island, WA. However, these aircraft will conduct training in the HSTT Study Area.
Coronado-04	Proposed Platforms p. 2-68. Ships The document indicates the CVN-21 Program is designed to replace the Nimitz class carriers with the first carrier CVN 78 expected in 2015. Where will this new carrier be home-based, at NASNI? What type of new supportive/maintenance facilities will be required? How frequently is maintenance required? How many new personnel are associated with this carrier?	The purpose of the HSTT EIS/OEIS is to analyze only the training and testing activities associated with the CVN-21 and other new systems and platforms. All homeporting questions raised in the comment are not associated with this study, and would be addressed in separate Navy homeporting environmental planning documentation.
Coronado-05	Proposed Platforms p. 2-71 Missiles/Rockets/Bombs The document indicates Guided Rocket Systems will be introduced and used on the MH-60 helicopters. The MH-60's were recently relocated to NASNI. Where will this new training take place with the rocket systems and MH-60's and how many events over a month and year's period are expected to occur and what is the decibel level? Kinetic Energy Weapons will use electromagnetic kinetic energy weapons to accelerate projectiles to supersonic velocities. It notes these weapons will be operated from ships, firing projectiles toward land targets. What land area would be recipient of firing projectiles? Would this occur within the SSTC? It is not clearly identified where many of the other platforms will occur. Clarify which activities would occur within the SSTC.	The annual number and location of all training activities are included, along with any ordnance expended, in Table 2.8-1, beginning on p. 2-77 of the Draft EIS/OEIS. Regarding the rocket systems, all missile and rocket firings would occur well offshore, beyond sight and hearing of Southern California. The only use of kinetic energy weapons would be testing at the Pacific Missile Range Facility in the Hawaii Range Complex. Neither the kinetic energy weapons testing, nor any missile or rocket firings would occur in or near SSTC.
Coronado-06	Proposed New Activities: p. 2-73 Where will the surface-to-surface missile exercises occur? What will be the frequency of these exercises and how much noise will be generated?	The annual number and location of all training activities are included, along with any ordnance expended, in Table 2.8-1, beginning on p. 2-77 of the Draft EIS/OEIS.
Coronado-07	Alternative 2 p. 2-74 Alternative 2 is the preferred alternative and identifies the establishment of new range capabilities as well as adjustments to type and tempo of training and testing and establishment of additional locations to conduct activities between the range complexes. Please clarify what type and quantity of "adjustments" will be made to type and tempo of training and testing as it relates to SSTC. Will the training be intensified beyond what was addressed in the EIS completed for the SSTC? The EIS for the SSTC indicated there would not be measurable increases in personnel or associated traffic; however, the City disagreed. Again, there appears to be an	The annual number and location of all training activities are included, along with any ordnance expended, in Table 2.8-1, beginning on p. 2-76 of the Draft EIS/OEIS. As shown in Table 2.8-1, no activities located at SSTC will increase over those analyzed in the SSTC EIS.

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	incremental expansion of activities, noise, personnel and associated traffic within Coronado due to expanded/intensified operations; notably, p. 2-75 indicates a 10% increase; however, these impacts are not being analyzed nor is any mitigation proposed.	
Coronado-08	Table 2.8-1 Baseline and Proposed Training Activities: There are significant increases in activity levels with the preferred alternative 2. Revise/clarify the table to clearly illustrate where the activities within the SOCAL area will occur. Please clarify volumes/activities within the SSTC.	The activities listed in Table 2.8-1 are described both by location, and by number of annual events. Those occurring at SSTC clearly state SSTC under "Location" in the table. If an activity does not specifically list SSTC, then it would not occur there.
State of Hawaii, Department of Business, Economic Development, and Tourism, Office of Planning	It is the responsibility of the Department of the Navy, pursuant to 15 CFR 930, Subpart C, to demonstrate to the Hawaii CZM Program that the activities proposed in the HSTT EIS/OEIS remain consistent with the activities outlined and conclusions made in the 2008 Hawaii Range Complex EIS/OEIS CZMA coastal consistency determination. The 2009 Navy De Minimis Activities List is not applicable to activities that are subject to the EIS level of NEPA compliance, such as the activities included in the HSTT EIS/OEIS. We will provide the Navy with guidance and assistance for consistency determinations in accordance with 15 CFR 930.34(d), if requested. In order for the Hawaii CZM Program to provide consistency guidance, the Navy must identify and compare the activities proposed in the HSTT EIS/OEIS with the activities included in the 2008 Hawaii Range Complex EIS/OEIS CZMA coastal consistency determination. Specifically, activities that must be identified include: activities that are new and/or different from those activities reviewed in 2008; activities that are a continuation of the activities reviewed in 2008; and activities that are a continuation of the activities reviewed in 2008, but have changed in scope, size, operation, scale, intensity, and/or frequency. This information is necessary to identify the applicable Hawaii CZM Program enforceable policies. Continuity of consistency from the Navy's 2008 federal consistency determination cannot be presumed for the HSTT activities. In order for us to determine whether the 2008 HRC CZMA consistency determination can be applied to the HSTT activities, the Navy must provide a comparative CZMA consistency analysis between the 2008 HRC activities and the HSTT activities. It is our position that a new CZMA consistency determination is required for HSTT activities, as explained in response no. 3, below. The 2009 Navy CZMA De Minimis Activities List, which was developed cooperatively by the Hawaii CZM Program and the Department of the Navy, and approved by the Office of Planning on July 9, 2009, is not applicable to activities that are subject to the EIS level of NEPA compliance. EIS level activities, such as the activities included in the HSTT EIS/OEIS, are not de minimis activities. Therefore, we disagree with the application of the Navy CZMA De Minimis Activities List to HSTT activities. We disagree with the Navy's position that, "no further CZMA federal consistency review is required." A CZMA consistency determination is required for all HSTT activities that were not previously reviewed by the Hawaii CZM Program. The HSTT EIS/OEIS by itself does not fulfill the content requirements of a consistency determination. The required	The Navy submitted a Consistency Determination to the State of Hawaii for the entirety of the Hawaii Training and Testing activities. Subsequent correspondence between the Hawaii Office of Planning and the Navy is included in Appendix C (Agency Correspondence).

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	content of a consistency determination is identified in 15 CFR 930.39. The CZM consistency determination must also include the activities that were reviewed m the 2008 HRC EIS/OEIS CZMA coastal consistency determination, but have either changed, will result in a cumulative impact with the new HSTT activities, or were issued consistency objections that remain unresolved. In addition, information in the HSTT EIS/OEIS that was not available to us in 2008 will cause us to reevaluate previously reviewed activities. For example, the 2008 Hawaii Range Complex Final EIS/OEIS, Section 4.1.2.3 Environmental Consequences- Sea Turtles, indicates that activities proposed under Alternatives 1 and 2, i.e., sonar use and underwater detonations, would not affect sea turtles, and for compliance under ESA the "Navy finds that these activities are not likely to affect green, olive ridley, loggerhead, hawksbill, or leatherback sea turtles." However, the HSTT Draft EIS/OEIS, Section 3.5 Sea Turtles, indicates that activities involving acoustic stressors, physical disturbances, and strike stressors, "may affect and are likely to adversely affect green, hawksbill, olive ridley, leatherback, and loggerhead sea turtles." The substantial difference in reported anticipated impacts to sea turtles, which are State of Hawaii coastal resources, warrants supplemental federal consistency review pursuant to 15 CFR Section 930.46. There is also new evidence that Navy SINKEX exercises can cause spikes in PCB levels in fish (Honolulu Star Advertiser, March 5, 2012). This new information will cause us to reevaluate our previous consistency concurrence for SINKEX. Please note that the Office of the Planning is the authorized lead agency for the Hawaii CZM Program. All future correspondence regarding the Hawaii CZM Program should be sent directly to the Office of Planning at the above mailing address. We are confident that we can arrive at a solution that allows the Navy to carry out its mission while ensuring consistency with the CZMA, both of which are important to the public health and safety of the people of the United States. If you have any questions, please call John Nakagawa of our CZM Program at 587-2878.	
State of Hawaii, Department of Health, Environmental Planning Office	The Department of Health (DOH), Environmental Planning Office (EPO), acknowledges receipt of your letter, dated May 3, 2012. Thank you for allowing us to review and comment on the subject document. The document was routed to the various branches of the Environmental Health Administration. We have no comments at this time, but reserve the right to future comments. We strongly recommend that you review all of the Standard Comments on our website;. www.hawaii.gov/health/environmental/env-planning/landuse/landuse.html. Any comments specifically applicable to this application should be adhered to. The United States Environmental Protection Agency (EPA) provides a wealth of information on their website including strategies to help protect our natural environment and build sustainable communities at: http://water.epa.gov/ infrastructure/sustain/ . The DOH encourages State and county planning departments, developers, planners, engineers and other interested parties to apply these strategies and environment	Thank you for participating in the NEPA process.

Commenter	Comment	Navy Response
	principles whenever they plan or review new developments or redevelopments projects. We also ask you to share this information with others to increase community awareness on healthy, sustainable community design. If there are any questions about these comments please contact me.	
State of Hawaii, Department of Land and Natural Resources-01	The Department of Land and Natural Resources (Department) has reviewed the Navy's Hawaii-Southern California Training and Testing Activities Draft Environmental Impact Statement/Overseas Environmental Impact Statement (DEIS/OEIS) made available in May, 2012. We understand that this DEIS/OEIS supports a request for a new letter of authorization for incidental take of marine mammals for January 2014 through December 2018. We also understand that a Marine Mammal Protection Act letter of authorization for the take of marine mammals may require the National Marine Fisheries Service to support additional mitigation measures or monitoring beyond those contained in the DEIS/OEIS. The Department has concerns that the DEIS/OEIS does not acknowledge the scientific documentation of strandings of marine mammals that may be associated with the types of activities proposed by the Navy. For example, the work of Wang & Yang (2006) indicating pygmy killer whales stranded in Taiwan as a result of active sonar & seismic operations is dismissed as "not supported by the data available" on page 3.4-45. In addition, there is no mention of the concurrent and unusual melon-headed whale activity in Hanalei Bay, Kaua'i and Sasanhaya Bay, Rota, Northern Mariana Islands in 2004. These "strandings" are both included in the report "Marine Mammal Strandings Associated with U.S. Navy Sonar Activities" (April 2012) associated with the Atlantic Fleet Training and Testing EIS (http://aftteis.com/Portals/4/aftteis/Supporting%20Technical%20 Documents/Marine%20Mammal_Stranding_Report_ v02.pdf). We suggest that the Hawaii-Southern California DEIS/OEIS include details of the Hanalei Bay incident and that it acknowledge the heightened risk for certain species documented to strand during Naval activities. In addition to melon-headed whales, beaked whales are considered to be especially vulnerable to injury and death associated with Navy sonar (five beaked whale stranding events with potential links to Navy sonar activity are described in the Atlantic EIS cited above). Although such strandings of beaked whales associated with Naval exercises have not been seen in Hawai'i, the science indicates that animals affected by Navy sonar in Hawai'i may not be easily detectable (Faerber and Baird 2010). We recommend that the Navy expand its description of potential impacts to include a more thorough treatment of historical stranding information as done for the Atlantic EIS and acknowledge that species such as melon-headed whales and beaked whales have higher risks for injury and death to sonar. Potentially, a variable regarding higher risk should be incorporated into the model for calculating the take of these species.	The Navy fully acknowledged and considered all relevant and applicable research regarding strandings. The reference cited in the comment was evaluated as described in the EIS/OEIS. Regarding additional research, the Marine Mammal Stranding Report is included on the HSTTEIS.com website on the "Documents and References" page, under "HSTT Documents" and "Supporting Technical Documents." See: http://hstteis.com/DocumentsandReferences/HSTTDocuments/SupportingTechnicalDocuments.aspx

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
Hawaii DLNR-02	Page 3.4-95 of the DEIS/OEIS states, "As a result, no marine mammals addressed in this analysis are given differential treatment due to the possibility for acoustically mediated bubble growth." Regardless of the mechanism, it is clear that certain species, like the beaked and melon-headed whales, are affected by mid-frequency sonar. Bemaldo de Quiros et al. (2012b) found that deep diving marine mammals have a higher risk of decompression illness; that risk should be considered in terms of how this affects the level of take associated with sonar activities. New approaches for examining whether decompression has occurred have recently been published and should be included in established protocols for necropsy (Bernal do de Quiros et al. 2012a, 2012b).	The potential risk from sonar and other sound sources affecting the behavior of marine mammals, including the potential for acoustically mediated bubble growth, was taken into account in the Draft EIS/OEIS analysis. The discussion of this phenomenon is presented in the EIS/OEIS in Section 3.4.3.1.2.2 (Nitrogen Decompression). As noted in that section, recent modeling by Kvadsheim, Miller, et al. (2012) determined that while behavioral and physiological responses to sonar have the potential to result in bubble formation, the actually observed behavioral responses of cetaceans to sonar did not imply any significantly increased risk of over what may otherwise occur normally in individual marine mammals. The reports cited in the comment (Bernal de Quiros et al. 2012a, 2012b) were reviewed, but do not add any substantive new information to the analysis of proposed actions covered in this EIS/OEIS.
Hawaii DLNR-03	Although not described in detail, five stranding events identified as including U.S. Navy exercises as a contributing cause are listed on page 3.4-113. This and other stranding events illustrate the need for mitigation plans for live and dead strandings. Although we are aware that the Navy has participated in carcass removal and necropsy in past strandings in Hawai'i, we encourage the Navy to develop a more formal mitigation plan as part of the DEIS/OEIS. We understand that a regional stranding implementation plan is being developed collaboratively between the Navy and NOAA. We encourage the Navy (and NOAA) to seek input from the State (and territories) and to incorporate cultural considerations into protocols. This does not require the Navy to take formal responsibility for causing any marine mammal stranding, but it would make the Navy a formal partner in the activities necessary to deal with stranded animals. This should include monetary support for removal of animals and appropriate necropsy and sampling.	Although the comment is correct in that the EIS discusses five stranding events, including this discussion is for comprehensiveness and not meant to infer that Navy was a contributing cause to each of those strandings. Regarding the second part of the statement, in 2009, the Navy and NMFS developed stranding protocols and plans for each range complex that provide guidelines for response to strandings during Navy major training exercises (MTEs). Additionally, the Navy and NMFS signed a National MOU (PR-055) for stranding investigations that establishes a framework consistent with federal fiscal law requirements whereby the Navy may assist NMFS with response to and investigation of Uncommon Stranding Events (USEs) during MTEs. One component of the MOU is the regional stranding implementation plans (RSIAP) for Hawaii and Southern California that you reference. The RSIAPs delineate what the Navy and NMFS can contribute in regards to services in response to a marine mammal stranding during an MTE. The RSIAP does not have provisions for directing NOAA's handling of the stranding (including cultural practices), guiding the necropsy, nor specify direct Navy financial participation. Instead it provides guidance on things such as access to Navy installations for necropsies, availability of specialized equipment and other logistic considerations to assist stranding investigations.
Hawaii DLNR-04	Because the Navy's model of biologically significant population consequences of Navy activities included abundance estimates, the Navy DEIS/OEIS analyzed what are now considered separate populations of marine mammals associated with individual Hawaiian Islands regions. This is biologically inappropriate and does not account for the	The analysis of impacts to marine mammals in the Hawaiian Islands uses the best available science and was undertaken with National Marine Fisheries Service (NMFS) in a role as a cooperating agency for the EIS/OEIS. This included review and comment by NMFS staff

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	lack of dispersal among island regions. Because populations of many odontocete species are scientifically documented to be local and island-associated, an analysis of impact by population is necessary to assess affects to these populations. If this assessment cannot be performed now because of the need to use abundance estimates in the model, we suggest the following. These local populations are separate should be acknowledged and described, with a full literature review, in the DEIS/OEIS. The letter of authorization and DEIS/OEIS should also include language that reflects a commitment to do new calculations as abundance estimates become available. With the new Guidelines for Marine Mammal Stock Assessments being finalized and the new research that is becoming available, there should be new abundance estimate determinations for many of these stocks before the next reauthorization.	marine biologists in their role as the federal regulator for the Marine Mammal Protection Act (MMPA). Full and complete information was provided in the EIS/OEIS (see Section 3.4, Marine Mammals) with regard to the present knowledge regarding stocks ("populations") of marine mammals. This includes coordination with NMFS scientists on the latest emergent data presented in the draft Pacific Stock Assessment Report for 2012 which had yet to be finalized (as of Nov 2012). NMFS will determine the appropriate Terms and Conditions for the MMPA Letter of Authorization and the Navy will continue to coordinate with them in their regulatory role.
Hawaii DLNR-05	The Department supports the continued implementation of Marine Species Awareness Training and the use of lookouts. We suggest that mitigation measures should also include passive acoustic monitoring to help detect cryptic and long-diving marine mammals. The DEIS/OEIS mentions that marine mammals are sometimes detected this way, but does not include passive acoustic detection in protocols for mitigation, with the exception of increased vigilance by lookouts. Passive acoustic detection and localization of marine mammals has progressed significantly in the last few years. The Journal of the Acoustical Society of America will be publishing a special issue on methods for marine mammal passive acoustics later this year. We encourage the Navy to continue to get the latest information to inform mitigation that includes passive acoustic monitoring and detection.	The Navy is using both passive acoustic monitoring and visual detection when feasible, and will continue to use the latest information in developing mitigation measures. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring), there are limitations to the effectiveness of passive acoustic monitoring. Passive systems are capable only of detecting vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals.
Hawaii DLNR-06	The Navy's main mitigation measures include visual detection within a radius of the activity and cessation of the activity until the marine mammal has not been seen for 30 minutes. This may not cover the beaked whales and sperm whales well, as these species can be submerged for more than an hour at a time. We suggest movement to a new area or at least an hour without seeing these species before restarting activities. We also encourage as much wait time as possible for cryptic species that are difficult to see, such as pygmy and dwarf sperm whales.	Dive behavior varies amongst species. As described in the Dive Distribution and Group Size Parameters for Marine Species Occurring in Navy Training and Testing Areas in the North Atlantic and North Pacific Oceans technical report, a 30 minute waiting period accounts for the dive capabilities typical of most species. Post-sighting activity recommencement wait periods longer than 30 minutes would be impracticable to implement and would decrease realism of activities. For activities involving platforms restricted by fuel or other constraints (e.g., helicopters), the wait times have been adjusted based on operational need and practicability of implementation. A discussion of the effectiveness of each wait time is provided in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) for each activity. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal surveys, are generally available to Navy Lookouts on board vessels over 60'. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		are present, there are always more than the "one or two personnel" described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website. Lastly, species-specific identification of marine mammals is not a Lookout requirement; therefore, a single activity-specific waiting time is needed for all species.
Hawaii DLNR-07	The Navy acknowledges on page 3.4-92 that long-beaked dolphins have been directly killed by Navy activity in an incident involving explosives. This illustrates the importance of the use of mitigation zones. Some odontocetes are more cryptic and surface less often than long-beaked dolphins. As such, we recommend that the Navy not reduce any of the mitigation zones used in the previous EIS/OEIS. Smaller mitigation zones, as proposed in the DEIS/OEIS, will only increase risk to marine mammals. Even if animals are not at risk for direct injury by the sound, it is clear that behavioral responses of marine mammals can be contributing factors to injury and death, suggesting that mitigation zones should be conservatively large to account for behavior-induced injury.	The Navy revised its mitigation measures following the incident described in the comment. The mitigation measures for explosives training using both positive control firing devices and time-delay firing devices are described in the Final EIS/OEIS in Sections 5.3.2.1.2.4 and 5.3.2.1.2.5 respectively. The decrease in mitigation zone size will allow for a more focused survey effort over a smaller area, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals.
Hawaii DLNR-08	The Department is aware that the Navy has considered and discarded a list of mitigation measures described on pages 5-52 and 5-53. The Department encourages the Navy to reconsider some of these measures. These include sharing marine mammal sighting data to augment scientific information, minimizing testing and training activity that takes place during sea states or light levels at which marine mammals are unlikely to be seen by, and avoiding "hot spots" of marine mammal activity, particularly for those animals that are listed or candidate species under the Endangered Species Act. The Navy should identify known "hot spots" for species and preferentially avoid hot spots for Endangered, Threatened, and Candidate marine mammals unless deemed necessary. There is already some mitigation of that nature in place for humpback whales. There is research on monk seal and false killer whale movements (e.g. Baird et al. 2012) that should be considered in the DEIS/OEIS as areas to avoid Navy activity if possible. The Department recognizes that the Navy must have the flexibility to train and test under a variety of circumstances, but we encourage the Navy to avoid training and testing in and near any state marine protected areas as much as is possible.	The Navy's overall approach to assessing potential mitigation measures was based on two principles: (1) mitigations will be effective at reducing potential impacts on the resource; and (2) from an operational perspective, the mitigations are practicable and executable while not compromising safety and readiness. Through extensive discussion, NMFS and Navy have identified mitigation measures that are practicable and reasonably effective. For example, the safety zones proposed will reduce the likelihood of physiological harm, the number of marine mammals exposed, and the intensity of those exposures. With regard to sharing marine mammal sighting data, the Navy has adopted an integrated comprehensive monitoring program (see Final EIS/OEIS Section 5.5, Monitoring and Reporting) that does provide information that is available and useful to the scientific community in annual monitoring reports. The Navy has proposed several Mitigation Areas (such as the Humpback Whale Cautionary Area), and the mitigation measures identified throughout Chapter 5 will apply to all marine mammals year round, and will be applied regardless of the location of the activity. However, any future

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
		determination of "hot spots" or biologically important areas will require an intense effort in gathering expert opinion. In that regard, Navy has, and will continue to support the Cetacean and Sound Mapping (CetMap) project, including representation on the CetMap Density and Distribution Mapping Working Group. Navy is an active sponsor and participant in CetMap, and the CetMap process is based on the same process Navy used to estimate population density in the HSTT EIS/OEIS and LOA Application. In 2012, the CetMap panel of experts determined that no biologically important areas (the panel determined that "hot spots" is not an appropriate term) could be identified based on data availability and information at hand. Furthermore, no follow-on products have identified areas of recommended avoidance. It is important to note that the areas appearing on the CetMap website are a preliminary draft that needs considerable additional input from the larger biological community before being used to identify biologically important areas in the ocean.
Hawaii DLNR-09	The DEIS/OEIS states that no consultation is needed with the Hawaiian Islands Humpback Whale National Marine Sanctuary (HIHWNMS) and for the new letter of authorization. As the co-manager of the HIHWNMS, the State of Hawai'i disagrees with this point. We request that the Navy engage in a formal consultation with the HIHWNMS, as the preferred alternative (2), does include changes to activities and level of activities that could affect humpback whales. The DEIS/OEIS also includes information to support the LOA request to increase in the number of vessel strikes to large whales. We are supportive of the mitigation already in place for protecting whales in sanctuary waters, but we believe a new consultation is needed with the new proposed activity in alternative 2. The National Marine Sanctuaries Act and the implementing act of the HIHWNMS allow management of activities outside sanctuary waters if those activities affect sanctuary resources, so even if new activities will not take place within the boundaries of the sanctuary, the sanctuary should be consulted for any new activities that could impact humpback whales.	For the HSTT EIS activities, the Navy will continue to conduct anti-submarine warfare training and testing, consisting of mid- and high-frequency active sonar use. This type of activity occurs throughout the range complex, and overlaps with the boundaries of the sanctuary primarily around the islands of Maui, Lanai, and Molokai. Navy activities within the HIHWNMS are specifically identified in Appendix F of the Final Management Plan/Final EIS Volume II (National Oceanic and Atmospheric Administration 1997). These Navy activities are exempt from the prohibitions in the Sanctuary. The Navy does not propose new or modified activities in the HIHWNMS, or activities that are different from those currently conducted in this area. Therefore, proposed activities are consistent with those activities currently conducted in this area, and those described in the sanctuary's Final Management Plan/Final EIS. These HSTT activities would continue to be exempt from the prohibitions identified in the Sanctuary's regulations. HSTT activities within the HIHWNMS would be conducted with an extensive set of mitigations measures (see Chapter 5) and will avoid to the maximum extent practicable any adverse impacts on the Sanctuary resources and qualities.
Hawaii DLNR-10	For other non-marine mammal issues, underwater explosions on the seafloor within the Hawaii Range Complex are proposed for depths between 6' to 100' (pg 3.3-14) on soft-bottom habitats to reduce impacts. Charges should also be set not only in soft-bottom	The Navy conducts explosive training in locations used consistently for these activities for decades. These locations are sufficiently distant from live corals. Large explosive charges occur farther from shore,

Table E.3-1: Responses to Comments from Agencies (continued)

Commenter	Comment	Navy Response
	habitats but sufficiently away from live corals to minimize live coral trauma. Large explosive charges should be used outside of State marine waters.	outside of State marine waters.
Hawaii DLNR-11	The Navy should conduct studies on the effects of explosives on marine fishes within the Range Complex (chapter 3.9.3.1) to document the extent of kills associated with various fleet training operations. The studies could estimate the total numbers and species of marine life that are known to have been killed during different types of operations. This could provide important information on which operations cause the most kills and potentially ways to mitigate such losses.	The Navy is relying on the best available research regarding explosive effects to marine fishes. The EIS/OEIS analysis of all impacts to fishes is a reflection of this research.
Hawaii DLNR-12	Unexploded munitions (chapters 3.3.3.2.5 & 3.7.3.2.2) should be carefully tracked to enable subsequent removal, especially if they fall within State marine waters or in sensitive habitat areas. Such unexploded ordnances should be removed immediately to minimize encrusting organisms from covering the ordnance, making finding and removing such ordnance more difficult with the passage of time.	All explosive ordnance such as bombs, missiles, and other projectiles are used outside Hawaii State marine waters. Any unexploded ordnance settles to the ocean bottom in very deep water, making it extremely impractical to recover. The fate of these military munitions in the marine environment is analyzed in Section 3.1.3.1.5 (Fate of Military Munitions in the Marine Environment) of the EIS/OEIS.
Hawaii DLNR-13	Chapter 3.5 Marine sea turtles appears to be missing from the documents as Vol. I ends at chapter 3.4 Marine Mammals, and Vol. 2 begins at chapter 3.6 Seabirds.	This mistake was limited to the volume uploaded to the HSTTEIS.com website and has been corrected. Thank you for bringing this to the Navy's attention.
Hawaii DLNR-14	Amphibious vessels would intentionally contact the seafloor (pg 3.3-19). To the extent practical, such landings should be limited to sand beaches or soft-bottom habitats to minimize impacts to hard bottom. The operational routes of the amphibious vessels should also be pre-determined to avoid live coral beds or hard bottom habitats. In the past, the routes used have been over hard bottoms, and groundings have caused damage to both the sea floor habitat and to the vessels. Unforeseen vessel groundings should be reported to the State immediately so that damage assessments can be conducted and corrective actions taken, as needed. The Navy should work collaboratively with the State throughout such operations to minimize damage. The State of Hawai'i appreciates the value of military readiness but also believes strongly in protection of all state marine resources and culture that make a Hawai'i unique and special place. We encourage collaboration and dialogue among our agencies and the Navy to provide the best protection to both our people and our environment.	All amphibious landings occur only on pre-determined and routinely used sites where a pre-landing analysis has confirmed the absence of corals.
State of Hawaii, Department of Land and Natural Resources,	Thank you for the opportunity to review and comment on the subject matter. The Department of Land and Natural Resources (DLNR) Land Division distributed or made available a copy of your report pertaining to the subject matter to DLNR Divisions for their review and comments. At this time, enclosed are comments from (I) Land Division - Oahu District; (2) Land Division - Hawaii District; (3) Land Division - Maui District; (4) Engineering Division; (5)	Thank you for participating in the NEPA process.

Ocean Recreation		
Department of Emergency Management, City and County of Honolulu	The City supports the U.S. Navy's mission to maintain, train and equip combat-ready military forces capable of winning wars, deterring aggression and maintaining freedom of the seas. Furthermore, the City appreciates the U.S. Navy's open communication with the community through scheduled and announced open house public meetings (i.e. Friday, June 15, 2012, McKinley High School); representatives of OEM will participate in this open house. Upon review of the Draft EIS/OEIS we believe the U.S. Navy's standard operating procedures, mitigation measures and active monitoring will assure that operation, training and testing impacts to the people of Honolulu, its lands and waters are minimal. We believe the proposed use of active sonar and explosives in the Study Area in compliance with existing national environmental policies will have minimal impact upon public health and safety to citizens, cultural resources, general and unique Hawaiian marine life. We defer to our sister counties and the State of Hawai'i, comments in reference to portions of the HSTT activities which impact their local area.	Thank you for participating in the NEPA process.
Department of Parks and Recreation, City and County of Honolulu	Thank you for the opportunity to review and comment on the Draft Environmental Impact Statement for the subject training and testing activities of the United States Navy. The Department of the Parks and Recreation has no comment, as the proposed activities will have no impact to any program or facility of the Department. you may remove us as a consulted party to the balance of the EIS process.	Thank you for participating in the NEPA process.

Table E.3-2 contains comments from Native American Tribes received during the public comment period and the Navy's response. Responses to these comments were prepared and reviewed for scientific and technical accuracy and completeness. Comments appear as they were submitted and have not been altered.

Table E.3-2: Responses to Comments from Native American Tribes

Commenter	Comment	Navy Response
Pala Tribal Historic Preservation Office	We have consulted our maps and determined that the project as described is not within the boundaries of the recognized Pala Indian Reservation. The project is also beyond the boundaries of the territory that the tribe considers its Traditional Use Area (TUA). Therefore, we have no objection to the continuation of project activities as currently planned and we defer to the wishes of Tribes in closer proximity to the project area. We appreciate involvement with your initiative and look forward to working with you on future efforts.	Thank you for participating in the NEPA process.
Soboba Band of Luiseno Indians	The Soboba Band of Luisei'io Indians appreciates your observance of Tribal Cultural Resources and their preservation in your project. The information provided to us on said project(s) has been assessed through our Cultural Resource Department, where it was concluded that although it is outside the existing reservation, the project area does fall within the bounds of our Tribal Traditional Use Areas. At this time the Soboba Band does not have any specific concerns regarding this project, but wishes to defer to the to other tribes closer to the project area. The tribe requests notification of any inadvertent discoveries that may be discovered during the course of the project.	Thank you for participating in the NEPA process.

Table E.3-3 contains comments from non-governmental organizations received during the public comment period and the Navy's response. Responses to these comments were prepared and reviewed for scientific and technical accuracy and completeness. Comments appear as they were submitted and have not been altered.

Table E.3-3: Responses to Comments from Organizations

Commenter	Comment	Navy Response
Animal Inc. (Electronic)	I greatly urge you to protect dolphins and whales along the west coast who lately have been at risk of dying out because of dangerous toxins coming from boats, and fishing nets. Some people might be thinking the navy is responsible for this. Thank you for reading this letter, Ellie Rose Mattoon Manager of Mammal department Animal INC.	Thank you for participating in the NEPA process.
Aquarium Maintenance-01 (Electronic)	I am outraged that the U.S. Navy would go ahead with sonar testing that could kill and harm marine mammals 2.8 million times a year over a five year period. The proposed training and testing activities off the coasts of Hawaii, Southern California, the Atlantic seaboard and the Gulf States from 2014 to 2019 gives these figures in your Draft Environmental Impact Statements. The Navy's projected damage to whales and dolphins is astounding. It is a vast increase over previous estimates of potential harm for the same regions. The numbers for far-reaching harm that will be inflicted on marine mammals during these testing activities is staggering: over 5,000,000 instances of temporary hearing loss, 16,000 instances of permanent hearing loss, almost 9,000 lung injuries, and over 1,800 deaths. An estimated 11,200 whales and dolphins will be deafened. What is unstated is that whales and dolphins depend on sound to navigate, communicate and survive. What is not presented in your analysis are reasonable alternatives to reduce the unprecedented damage to marine animals.	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 of the Draft EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Draft EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities. The increase in harassment levels is due to several contributing factors that make it inappropriate to compare takes from previous studies: • An increase in training and testing activities and the inclusion of more activities and sources, such as pierside sonar testing, to meet emerging requirements • This EIS/OEIS now covers most testing, which was previously covered under other environmental analyses. • This EIS/OEIS now includes a number of previously unanalyzed sound sources • Combined geographical areas (inclusion of both SOCAL and Silver Strand Training Complexes, and areas not previously analyzed such as San Diego Bay) • Included activities conducted along a transit corridor between SOCAL and Hawaii that account for additional potential harassments • Updated marine mammal density information that reflects current species abundance • New acoustic effects model that provides a more accurate prediction of animal movement and therefore, potential exposures

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		• New acoustic threshold criteria based on the best available science that is more protective of marine mammals, extends the ranges to effects of sound sources, and results in higher numbers of predicted level A takes. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf]. As noted in the Final EIS/OEIS, the design of the modeling and input factors has insured that the quantification of effects to marine mammals is a purposefully conservative overestimate of impacts. The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS. The number of marine mammal harassment exposures is only an estimate, not a prediction. The revised estimates now account for mitigation and avoidance, to provide a more holistic approach to analysis.
Aquarium Maintenance-02	Your mitigation plan, based on the ability of lookouts to detect whales and dolphins, will not achieve a significant reduction in damage to marine life. These same plans have been found by Federal courts to be inadequate and ineffective. Visual surveillance may be impaired at sea and unsuitable for distinguishing deep-diving species that spend little time at the surface. If fully effective, it would only protect species from the most serious injuries. I call on the Navy to please identify and set aside areas of high marine mammal density which is acknowledged to be the most effective means of reducing marine mammal injury. If the United States and its Navy wish to be seen as a leader in saving marine life, it must significantly reduce the levels of death and injury to whales, dolphins and other marine life involved in these plans. Thank you for the opportunity to comment. I hope to hear this testing is stopped since the damage to our oceans would be horrific.	As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy evaluated the effectiveness and practicability of a number of potential mitigation measures. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal surveys, are generally available to Navy Lookouts on board vessels over 60'. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the "one or two personnel" described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
Audubon Society, San Diego -01 (Electronic)	The San Diego Audubon Society has attended outreach sessions and reviewed the Subject EIS. We urge that the Navy seriously consider the following comments and upgrade the Final EIS to incorporate them to actually minimize the environmental impacts of this Training and Testing project. If these issues are not addressed, the EIS will clearly fail to satisfy the intent and the letter of NEPA. PROTECTION OF SEABIRDS Section 3.6.3, Environmental Consequences states: "Certain activities take place in specific locations or depth zones within the Study Area outside of the range or foraging abilities of seabirds. Therefore, seafloor device strike, cable and wire entanglement, parachute entanglement, and ingestion of munitions were not carried forward in this analysis for seabirds." However other activities, such as those near San Diego, the Channel Islands, Coronado Island, the Hawaiian Islands, etc. will take place well within range and foraging range of seabirds including those listed as threatened and endangered. So, an analysis of the impacts of those activities must be included in the EIS for those areas. It is especially difficult to accept the cavalier dismissal of those impacts for the endangered California Least Terns. Their foraging range is only known for breeding adults and fledglings during nesting season. Their foraging area for the rest of the year is assumed to be at sea somewhere, but the distribution is not known. If the Navy is basing its assumption on information on the distribution of Least Terns that is not available to the regulatory and ornithological community, the EIS must provide that information for their assessment. Failing that, the EIS must address these potential impacts. The document identifies several species of seabirds that warrant protection under the Endangered Species Act and the International Migratory Species Act. Some of these species dive many feet underwater to find and catch fish. The EIS includes an acoustical/physiological analysis addressing a range of impacts on marine mammals, from temporary hearing loss to mortality, as a function of the distance between the mammal and the transmitting sonar platform. But, the EIS asserts that no damage will be done to diving seabirds by high power sonar transmissions. We did not find any analysis to support that very unlikely conclusion. We urge that the likely impacts to seabirds be quantified and presented in the EIS. The EIS states "… military readiness activities are exempt from the take prohibitions of the Migratory Bird Treaty Act provided they do not result in a significant adverse effect on a population of a migratory seabird species." But, to satisfy NEPA, the EIS needs to assess, quantify, and present the likely impacts to these species, even if no mitigation will be required under the Migratory Bird Treaty Act. Otherwise reviewers will not be able to assess whether the project is likely to or not likely to result in a significant adverse effect on a population of a migratory seabird species or specific population of that species. The EIS mentions that marine mammals are detected by trained observers with	A thorough analysis of acoustic impacts to seabirds appears in Section 3.6.3.1 (Acoustic Stressors) which was based on the best available science. This section addressed deep diving birds. The EIS/OEIS concluded there would be no long-term impacts from sonar to Marine Habitats (3.3) or Fish (3.9), and no indirect impacts are expected for seabirds. Because the Navy's proposed activities are not likely to result in impacts to birds, identification of birds by Navy Lookouts would provide no discernable benefit. In conjunction with the NEPA process, the Navy has completed consultations with USFWS and NMFS under the ESA and MSFCMA, and required coordination under all other applicable laws.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	binoculars. We urge that those observers also be trained to detect the listed threatened or endangered seabirds that are known to frequent the training and testing areas and that high power sonar transmissions be delayed while the threatened and endangered species are foraging within a range that could cause damage to the seabirds.	
Audubon, SD-02	ALTERNATIVES The document states that having trained lookouts with binoculars on transmitting ships will adequately reduce the impacts of high power sonar transmissions on marine mammals This is a very crude approach considering the technology available to the Navy. Lookouts may be effective in some ideal situations, but the Navy should address alternatives that might be more effective to significantly reduce impacts on marine mammals. The Navy has a large scientific staff that is uniquely appropriate for addressing technical solutions to undersea problems such as the detection and tracking of marine mammals. We will list a few alternatives in the following paragraphs, but the Navy should have addressed all of these and more in the preparation of this EIS. Marine mammals are typically more visible from the air than from the bridge of a ship. Helicopters or drones could be used to detect and track whales at longer ranges than observers on the bridge. Doing so would give the Navy the flexibility to have the ship change course and or speed to avoid proximity instead of only having the option to terminate transmissions when a marine mammal is nearby – the only option available if on-board lookouts are the only sensor system being used. Much of the activity under this project will be located in training and testing ranges that have a variety of sensors and analysis equipment that evaluate the performance of the systems being tested. Can these instruments be used to determine the relative locations of ships and marine mammals? If not, can they be modified to do so? These test ranges have range support vessels that are, or can be, equipped with low power, medium resolution sonar systems and additional locations for lookouts that can be used to detect and keep track of marine mammals in the test ranges. Using such vessels to track whales in the vicinity of a transmitting ship could substantially reduce the likelihood of inadvertently damaging a marine mammal. The blow of a large marine mammal has a large heat signature. The EIS should investigate using heat detection systems on the transmitting ship and/or on support craft to increase the likelihood of detecting a marine mammal before it gets close enough to be damaged by a high power active sonar transmission. Woods Hole Oceanographic Institute has developed sonar buoys to provide information for the protection of Right Whales from shipping on the East Coast. The use of the WHOI-type buoys or conventional sonobuoys or other remote acoustic sensors should have been addressed and analyzed in the EIS. The Navy's existing undersea surveillance system might be useful to detect and localize vocalizations of larger marine mammals in a large portion of the operating and transit area of this project to avoid	As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of a number of potential mitigation measures. Through consultation and permitting with NMFS, the Navy refined the mitigation measures, which are now presented in Chapter 5 of this Final EIS/OEIS. Through careful exploration of all mitigation measures to determine which were the most effective, the Navy has chosen the measures to mitigate potential impacts to marine mammals while still being able to meet its operational needs to train for real-world conditions. Specific mitigation measures are outlined in the following sections: Section 5.3.1 (Lookout Procedural Measures), Section 5.3.2 (Mitigation Zone Procedural Measures), and Section 5.3.3 (Mitigation Areas). Specifically, Section 5.3.3.1 (Marine Mammal Habitats) addresses important habitat areas. The Navy uses airborne search assets when available, and the use of acoustic monitoring is not always warranted, nor practicable from an operational standpoint. Some events do use passive acoustic monitoring as part of the mitigation when practicable, including Improved Extended Echo Ranging Sonobuoys, Explosive Sonobuoys using 0.6-2.5 Pound Net Explosive Weight, Explosive Torpedo Testing, and Sinking Exercises. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf].

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	impacts in real time. But, it was not addressed in the EIS. CONCLUSIONS The populations of many threatened, endangered, and other species are declining due to declining fisheries, declining nesting opportunities, increasing predation, climate change, ocean litter, etc. We urge that this EIS be reissued and modified to seriously analyze and quantify the project's impacts to seabirds and identify means to reduce those impacts. The populations of many species of marine mammals are also declining because of collisions with ships, noise pollution, declining fisheries, climate change, etc. This project needs to seriously minimize its contribution to the decline of these species. Its reliance on lookouts with binoculars instead of also addressing a range of other promising alternatives does not fulfill the letter or the intent of NEPA. We urge that the Navy reissue this EIS with a serious and positive review of alternatives that will significantly reduce the project's impacts on marine mammals. This EIS is obviously very costly due to its size. The environment, the Navy, and taxpayers would have benefited if the emphasis had been on quality and rigor instead of volume. We urge that it be rewritten and reissued with that emphasis. In case of questions or follow-up, I can be reached at 619-224-4591 or peugh@sandiegoaudubon.org	
Center for Biological Diversity (Oral-Oahu)	I'm Miyoko Sakashita, Center for Biological Diversity, and we also will be submitting some written comments. And I think that the main thing I want to do is express concern about the sheer number of takes that are associated with the DEIS. It looks like it's about 14 million, and that it -- in Hawaii alone it's about a 400 percent increase from the prior activities. And while I think it's good that the modeling has become better and is probably a more accurate assessment of impact on marine mammals and other species, but this is a very large number and a primary concern. Those concerns for us, you know, first of all, are sonar impact on marine mammals, the ability to cause hearing loss, and even in 2004 was supposedly to be associated with about 200 whales stranding in Hanalei Bay, as well as other impacts, especially on fish, that really need to be taken into account. There are reports of other known acoustic disturbances that have caused problems with fish with hearing loss with reproductive issues and developmental issues, and in areas where there have acoustic activities, there's been noticed catch decreases for fishermen on the order of about 40 to 80 percent, so we think that should be looked at. Other concerns in addition to the sonar impacts are things like the toxins that will be released from ordnances, ammunitions, sinking ships that can potentially get into the food chain and affect marine life and get in the fish and affect people. I guess underwater explosions and their direct impact on killing species and disturbing habitat is another concern. And then we -- I know -- I think that the primary reason that I raise these	The increase in harassment levels is due to several contributing factors that make it inappropriate to compare takes from previous studies: • An increase in training and testing activities and the inclusion of more activities and sources, such as pierside sonar testing, to meet emerging requirements • This EIS/OEIS now covers most testing, which was previously covered under other environmental analyses. • This EIS/OEIS now includes a number of previously unanalyzed sound sources • Combined geographical areas (inclusion of both SOCAL and Silver Strand Training Complexes, and areas not previously analyzed such as San Diego Bay) • Included activities conducted along a transit corridor between SOCAL and Hawaii that account for additional potential harassments • Updated marine mammal density information that reflects current species abundance • New acoustic effects model that provides a more accurate prediction of animal movement and therefore, potential exposures

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	concerns is the real need to look at a very significant alternative that protects the most biologically sensitive areas, and things like that would be potentially coastal areas, proposed monk seal habitat, and other areas that are marine managed areas that should be considered in the alternative. Well, thank you for your time, and we of course would like to see full compliance with the Endangered Species Act, Environmental Protection Act, Migratory Bird Treaty Act, and all that other slew of environmental laws out there to protect the animals.	• New acoustic threshold criteria based on the best available science that is more protective of marine mammals, extends the ranges to effects of sound sources, and results in higher numbers of predicted level A takes. Also based on response to comments, Navy has supplemented the discussion regarding hearing loss as a general topic. Please see the project web site (www.HSTTEIS.com) for the Marine Mammal Stranding Report which has a full review of the scientific record concerning marine mammal strandings and sonar use, including the Hanalei Bay event, and sonar use. Regarding impacts to fish, a thorough analysis of acoustic impacts to fish appears in Section 3.9 (Fish) of the Draft EIS/OEIS. The EIS/OEIS concluded there would be no long-term impacts from sonar to fish, and there is no evidence or research indicating decreased fish catch resulting from Navy activities. Regarding toxins entering the food chain, the EIS/OEIS includes analysis of this issue in two sections; Section 3.1 (Sediments and Water Quality) and Section 3.9 (Fish). In both sections, the conclusions indicate that all levels of metals, chemicals, and other byproducts would be either below detectable levels or at levels below existing standards, regulations, and guidelines. In conjunction with the NEPA process, the Navy has completed consultations under the ESA and MSFCMA, and required coordination under all other applicable laws.
Cetacean Commonwealth (Electronic)	As to our comments on this Draft EIS, we respectfully request that in whatever ways you can express our concerns for the wellbeing of our People of the Sea, you offer them on our behalf. As the articles in the Hawaii Tribune-Herald June 6 & 7th point out there are many more deaths through fishing nets and lines, pollution, toxins, dead zones, off shore seismic testing and so on. We know this, of course. We have learned first- hand of your efforts in extra mitigation and being super mindful through our visits to PMRF and appreciate the work done. Shifting the dates of these exercises to times and locations when the waters are largely empty of Cetacea in numbers would be a Miracle, leaving them to breed and calve in relative security. Surely with all the sophisticated technology at the Navy’s finger tips a way can be found to keep the ships and their trainings with live fire and sonar well away from these makamae (precious) Global Treasures, each and every one of them. On Behalf of the Cetacean Commonwealth, Star Newland Domestic Harmony Awareness*Action Initiative www.planetpuna.com	As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy evaluated the effectiveness and practicability of a number of potential mitigation measures. Through consultation and permitting with NMFS and USFWS, the Navy refined the mitigation measures, which are now presented in Chapter 5 of this Final EIS/OEIS.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
The Chamber of Commerce of Hawaii (Written)	The Chamber of Commerce of Hawaii and its Military Affairs Council are in full support of the recommendation to adopt Alternative 2 (preferred alternative) as outlined in the Hawaii-Southern California Training and Testing Activities, Draft Environmental Impact Statement/Overseas Environmental Impact Statement, dated 12 May 2012. The rising security concerns in the Asia Pacific region have required the US to step up its security and foreign policy strategies to deter and contain military aggression. Moreover, more than 50% of the world's commerce and trade flows through the region and any breakdown in security would serve to seriously threaten the economies of the US and our Asia Pacific partners. Based on our review of the EIS/OEIS, it is our understanding that Alternative 2 provides for consolidating three previously approved environmental documents into one planning document. This reassessment would provide for reauthorizing previous approvals granted under the Marine Mammal Act (MMA) and the Endangered Species Act (ESA). Alternative 2 further provides for the expansion of Study Area boundaries and specifies adjustments in the location, types, and tempo of training and testing activities. We believe that the actions proposed in the EIS/OEIS satisfy the requirements outlined in the NEPA, MMPA, and ESA, and would enable the US Navy to satisfactorily meet the requirements placed on the 21" century naval force. We are not clear on NEPA procedures, but The Chamber suggests that the Navy seek written concurrences of federal agencies that are responsible for monitoring compliance with the NEPA, MMA, ESA, and other governing regulations. We believe that this validation is essential to demonstrating to the public that the governing agencies agree that the US Navy has satisfactorily met the requirements established in federal laws prior to the rendering of a Record of Decision.	Thank you for participating in the NEPA process.
Earthjustice-01 (Electronic)	Earthjustice submits these comments on behalf of the Center for Biological Diversity in response to the U.S. Navy's request for public input on the draft environmental impact statement/overseas environmental impact statement ("DEIS") for Hawaii-Southern California Training and Testing Activities, 77 Fed. Reg. 27,743 (May 11, 2012). These comments necessarily will be brief because, frankly, the Navy has failed to provide the public with adequate time to wade through the over 1600 pages of the DEIS's two volumes. Allowing a mere fifteen days beyond the 45-day bare minimum the National Environmental Policy Act ("NEPA") requires for public review of even abbreviated draft EIS's is far short of what is required to give the public a meaningful opportunity for input. See 40 C.F.R. § 1506.10(c); California v. Block, 690 F.2d 753, 770 (9th Cir. 1982) ("NEPA's public comment procedures are at the heart of the NEPA review process"). If the Navy truly wished to hear from the people of Hawai'i regarding their concerns about the potential environmental impacts associated with this project, it would have given them more time. We are aware that other parties are submitting comments on the deficiencies of the Navy's analysis of proposed training activity impacts and proposed	The Navy has complied with all NEPA notification requirements under 40 C.F.R. Part 1506. NEPA regulations require that agencies not allow less than 45 days for comments on a Draft EIS. Please note that public comments are very important to the NEPA process. The Navy included an extra 15 days for review of this document for an extended comment period of 60 days total. The Navy also offered various opportunities for the public to learn about and comment on this proposal, including a project website that allowed viewing, downloading and commenting on the EIS/OEIS, and six public meetings across Southern California and Hawaii.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	mitigations, and we share their concerns.	
Earthjustice-02	Given the limited time to review the DEIS, we will focus our comments on highlighting a fatal flaw that can only be cured by issuance of a revised DEIS (with, hopefully, improved analysis): the Navy's total failure to evaluate a true "no action" alternative. NEPA commands all federal agencies, including the Navy, to prepare an environmental impact statement ("EIS") for all "major Federal actions significantly affecting the quality of the human environment." 42 U.S.C. § 4332(2)(C). "The primary purpose of an [EIS] is to serve as an action-forcing device to insure that the policies and goals defined in [NEPA] are infused into the ongoing programs and actions of the Federal Government." 40 C.F.R. § 1502.1. An EIS must "provide full and fair discussion of significant environmental impacts and [must] inform decisionmakers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment." Id. An EIS must discuss, among other things: the environmental impact of the proposed federal action, any adverse and unavoidable environmental effects, any alternatives to the proposed action, and any irreversible and irretrievable commitment of resources involved in the proposed action. 42 U.S.C. § 4332(2)(C); see also id. § 4332(2)(E). The alternatives section "is the heart of the environmental impact statement." 40 C.F.R. § 1502.14. In this section, the Navy must "[r]igorously explore and objectively evaluate all reasonable alternatives," devoting "substantial treatment to each alternative considered in detail ... so that reviewers may evaluate their comparative merits." Id. § 1502.14(a), (b). NEPA specifically mandates that every EIS "[i]nclude the alternative of no action." Id. § 1502.14(d). The core purpose of the alternatives analysis is to "sharply defin[e] the issues and provid[e] a clear basis for choice among options by the decisionmaker and the public." Id. § 1502.14. NEPA's goal is to ensure "that federal agencies infuse in project planning a thorough consideration of environmental values." Conner v. Burford, 836 F.2d 1521, 1532 (9th Cir. 1988). "The consideration of alternatives requirement furthers that goal by guaranteeing that agency decisionmakers '[have] before [them] and take [ ] into proper account all possible approaches to a particular project (including total abandonment of the project) which would alter the environmental impact and the cost-benefit balance.'" Bob Marshall Alliance v. Hodel, 852 F.2d 1223, 1228 (9th Cir. 1988) (citation omitted). The Ninth Circuit has emphasized that "[i]nformed and meaningful consideration of alternatives-including the no action alternative-is … an integral part of the statutory scheme." Id. (emphasis added). In the DEIS, the Navy purports to consider a "no action" alternative, but fails to do so. The DEIS asserts that the "no action" alternative may be "thought of in terms of continuing with the present course of action until that action is changed." DEIS at 2-63. Accordingly, rather than analyze a "no action" alternative that involves ceasing training and testing activities, the DEIS evaluates only the continuation of "currently conducted training and testing activities (baseline activities) and force structure (personnel, weapons and assets) requirements as defined by existing Navy	The Navy's selection and analysis of alternatives in the EIS/OEIS meets all NEPA requirements. The Alternatives carried forward meet the Navy's purpose and need to ensure that it can fulfill its obligation under Title 10. As stated in Section 2.6 (No Action Alternative), the Council on Environmental Quality "allows the No Action Alternative to be thought of in terms of continuing with the present course of action until that action is changed. The No Action Alternative for this EIS/OEIS would continue currently conducted training and testing activities (baseline activities) and force structure (personnel, weapons and assets) requirements as defined by existing Navy environmental planning documents." It is erroneous to assume the Navy's training and testing is conducted pursuant to MMPA incidental take authorizations. The training and testing activities are continuing pursuant to the Navy's Title 10 responsibilities and the Fleet Readiness Training Plan that implements those requirements.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	environmental planning documents." Id. The flaw in the Navy's logic is that current training and testing activities occur pursuant to Marine Mammal Protection Act ("MMPA") incidental take authorizations, issued by the National Marine Fisheries Service ("NMFS"), and those authorizations will expire in early 2014. Id. at 1-3. Thus, to conduct training and testing beyond early 2014, the Navy needs new authorizations from NMFS. The Navy knows this; the DEIS expressly states that it is "needed to support the Navy's request to obtain an incidental take authorization from NMFS" for the next phase of operations and that "[t]he Navy will use this new analysis to support incidental take authorizations under the MMPA." Id.; see also id. at 1-12 ("this document will serve as NMFS's NEPA documentation for the rule-making process under the MMPA"). Presumably, NMFS also intends to rely on this round of NEPA analysis to support any incidental take statements issued pursuant to the Endangered Species Act. In situations involving "federal decisions on proposals for projects," such as whether to issue a new incidental take authorization for proposed Navy training and testing, the Council on Environmental Quality has stated that "no action" means "the proposed activity would not take place." 46 Fed. Reg. 18,026, 18,027 (Mar. 23, 1981). Thus, to support NMFS's permitting decision, the Navy was obliged, but failed, to evaluate a true "no action" alternative involving denial of the request for incidental take authorization. See, e.g., Western Watersheds Project v. Rosenkrance, 2011 WL 39651, at *10 (D. Idaho Jan. 5, 2011) ("Most troubling is that BLM did not consider a real no action alternative. … If BLM truly did take no action, then the old grazing permits would expire, no new permits would issue, and no range improvements would occur. No action would be no action. This is a reasonable, and obvious, alternative to issuing new grazing permits."); Ocean Mammal Institute v. Gates, 546 F. Supp. 2d 960, 977 (D. Haw. 2008) ("The Court … fails to see how a 'no action' alternative that involves the continuation of individual training exercises using MFA sonar subject to the Navy's discretionary environmental review falls within NEPA's explicit alternatives analysis requirement"). Having failed to evaluate the required "no action" alternative, the Navy may not proceed with finalizing the DEIS. See ʻĪlioʻulaokalani Coalition v. Rumsfeld, 464 F.3d 1083, 1101 (9th Cir. 2006) (failure to consider reasonable alternative "renders the Army's EISs inadequate"). Rather, the Navy must issue a revised DEIS that analyzes a true "no action" alternative (i.e., no incidental take authorizations), providing the requisite "benchmark" to permit the public and Navy "decisionmakers to compare the magnitude of environmental effects of the action alternatives." 46 Fed. Reg. at 18,027. The Navy then must circulate the revised DEIS for another round of public review and comment. See 40 C.F.R. § 1502.9. Thank you for your consideration of these comments. Please feel free to contact me via email (dhenkin@earthjustice.org) or telephone (808-599-2436, ext. 6614) if you would like to discuss our concerns.	

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
Humane Society, Hawaii (Oral-Hilo)	I'm Inga Gibson. I'm the Hawaii State Director with the Humane Society, United States. We will be submitting formal written comments, but I wanted to make a few comments for the record, if I may. We are very concerned, obviously, with the potential impacts on marine mammals and other animals in the Pacific and Hawaii. We're especially concerned about the potential permanent and temporary hearing loss, lung injuries, gastrointestinal injuries, and death. We understand that there's no presentation or analysis of alternatives at this time that would in any way significantly reduce the unprecedented impacts and level of harm to these marine animals, many of which are protected under both the MMPA and the SMR, or in some cases are critically endangered, such as the Hawaiian monk seal. We are concerned with the Navy's mitigation scheme, centered on the ability of lookouts for whales and dolphins, and do not believe that it will result in an appreciative decrease in marine mammal take. Furthermore, we are concerned that the Navy appears to dismiss what is acknowledged to be the most effective means to reduce marine mammal take and avoiding areas associated with high marine mammal density. That, again, is what we would like to see, is an avoidance and a better scheme in avoiding altogether some of the areas where there is strong marine mammal presence. We also encourage the Navy in their continued efforts to be seen as an effective steward of the ocean environment to take steps to significantly reduce the level of harm in training and testing activities. Again, we'll be submitting formal more detailed written comments. There is also concern about the significant increase in the proposed takes under the new DEIS from the prior EIS and the numbers of animals potentially impacted. Also a concern with the verification of take, and the methods used to verify take, if that is even verified. Again, thank you for this opportunity.	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from active sonar and explosives were analyzed in Chapter 3 of the Draft EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Draft EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf]. The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS. The number of marine mammal harassment exposures must be estimated scientifically using complex modeling, but it is only an estimate, not a prediction. This estimate needs to encompass the capacity of what could occur to ensure Navy's permits are not exceeded. The revised estimates now account for mitigation and avoidance, to provide a more holistic approach to analysis. As noted in the Final EIS/OEIS, the design of the modeling and input factors has insured that the quantification of effects to marine mammals is a purposefully conservative overestimate of impacts. The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS. The number of marine mammal harassment exposures is only an estimate, not a prediction. The revised estimates now account for mitigation and avoidance, to provide a more holistic approach to analysis. Also based on response to comments, Navy has supplemented the discussion regarding hearing loss as a general topic.
Koholā Leo-01 (Electronic)	To Whom it may concern This DEIS is fatally flawed and fails to comply with the basic requirements of NEPA. And it fails to properly analyze impacts on marine mammals. The Navy's assessment of impacts is consistently undermined by its failure to meet these fundamental responsibilities of scientific integrity, methodology, investigation, and disclosure. The DEIS disregards a great deal of relevant information adverse to the Navy's interests,	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 of the Draft EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Draft EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	uses approaches and methods that would not be acceptable to the scientific community, and ignores whole categories of impacts. In short, it leaves the public with an analysis of harm—behavioral, auditory, and physiological—that is at odds with established scientific authority and practice. The Navy must revise its acoustic impacts analysis, including its thresholds and risk function, to comply with NEPA. The DEIS fails to address other impacts to marine mammals including: stress & indirect effects.	Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf]. The Navy has used the best available science in the development of this EIS/OEIS, and is fully compliant with all applicable environmental laws, including NEPA.
Koholā Leo-02	The DEIS fails to address effects of toxic chemicals, hazardous materials and waste oil spills on cetaceans and all marine life. The Navy must adequately evaluate impacts and propose mitigation for each category of harm for all species marine life. And each individual federal activity that is to have a significant environmental impact should have its own environmental analysis. For example RIMPAC and DARPA each need their own separate EIS. To comply with NEPA, an agency must discuss measures designed to mitigate its project's impact on the environment. See 40 C.F.R. § 1502.14(f). There is a large and growing set of options for the mitigation of noise impacts to marine mammals and other marine life, some of which have been imposed by foreign navies—and by the Navy itself, in other contexts—to limit harm from high-intensity sonar exercises. Yet here the Navy does little more than set forth an abbreviated set of measures, dismissing effective measures out of hand. The Navy's reliance on visual observation as the mainstay of its mitigation plan is therefore profoundly misplaced. The Navy can, and must, do more to mitigate the harm on marine wildlife.	The reasonably foreseeable effects of chemicals and other materials were fully analyzed in the Draft EIS/OEIS in Section 3.1 (Sediments and Water Quality) for their direct effect on water quality, and in Section 3.4 (Marine Mammals), Section 3.5 (Sea Turtles), Section 3.6 (Seabirds), Section 3.7 (Marine Vegetation), Section 3.8 (Marine Invertebrates), and Section 3.9 (Fish) for their potential secondary impacts to marine life. The Navy used the best available science and a comprehensive review of past, present and reasonably foreseeable actions to develop a robust Cumulative Impacts analysis. See Chapter 4 of the EIS/OEIS. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy evaluated the effectiveness and practicability of a number of potential mitigation measures. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment,

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal surveys, are generally available to Navy Lookouts on board vessels over 60'. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the "one or two personnel" described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		accessible on the NMFS Office of Protected Resources website. The Navy is committed to protecting the marine environment during the conduct of its training and testing activities. As described in Chapter 5 of the EIS/OEIS, the Navy has used extensive measures to protect the marine environment while training and testing for nearly a decade.
Koholā Leo-03	Given the scope of the proposed action, the deficiencies of the Navy's cumulative impacts assessment represents a critical failure of the DEIS. In relation Sonar impact on cetaceans the likely cause of mass strandings are panic, bubble formation and/or decompression sickness (based on real scientific published papers): 1) Sonar caused panic reactions leading to strandings followed by death 2) Sonar caused decompression sickness (the bends) followed by death 3) The bends caused by sonar even in the absence of panic These three points were either not included or not addressed in a scientifically relevant matter. The following five papers must be included in the EIS and the data should be researched and analyzed by NON-Navy scientists and contractors: J. R. POTTER;, 'A Possible Mechanism for Acoustic Triggering of Decompression Sickness Symptoms in Deep-Diving Marine Mammals' Paper presented at the IEEE International Symposium on Underwater Technology 2004, Taipei Taiwan, April 2004. PARSONS, E. C. M.; SARAH J. DOLMAN; ANDREW J. WRIGHT; NAOMI A. ROSE and W. C. G. BURNS. MARINE POLLUTION BULLETIN 56(7):1248-1257. 2008. Navy sonar and cetaceans: Just how much does the gun need to smoke before we act? TYACK, PETER L. JOURNAL OF MAMMALOGY 89(32):549-558. 2008. Implications for marine mammals of large-scale changes in the marine acoustic environment. WRIGHT, A. J.; N. AGUILAR SOTO; A. BALDWIN; M. BATESON; C. BEALE; C. CLARK; T. DEAK; E. EDWARDS; A. FERNANDEZ; A. GODINHO; L. HATCH; A. KAKUSCHKE; D. LUSSEAU; D. MARTINEAU; L. ROMERO; L. WEILGART; B. WINTLE; G. NOTARBARTOLO DI SCIARA and V. MARTIN. INTERNATIONAL JOURNAL OF COMPARATIVE PSYCHOLOGY 20(2-3):274- 316. 2007. Do marine mammals experience stress related to anthropogenic noise? FAERBER, M .M., R. W. BAIRD. 2010.	Discussion of the general topics ("panic, bubble formation and/or decompression sickness") noted in the comment were thoroughly discussed in the Draft EIS/OEIS. In particular see Section 3.0.5.7.1.3 (Physiological Responses) for the presentation of the conceptual framework for analysis and Section 3.4.3.1.2.1 (Direct Injury). For a specific discussion of strandings, see Section 3.4.3.1.2.7 (Stranding) and note that a more detailed presentation was offered in a companion Cetacean Stranding Technical Report ("Marine Mammal Strandings Associated with U.S. Navy Sonar Activities") that is referenced in the DEIS/OEIS and available on the HSTT EIS/OEIS website (HSTTEIS.com). The three points raised ["1) Sonar caused panic reactions leading to strandings followed by death 2) Sonar caused decompression sickness (the bends) followed by death 3) The bends caused by sonar even in the absence of panic"], are covered within the material as described above. With regard to the references noted, while these particular five references were not cited, all were reviewed during preparation of the Draft EIS/OEIS except Potter (2004), which discusses a hypothesis covered in the Draft EIS/OEIS using the following more recent science and data from seven references: Dennison et al. (2011); Fahlman et al. (2006); Hooker et al. (2009); Moore et al. (2009); Southall et al (2007); Tyack et al. (2006); Zimmer and Tyack (2007). Finally, the EIS/OEIS has been created with National Marine Fisheries Service acting as a cooperating agency with input to both the Draft and Final versions. The team also includes a number of non-governmental scientists and subject matter experts.
Koholā Leo-04	Does a lack of observed beaked whale strandings in military exercise areas mean no impacts have occurred? A comparison of stranding and detection probabilities in the Canary and main Hawaiian Islands. Marine Mammal Science DOI: 10.1111/j.1748-7692.2010.00370.x In the DIES the Navy also fails to include data from the July 2004 Hanalei Bay event, in which 150-200 melon-headed whales were embayed for more than 24 hours during the Navy's Rim of the Pacific exercise. According to the Navy's analysis, predicted mean received levels (from mid-frequency sonar) inside and at the	Please see the project web site (www.HSTTEIS.com) for the Marine Mammal Stranding Report which has a full review of the scientific record concerning marine mammal strandings, including the Hanalei Bay event, and sonar use. Information regarding distribution of marine mammals around the Hawaiian Islands is provided in the Draft EIS/OEIS based on the best available information.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	mouth of Hanalei Bay ranged from 137.9 dB to 149.2 dB. The Navy has from the beginning denied any connection between its major international exercise and the mass stranding. However, the Navy's specious reasoning is at odds with the stranding behavior observed during the event and with NMFS' report on the matter, which ruled out every other known potential factor and concluded that sonar was the "plausible if not likely" cause. The Navy's failure to incorporate these numbers into its methodology as another data set is unjustifiable. Hawaii is very different from other areas. The EIS needs to identify areas where the species are for each island. On October 28, 2004 the European Parliament passed a resolution that is probably one of the strongest statements by an international body yet on the issue of military sonar and its impact on cetaceans. This resolution called on the European Commission and the Member States to: ''adopt a moratorium on the deployment of high-intensity active naval sonars until a global assessment of their cumulative environmental impact on marine mammals, fish and other marine life has been completed"; and ''immediately restrict the use of high-intensity active naval sonars in waters falling under their jurisdiction"; as well as to ''set up a Multinational Task Force to develop international agreements regulating noise levels in the world's oceans, with a view to regulating and limiting the adverse impact of anthropogenic sonars on marine mammals and fish." (European Commission, 2004) Indeed, the greatest user of military sonars in the world, the US Navy, appears to be in denial about the situation and dismissive of the concerns of the majority of the population and other nations. And the most shocking part of the document is the "justification" for the NOAA Marine Fisheries "take" permit to harm and kill endangered marine mammals more than 33 million times during five years of testing and training with sonar and explosives. Including more than five million instances of temporary hearing loss, 16,000 instances of permanent hearing loss (since no one involved in this DEIS seems to understand science, here is an important fact: a deaf cetacean is a dead cetacean), almost 9,000 lung injuries, and more than 1,800 deaths. These numbers are unconscionable and unacceptable! So, again we state your "science" in the DEIS is severely flawed and inadequate! We request this DEIS be re-done by non-Navy professionals. For the whales and healthy oceans, Sincerely, Koholā Leo (Whale Voice) http://www.koholaleo.com/	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 of the Draft EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Draft EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities. As noted in the Final EIS/OEIS, the design of the modeling and input factors has insured that the quantification of effects to marine mammals is a purposefully conservative overestimate of impacts. The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS. The number of marine mammal harassment exposures is only an estimate, not a prediction. The revised estimates now account for mitigation and avoidance, to provide a more holistic approach to analysis. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf].
Na Kupuna Moku O Keawe	Please excuse me. I am grossly unprepared for this. I did not even know of this meeting or that the process had gone this far until yesterday afternoon. One of my major concerns is, is that I've been involved with the military buildup here in the islands. Aloha. My name is Hanalei Fergerstrom. I am a spokesman for Na Kupuna Moku O Keawe, which encompasses all six major districts of the island of Hawaii. So for those of you who do not know, this is the council of the elders. I'm also a haumana of the Heiau O Lono. This is a religious organization (inaudible). Anyway, I have been involved with the military buildup here for over 12 years. I was involved with the low sonar frequency	The Navy shares your desire to preserve marine life. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	testing that was done here, I believe, about 12 years ago. I actually filed suit against the Navy. During that time, my suit was denied because it was basically moot. You were just pulling out of Hawaii. But I am on your mailing list, so I am very shocked that this has gone this far and I have not been provided with information. As you know, information is critical for a proper response. I have been working with different branches. I've spent the last two years working with the Army on the Pohakuloa buildup, which is actually coupled with this in some fashion or form. Again I'm a little bit outraged because I do not have this information. I am grossly unprepared, but I have to try to do something. I have been successful in getting myself on the mailing list. People are aware of me. I've been promised a hard copy because I need the hard copy to make a proper response by your July 10th deadline. Of course when I looked at your timeline, this has been going on for quite some time, and if I had had this information from the start, perhaps I would not feel so intimidated and overwhelmed. One of the things that is extremely important to add into this fray of things is that the environment includes me. I am a part of this environment. The Hawaiian people, the Hawaiian Islands are part of this environment. It is not just the ocean. Secondly, because a lot of this testing that is going to be done or this project that is going to be deployed is going to be done in large part in international waters, and when you talk about in the EIS, it affects many countries -- and I refer to subjects such as RIMPAC -- that other countries also need to be informed of where you are and participate in the EIS process because it affects all the Pacific region. Sorry. You threw me off with that one-minute thing. Please don't hold me to that. As long as we make sure, I'd like to utilize the time. Again I am grossly unprepared. I did not find out about this meeting until last evening. And interestingly enough I went to the Pacific Command to try to get some information, and Google cited it as an unsafe link. That's something that you should be aware of. As I said 12 years ago, the kohola and the nai'a that are the most impacted that have been most frequently (inaudible) are not just large fish. They are my family, my blood, my blood, which can be established through the Kumulipo, the Hawaiian creation chant. I am also a Hiapo Na Koa O Pu'ukohola, or the Warriors from the Mound of the Whale. So we are very familiar with this. We are very, very concerned that a whole lot of things are not being considered. You refer to the larger species of mammals like the porpoises and the whales, but we are island people, and so the effect on smaller fish and the crustaceans and how it affects -- Okay. So you see the problem we have here, not being able to talk about this because how can you possibly do this if you're constantly cut off after three minutes? Thank you, and I want to register my objection. Thank you.	monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf]. The Navy is not aware of any documented cases of sonar harming people. Also based on response to comments, Navy has supplemented the discussion regarding hearing loss as a general topic.
Natural Resources Defense Council (NRDC)-1	The Navy's compliance with the National Environmental Policy Act ("NEPA"), 42 U.S.C. 4321 *et seq*., for its training and testing activities in the Pacific Ocean is entering a new phase. For the first time, the Navy is providing a more comprehensive picture of the training and testing activities it is conducting and plans to conduct from January 20 14 to January 20 19 in Hawaii and Southern California waters and the impacts to the	The Navy shares your desire to preserve marine life. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
(Written)	environment from those activities. Unfortunately, it is a picture of unprecedented harm: over 14 million instances of "take" (behavioral impacts, harassment, injury) over five years (from January 2014 to January 2019), including almost 3 million instances of temporary hearing loss, over 5,000 instances of permanent hearing loss, almost 3,000 lung injuries, and 1,000 deaths from the use of sonar and explosives. DEIS at 3.4-167 to 168; 3.4-171 to 172. While these predictions of injury are shocking - and, we believe, still underestimate the harm to marine mammals from the Navy's activities they confirm what stranding events have evidenced, scientists have studied, and the public has believed for years: Navy training and testing activities endanger whales and dolphins at intolerable levels.	broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf]. As noted in the Final EIS/OEIS, the design of the modeling and input factors has insured that the quantification of effects to marine mammals is a purposefully conservative overestimate of impacts. The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS. The number of marine mammal harassment exposures is only an estimate, not a prediction. The revised estimates now account for mitigation and avoidance, to provide a more holistic approach to analysis. An integrated monitoring plan for the activities in the HSTT Study Area is also planned as presented in Section 5.5.1.1 (Integrated Comprehensive Monitoring Program) of the EIS/OEIS. In addition, the Navy implements, to the maximum extent practicable, mitigation measures during its training and testing events as developed with NMFS as the regulatory agency under MMPA and ESA. The Navy will continue to implement the monitoring and research programs where training has been occurring to determine if there are identified impacts as a result of those activities and will do so in the HSTT Study Area associated with future training occurring there. The Navy will continue to be a leader in funding of research to better understand the potential impacts of Navy training activities and to operate with the least possible impacts while meeting training and testing requirements.
NRDC - 2	While the scale of impacts does not change the Navy's obligations under NEPA, it highlights why it so important that the Navy's DEIS fully comply with both the letter and spirit of the law. As Congress intended when it passed NEPA, faced with such harm, the DEIS must help decision makers make fully informed decisions on the proposed activities; after reviewing the DEIS, decision makers must understand the breadth of harm to impacted species, must be able to choose a course of action from a range of alternatives that provide options for meeting the Navy's goals while still reducing harm to species, and must have at their disposal a range of mitigation measures that will significantly lessen environmental impacts. For the reasons discussed in detail below, we believe that the DEIS fails to meet these requirements and does so in such a way that the failures cannot be remedied through the issuance of a final EIS. Accordingly, we believe that the document must be thoroughly revised and reissued as a draft for further public review and comment.	The Navy complies with all applicable environmental laws, including NEPA. As such, the Navy has developed this EIS/OEIS to meet the requirements of these laws. Please see Chapter 2 (Description of Proposed Action and Alternatives), which includes selection criteria and alternatives considered but eliminated (Section 2.5.1 Alternatives Eliminated from Consideration). Please see Chapter 3 (Affected Environment and Environmental Consequences) for the description of the affected environment and environmental consequences of the Navy's Proposed Action. Chapter 4 contains a comprehensive cumulative impacts analysis. Information on mitigation measures can be found in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS. Please see *Criteria and Thresholds for U.S. Navy Acoustic and Explosive Effects Analysis* technical report on the project web site for a discussion of the acoustic impact

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		modeling approach, which addresses the scientifically established criteria for injury, mortality, and harassment under the MMPA.
NRDC - 3	Our overriding concern is the Navy's failure to protect biologically important areas for marine mammals within the Hawaii-Southern California Training and Testing ("HSTT") Study Area. There is a general consensus among the scientific community, as NOAA has recognized, that "[p]rotecting marine mammal habitat is ...the most effective mitigation measure currently available" to reduce the harmful impacts of midfrequency sonar on marine mammals(2) Nonetheless, other than a relatively small "cautionary area" for humpback whales off Hawaii, the DEIS does not consider establishing any additional protection zones in the HSTT Study Area where training or testing could be limited or excluded, despite the common-sense efficacy of such measures. (2) See Letter from Jane Lubchenco, Under Secretary of Commerce for Oceans and Atmosphere to Nancy Sutley, Chair, Council on Environmental Quality dated Jan. 19,2010, available at http://www.nrdc.org/medialdocsIl00119.pdf; see also Agardy, T., Aguilar Soto, N., Cafiadas, A., Engel, M., Frantzis, A., Hatch, L., Hoyt, E., Kaschner, K., LaBrecque, E., Martin, V., Notarbartolo di Sciara, G., Pavan, G., Servidio, A., Smith, B., Wang, J., Weilgart, L., Wintle, B., and Wright, A. A global scientific workshop on spatio-temporal management of noise. Report of workshop held in Puerto Calero, Lanzarote, (June 4-6,2007); ECS Working Group: Dolman, S., Aguilar Soto, N., Notabartolo di Sciara, G., Andre, M., Evans, P., Frisch, H., Gannier, A., Gordon, J., Jasny, M., Johnson, M., PapanicolopuJu, I., Panigada, S., Tyack, P., and Wright, A. Technical report on effective mitigation for active sonar and beaked whales. Working group convened by European Cetacean Society, (2009); OSPAR Commission, Assessment of the environmental impact of underwater noise. OSPAR Biodiversity Series, (2009); Parsons, E.C.M., Dolman, S.J., Wright, A.J., Rose, N.A., and Burns, W.C.G. Navy sonar and cetaceans: just how much does the gun need to smoke before we act? Marine Pollution Bulletin 56: 1248-1257 (2008).	As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of a number of potential mitigation measures. The Navy has undertaken consultation with NMFS for the proposed and ongoing activities in the Study Area. The Navy refined the mitigation measures, which are now presented in Chapter 5 of this Final EIS/OEIS. Through careful exploration of all mitigation measures to determine which were the most effective, the Navy chose the measures to mitigate potential impacts to marine mammals while still being able to meet its operational needs to train for real-world conditions. The Navy's specific mitigation measures are outlined in the following sections: Section 5.3.1 (Lookout Procedural Measures), Section 5.3.2 (Mitigation Zone Procedural Measures), and Section 5.3.3 (Mitigation Areas). Specifically, Section 5.3.3.1 (Marine Mammal Habitats) addresses important habitat areas.
NRDC - 4	The Navy's failure is in stark contrast to both the unprecedented level of harm and the varied activities taking place over such a large area. In all, the HSTT Study Area encompasses over 2 million square nautical miles across the Pacific Ocean from Southern California to the International Date Line, with the majority of training and testing activities focused in an area 1.5 times the size of Texas, about 355,000 nm^2• The Navy's preferred alternative would use many different sources and frequencies of active sonar, including over 25,500 hours from mid-frequency sources every year. DEIS at 3.0-46. These training exercises would also employ a battery of other acoustic sources and explosives detonations in ocean surface and undersea areas, special use airspace, and training land areas. The Navy's failure is particularly troubling in light of the emerging scientific consensus about biologically important areas in the HSTT Study Area. For the last year and a half,	The Navy has and will continue to support the Cetacean and Sound Mapping project, including providing representation on the Cetacean Density and Distribution Mapping Working Group (CetMap). This working group has two objectives: First, to create regional cetacean density and distribution maps that are time- and species-specific, using survey data and models that estimate density using predictive environmental factors. With the exception of the Atlantic and Gulf of Mexico, the Navy has considered this information as part of the impact and mitigation assessment process. For the Atlantic and Gulf of Mexico, the Navy OPAREA Density Estimates on the Spatial Decision Support System for the Strategic Environmental Research and Development Program (available at http://seamap.env.duke.edu/serdp_map.php), are still considered the

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	the National Oceanic and Atmospheric Administration ("NOAA") has been guiding the work of two working groups to improve the tools available to agencies, including the Navy, to evaluate and mitigate the impacts of anthropogenic noise on marine mammals. The Working Groups' draft products were recently released and one key product of this effort was the Cetacean Density and Distribution Mapping Working Group's (CetMap) identification of marine mammal "hot spots" in the HSTT Study Area - biologically important areas for marine mammals as evidenced by increases in density and distribution or modeled based on important habitat. Because CetMap's products were not released prior to the completion of the DEIS, the information was not incorporated into the Navy's analysis through the development of reasonable alternatives or examined as possible mitigation measures based on limiting or excluding training and testing activities in these hot spots. The fact that the Navy must analyze this new information and determine how it will impact its development of alternatives and mitigation measures supports a revision of the DEIS, which would place the Navy's analysis of this critical information before the public, giving the public an opportunity to comment thereon.	best available data (Read and Halpin 2010[1]). Second, and separately, to augment the more quantitative density mapping and provide additional context for impact analyses, the CetMap also identifies areas of specific importance for cetaceans, such as reproductive areas, feeding areas, migratory corridors, and areas in which small or resident populations are concentrated, otherwise referred to as "biologically important areas." The working group determined that "hot spots" is not an appropriate term and chose to call them Biologically Important Areas. Biologically important areas information was based largely on observational data of animals exhibiting biologically important behaviors. The biologically important areas were only characterized for species, areas, and seasons where there were enough data to support the biologically important areas identification within the U.S. Exclusive Economic Zone. Most of these assessments are not based on CetMap density work products but on published and often unpublished data held by individual researchers. They only characterized the observational data available and did not use density or habitat-based models to determine the biologically important areas. Biologically important areas are not being designated by CetMap for the purpose of identifying areas off limit to human activities like sonar. Instead, information is being collected to provide additional context within which to examine potential interactions between cetaceans and human activities. This information can assist resource managers with planning, analyses, and decisions regarding how to reduce adverse impacts to cetaceans resulting from human activities. Some preliminary draft results are currently being released on http://cetsound.noaa.gov/important.html. The CetMap Working Group is also undertaking external review of the documents by subject matter experts outside National Oceanic and Atmospheric Administration and is preparing a collection of manuscripts focused on the biologically important areas that will be submitted to a scientific journal for external peer review by subject matter experts. The Navy also recommended to NMFS that a formal expert elicitation on biologically important areas results be conducted, including data review by a larger body of marine scientists and stakeholders. When appropriate, NMFS provides draft CetMap information for Navy consideration. As part of the ESA and MMPA processes, NMFS requested the Navy to consider some specific preliminary draft areas

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		as part of its mitigation analysis. As of the date of publication of the Final EIS/OEIS, this process is still ongoing; however, the results will be summarized in the Navy's Record of Decision and in NMFS Biological Opinion. If additional biologically important areas are identified by NMFS after the Navy's Record of Decision, the Navy and NMFS will use the Adaptive Management process to assess whether any additional mitigation should be considered in those areas. [1] Read, A. J. and P. Halpin. 2010. Predictive Spatial Analysis of Marine Mammal Habitats. Final Report. SERDP Project SI-1390. January 2010. 292 pp.
NRDC - 5	As you know, NEPA requires the Navy to employ rigorous standards of environmental review, including a full explanation of potential impacts, a comprehensive analysis of all reasonable alternatives, a fair and objective accounting of cumulative impacts, and a thorough description of measures to mitigate harm. Unfortunately, the DEIS released by the Navy falls far short of these mandates and fails to satisfy the Navy's legal obligations under NEPA. Thus, the Navy must revise the environmental impacts, alternatives, cumulative impacts and mitigation analysis in the DEIS (described in detail in Appendix A) and reissue the document for public review and comment. It must also fully address the considerable scientific record that has developed around sonar and whale injury and mortality, and adjust its acoustic impacts analysis and assessment model accordingly (discussed in Appendices B and C).	The Navy complies with all applicable environmental laws, including NEPA. As such, the Navy has developed this EIS/OEIS to meet the requirements of these laws. Please see Chapter 2 (Description of Proposed Action and Alternatives), which includes selection criteria and alternatives considered but eliminated (Section 2.5.1, Alternatives Eliminated from Consideration). Please see Chapter 3 (Affected Environment and Environmental Consequences) for the description of the affected environment and environmental consequences of the Navy's Proposed Action. Chapter 4 contains a comprehensive cumulative impacts analysis. Information on mitigation measures can be found in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS. Please see *Criteria and Thresholds for U.S. Navy Acoustic and Explosive Effects Analysis* technical report on the project web site for a discussion of the acoustic impact modeling approach, which addresses the scientifically established criteria for injury, mortality, and harassment under the MMPA. For a complete analysis of stranding events, please see the Marine Mammal Stranding Report, found on the HSTTEIS.com website at: http://hstteis.com/Portals/0/hstteis/SupportingTechnicalDocs/.
NRDC - 6	The Navy Has Not Taken a "Hard Look" Under NEPA NEPA requires that the potential environmental impacts of any "major Federal actions significantly affecting the quality of the human environment" be considered through the preparation of an environmental impact statement ("EIS"). Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 348 (1989); 42 U.S.C. § 4332. The fundamental purpose of an EIS is to compel decision-makers to take a "hard look" at a particular action - both at the environmental impacts it will have and at the alternatives and mitigation measures available to reduce those impacts - before a decision to proceed is made. 40 C.F.R. §§ l500.l(b), 1502.1; Baltimore Gas & Electric v. NRDC, 462 U.S. 87,97 (1983); Robertson,	The EIS/OEIS has taken a "hard look" at potential environmental consequences of the Proposed Action and alternatives, and provides sufficient information for careful agency decision-making. The Navy considered the best available science in preparation of this EIS/OEIS and is in consultation with NMFS as the regulator and a cooperating agency with regard to the Proposed Action, the potential environmental impacts, and any resultant mitigation measures as conditions of anticipated authorizations under the MMPA or reasonable and prudent measures resulting from issuance of a

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	490 U.S. at 349. While NEPA "does not commend the agency to favor an environmentally preferable course of action," an agency may only make a decision to proceed after taking a "hard look" at environmental consequences. Sabine River Auth. v. Dep't of Interior, 951 F.2d 669, 676 (5th Cif. 1992)(internal citations omitted).	Biological Opinion under ESA.
NRDC - 7	As the DEIS makes clear, the proposed activities pose a significant risk to whales, fish, and other wildlife that depend on sound for breeding, feeding, navigating, and avoiding predators-in short, for their survival. Under every Alternative, the Navy would employ mid-frequency active sonar, which has been implicated in mass injuries and mortalities of whales around the globe.[4] The same technology is known to affect marine mammals in countless other ways, inducing panic responses, displacing animals, and disrupting crucial behavior such as foraging. In addition, the Navy's training and testing with explosives will kill wildlife and leave animals with permanent injuries to their internal organs. The Navy expects to take more than 40 different species of marine mammals, including 7 species listed as endangered or threatened under the Endangered Species Act ("ESA"). DEIS at 3.4-2 to I 1. The Pacific Fleet's training and testing activities would also affect fisheries and essential fish habitat, injure tens of thousands of sea turtles, and release a large amount of hazardous and expended materials into the waters. See Appendices A and B for a detailed discussion of impacts. Footnote 4.. Military sonar generates intense sound that can induce a range of adverse effects in whales and other species - from significant behavioral changes to injury and death. The most widely reported and dramatic of these events are the mass strandings of beaked whales and other marine mammals that have been associated with military sonar use. A brief summary of the stranding record appears in Appendix B.	The Navy shares your desire to preserve marine life. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a species-level risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf]. An integrated monitoring plan for the activities in the HSTT Study Area is also planned as presented in Section 5.5.1.1 (Integrated Comprehensive Monitoring Program) of the EIS/OEIS. In addition, the Navy implements, to the maximum extent practicable, mitigation measures during its training and testing events as developed with NMFS as the regulatory agency under MMPA and ESA. The Navy will continue to implement the monitoring and research programs where training has been occurring to determine if there are identified impacts as a result of those activities and will do so in the HSTT Study Area associated with future training occurring there. The Navy will continue to be a leader in funding of research to better understand the potential impacts of Navy training activities and to operate with the least possible impacts while meeting training and testing requirements.
NRDC - 8	While the Navy has made progress in assessing the impacts its activities have on the environment, it continues to underestimate harm by disregarding a great deal of relevant information and using approaches that are the opposite of precautionary when factoring uncertainty. As discussed in Appendix C, in revising its DEIS, the Navy must adjust its thresholds for impact and modeling by incorporating the considerable scientific record showing that impacts are even greater than the Navy estimates.	The criteria and thresholds for determining potential effects to marine species used in the HSTT EIS/OEIS and related consultation documents were carefully revised from that used in previous Navy EISs based on best available science, which included lowering the thresholds over much of the hearing range of many species of marine mammals. This included revising the permanent threshold shift threshold for all marine mammal species based on best available science.
NRDC - 9	The Navy Fails to Identify and Analyze Reasonable Alternatives As you are aware, both of the Navy's action alternatives (Alternative 1 and 2) would dramatically increase the amount of training and testing in Hawaii and Southern	The differences between Alternatives 1 and 2 are detailed in Sections 2.7 (Alternative 1: Expansion of the Study Area Plus Adjustments to the Baseline and Additional Weapons, Platforms, and Systems) and 2.8 (Alternative 2: Includes Alternative 1 Plus Increased Tempo of

Commenter	Comment	Navy Response
	California and subject marine mammals to an unprecedented level of harm, including death, lung injuries, gastro-intestinal injuries, hearing loss, and significant behavioral reactions like habitat abandonment. Neither alternative presents an option that would significantly reduce the predicted harm to the marine environment and wildlife. For example, both of the Navy's alternatives result in the exact same number of marine mammal takes from training with sonar - over 2.5 million per year. For training then, the DEIS offers no alternative for a decision maker wishing to reduce the harm to marine mammals.	Training and Testing Activities) of the Final EIS/OEIS. The Navy developed the alternatives considered in this EIS/OEIS after careful assessment of the Navy's training and testing requirements by subject matter experts, including military units and commands that perform the training and testing, and Navy environmental managers and scientists. A reduction in training and testing activities would fail to meet the Purpose and Need and would not allow the Navy to meet its obligations under Title 10 of the United States Code. Refer to Section 2.5 (Alternatives Development) of the Final EIS/OEIS for an explanation of the development of alternatives.
NRDC - 10	It is obvious that the Navy's alternatives were not selected to "inform decision-makers and the public" of how it could "avoid or minimize adverse impacts or 'enhance the quality of the human environment." 40 C.F.R. § 1502.1. While the Navy purportedly presents two reasonable alternatives, it leaves no room for decision makers to choose anything but its preferred alternative, which "is contingent upon [and allows for] potential budget increases, strategic necessity, and future training and testing requirements." DEIS at ES-8; 2-74 (emphasis added). A decision maker that wishes to meet the Navy's needs is compelled to choose the preferred alternative. In addition, even if Alternative I also met the Navy's strategic necessity and future training and testing requirements and a decision maker felt free to considering choosing it over the Navy's preferred alternative, he or she would be hard pressed to identify which alternative works to avoid or minimize adverse environmental impacts, let alone enhance the quality of the human environment. Both alternatives inflict an unprecedented amount of harm on marine life. Neither alternative was developed with an eye to minimizing adverse environmental impacts, but instead reflect differences entirely unrelated to the proposed action's environmental impacts. Such differences in capabilities, tempo, and locations are entirely based on operational needs, not on factors related to environmental impacts. As such, they fail to provide the public and decision makers with any options for significantly limiting the impact to marine wildlife. The development of alternatives in this manner violates NEPA, reflecting a classic post hoc rationalization for a decision unlawfully made before environmental impacts and reasonable alternatives were considered.	The EIS/OEIS reviewed potential environmental consequences (Chapter 3, Affected Environment and Environmental Consequences) of the Proposed Action and alternatives, and provides sufficient information for careful agency decision making. The Navy attempted to establish alternatives based on geographical alternatives (Section 2.5.1, Alternatives Eliminated From Further Consideration and Section 5.2.2.1, Lessons Learned from Previous Environmental Impact Statements/Overseas Environmental Impact Statements), but this approach proved to not be feasible. The Navy is not obligated by NEPA to consider alternatives that are not feasible. Therefore, the only reasonable alternatives for the Navy to consider to meet its purpose and need must differ in training tempo, capabilities, and locations. The alternatives carried forward meet the Navy's purpose and need to ensure that it can fulfill its obligation under Title 10. The selection of an alternative by the decision maker will be based on a review of all relevant facts, impact analyses, comments received via the EIS/OEIS public participation process, and the requirements of the Navy in order to fulfill its mission. The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS. Most impacts from the Proposed Action are expected to be brief and recoverable. Long-term impacts to a small number of individuals are not expected to have long-term population consequences.
NRDC - 11	In addition, even if Alternative I also met the Navy's strategic necessity and future training and testing requirements and a decision maker felt free to considering choosing it over the Navy's preferred alternative, he or she would be hard pressed to identify which alternative works to avoid or minimize adverse environmental impacts, let alone enhance the quality of the human environment. Both alternatives inflict an unprecedented amount of harm on marine life. Neither alternative was developed with	The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Sections 2.5 through 2.8 and explains why the Navy has considered but eliminated alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration). The Alternatives carried forward meet the Navy's purpose and need to ensure that it can fulfill its obligation

	an eye to minimizing adverse environmental impacts, but instead reflect differences entirely unrelated to the proposed action's environmental impacts. Such differences in capabilities, tempo, and locations - are entirely based on operational needs, not on factors related to environmental impacts. As such, they fail to provide the public and decision makers with any options for significantly limiting the impact to marine wildlife. The development of alternatives in this manner violates NEPA, reflecting a classic post hoc rationalization for a decision unlawfully made before environmental impacts and reasonable alternatives were considered.	under Title 10. Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) includes mitigation measures designed to reduce potential impacts.
NRDC - 12	The Navy Fails to Consider Effective Mitigation There is general consensus that protection areas - in which the use of mid-frequency sonar would not occur - represent the most effective means currently available to reduce the impacts of mid-frequency sonar on marine mammals.[5] In 2010, the National Oceanic Atmospheric Administration ("NOAA") completed a review of the Navy's sonar mitigation. It concluded that "ongoing mitigation efforts, in our view, must do more" to address uncertainties and protect marine mammals.[6] Nonetheless, the Navy's OEIS proposes the same mitigation scheme that NOAA found lacking. While NOAA emphasized the importance of habitat identification and avoidance, stating that "[p]rotecting important marine mammal habitat is generally recognized to be the most effective mitigation measure currently available," the Navy makes no provision for protecting areas in the HSTT Study Area in addition to the limited area for humpback whales.?	As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of a number of potential mitigation measures. Through consultation and permitting with NMFS, the Navy refined the mitigation measures, which are now presented in Chapter 5 of this Final EIS/OEIS. Through careful exploration of all mitigation measures to determine which were the most effective, the Navy has chosen the measures to mitigate potential impacts to marine mammals while still being able to meet its operational needs to train for real-world conditions. Specific mitigation measures are outlined in the following sections: Section 5.3.1 (Lookout Procedural Measures), Section 5.3.2 (Mitigation Zone Procedural Measures), and Section 5.3.3 (Mitigation Areas). Specifically, Section 5.3.3.1 (Marine Mammal Habitats) addresses important habitat areas.
NRDC - 13	Appendix A contains a detailed description of mitigation measures that the Navy can and should - adopt.	Through careful exploration of all mitigation measures to determine which were the most effective, the Navy has chosen the measures to mitigate potential impacts to marine mammals while still being able to meet its operational needs to train and test for real world conditions. Specific mitigation measures are outlined in the following sections: Section 5.3.1 (Lookout Procedural Measures), Section 5.3.2 (Mitigation Zone Procedural Measures), and Section 5.3.3 (Mitigation Areas). Specifically, Section 5.3.3.1 (Marine Mammal Habitats) addresses important habitat areas. The Navy is in consultation with NMFS as the regulator and a cooperating agency with regard to the Proposed Action, the potential environmental impacts, and any resultant mitigation measures as conditions of anticipated authorizations under the MMPA or reasonable and prudent measures resulting from issuance of a Biological Opinion under ESA.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 14	At a minimum, however, the Navy must assess the value of marine mammal habitat in the HSTT Study Area and protect any higher-value areas identified.	The mitigation measures identified throughout Chapter 5 will apply to protect all marine mammals year round, and will be applied regardless of the location of the activity. In 2012, the CetMap panel of experts determined that no biologically important areas could be identified based on data availability and information at hand. Furthermore, no follow-on products have identified areas of recommended avoidance. It is important to note that the areas appearing on the CetMap website are a preliminary draft that needs considerable additional input from the larger biological community before being used to identify biologically important areas in the ocean.
NRDC - 15	As noted, NOAA recently completed a series of workshops designed to learn more about marine mammal "hot spots." The results of these workshops are now available and the Navy must assess the information and develop mitigation measures based on protecting important marine mammal habitat. To offer full protection to the marine mammals found in these "hot spots," the Navy should develop mitigation measures that bar the use of sonar in the areas and provide a buffer for them that limits the received level of sound. At a minimum, the Navy should establish cautionary areas in these habitats.	The Navy has and will continue to support the Cetacean and Sound Mapping project, including providing representation on the Cetacean Density and Distribution Mapping Working Group (CetMap). This working group has two objectives. First, to create regional cetacean density and distribution maps that are time- and species-specific, using survey data and models that estimate density using predictive environmental factors. With the exception of the Atlantic and Gulf of Mexico, the Navy has considered this information as part of the impact and mitigation assessment process. For the Atlantic and Gulf of Mexico, the Navy OPAREA Density Estimates on the Spatial Decision Support System for the Strategic Environmental Research and Development Program (available at http://seamap.env.duke.edu./serdp/serdp_map.php), are still considered the best available data (Read and Halpin 2010[1]). Second, and separately, to augment the more quantitative density mapping and provide additional context for impact analyses, the CetMap is also identifying areas of specific importance for cetaceans, such as reproductive areas, feeding areas, migratory corridors, and areas in which small or resident populations are concentrated, otherwise referred to as “biologically important areas.” The working group determined that "hot spots" is not an appropriate term and chose to call them Biologically Important Areas. Biologically important areas information was based largely on observational data of animals exhibiting biologically important behaviors. The biologically important areas were only characterized for species, areas, and seasons where there were enough data to support the biologically important areas identification within the U.S. Exclusive Economic Zone. Most of these assessments are not based on CetMap density work products but on published and often unpublished data held by individual researchers.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		They only characterized the observational data available and did not use density or habitat-based models to determine the biologically important areas. Biologically important areas are not being designated by CetMap for the purpose of identifying areas off limit to human activities like sonar. Instead, information is being collected to provide additional context within which to examine potential interactions between cetaceans and human activities. This information can assist resource managers with planning, analyses, and decisions regarding how to reduce adverse impacts to cetaceans resulting from human activities. Some preliminary, draft results are currently being released on http://cetsound.noaa.gov/important.html. The CetMap Working Group is also undertaking external review of the documents by subject matter experts outside National Oceanic and Atmospheric Administration and is preparing a collection of manuscripts focused on the biologically important areas that will be submitted to a scientific journal for external peer review by subject matter experts. The Navy also recommended to NMFS that a formal expert elicitation on biologically important areas results be conducted, including data review by a larger body of marine scientists and stakeholders. When appropriate, NMFS provides draft CetMap information for Navy consideration. As part of the ESA and MMPA processes, NMFS requested the Navy to consider some specific preliminary draft areas as part of its mitigation analysis. As of the date of publication of the Final EIS/OEIS, this process is still ongoing; however, the results will be summarized in the Navy's Record of Decision and in NMFS Biological Opinion. If additional biologically important areas are identified by NMFS after the Navy's Record of Decision, the Navy and NMFS will use the Adaptive Management process to assess whether any additional mitigation should be considered in those areas. [1] Read, A. J. and P. Halpin. 2010. Predictive Spatial Analysis of Marine Mammal Habitats. Final Report. SERDP Project SI-1390. January 2010. 292 pp.
NRDC - 16	Conclusion Our organizations recognize the Navy's important role in ensuring national security. We also value the security a clean and healthy environment provides. National security and environmental integrity are not mutually exclusive, and we encourage the Navy to train and test in ways that protect Hawaii's and Southern California's valuable natural resources. Thus, for the reasons set forth above and in greater detail in the Appendices below and attached critique by Dr. David Bain, we urge the Navy to satisfy its obligations under NEPA and other applicable laws by revising its DEIS, taking a "hard	The Navy complies with all applicable environmental laws, including NEPA. The EIS/OEIS has taken a "hard look" at potential environmental consequences of the Proposed Action and alternatives, and provides sufficient information for careful agency decision-making. The Navy considered the best available science in preparation of this

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	look" at impacts and identifying and analyzing reasonable alternatives and mitigation measures that will significantly reduce the impact to the marine environment.[8] Upon revision the DEIS should be released to the public for review and comment.	EIS/OEIS and is in consultation with NMFS as the regulator and a cooperating agency with regard to the Proposed Action, the potential environmental impacts, and any resultant mitigation measures as conditions of anticipated authorizations under the MMPA or reasonable and prudent measures resulting from issuance of a Biological Opinion under ESA.
NRDC - 17	APPENDIX A As set forth below, the Navy's DEIS does not meet the rigorous standards set forth in the National Environmental Policy Act. We urge the Navy to revise and then reissue its DEIS, substantially altering the approach it has taken thus far. The Navy's scope of review must be expanded, its alternatives analysis broadened, its mitigation plan significantly improved, and its impact assessment revised to reflect the scientific evidence of mid-frequency sonar's effects on marine life. These critical steps must be undertaken if the Navy's EIS is to comply with federal law. I. Legal Framework: The National Environmental Policy Act The National Environmental Policy Act of 1969 ("NEPA") "declares a broad national commitment to protecting and promoting environmental quality." Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 348 (1989). NEPA establishes a national policy to "encourage productive and enjoyable harmony between man and his environment" and "promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man." 42 U.S.C. § 4321. In order to achieve its broad goals, NEPA mandates that "to the fullest extent possible" the "policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with [it]." 42 U.S.C. § 4332. Central to NEPA is its requirement that, before any federal action that "may significantly degrade some human environmental factor" can be undertaken, agencies must prepare an EIS. Steamboaters v. F.E.R.C., 759 F.2d 1382, 1392 (9th Cir. 1985) (emphasis in original). The requirement to prepare an EIS "serves NEPA's action-forcing purpose in two important respects." Robertson, 490 U.S. at 349. First, "the agency, in reaching its decision, will have available, and will carefully consider. detailed information concerning significant environmental impacts[,]" and second, "the relevant information will be made available to the larger audience that may also play a role in both the decisionmaking process and the implementation of that decision." Id. (emphasis added). As the Supreme Court explained: "NEPA's instruction that all federal agencies comply with the impact statement requirement. .. 'to the fullest extent possible' [cit. omit.] is neither accidental nor hyperbolic. Rather the phrase is a deliberate command that the duty NEPA imposes upon the agencies to consider environmental factors not be shunted aside in the bureaucratic shuffle." Flint Ridge Development Co. v. Scenic Rivers Ass'n, 426 U.S. 776, 787 (1976). The fundamental purpose of an EIS is to force the decision-maker to take a "hard look"	As explained above, the Navy's statement of the purpose and need for the Proposed Action is detailed and specific, the scope of the Proposed Action is described in exhaustive detail after careful assessment of training and testing requirements, and the alternatives have been developed in accordance with NEPA standards. The EIS/OEIS is the product of extensive analysis applying best available science, including methodologies for analyzing impacts of mid-frequency active sonar on marine mammals that were developed in close consultation with NMFS, a cooperating agency in the development of this EIS/OEIS, the recognized experts in the marine environment, and the agency designated by law under the MMPA with jurisdiction over the protection of the marine environment. The Navy has developed, refined and adopted mitigation measures to address environmental impacts in every affected resource area, and has identified any unavoidable impacts of the Proposed Action. The Navy has further conducted an appropriate analysis of cumulative effects of its Proposed Action. The EIS/OEIS takes a "hard look" at potential environmental consequences of the Proposed Action and alternatives, and provides sufficient information for careful agency decision-making.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	at a particular action - at the agency's need for it, at the environmental consequences it will have, and at more environmentally benign alternatives that may substitute for it before the decision to proceed is made. 40 C.F.R. §§ 1500.I(b), 1502.1; Baltimore Gas & Electric v. NRDC, 462 U.S. 87,97 (1983). This "hard look" requires agencies to obtain high quality information and accurate scientific analysis. 40 C.F.R. § 1500.1 (b). "General statements about possible effects and some risk do not constitute a hard look absent a justification regarding why more definitive information could not be provided." Klamath-Siskiyou Wilderness Center v. Bureau of Land Management, 387 F.3d 989, 994 (9th Cir. 2004) (quoting Neighbors of Cuddy Mountain v. United States Forest Service, 137 F.3d 1372, 1380 (9th Cir. 1998». The law is clear that the EIS must be a pre-decisional, objective, rigorous, and neutral document, not a work of advocacy to justify an outcome that has been foreordained. In nearly every respect, despite the length and information provided, the Navy's DEIS fails to meet the high standards of rigor and objectivity required under NEPA. The Navy has failed to conduct the "hard look" necessary to thoroughly examine the many environmental consequences of its proposed action.	
NRDC - 18	The Navy Fails to Properly Analyze Impacts on Marine Mammals The Navy's OEIS does not properly analyze environmental impacts. Despite the unprecedented level of harm the Navy predicts, its analysis nonetheless understates the potential effects of its training and testing activities on marine wildlife and fails to acknowledge risks posed to a wide range of marine species from its activities. The DEIS concludes that no "marine mammal strandings or mortality will result from the operation of sonar or other acoustic sources during Navy exercises within the Study Area." DEIS at 3.4-152. The Navy reaches this conclusion despite acknowledging the importance of sound to marine mammal existence and the hundreds of thousands of instances of hearing loss its activities will inflict on marine mammals. For example, the Navy states that "it is likely that a relationship between the duration, magnitude, and frequency range of hearing loss could have consequences to biologically important activities (e.g., intraspecific communication, foraging, and predator detection) that affect survivability and reproduction." OEIS at 3.4-97 to 98. The Navy's statements are clearly contradictory; on the one hand the Navy states that a connection between survivability and hearing loss is likely, which must be placed in the context of its prediction of 3 million instances of temporary hearing loss, while on the other it concludes that no mortality will result from the use of sonar. The Navy's conclusions are unsupported by its own analysis. Finally, as discussed in detail in Appendix C and the attached critique by Dr. David Bain, the Navy's assessment of acoustic impacts is also highly problematic and likely underestimates the impacts to marine mammals.	The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS, using the most current, relevant scientific information. The number of marine mammal harassment exposures must be estimated scientifically using complex modeling, but the resulting estimates must then be analyzed in context of the limitations of that modeling. Since the Draft EIS/OEIS was released, adjustments were made to the quantified results of the marine mammal acoustic effects analysis. These changes were presented in the Navy's Letter of Authorization application to NMFS and are reflected in this Final EIS/OEIS. Modifications to the requested take numbers outlined in the Draft EIS/OEIS were presented in the Proposed Rule and are a result of consultation with NMFS, as well as refinements to training and testing modeling inputs and minor changes to Navy training and testing as a result of emerging requirements. In consultation with NMFS, the Navy made post-model adjustments to further refine the numerical analysis of acoustic effects so as to include by considering animal avoidance of sound sources, avoidance of areas of activity before use of a sound source or explosive, and implementation of mitigation. Section 3.4.3.1.5.5 (Marine Mammal Avoidance of Sound Exposures) and Section 3.4.3.1.5.6 (Implementing Mitigation to Reduce Sound Exposures), describes in detail the post-model adjustments made to further refine the numerical analysis of acoustic effects. Also based on response to comments, Navy has supplemented the discussion regarding hearing loss as a general

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		topic. With regard to the critique by Dr. David Bain, this same critique was provided as comment on the 2009 HRC EIS/OEIS so was certainly considered in the development of the present HSTT EIS/OEIS. As noted in response then and presented in the current document, the design of the modeling and input factors has insured that the quantification of effects to marine mammals is a purposefully conservative overestimate of impacts.
NRDC - 19	Acoustic Impacts on Marine Mammals NEPA requires agencies to ensure the "professional integrity, including scientific integrity," of the discussions and analyses that appear in EISs. 40 C.F.R. § 1502.24. To that end, they must make every attempt to obtain and disclose data necessary to their analysis. See 40 C.F.R. § IS02.22(a). Agencies are further required to identify their methodologies, indicate when necessary information is incomplete or unavailable, acknowledge scientific disagreement and data gaps, and evaluate indeterminate adverse impacts based upon approaches or methods "generally accepted in the scientific community." 40 C.F.R. §§ 1502.22(2), (4), 1502.24. Such requirements become acutely important in cases where, as here, so much about a program's impacts depend on newly emerging science. In this case, the Navy's assessment of impacts is consistently undermined by its failure to meet these fundamental responsibilities of scientific integrity, methodology, investigation, and disclosure. As set forth in greater detail in Appendix C and the attached critique by Dr. Bain, the DEIS disregards a great deal of relevant information adverse to the Navy's interests, uses approaches and methods that would not be acceptable to the scientific community, and ignores whole categories of impacts. In short, it leaves the public with an analysis of harm-behavioral, auditory, and physiological-that is at odds with established scientific authority and practice. The Navy must revise its acoustic impacts analysis, including its thresholds and risk function, to comply with NEPA.	The marine mammal acoustical analysis is based on the use of the best available science (see Section 3.4, Marine Mammals) as it applies to mid-frequency and high-frequency sources used during training and testing in the HSTT Study Area. The Navy has been thorough in its use of all relevant data and studies available on the marine environment as required by NEPA.
NRDC - 20	Other Impacts on Marine Mammals The activities proposed for the HSTT Study Area may have impacts that are not limited to the effects of ocean noise. Unfortunately, the Navy's analysis of these other impacts is cursory and inadequate. First, the Navy fails to adequately assess the impact of stress on marine mammals, a serious problem for animals exposed even to moderate levels of sound for extended periods.[9] DEIS at 3.4-99 to 100. As the Navy has previously observed, stress from ocean noise-alone or in combination with other stressors, such as biotoxins-may weaken a cetacean's immune system, making it "more vulnerable to parasites and diseases that normally would not be fatal."[10] Moreover, according to	Exposure to mid or high frequency active sonar will not result in a chronic noise environment in the HSTT Study Area. Sonar pings are brief and intermittent with an animal exposed at most approximately two times a minute for several minutes if the animal is undetected by Navy Lookouts. Given the manner in which sonar is typically used, and the movement of the participants, it is extremely unlikely that individual animals would be exposed to sonar long enough for stress or injury to occur. Studies of odontocetes chased during purse seining of tuna showed

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	studies on terrestrial mammals, chronic noise can interfere with brain development, increase the risk of myocardial infarctions, depress reproductive rates, and cause malformations and other defects in young-all at moderate levels of exposure. I t Because physiological stress responses are highly conservative across species, it is reasonable to assume that marine mammals would be subject to the same effects and recent research is bearing this out. A study of North Atlantic right whales produced evidence showing that exposures to low-frequency ship noise may be associated with chronic stress in whales. 12 For the Navy, Stich studies should be particularly relevant when assessing impacts on those marine mammal populations that are subjected to stress inducing impacts from training and testing activities on a regular basis. Nonetheless, despite the potential for stress in marine mammals and the significant consequences that can now from it, the Navy unjustifiably assumes that such effects would be minimal. <J See National Research Council, Ocean Noise and Marine Mammals. 10 Navy, Hawaii Range Complex Draft Environmental Impact Statement! Overseas Environmental Impact Statement at 5-19 to 5-20 (2007). Additional evidence relevant to the problem of stress in marine mammals is summarized in A.J. Wright, N. Aguilar Soto. A.L. Baldwin, M. Bateson, C.M. Beale, C.Clark, T. Deak, E.F. Edwards, A. Fernandez, A. Godinho, L. Hatch, A. Kakuschke, D.Lusseau, D. Martineau, L.M. Romero, L. Weilgart, B. Wintle, G. Notarbartolo di Sciara, and V. Martin, Do marine mammals experience stress related to anthropogenic noise?, 20 International Journal of Comparative Psychology, 274-316 (2007): see also T.A. Romano, M.J. Keogh, C. Kelly, P. Feng, L. Berk, C.E. Schlundt, D.A. Carder, and 1.1. Finneran, Anthropogenic Sound and Marine Mammal Health: Measures of the Nervous and Immune Systems Before and After Intense Sound Exposure, 61 Canadian Journal of Fisheries and Aquatic Sciences 1124, 1130-31 (2004). 11 See, e.g., E.F. Chang and M.M. Merzenich, Environmental Noise Retards Auditory Cortical Development, 300 Science 498 (2003) (rats); S.N. Willich, K. Wegscheider, M. Stallmann, and T. Keil, Noise Burden and the Risk of Myocardial Infarction, European Heart Journal (2005) (Nov. 24,2005) (humans); F.H. Harrington and A.M. Veitch, Calving Success of Woodland Caribou Exposed to Low Level Jet Fighter Overflights, 45 Arctic vol. 213 (1992) (caribou) 12 R. M. Rolland, S. E. Parks, K. E. Hunt. M. Castellote. P. J. Corkeron, D. P. Nowacek. S. K. Wasser, and S. D. Krauss. 2012. "Evidence That Ship Noise Increases Stress in Right Whales." Proceedings of the Royal Society of Biology. 10. 1098/rspb.2011.2429.	stress effects when pursued for long periods (30-40 minutes) but most of those animals recovered (Edwards 2007 International Journal of Comparative Psychology, 20: 217-227). Since the impact from noise exposure and the Navy training and testing events in general should be transitory given the movement of the participants, any stress responses should be short in duration and have less than biologically significant consequences.
NRDC - 21	Second, in the course of its training activities, the Navy would release a host of toxic chemicals, hazardous materials and waste into the marine environment that could pose a threat to marine mammals over the life of the range. For example, under its preferred alternative, the Navy plans to abandon approximately 370,000 pounds of potentially toxic metals in HSTT Study Area waters. DEIS at 3.1-44 to 45. Nonetheless, the OEIS fails to adequately consider the cumulative impacts of these toxins on marine mammals from past, current, and proposed training exercises. Careful study is needed into the way	This statement is inaccurate. Chapter 3.1 (Sediments and Water Quality) did not state that 370,000 pounds of potentially toxic metals would be abandoned. The chapter concludes that chemical, physical, or biological changes to sediment or water quality would be measurable but below applicable standards, regulations, and guidelines, and would be within existing conditions or designated uses. Neither state nor federal standards or guidelines would be violated.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	toxins might disperse and circulate within the area and how they may affect marine wildlife.	
NRDC - 22	The Navy's assumption that expended materials and toxics would dissipate or become buried in sediment leads to a blithe conclusion that releases of hazardous material would have no adverse effects. Given the amount of both hazardous and nonhazardous materials, this discussion is inadequate under NEPA.	The EIS/OEIS document presents a thorough description and analysis in Section 3.1.3 (Environmental Consequences) of amounts and types of specific training materials as well as chemical composition and breakdown processes of expended materials. Based on the best available science, the impact of explosives, explosion byproducts, and metals on sediment and water quality would be both short- and long-term, and localized. Chemical, physical, or biological changes in sediment or water quality would be measurable, but below applicable standards and guidelines, and would be below or within existing conditions or designated uses. The impact of chemicals other than explosives and other materials on sediment and water quality would be both short- and long-term, and localized. Chemical, physical, or biological changes in sediment or water quality would not be detectable, and would be below or within existing conditions or designated uses. Therefore, no water or sediment toxicity would occur, so no adverse effects on marine organisms would be expected.
NRDC - 23	In addition, the Navy also plans to abandon cables, wires, and other items that could entangle marine wildlife, including more than 67,000 parachutes. DEIS at 3.3-26. Acknowledging that entanglement is a serious issue for marine mammals (e.g., "From 1998-2005, based on observer records, five fin whales (CA/OR/WA stock), 12 humpback whales (Eastern North Pacific stock), and six sperm whales (CA/OR/WA stock) were either seriously injured or killed in fisheries off the mainland West Coast of the U.S." DEIS at 3.4-250), the DEIS nonetheless dismisses the threat posed by abandoning 67,000 parachutes, claiming without support that a marine mammal that did become entangled could easily become free. DEIS at 255. Again, this discussion and analysis is inadequate under NEPA.	The studies regarding marine mammal entanglement involve primarily fishing gear, which include items designed to ensnare and result in entanglement. Unlike typical fishing nets and lines, the Navy's equipment is not designed for trapping or entanglement purposes. The Navy deploys equipment designed for military purposes and strives to reduce the risk of accidental entanglement posed by any item it releases into the sea.
NRDC - 24	Third, the Navy fails to consider the risk of ship collisions with large cetaceans, as exacerbated by the use of active acoustics. For example, right whales have been shown to engage in dramatic surfacing behavior, increasing their vulnerability to ship strikes, on exposure to mid-frequency alarms above 133 dB re 1 μPa (SPL)-a level of sound that can occur many tens of miles away from the sonar systems slated for the range. 13 It should be assumed that other large whales (which, as the OEIS repeatedly notes, are already highly susceptible to vessel collisions) are subject to the same hazard. As the Navy notes, "[v]essel strikes from commercial, recreational, and Navy vessels are known to affect large whales in the HSTT Study Area and have resulted in serious injury and	Ship strikes were discussed in the Draft EIS/OEIS, Section 3.4.3.3.1 (Impact from Vessels). Results of the research by Nowacek et al (2004) where right whales reacted to an "alert stimuli," used a sound source that was designed to cause a reaction in right whales and has almost no correlation to any sound source used by the U.S. Navy. The results of the Nowacek et al (2004) study were not used in the Navy's ship strike analysis; however, the results were used to develop the risk function from which the quantification of predicted exposures was derived. With regard to the vessel strike calculations, those were done

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	occasional fatalities to cetaceans." DEIS at 3.4-235. And while the Navy analyzes the threat of ship strikes generally (DEIS at 3.4-234 to 245), it uses a basic probability calculation as opposed to the kind of modeling for take that it uses for other impacts (e.g., acoustic sources), which can underestimate the impact from ship strikes.	using years of National Oceanic and Atmospheric Administration historical strike data to assess the probability of ship strike. The use of historical trend data is considered to be the most accurate means to assess the probability of future strikes since there is no scientific method to otherwise make such an assessment.
NRDC - 25	Fourth, the Navy does not adequately analyze the potential for and impact of oil spills. As evidenced by the 1989 Exxon Valdez oil spill and the 2010 BP Deepwater Horizon disaster, there is a risk of an oil spill in areas where oil is produced and transported, such as areas of Southern California. This risk is exacerbated by increasing the tempo and intensity of Navy training, which will involve more vessels, more transits, and longer missions throughout the HSTT Study Area.[14] In light of this history and the extraordinarily valuable and sensitive natural resources that occur in Southern California, the Navy must evaluate its spill response plan and station salvage equipment accordingly. 14- We note that the Navy should include in its analysis and disclose to the public a chart that shows how its operating areas overlap shipping lanes, recommended routes, and Areas to Be Avoided as an indication of the potential for conflict with other vessels.	The analysis presented in the EIS/OEIS is limited to the activities and reasonable outcomes of such activities. As accidents involving other vessels and oil spills are not reasonably foreseeable, nor anticipated, the impact of such occurrences are not addressed or analyzed. The Navy has plans and procedures for preventing, reporting, and responding to oil spills. Although the number of training and testing activities is likely to increase, multiple activities usually occur from the same vessel, thus increased number of activities is not expected to result in an increase in vessel use or transit.
NRDC - 26	Finally, the Navy's analysis cannot be limited only to direct effects, i.e., effects that occur at the same time and place as the training exercises that would be authorized. 40 C.F.R. § 1508.8(a). It must also take into account the activity's indirect effects, which, though reasonably foreseeable (as the DEIS acknowledges), may occur later in time or are further removed. 40 C.F.R. § 1508.8(b). This requirement is particularly critical in the present case given the potential for sonar exercises to cause significant long-term impacts not clearly observable in the short or immediate term (a serious problem, as the National Research Council has observed). 15 Thus, for example, the Navy must not only evaluate the potential] for mother-calf separation but also the potential for indirect effects-on survivability-that might arise from that transient change. 40 C.F.R. § 1502. 16(b). Without further consideration of these impacts, and mitigation and alternatives developed to address those impacts, the DEIS does not pass NEPA muster. 15 "Even transient behavioral changes have the potential to separate mother-offspring pairs and lead to death of the young, although it has been difficult to confirm the death of the young." National Research Council. Ocean Noise and Marine Mammals at 96.	The potential for indirect effects on marine mammals has been considered in Section 3.4 (Marine Mammals) in developing the methodology for assessing acoustic impacts, and it is thereby acknowledged that direct acoustic harassment of an individual can lead to other, indirect effects. As depicted in Figure 3.0-18, the Navy's analysis considers all potential impacts resulting from exposure to acoustic sources. In figure 3.0-18, the effects are shown in terms of physiological responses, behavioral responses, potential costs to the animal, recovery, and long-term consequences. The likely existence of such effects is accounted for in the estimation of "take" and they are otherwise not predictable or amenable to quantification. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf].

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 27	Other Impacts on Wildlife The same concerns that apply to marine mammals - such as injury or death from midfrequency active sonar, collisions with ships, bioaccumulation of toxins, and stress apply to sea turtles, birds and other biota as well. The Navy must adequately evaluate impacts and propose mitigation for each category of harm. 40 C.F.R. §§ 1502.14, 1502.16. The Navy limits its analysis of the effects of mid-frequency active sonar on sea turtles on the grounds that their best hearing range appears to occur below 1 kHz. DEIS at 3.55 to 6; 3.5-40. Nevertheless, even with this limitation, the Navy predicts nearly 8,000 instances of temporary hearing loss for sea turtles, over 700 instances of permanent hearing loss, 65 instances of gastrointestinal injury, and 25 deaths from acoustic sources, like sonar, and explosives over five years. DEIS at 3.5-42; 3.5-47. Given the endangered status of sea turtles, there is little room for error in assessing impacts. While predicting death and permanent injury to members of these species and acknowledging a complete lack of density data for the species in open ocean conditions, the Navy nonetheless concludes that "population level impacts are not expected." DEIS at 3.5-42. Yet such conclusions are made without analyzing the impacts against the specific status of each species, even while acknowledging that many of the species have decreasing long-term population trends (e.g., hawksbiII sea turtles at DEIS 3.5-13) and that studies indicate that many populations in the HSTT Study Area may be genetically distinct and require independent management (e.g., green sea turtles at OEIS 3.5-7). The Navy must rigorously analyze predicted impacts against the status of the species in the HSTT Study Area before concluding that no population-level impacts are expected.	The Navy has analyzed potential impacts from ship strikes, bioaccumulation of toxins, and stress on multiple species within the applicable marine resources sections. The Navy has included mitigation measures for each resource within each respective section and within Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring). Regarding sea turtles, while there are some sea turtles that may be able to hear sounds at 1 kHz, there is a very large difference between sounds at 1 kHz and sounds at 3.5 kHz than would be evident in simply looking at the difference between the numbers (a delta of -2.5). Current best available science and all available indications are that they are not likely able to hear mid-frequency sonar. Potential impacts related to bioaccumulation are discussed in the EIS/OEIS in Section 3.4.3.7 (Secondary Stressors). Finally, in the absence of scientific studies, reliance on professional judgment is required. Statements on the behavior of animals contained in the EIS/OEIS are based on the best available science. The Navy consulted with the U.S. Fish and Wildlife Service as appropriate.
NRDC - 28	Nor is the Navy's reasoning with regard to seabirds any more sound. Although the Navy acknowledges that "[t]here is little published literature on the hearing abilities of birds underwater... [and] no measurements of the underwater hearing of any diving birds" (DEIS at 3.6-8), it then inexplicably concludes that "any sound exposures would be minimal and are unlikely to have a long-term impact on an individual or a population." DEIS at 3.6-27. Such reasoning does not bear up to any serious scrutiny. See, e.g., the entirely unsupported assertion that "[s]eabirds would avoid any additional exposures during a foraging dive when they surface" (OEIS at 3.6-24). Seabirds occur in the HSTT Study Area, dive underwater (in some cases to depths of hundreds of feet), and are sensitive to the frequencies used by the Navy's acoustic sources. They must receive further analysis in the DEIS, both for the direct impacts they may suffer on exposure to the Navy's acoustic sources and for the impacts they may incur indirectly through depletion of prey species and hard bottom habitat. 40 C.F.R. § l502.16(a), (b). Without further consideration of these species, the Navy's review is incomplete.	A thorough analysis of acoustic impacts to seabirds appears in Section 3.6.3.1 (Acoustic Stressors) which is based on the best available science. This section addressed deep diving birds. The EIS/OEIS concluded there would be no long-term impacts from sonar to marine habitats (see Section 3.3 [Marine Habitats]) or fish (see Section 3.9 [Fish]), and therefore no indirect impacts are expected for seabirds.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 29	The Navy Failed to Analyze the Impacts on Fish and Fisheries The HSTT Study Area is a highly productive region for fish and invertebrate populations. It supports some of the most productive and commercially important fisheries in the United States (including market squid, pacific sardine, swordfish, and tuna). The HSTT Study Area supports hundreds of other species, many with federally designated essential fish habitat in the Study Area. In its OEIS, the Navy discusses many of the unknowns regarding impacts from training and testing on fish (e.g., "While statistically significant losses were documented in the two groups impacted, the researchers only tested that particular sound level once, so it is not known if this increased mortality was due to the level of the test signal or to other unknown factors." DEIS at 3.9-30), while also acknowledging that "potential impacts on fish from acoustic and explosive stressors can range from no impact brief acoustic effects, tactile perception, and physical discomfort, to slight injury to internal organ and the auditory system do death of the animal" DEIS at 3.9-57. Nonetheless, the DEIS concludes that that its training activities - including both the use of mid-frequency active sonar and underwater detonations - would have no significant impact on fish, fisheries and essential fish habitat. The Navy's conclusion not only contradicts the available scientific literature on noise but also ignores the valid concerns of fishermen. For example, fisherman concerned with declining catch rates wrote letters opposing the Navy's proposal to build an Undersea Warfare Training Range off the coast of North Carolina in 2005. Those fishermen reported sharp declines in catch rates in the vicinity of Navy exercises. Decline in Catch Rates For years, fisheries in various parts of the world have complained about declines in their catch after intense acoustic activities (including naval exercises) moved into the area, suggesting that noise is seriously altering the behavior of some commercial species. A group of Norwegian scientists attempted to document these declines in a Barents Sea fishery and found that catch rates of haddock and cod (the latter known for its particular sensitivity to low-frequency sound) plummeted in the vicinity of an airgun survey across a 1600-square-mile area. In another experiment, catch rates of rockfish were similarly shown to decline. I? Drops in catch rates in these experiments range from 40 to 80 percent. 18 A variety of other species, herring, zebrafish, pink snapper, and juvenile Atlantic salmon, have been observed to react to various noise sources with acute alarm. In their comments On the Navy's Draft Environmental Impact Statement for the proposed Undersea Warfare Training Range off the coast of North Carolina, several fishermen and groups of fishermen independently reported witnessing sharp declines in catch rates of various species when in the vicinity of Navy exercises. - These reports are also indicative of behavioral changes -such as a spatial redistribution of fish within the water column - that could similarly affect the fisheries in the HSTT Study Area. 16 See "'Noisy' Royal Navy Sonar Blamed for Falling Catches," Western Morning News, Apr. 22, 2002 (sonar off the U.K.); Percy J. Hayne, President of Gulf Nova Scotia Fleet	While the EIS/OEIS concludes there will be impacts from the Proposed Action to fish, those impacts do not translate into impacts to socioeconomic resources. Impacts analyzed in the EIS/OEIS consider the individual and the population. Impacts to single individuals do not translate to impacts on the entire population or the resource as a whole. The conclusions presented in the EIS/OEIS are fully supported in the analysis. Concerns of commercial fisherman were addressed in the EIS/OEIS (see Section 3.11.3 [Environmental Consequences]). Favored fishing areas change over time with fluctuations in fish populations and communities, preferred target species, or fishing modes and styles. Declines in fishing rates can be attributed to several factors both natural and anthropogenic. Section 3.9 (Fish) concluded no long-term impacts to fish populations are anticipated, therefore, Section 3.11 (Socioeconomic Resources) correctly concluded there would be no indirect impacts to commercial and recreational fishing.

NRDC - 30	Permanent Injury and Mortality The Navy's conclusion that underwater noise will result in only "minimal harm" to fish ignores the scientific literature. A number of studies, including one on non-impulsive noise, show that intense sound can kill eggs, larvae, and fry outright or retard their growth in ways that may hinder their survival later.[21] Significant mortality for fish eggs has been shown to occur at distances of 5 meters from an airgun source; mortality rates approaching 50 percent affected yolk sac larvae at distances of 2 to 3 meters.[22] With respect to mid-frequency sonar, the Navy itself has noted that "some sonar levels have been shown [in Norwegian studies] to be powerful enough to cause injury to particular size classes of juvenile herring from the water's surface to the seafloor."[23] Also, larvae in at least some species are known to use sound in selecting and orienting toward settlement sites.[24] Acoustic disruption at that stage of development could have significant consequences.[25] Although the Navy acknowledges studies showing that eggs and larvae are more susceptible to sound, it tries to distinguish them by stating that they "were laboratory studies, however, and have not been verified in the field." DEIS at 3.9-	The approach to analysis (Section 3.0.5.4, Resource-Specific Impacts Analysis for Individual Stressors) states the analysis begins with individual organisms and their habitats, and then addresses populations, species, communities, and representative ecosystem characteristics, as appropriate. Impacts on a resource, not listed as a federally protected species, are not based on impacts on individuals, but rather to the entire population. Section 3.9.3.1.2 (Impacts from Sonar and Other Non-Impulsive Acoustic Sources) and Section 3.9.3.1.3 (Impacts from Explosives and Other Impulsive Acoustic Sources) address potential impacts from all acoustic sources on fish, including non-impulsive noise and swimmer defense airguns. The conclusions reached in the EIS/OEIS are based on the best available science and are fully supported by the science and the analysis.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	32. However, federal law does not allow the Navy to ignore the valid scientific studies that have already been conducted simply because they are contrary to its interest. As the Navy is aware after recently completing consultation with both NMFS (for salmon) and the U.S. Fish and Wildlife Service (for bull trout) over its Explosive Ordinance Disposal ("EOD") training exercises in Puget Sound, underwater explosions are responsible for high direct mortality to fish species present in the area. Indeed, the underwater detonation of just five pounds of plastic explosives has been observed to kill over 5,000 fish with swim bladders, with more accurate estimates ranging as high as 20,000 fish. There are a variety of live-fire training exercises, some of which involve underwater explosions of torpedoes and other ordnance that will take place in the HSTT Study Area. Given the variety of fish and fisheries inhabiting these waters, the Navy's failure to analyze these effects in significant detail is stunning. 21 See,e.g., C. Booman, J. Dalen, H. Leivestad, A. Levsen, T. van der Meeren, and K. Overseas Environmental Impact Statement for the Southern California Range Complex 3.7-66 to 3.7-67 (2008). In the HSTT Study Area, the Navy would operate sonar at higher levels than those used in the Norwegian studies. 24 S.D. Simpson, M. Meekan, J. Montgomery, R. McCauley. R., and A. Jeffs, Homeward Sound, 308 Science 221 (2005). 1'; Popper, Effects of Anthropogenic Sounds at 27.	
NRDC - 31	Hearing Loss One series of recent studies showed that passing airguns can severely damage the hair cells of fish (the organs at the root of audition) either by literally ripping them from their base in the ear or by causing them to "explode."[26] Fish, unlike mammals, are thought to regenerate hair cells, but the pink snapper in these studies did not appear to recover within approximately two months after exposure, leading researchers to conclude that the damage was permanent.[27] It is not clear which elements of the sound wave contributed to the injury, or whether repetitive exposures at low amplitudes or a few exposures at higher pressures, or both, were responsible.[28] As with marine mammals,	The Navy has provided the best available science in reviewing impacts to fish from mid-frequency sonar. Section 3.9.3.1 (Acoustic Stressors) and discussion therein explains various studies currently available into the impact of sonar on varying fish species, including a study published by Doksaeter, et al (2009) in which the authors concluded that mid-frequency sonars could be used without substantially affecting the fish. While the effects of sound on all species of fish have not been studied, leaving much unknown, there are reasonable extrapolations that can

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	sound has also been shown to induce temporary hearing loss in fish. Even at fairly moderate levels, noise from outboard motor engines is capable of temporarily deafening some species of fish, and other sounds have been shown to affect the short term hearing of a number of other species, including sunfish and tilapia.[29] For any fish that is dependent on sound for predator avoidance and other key functions, even a temporary loss of hearing (let alone the virtually permanent damage seen in snapper) will substantially diminish its chance of survival.[30] 26 R. McCauley. J. Fewtrell, and A.N. Popper. High Intensity Anthropogenic Sound Damages Fish Ears, 113 Journal of the Acoustical Society of America 640 (2003). 27 Id. at 641 (some fish in the experimental group sacrificed and examined 58 days after exposure). 28 Id. 29 A.R. Scholik and H.Y. Yan, Effects of Boat Engine Noise all the Auditory Sensitivity of tile Fathead Minnow. Pimephales promelas, 63 Environmental Biology of Fishes 203-09 (2002); AR. Scholik and H. Y. Yan, The Effects of Noise on the Auditory Sensitivity of the Bluegill Sunfish. Lepomis macrochirus, 133 Comparative Biochemistry and Physiology Part A at 43-52 (2002); M.E. Smith, A.S. Kane. & A.N. Popper, Noise-Induced Stress Response and Hearing Loss in Goldfish (Carassius auratusl. 207 Journal of Experimental Biology 427-35 (2003); Popper, Effects of Anthropogenic Sounds at 28. 30 See Popper, Effects of Anthropogenic Sounds at 29; McCauley et at., High Intensity Anthropogenic Sound Damages Fish Ears, at 641.	be made based on the general anatomy of fish and from the representative species that have been studied. Based on those studies and as detailed in Section 3.9 (Fish), it is unlikely that sonar will adversely affect most fish given most fish cannot hear in the frequency range of the mid- and high-frequency sonar Navy is proposing to use. In addition, Navy has been conducting these same training activities for many decades in Southern California and Hawaii and both of which support healthy and diverse fisheries.
NRDC - 32	Breeding Behavior NMFS has observed that the use of mid-frequency sonar could affect the breeding behavior of certain species, causing .them, for example, to cease their spawning choruses, much as certain echolocation signals do. The repetitive use of sonar and other active acoustics could thus have significant adverse behavioral effects on some species of fish and those who depend on them.	The EIS/OEIS included findings by Popper et al (2007) who exposed rainbow trout, a fish sensitive to low frequencies, to high-intensity low-frequency sonar (215 dB re 1 μPa^2 170-320 Hz) with receive level for two experimental groups estimated at 193 dB for 324 or 648 seconds. Fish exhibited a slight behavioral reaction, and one group exhibited a 20-dB auditory threshold shift at one frequency. No direct mortality, morphological changes, or physical trauma was noted as a result of these exposures. These results of low-frequency sonar effects on low-frequency sensitive rainbow trout suggests that similar results may be found with mid-frequency active sonar use when applied to mid-frequency sensitive fish. The assessment for the proposed mid-frequency sound sources (at or above the 3.5 kHz center frequency) suggests that with few exceptions, fish cannot hear sounds above about 3 kHz (Popper 2003, Hastings and Popper 2005). Thus, it is expected that most fish species would not be able to hear the mid-frequency sonar proposed for use. If responses to mid-frequency sonar use do occur, behavioral responses would be brief, reversible, and not biologically significant. Sustained

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		auditory damage is not expected. Sensitive life stages (juvenile fish, larvae and eggs) very close to the sonar source may experience injury or mortality, but below the level of loss of larval and juvenile fish from natural causes. The use of Navy mid-frequency sonar would not compromise the productivity of fish or adversely affect their habitat.
NRDC - 33	In sum, the Navy arbitrarily dismisses the potential for adverse impacts on fish. The Navy also capriciously dismisses the notion that fisheries in the area would suffer economic loss, even though - judging by the comments from North Carolina fishermen in 2005 - its training activities appear to have disrupted fishing in the past. Just like the training proposed in North Carolina, the available evidence here underscores the need for a more serious and informed analysis than the Navy currently provides. To comply with the requirements of NEPA, the Navy should rigorously analyze the potential for behavioral, auditory, and physiological impacts on fish, including the potential for population-level effects, using models of fish distribution and population structure and conservatively estimating areas of impact from the available literature. 40 C.F.R. §1502.22. The Navy must also meaningfully assess the economic consequences of reduced catch rates on commercial and recreational fisheries (as well as on marine mammal foraging) in the HSTT Study Area. It should also consider avoiding essential fish habitat, spawning grounds and other areas of important habitat for fish species, especially hearing specialists. Notably, as with marine mammals, the Navy does not consider exclusion of important fish habitat or fisheries in the HSTT Study Area.	The Navy has conducted a thorough and complete analysis considering fish species and habitat. The Navy has found through the analysis that the proposed actions would not impact fish populations or their habitat. Certain types of training activities would not take place in certain habitats, for example, sinking exercises (SINKEXs) can only occur in waters that meet depth and distance from shore requirements. Therefore, a SINKEX could not occur on a seamount that is less than 6,000 feet below sea level.
NRDC - 34	The Navy's Proposed Mitigation Measures Fail to Protect Marine Wildlife To comply with NEPA, an agency must discuss measures designed to mitigate its project's impact on the environment. See 40 C.F.R. § 1502.14(f). There is a large and growing set of options for the mitigation of noise impacts to marine mammals and other marine life, some of which have been imposed by foreign navies[32]--and by the Navy itself, in other contexts-to limit harm from high-intensity sonar exercises. Yet here the Navy does little more than set forth an abbreviated set of measures, dismissing effective measures out of hand. All of the mitigation that the Navy has proposed for sonar impacts boils down to the following: a very small safety zone around the sonar source, maintained primarily with visual monitoring by personnel with other responsibilities, with aid from shipboard passive monitoring when personnel are already using such technology. Under the proposed scheme, operators would power-down the system if a marine mammal is detected within 1,000 yards and shut-down the system if a marine mammal is detected within 200 yards. DEIS at 5-24. 32 See S.J. Dolman, C.R. Weir, and M. Jasny, Comparative Review of Marine Mammal Guidance Implemented during Naval Exercises, _ Marine Pollution Bulletin _ (Dec. 12,2008).	Each nation has its own training and testing needs based on that nation's forces, capabilities and missions. For the U.S. Navy, the ability to conduct anti-submarine warfare around varying underwater topography is critically necessary in order to fight the growing submarine threat. The Navy has comprehensively evaluated mitigation measures used by other navies to determine the benefits of implementing similar measures. Based on its assessment the Navy found that most other navies do not possess an integrated strike group or have other integrated training requirements like the United States. As integrated strike groups, U.S. Navy requirements frequently include operating within defined distances to suitable landing fields for aircraft safety, thereby geographically constraining the entire strike group. In coordination with NMFS, Navy's proposed mitigation measures were carefully customized for effectiveness in reducing potential impacts on an affected resource and to ensure, from a military perspective, that the mitigations are practicable and executable, and that safety and operational readiness can be maintained.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		As described in more detail to specific comments that follow, several measures were eliminated because they were determined to be unfeasible, present a safety risk, provide no known or scientifically-based protective benefits, or have an unacceptable impact on training fidelity. Through careful exploration of all mitigation measures to determine which were the most effective, the Navy has chosen the measures to mitigate potential impacts to marine mammals while still being able to meet its operational needs to train and test for real world conditions. Specific mitigation measures are outlined in the following sections: Section 5.3.1 (Lookout Procedural Measures), Section 5.3.2 (Mitigation Zone Procedural Measures), and Section 5.3.3 (Mitigation Areas). Specifically, Section 5.3.3.1 (Marine Mammal Habitats) addresses important habitat areas. The decrease in mitigation zone size will allow for a more focused survey effort over a smaller area, and will consequently increase the likelihood of avoidance of injury and larger threshold shifts that would result in recovery (i.e., TTS) to marine mammals. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf].
NRDC - 35	This mitigation scheme disregards the best available science on the significant limits of visual monitoring. Visual detection rates for marine mammals generally approach only 5 percent. Moreover, the species perhaps most vulnerable to sonar-related injuries, beaked whales, are among the most difficult to detect because of their small size and diving behavior. It has been estimated that in anything stronger than a light breeze, only one in fifty beaked whales surfacing in the direct track line of a ship would be sighted; as the distance approaches 1 kilometer, that number drops to zero.[33] Many other whales are also hard to detect, especially depending on seasonality, geography, and behaviors. For example, the visual and acoustic detection rates of blue whales, which are susceptible to ship strikes in Southern California, differ seasonally and geographically, suggesting that a single detection mode (e.g., visual) may be insufficient to detect blue whales in all seasons and regions.[34] The Navy's reliance on visual observation as the	As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	mainstay of its mitigation plan is therefore profoundly misplaced. 33 J. Barlow and R. Gisiner, Mitigating. Monitoring, and Assessing the Effects of Anthropogenic Noise on Beaked Whales, 7 Journal of Cetacean Research and Management 239-249 (2006). 34 E.M. Oleson, J. Calambokidis, J. Barlow and J.A. Hildebrand, Blue Whale Visual and Acoustic Encounter Rates in the Southern California Bight, 23(3) Marine Mammal Science 574-597 (2007)	mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal surveys, are generally available to Navy Lookouts on board vessels over 60'. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the "one or two personnel" described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website.
NRDC - 36	The Navy's ineffective mitigation measures are all the more remarkable given its adoption of more protective measures during previous training. For example, the Atlantic Fleet has repeatedly sited exercises beyond the continental shelf and Gulf Stream, relocated exercises out of important habitat and to avoid certain species, and used a technique called "simulated geography" to avoid canyons and near-shore areas on at least three of its major ranges. It has also restricted sonar use at night when marine mammals are harder to detect, as well as minimized the use of sonar from multiple sources at the same time.[35] In this light, the Navy's claims that it cannot implement more protective mitigation measures ring false. DEIS at 5-52 to 57. Although the Navy goes to some pain to describe "mitigation measures considered but eliminated"--primarily because of "unacceptable impacts on the proposed activity"—its previous adoption of the same measures belies its argument. Clearly the Navy has done more to mitigate the harmful effects of sonar in previous exercises than what it proposes for the HSTT activities. It can, and must, do more to mitigate the harm on marine wildlife. 35 Final Comprehensive Overseas Environmental Assessment for Major Atlantic Fleet Training Exercises February 2006, Prepared for United States Fleet Forces Command in accordance with Chief of Naval Operations Instruction 5090.1B pursuant to Executive Order 12114; See also Atlantic Fleet Exercises Using Mid-Frequency Sonar Mitigation Chart.	The Navy acknowledges the limitations of visual shipboard monitoring and uses aerial monitoring and passive acoustic monitoring for multi-faceted monitoring where practical. The EIS/OEIS, Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring), presents the U.S. Navy's mitigation measures, outlining steps that would be implemented to protect marine mammals and Federally listed species during training and testing events. In general, there are usually more ships and more observers present on Navy ships, and additional aerial assets engaged in exercise events than used during trackline detection during a survey, therefore increasing the potential to detect marine mammals during a Navy activity. Section3.4.3.1.8.1Model Assumptions and Limitations) in the EIS/OEIS provides a more robust discussion on marine mammal sightability and the inclusion of implementing mitigation measures to reduce the effects of sound exposures on marine mammals. Section 3.4.3.2 (Analysis of Effects on Marine Mammals) has been revised to account for the Navy's mitigation measures and marine mammal behavioral responses to more accurately reflect the predicted potential effects on marine mammals. The measures that Natural Resources Defense Council refers to have not been in place since January 2009, and are not included in the current permits. Section 5.3.4 (Mitigation Measures Considered but Eliminated) includes a complete list of mitigation measures that the Navy has considered but eliminated because the measures are ineffective at reducing environmental impacts, currently have an unacceptable operational impact, or are expected to have an unacceptable operational impact in the future. As described in Section 5.3.4 (Mitigation Measures Considered but Eliminated), it is critical that the Navy be able to conduct anti-submarine warfare training in a variety of environmental and bathymetric conditions, including in the vicinity of canyons and during periods of low visibility. The Navy continuously collects information on the effectiveness of mitigation measures and their impact on military readiness. This accumulation of information helped shaped the Navy's operational assessments throughout Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Draft and Final EIS/OEIS. As part of the mitigation evaluation process, the Navy did not recommend continuing to

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		implement mitigation measures that were causing unacceptable operational impacts, including interfering with the Navy's ability to meet all or part of its military readiness requirements.
NRDC - 37	Protection Zones As discussed above, there is scientific consensus that geographic mitigation represents the most effective means currently available to reduce the impacts of mid-frequency sonar on marine mammals.[36] It was with that understanding that NOAA launched a multi-year effort to improve the tools available to agencies, including the Navy, for evaluating and mitigating the impacts of anthropogenic noise on marine mammals. One of NOAA's Working Groups, CetMap, is identifying marine mammal "hot spots" in the HSTT Study Area - biologically important areas for marine mammals as evidenced by increases in density and distribution or modeled based on important habitat features. CetMap's identification of these areas should form a basis for creating protection zones where training activities could be barred or limited.	The Navy's overall approach to assessing potential mitigation measures was based on two principles: (1) mitigations will be effective at reducing potential impacts on the resource; and (2) from an operational perspective, the mitigations are practicable and executable while not compromising safety and readiness. Through extensive discussion, NMFS and Navy have identified mitigation measures that are practicable and reasonably effective. For example, the safety zones proposed will reduce the likelihood of physiological harm, the number of marine mammals exposed, and the intensity of those exposures. The Navy has proposed several Mitigation Areas (such as the Humpback Whale Cautionary Area), and the mitigation measures identified throughout Chapter 5 will apply to all marine mammals year round, and will be applied regardless of the location of the activity. However, any future determination of "hot spots" or biologically important areas will require an intense effort in gathering expert opinion. In that regard, Navy has, and will continue to support the Cetacean and Sound Mapping (CetMap) project, including representation on the CetMap Density and Distribution Mapping Working Group. Navy is an active sponsor and participant in CetMap, and the CetMap process is based on the same process Navy used to estimate population density in the HSTT EIS/OEIS and LOA Application. In 2012, the CetMap panel of experts determined that no biologically important areas (the panel determined that "hot spots" is not an appropriate term) could be identified based on data availability and information at hand. Furthermore, no follow-on products have identified areas of recommended avoidance. It is important to note that the areas appearing on the CetMap website are a preliminary draft that needs considerable additional input from the larger biological community before being used to identify biologically important areas in the ocean.
NRDC - 38	The following biologically important areas are but a sample of the kind of areas that should be analyzed by the Navy for the development of protection zones as informed by the results of CetMap: 1) Important habitat for Blainville's beaked whale west of the Big Island.- Satellite tagging data, photo-identification data and survey data dating from 1989 to 2009 indicate the existence of a small, island-associated population of Blainville's beaked whales that	Navy has, and will continue to support the Cetacean and Sound Mapping (CetMap) project, including representation on the CetMap Density and Distribution Mapping Working Group. Navy is an active sponsor and participant in CetMap, and the CetMap process is based on the same process Navy used to estimate population density in the HSTT EIS/OEIS and LOA Application. In 2012, the CetMap panel of experts determined that no biologically important areas (the panel

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	exhibits strong site fidelity to an area on the leeward (west) side of the island of Hawaii.[37] 2) Important habitat for Cuvier's beaked whale around the Big Island.- Long-term photo-identification data indicate high site fidelity of Cuvier's beaked whales off the island of Hawaii.[38] Satellite tagging data indicate individuals are resident to the island using both the east and west sides of the island.[39] Photographic mark-recapture data indicate the population is small and, thus, may need additional protection.[40] 3) Important habitat for Hawaii insular false killer whales between east Oahu and north Maui and off Hawaii Island--Tagging data indicates that two particularly high use areas exist for the insular population of false killer whales, a species of conservation concern.[41] One of these extends from the east side of Oahu to the north side of Maui, and the other lies off the north end of Hawaii Island. 4) Important habitat for Hawaii island resident population of melon-headed whales. A small, demographically isolated population of melon-headed whales has been identified that is resident to the west side of the island, which may need additional protection.[42] 5) Seasonal calving grounds for the humpback whale.- Humpback whales use breeding habitat in the coastal regions and shallow banks within these areas, as established by aerial survey and other effort.[43] For purposes of mitigation, this area would include the Hawaiian Islands Humpback National Marine Sanctuary and, more generally, all waters less than 200m in depth in the Four Island Region, Penguin Bank, Kauai, and Niihau. 6) Important habitat for vulnerable resident odontocele populations around the main Hawaiian Islands.- Biologically important areas should be identified for a number of discrete, island-associated populations, including melon-headed whales,[44] false killer whales,[45] rough-toothed dolphins,[46] spinner dolphins,[47] bottlenose dolphins,[48] pygmy killer whales,[49] pantropical spotted dolphins,[50] short-finned pilot whales,[51] and dwarf sperm whales.[52] 7) Papahanaumokuakea (Northwest Hawaiian Islands) Marine National Monument.- This biologically important area is a marine protected area established by President George W. Bush for its unique biodiversity, including marine mammal biodiversity. The area was also named in a previous court order on LFA as an example of an area from which sonar training should be excluded. 8) Cross Seamount and other seamounts west of the island of Hawaii.- In general, seamounts are known to enhance secondary productivity and concentrate prey, resulting in areas of higher biological density for marine mammals and other species.[53] More specifically, the area around Cross Seamount represents probable offshore feeding habitat for beaked whales, based on acoustic data showing beaked whale foraging echolocation signals occurring there most nights (75%) over a year-long study period.[54] [n addition, scientists have identified three species (false killer whales, rough-toothed dolphins and striped dolphins) on the slopes of Jaggar Seamount, and sperm whales on Indianapolis Seamount.[55]	determined that "hot spots" is not an appropriate term) could be identified based on data availability and information at hand. Furthermore, no follow-on products have identified areas of recommended avoidance. It is important to note that the areas appearing on the CetMap website are a preliminary draft that needs considerable additional input from the larger biological community before being used to identify biologically important areas in the ocean. For additional information regarding specific comments: 1), 3), 4) 8), 9), 10) and 12): Please refer to Section 5.3.4.1.7 (Avoiding Locations Based on Bathymetry and Environmental Conditions) for a discussion of habitat avoidance. 2) Mitigation will be implemented within the mitigation zone for all marine mammals regardless of species. Passive acoustic monitoring will be used to inform visual observations because resources are not available for the Navy to locate vocalizing animals through passive acoustics during training and testing activities. Mitigation specific to beaked whales and “significant aggregations” are not necessary because the mitigation will be implemented for all species. 5) Please refer to Section 5.3.4.1.11 (Avoiding Marine Species Habitats) for discussion of seasonal restrictions. The Navy has proposed several seasonal measures, as discussed in Section 5.3.3 (Mitigation Areas). 6) Please refer to Section 5.3.4.1.6 (Limiting Access to Training and Testing Locations) for a discussion on limiting activities to abyssal waters and offshore habitats. 7) Establishment of the Papahanaumokuakea Marine National Monument included language specifically excluding all military activities from the listed prohibitions as long as the military exercises and activities are “carried out in a manner that avoids, to the extent practicable and consistent with operational requirements, adverse impacts on monument resources and qualities.” The Proclamation’s protection of military activities was confirmed in January 2009 when President George W. Bush stated “…I confirm that the policy of the United States shall be to continue measures established in the Papahanaumokuakea Marine National Monument to protect the training, readiness, and global mobility of U.S. Armed Forces.” Please refer to Section 6.1.2 (Marine Protected Areas) for a discussion on the Marine Protected Areas contained with the Study Area. Please refer to Section 5.3.4.1.3 (Reducing Sonar Source Levels and Total Number of

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	9) Tanner and Cortez Bank.- Compiled survey data and features analysis confirm Tanner and Cortez Banks as relatively high density areas for blue, fin, beaked, sperm, humpback whales and Kogia spp. This feature (including both banks out to the 1000m isobath) accounted for 35% of the total sightings of these species throughout the California Bight region, based on our analysis of 13 surveys conducted between 1975 and 2004.[56] Tanner and Cortez Banks and their southern edge extending into Tanner Canyon appear to be highly important feeding grounds for blue and fin whales (Calambokidis pers. comm.) and possibly beaked and sperm whales as well. Humpback whales are not as common as blue and fin whales in the deeper waters of the Bight, but are also observed at least occasionally around Tanner and Cortez Banks. Earlier pinniped surveys observed high numbers of fur seals near Tanner Bank as well. 10) Areas of importance to beaked whales.- Recently, NMFS' Southwest Fisheries Science Center has conducted a combined visual and towed passive acoustic survey of potential beaked whale habitat off Southern California. Those surveys have identified a few areas with apparent high occurrence of beaked whales, representing portions - and particularly the northern edges - of certain ocean basins. These areas include portions of the Santa Cruz Basin (which lies outside SOCAL but within the Pt. Mugu Sea Range), of the San Nicolas Basin (west of the SCORE range), of the Catalina Basin, and of the San Diego Trough. 11) Channel Islands National Marine Sanctuary ("NMS").- The Channel Islands NMS is an area of enormous marine biodiversity and must be considered for additional protections. 12) Additional areas.- As informed by CetMap, additional areas may include shelf waters north of San Nicholas Island and Lorna and La Jolla Canyons. By failing to design and discuss mitigation for these and similar areas, the Navy failed to comply with NEPA. See 40 C.F.R. § 1502. 14(f). The Navy must revise and reissue its DEIS after fully analyzing the information produced by CetMap and identifying reasonable mitigation that the public can review and submit comments on.	Hours) for a discussion on how the Navy uses active sonar at the lowest practicable source level consistent with mission requirements, and Section 5.5.2 (Reporting) for a discussion on the Navy's reporting requirements. 11) Please refer to Section 6.1.2 (Marine Protected Areas) for a discussion on the Marine Protected Areas contained with the Study Area.
NRDC - 39	Mitigation of Navy Debris and Expended Material The DEIS fails to set forth any mitigation measures concerning the massive amount of discarded debris and expended materials associated with its proposed activities in the HSTT Study Area. The Navy claims that ocean currents will rapidly disperse the expended materials and thus no mitigation is required. "In NEPA's demand that an agency prepare a detailed statement on 'any adverse environmental effects which cannot be avoided should the proposal be implemented,' is an understanding that the EIS will discuss the extent to which adverse effects can be avoided." Robertson, 490 U.S. at 352-53. The Navy's "all-or-nothing approach" is not a sufficient discussion of how the adverse impacts of expended material can be avoided. By failing to explore mitigation measures for expended materials, the Navy does not even attempt to avoid,	The Navy conducted a full analysis of the potential impacts of military expended materials on marine resources and has proposed several mitigation measures to help avoid or reduce those impacts. The analysis is contained throughout Chapter 3 (Affected Environment and Environmental Consequences) of the Draft and Final EIS/OEIS (e.g., Section 3.3.3.2.1, Impacts from Military Expended Materials discusses marine habitats). For example, military expended materials related to training exercises under a worst-case scenario under Alternatives 1 and 2 would not impact more than 0.00009 percent of the available soft bottom habitat annually within any of the range complexes. The Navy has standard operation procedures in place to reduce the

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	minimize, rectify, reduce, or compensate for its dumping of debris - all of which are options included in the CEQ regulation's definition of "mitigation." 40 C.F.R. §1508.20.	amount of military expended materials (Section 5.1.4.2, Weapons Firing Range Clearance), including recovering targets and associated parachutes to the maximum extent practical. In addition, the Navy has developed mitigation areas (Section 5.3.3.2, Seafloor Resources) to avoid and reduce potential impacts of military expended materials on seafloor habitats, including coral and hardbottom habitats.
NRDC - 40	Other Mitigation Measures In addition to considering protection zones and mitigation for expended materials, the Navy should adopt the following measures: I) Seasonal avoidance of marine mammal feeding grounds, calving grounds, and migration corridors;	In cooperation with NMFS, the Navy has developed a suite of mitigation measures that are practicable to implement and that allow training and testing activities to meet their readiness requirements. 1)The balance between Procedural Measures and Mitigation Area measures (see Section 5.2.3, Assessment Method) provide a way for the Navy to mitigate potential impacts while maintaining its military readiness objectives. Please refer to Section 5.3.4.1.11 (Avoiding Marine Species Habitats) for discussion of seasonal restrictions. The Navy has proposed seasonal measures, as discussed in Section 5.3.3 (Mitigation Areas), specifically Section 5.3.3.1.1.1 (Humpback Whale Cautionary Area) where mid-frequency active sonar training will not occur within the Humpback Whale Cautionary Area between 15 December and 15 April.
NRDC - 41	2) Avoidance of, or extra protections in, marine protected areas;	2) The Navy has identified areas and afforded extra protections in certain areas. For example, The Navy has designated a humpback whale cautionary area (described in Section 5.3.2, Mitigation Zone Procedural Measures), which consists of a 5 km (3.1 miles [mi.]) mitigation zone that has been identified as having one of the highest concentrations of humpback whales during the period between 15 December and 15 April. Navy activities within marine protected areas abide by the regulations of the individual marine protected area. Please refer to Section 6.1.2 (Marine Protected Areas) for a discussion on the Marine Protected Areas contained with the Study Area.
NRDC - 42	3) Avoidance of bathymetry likely to be associated with high-value habitat for species of particular concern, including submarine canyons and large seamounts, or bathymetry whose use poses higher risk to marine species;	3) Please refer to Section 5.3.4.1.7 (Avoiding Locations Based on Bathymetry and Environmental Conditions) for a discussion of habitat avoidance.
NRDC - 43	4) Avoidance of fronts and other major oceanographic features, such as the California Current and other areas with marked differentials in sea surface temperatures, which have the potential to attract offshore concentration of animals, including beaked whales;[57] 57 See, e.g., Carretta et al., U.S. Pacific Marine Mammal Stock Assessments: 2007 at 142 (reporting that "Baird's beaked whales have been seen primarily along the	4) As presented in Section 5.3.4.1.7 (Avoiding Locations Based on Bathymetry and Environmental Conditions) the issue of habitat avoidance has been discussed. Also note the same issue was raised and also analyzed in the previous Navy environmental documents for both SOCAL and Hawaii involving training and testing at sea since 2005. As presented in Section 5, there are many reasons why it is not

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	continental slope from late spring to early fall.").	practical or reasonable to avoid broad ocean areas where beaked whales might be located and/or areas where they have co-existed with Navy training and testing activities for decades. There is no direct evidence from Hawaii or Southern California suggesting Navy training and testing over many decades has had or may have any long term consequences to marine mammals. Using beaked whales as an example, based on a series of surveys from 2006 to 2008 and the high number encounter rate, Falcone et al. (2009) proposed that their observations suggested the ocean basin west of San Clemente Island may be an important region for Cuvier's beaked whales. For over three decades, this ocean area west of San Clemente has been the location of the Navy's instrumented training range and is one of the most intensively used training and testing areas in the Pacific, given the proximity to the Naval installations in San Diego. A more detailed discussion and additional information is presented in the last subsection of Section 3.4 titled "Summary of Observations During Previous Navy Activities". It includes details on the Navy's monitoring program (see Navy's monitoring reports available at http://www.navymarinespeciesmonitoring.us/ and also at the NMFS website; www.nmfs.noaa.gov/pr/permits/incidental.htm#applications) in the HSTT Study Area, which includes research, monitoring before, during, and after training and testing events since 2006, and the reports that have been submitted to and reviewed by NMFS. Based on this research, the Navy's assessment is that it is unlikely there will be impacts to populations of marine mammals (such as whales, dolphins and porpoise, seals and sea lions) having any long term consequences as a result of the proposed continuation of training and testing in the ocean areas historically used by the Navy. This assessment of likelihood is based on four indicators from areas in the Pacific where Navy training and testing has been ongoing for decades: (1) evidence suggesting or documenting increases in the numbers of marine mammals present, (2) examples of documented presence and site fidelity of species and long-term residence by individual animals of some species (including beaked whales), (3) use of training and testing areas for breeding and nursing activities, and (4) six years of comprehensive monitoring data indicating a lack of any observable effects to marine mammal populations as a result of Navy training and testing activities.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 44	5) Avoidance of areas with higher modeled takes or with high-value habitat for particular species;	5) Please refer to Section 5.3.4.1.11 (Avoiding Marine Species Habitats) for a discussion on marine species habitats with respect to modeled takes.
NRDC - 45	6) Concentration of exercises to the maximum extent practicable in abyssal waters and in surveyed offshore habitat of low value to species;	6) Please refer to Section 5.3.4.1.6 (Limiting Access to Training and Testing Locations) for a discussion on limiting activities to abyssal waters and offshore habitats.
NRDC - 46	7) Use of sonar and other active acoustic systems at the lowest practicable source level, with clear standards and reporting requirements for different testing and training scenarios;	7) The Navy concurs; please refer to Section 5.3.4.1.3 (Reducing Sonar Source Levels and Total Number of Hours) for a discussion on how the Navy uses active sonar at the lowest practicable source level consistent with mission requirements. See Section 5.5.2 (Reporting) for a discussion on the Navy's reporting requirements, which will be coordinated through NMFS through the permitting process.
NRDC - 47	8) Expansion of the marine species "safety zone" to a 4km shutdown, reflecting international best practice, or 2 km, reflecting the standard prescribed by the California Coastal Commission;[58] 46 California Coastal Commission, Adopted Staff Recommendation on Consistency Determination CD-08606 (2007); Approved Letter from M. Delaplaine, California Coastal Commission, to Rear Adm. Len Hearing, Navy (Jan. 11, 2007).	8) Please refer to Section 5.3.4.1.14 (Increasing the Size of Observed Mitigation Zones) for a discussion on mitigation zone expansion. The Navy recommended mitigation zones represent the maximum area the Navy can effectively observe based on the platform of observation, number of personnel that will be involved, and the number and type of assets and resources available. As mitigation zone sizes increase, the potential for reducing impacts decreases. For instance, if a mitigation zone increases from 1,000 to 4,000 yd. (914 to 3,658 m), the area that must be observed increases sixteen-fold. The Navy recommended mitigation measures balance the need to reduce potential impacts with the ability to provide effective observations throughout a given mitigation zone. There is no internationally recognized best practice with regard to mitigation zone distance. The mitigation zones discussed throughout the Draft EIS/OEIS and Final EIS/OEIS were developed using the latest best available science, are consistent with regulatory requirements and criteria, and are tailored to the Proposed Action; therefore, adopting other mitigation zones would neither be a practical nor effective mitigation scheme for the Proposed Action.
NRDC - 48	9) Suspension or relocation of exercises when beaked whales or significant aggregations of other species are detected by any means within the orbit circle of an aerial monitor or near the vicinity of an exercise;	9) Mitigation will be implemented within the mitigation zone for all marine mammals regardless of species. Passive acoustic monitoring will be used to inform visual observations. The technology is not available for the Navy to locate vocalizing animals through passive acoustics during training and testing activities. Mitigation specific to beaked whales and "significant aggregations" are not necessary because the mitigation will be implemented for all species, and any number of animals observed.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 49	10) Use of simulated geography (and other work-arounds) to reduce or eliminate chokepoint exercises in near-coastal environments, particularly within canyons and channels, and use of other important habitat;	10) The Navy does make use of simulated geography for training purposes. Please refer to Section 5.3.4.1.2 (Replacing Training and Testing with Simulated Activities) and Section 5.3.4.1.7 (Avoiding Locations Based on Bathymetry and Environmental Conditions) for a discussion on simulated activities and the importance of training in near-coastal environments with complex geography. The presence of canyons and channels are not necessarily indicative of important habitat.
NRDC - 50	11) Avoidance or reduction of training during months with historically significant surface ducting conditions, and use of power-downs during significant surface ducting conditions at other times;	11) Please refer to Section 5.3.4.1.9 (Avoiding or Reducing Active Sonar During Strong Surface Ducts) for a discussion of surface ducts. Training in surface ducting conditions is a critical component to military readiness because sonar operators need to learn how sonar transmissions are altered due to surface ducting.
NRDC - 51	12) Use of additional power-downs when significant surface ducting conditions coincide with other conditions that elevate risk, such as during exercises involving the use of multiple systems or in beaked whale habitat;	12) Please refer to Section 5.3.4.1.3 (Reducing Sonar Source Levels and Total Number of Hours) for a discussion of sonar levels and hours and Section 5.3.4.1.9 (Avoiding or Reducing Active Sonar During Strong Surface Ducts) for a discussion of surface ducts. Mitigation measures are implemented equally in all locations where the activity occurs. Refer to Chapter 3.4 (Marine Mammals) and the Navy Marine Species Density Database Technical Report for information on beaked whale habitat within the Study Area. Some species of beaked whales are found throughout the entire Study Area; therefore, implementing additional power-downs throughout the Study Area would cause an unacceptable impact to readiness.
NRDC - 52	13) Planning of ship tracks to avoid embayments and provide escape routes for marine animals;	13) Please refer to Section 5.3.4.1.6 (Limiting Access to Training and Testing Locations) for a discussion of limiting vessel movements. The Navy is not proposing to train or test in areas where marine animals would have no escape. The only location where the Navy has conducted sonar activities was in the Bahamas in 2000, but those conditions are not replicated within the HSTT Study Area.
NRDC - 53	14) Suspension or postponement of chokepoint exercises during surface ducting conditions and scheduling of such exercises during daylight hours;	14) Please refer to Section 5.3.4.1.8 (Avoiding or Reducing Active Sonar at Night and During Periods of Low Visibility) and Section 5.3.4.1.9 (Avoiding or Reducing Active Sonar During Strong Surface Ducts) for a discussion of activities conducted during varying environmental conditions. The Navy proposes to continue chokepoint exercises in Hawaii because of the valuable and necessary training they provide.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 54	15) Use of dedicated aerial monitors during chokepoint exercises, major exercises, and near-coastal exercises;	15) Some events can occur over several hours and is dependent upon multiple variables including, but not limited to, weather, background traffic, training requirements, delays for mitigation, etc., that may make it impractical and unsafe to have dedicated aerial monitors. Additionally some events typically occur near commercial and military airspace that would pose a serious risk to the survey and non-survey aircraft. If an aircraft is participating in the event they are used for survey as described in the mitigation proposed by Navy. While these activities can occur over several hours they often occur overan extended distance from land making a dedicated aerial survey platfrom unsafe and impractical. Navy already has mitigation in place designed to minimize potential effects from these activities. Refer to Section 5.3.4.1.12 (Increasing Visual and Passive Acoustic Observations) for additional discussion on visual observations or specific mitigations designed for activities involving the use of aerial monitors in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring). Please refer to Section 5.3.4.1.13 (Increasing Visual and Passive Acoustic Observations) for a discussion on visual observations.
NRDC - 55	16) Use of dedicated passive acoustic monitoring to detect vocalizing species, through established and portable range instrumentation and the use of hydrophone arrays off instrumented ranges;	16) Please refer to Section 5.3.4.1.13 (Increasing Visual and Passive Acoustic Observations) for a discussion on passive acoustic observations.
NRDC - 56	17) Modification of sonobuoys for passive acoustic detection of vocalizing species;	17) Mid-frequency active sonar training is required year-round in all environments, including night and low-visibility conditions. Training occurs over many hours or days, which requires large teams of personnel working together in shifts around the clock to work through a scenario. Training at night is vital because environmental differences between day and night affect the detection capabilities of sonar. Temperature layers that, which affect sound propagation, move up and down in the water column and ambient noise levels can vary significantly between night and day, which affects sound propagation and could affect how sonar systems are operated from day to night and vice versa. Consequently, personnel must train during all hours of the day to ensure they identify and respond to changing environmental conditions, and not doing so would unacceptably decrease training effectiveness and reduce the crews' abilities. Therefore, the Navy cannot operate only in daylight hours or wait for the weather to clear before training .Please refer to Section 5.3.4.1.13 (Increasing Visual and Passive Acoustic Observations) for a discussion on passive

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		acoustic observations. As described throughout Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring), Passive acoustic monitoring will be conducted with Navy assets, such as sonobuoys, when practicable. Passive sonobuoys are designed to detect submarine-produced sounds. Modifying sonobuoys and receiver equipment to focus on marine mammal vocalizations would detract from their ability to perform their primary mission.
NRDC - 57	18) Suspension or reduction of exercises outside daylight hours and during periods of low visibility;	18) Please refer to Section 5.3.4.1.8 (Avoiding or Reducing Active Sonar at Night and During Periods of Low Visibility) for a discussion of activities conducted during varying environmental conditions.
NRDC - 58	19) Use of aerial surveys and ship-based surveys before, during, and after major exercises;	19) Some events can occur over several hours and is dependent upon multiple variables including, but not limited to, weather, background traffic, training requirements, delays for mitigation, etc., that may make it impractical and unsafe to have dedicated aerial monitors. Additionally some events typically occur near commercial and military airspace that would pose a serious risk to the survey and non-survey aircraft. If an aircraft is participating in the event they are used for survey as described in the mitigation proposed by Navy. While these activities can occur over several hours they often occur overan extended distance from land making a dedicated aerial survey platfrom unsafe and impractical. Navy already has mitigation in place designed to minimize potential effects from these activities. Refer to Section 5.3.4.1.12 (Increasing Visual and Passive Acoustic Observations) for additional discussion on visual observations or specific mitigations designed for activities involving the use of aerial monitors in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring). Please refer to Section 5.3.4.1.13 (Increasing Visual and Passive Acoustic Observations) for a discussion on visual observations. Please refer to Section 5.3.4.1.13 (Increasing Visual and Passive Acoustic Observations) for a discussion on visual observations.
NRDC - 59	20) Use of all available range assets for marine mammal monitoring;	20) The current Navy monitoring program is composed of a collection of range-specific monitoring plans, each of which was developed individually as part of MMPA and ESA compliance processes as environmental documentation was completed. These individual plans establish specific monitoring requirements for each range complex or testing range and are collectively intended to address the Integrated Comprehensive Monitoring Plan top-level goals. Please see Section 5.5 (Monitoring and Reporting) for additional information on the Navy's

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		marine mammal monitoring.
NRDC - 60	21) Use of third-party monitors for marine mammal detection;	21) Please refer to Section 5.3.4.1.15 (Conducing Visual Observations Using Third-Party Observers) for a discussion on third-party observers.
NRDC - 61	22) Application of mitigation prescribed by state regulators, by the courts, by other navies or research centers, or by the U.S. Navy in the past or in other contexts;	22) Please refer to Section 5.3.4.1.16 (Adopting Mitigation Measures of Foreign Navies) for a discussion on foreign navies. Mitigation is developed in cooperation with NMFS and will be further refined through the MMPA and ESA consultation processes. Evaluation of past and present U.S. Navy mitigation measures is included throughout Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring); most measures originated through past environmental analyses and associated consultations with regulators. Mitigation measures are based on the best available science with regard to protection of marine mammals and the practicality of their implementation.
NRDC - 62	23) Avoidance of fish spawning grounds and of important habitat for fish species potentially vulnerable to significant behavioral change, such as widescale displacement within the water column or changes in breeding behavior;	23) This EIS/OEIS describes potential impacts to fish species and concludes that there are no impacts that would justify area avoidance for the Navy's proposed activities. Because of the wide variety of marine species in and around the HSTT Study Area, such avoidance areas as suggested in the comment would serve to exclude proposed activities from the entire Study Area. Please refer to Section 5.3.4.1.11 (Avoiding Marine Species Habitats) for a discussion of habitat avoidance. Also see Section 3.9 (Fish) regarding the effects determinations on fish in the FEIS/OEIS.
NRDC - 63	24) Evaluating before each major exercise whether reductions in sonar use are possible, given the readiness status of the strike groups involved;	24) Please refer to Section 5.3.4.1.3 (Reducing Sonar Source Levels and Total Number of Hours) for a discussion on how the Navy uses active sonar at the lowest practicable source level and number of hours consistent with mission requirements. Strike groups are constantly evaluated and exercises are modified to ensure each strike group receives the training necessary to achieve required readiness levels.
NRDC - 64	25) Dedicated research and development of technology to reduce impacts of active acoustic sources on marine mammals;	25) The Navy provides a significant amount of funding and support to marine research. Navy scientists work cooperatively with other government researchers and scientists, universities, industry, and non-governmental conservation organizations in collecting, evaluating, and modeling information on marine resources. Details on the Navy's involvement with future research will be worked out through the Navy and NMFS adaptive management process, which regularly considers

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		and evaluates the development and use of new science and technologies for Navy applications.
NRDC - 65	26) Establishment of a plan and a timetable for maximizing synthetic training in order to reduce the use of active sonar training;	26) Please refer to Section 5.3.4.1.2 (Replacing Training and Testing with Simulated Activities) for a discussion on simulated activities.
NRDC - 66	27) Prescription of specific mitigation requirements for individual classes (or sub-classes) of testing and training activities, in order to maximize mitigation given varying sets of operational needs; and	27) The Navy has developed mitigation by activity type to reduce potential impacts from the Proposed Action while not causing an unacceptable impact to readiness. Please refer to Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) for a discussion of these measures.
NRDC - 67	28) Timely, regular reporting to NOAA, state coastal management authorities, and the public to describe and verify use of mitigation measures during testing and training activities	28) Navy reporting requirements, including exercise and monitoring reporting, are described in Section 5.5.2 (Reporting). Reports are provided to NMFS as the regulator responsible for protecting marine mammals, and unclassified reports are publicly available on the Navy and NMFS websites. Please refer to Section 5.3.4.1.17 (Increasing Reporting Requirements) for additional discussion.
NRDC - 68	While the Navy considers, and summarily dismisses, many of these measures in its OEIS, it fails to do so in a manner permitted by NEPA and we note that similar or additional measures may be required under the Marine Mammal Protection Act, Endangered Species Act, and other statutes.	Comment noted. The Navy intends to work cooperatively with NMFS, the Navy's cooperating agency and the regulator under the MMPA, to finalize mitigation measures through the permitting and consultation processes for MMPA, ESA, and other laws as required.
NRDC - 69	The Navy Fails to Properly Analyze Cumulative Impacts In order to satisfy NEPA, an EIS must include a "full and fair discussion of significant environmental impacts." 40 C.F.R. § 1502.1. It is not enough, for purposes of this discussion, to consider the proposed action in isolation, divorced from other public and private activities that impinge on the same resource; rather, it is incumbent on the Navy to assess cumulative impacts as well, including the "impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future significant actions." Id. § 1508.7. A meaningful cumulative impact analysis must identify (1) the area in which the effects of the proposed project will be felt; (2) the impacts that are expected in that area from the proposed project; (3) other actions-past, present, proposed, and reasonably foreseeable-that have had or are expected to have impacts in the same area; (4) the impacts or expected impacts from these other actions; and (5) the overall impact that can be expected if the individual impacts are allowed to accumulate. Grand Canyon Trust v. FAA, 290 F.3d 339, 345 (D.C. Cir. 2002) (quotation and citation omitted). The Navy "cannot treat the identified environmental concern in a vacuum." TOMAC v. Norton, 433 F.3d 852, 863 (D.C. Cir. 2006) (quoting Grand Canyon Trust, 290 F.3d at 345). The Navy's cumulative impact analysis fails to meet these basic requirements.	The Navy used the best available science and a comprehensive review of past, present and reasonably foreseeable actions to develop a robust Cumulative Impacts analysis (Chapter 4, Cumulative Impacts). As required under NEPA, the level and scope of the analysis are commensurate with the potential impacts of the action as reflected in the resource-specific discussions in Chapter 3 (Affected Environment and Environmental Consequences). The EIS/OEIS considered its activities alongside those of other activities in the region whose impacts are "truly meaningful" to the analysis. Furthermore, the entire EIS/OEIS provides the cumulative impacts analysis, not just Chapter 4. Chapter 3, in particular, provides the current effects of past and present impacts and environmental conditions that represent the baseline of the environment as it is; Chapter 3 also discusses the consequences or potential future impacts from Navy activities. Chapter 4, then, discusses the other reasonably foreseeable activities to the extent they are known and the incremental impact of the Navy's proposal when added to past, present, and future impacts.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	Nowhere in its cumulative impact analysis does the Navy consider-let alone reach the conclusion-that the sum of the various environmental impacts that are enumerated will be limited. DEIS at 4-1 to 35. The Navy's analysis cannot provide such support because the Navy fails to explain what the sum of these impacts is expected to be. NEPA requires more than just a recital of possible impacts: it requires the Navy to actually analyze the overall impact of the accumulation of individual impacts. Grand Canyon Trust, 290 F.3d at 345. The DEIS fails to make this analysis.	
NRDC - 70	The Navy apparently believes it is enough to find that cumulative impacts will be "significant" and that, defying logic, impacts from its proposed activities will be relatively low when analysis is not warranted.[59] Yet most well-informed laypeople know that human activities have a significant impact on the marine environment, contributing to population declines, extinctions, and challenges to recovery. The Navy's recitation that it is hard out there for struggling species, offers no insight as to how impacts from its proposed activities should be placed in perspective when assessing cumulative threats to marine wildlife. To the extent that the Navy does offer perspective, it is to claim, without any support, that the relative contribution of its activities is low when compared to other threats. Such assertions are patently absurd given the amount of take - over 14 million instances of marine mammal take over 5 years, including almost 3 million instances of temporary hearing loss - projected to result from the Navy's activities. compared to other actions to support its conclusion that further 59) For marine mammals the Navy states: In summary, based on the analysis presented in Section 3.4 (Marine Mammals) the current aggregate impacts of past and present actions and reasonably foreseeable future actions are expected to result in significant impacts on some marine mammal species in the Study Area. Therefore, cumulative impacts on marine mammals would be significant without consideration of the impacts of Alternatives I or 2. Alternatives I and 2 would contribute to and increase cumulative impacts, but the relative contribution would be low compared to other actions. Further analysis of cumulative impacts on marine mammals is not warranted. DEIS at 4-28. The Navy makes an identical statement for other species. E.g., Sea turtles (DEIS at 431).	The Navy used the best available science and a comprehensive review of past, present and reasonably foreseeable actions to develop a robust Cumulative Impacts analysis (see Chapter 4, Cumulative Impacts). As required under NEPA, the level and scope of the analysis are commensurate with the potential impacts of the action as reflected in the resource-specific discussions in Chapter 3. The EIS/OEIS considered its activities alongside those of other activities in the region whose impacts are "truly meaningful" to the analysis. The impact analysis in the Final EIS/OEIS has been refined in coordination with NMFS. The number of marine mammal harassment exposures must be estimated scientifically using complex modeling, but it is only an estimate, not a prediction. This estimate needs to encompass the capacity of what could occur to ensure Navy's permits are not exceeded. The revised estimates now account for mitigation and avoidance, to provide a more holistic approach to analysis.
NRDC - 71	The Navy must also consider the full effects of its sonar training. It simply assumes that all behavioral impacts are short-term in nature and cannot affect individuals or populations through repeated activity-even though the anticipated takes of its preferred alternative would affect the same populations year after year. While the DEIS's analysis focuses on impacts over 5 years, naval training and testing will undoubtedly continue in the HSTT Study Area for the foreseeable future. At current rates, which is a conservative estimate given increases in training and testing activities over the last decade, the marine mammal populations of the HSTT Study Area will suffer nearly 100 million takes over the next 35 years.	The Navy used the best available science and a comprehensive review of past, present and reasonably foreseeable actions to develop a robust Cumulative Impacts analysis (see Chapter 4, Cumulative Impacts). As required under NEPA, the level and scope of the analysis are commensurate with the potential impacts of the action as reflected in the resource-specific discussions in Chapter 3. The EIS/OEIS considered its activities alongside those of other activities in the region whose impacts are "truly meaningful" to the analysis. The scope of the EIS/OEIS only extends to 2019, at which time, further NEPA analysis will be conducted for the permitting process. At that time, the needs of

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		the Navy's training and testing communities will be re-evaluated.
NRDC - 72	Nor does the Navy consider the potential for acute synergistic effects from sonar training. Although the OEIS discusses the potential for ship strike in the training area (OEIS 4-23 to 25 for marine mammals), it does not consider the greater susceptibility to vessel strike of animals that have been temporarily harassed or disoriented by certain noise sources. The absence of analysis is particularly glaring in light of the Haro Strait incident, in which killer whales and other marine mammals were observed fleeing away from the sonar vessel at high speeds.[60] Neither does the Navy consider the synergistic effects of noise with other stressors in producing or magnifying a stress-response.[61] For these reasons alone, the Navy should have concluded that the cumulative and synergistic impacts from sonar training are Significant and focused its efforts to analyze and develop mitigation measures to avoid those impacts.	Based on the page numbers described, this comment seems to have been made on the Navy's 2008 Atlantic Fleet Active Sonar Training EIS/OEIS for Navy training activities in the Atlantic Ocean, and not the HSTT DEIS/OEIS. Although the Navy acknowledges that acute synergistic effects are not well-studied and can only be accounted for qualitatively, a section for each resource exists that discusses this particular issue. For marine mammals, it is Section 3.4.4 (Summary of Impacts [Combined Impact of All Stressors] on Marine Mammals).
NRDC - 73	The Navy acknowledges that the HSTT Study Area is crowded with human and military activities, many of which introduce noise, chemical pollution, debris, and vessel traffic into the habitat of protected species. OEIS at 4-4 to 16. Yet it inexplicably fails to conclude what the cumulative effects will be for the environment other than saying the impacts will be "significant." NEPA's cumulative impacts analysis must require more than stating the obvious. Given the scope of the proposed action, the deficiencies of the Navy's cumulative impacts assessment represents a critical failure of the DEIS. At a minimum, the Navy must evaluate the potential for cumulative impacts on populations that will occur in and near the HSTT Study Area, clearly define the extent of expected cumulative impacts, and assess the potential for synergistic adverse effects (such as from noise in combination with ship-strikes).	The Navy used the best available science and a comprehensive review of past, present and reasonably foreseeable actions to develop a robust Cumulative Impacts analysis (see Chapter 4, Cumulative Impacts). As required under NEPA, the level and scope of the analysis are commensurate with the potential impacts of the action as reflected in the resource-specific discussions in Chapter 3. The EIS/OEIS considered its activities alongside those of other activities in the region whose impacts are "truly meaningful" to the analysis.
NRDC - 74	The Navy Fails to Properly Analyze Reasonable Alternatives To comply with NEPA, an EIS must "inform decision-makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment." 40 C.F.R. § 1502.1. The regulation itself describes the requirement as "the heart of the environmental impact statement." [d. at § 1502.14. Courts similarly portray the alternatives requirement as the "linchpin" of the EIS. Monroe County Conservation Council v. Volpe, 472 F.2d 693 (2d Cir. 1972). The agency must therefore "[r]igorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated." 40 C.F.R. § 1502.14(a). The agency must also state how the alternatives considered in the DEIS and decisions based on the DEIS will or will not achieve the requirements of sections 101 and 102(1) of NEPA and other environmental laws and policies. See 40 C.F.R. § 1502.2(d). Consideration of alternatives is required by (and must conform to the independent terms of) both sections lO2(2)(C) and lO2(2)(E) of NEPA. Here, the Navy's alternatives	The alternatives carried forward meet the Navy's purpose and need (Section 1.4, Purpose and Need) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration). The selection of an alternative by the decision maker will be based on a review of all relevant facts, impact analyses, comments received via the EIS/OEIS public participation process, and the requirements of the Navy in order to fulfill its mission.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	analysis misses the mark. Three alternatives are given in the DEIS: a No Action Alternative (maintaining the current level of activities), Alternative 1 (increasing training and testing activities and force structure changes), and the preferred Alternative 2 (Alternative 1 with range enhancements and more training and testing activities). These alternatives do not provide decision makers with a range of genuine choices. While the purpose of the alternatives analysis is to "consider the likely environmental impacts of the preferred course of action as well as reasonable alternatives," which "facilitates informed decisionmaking by agencies and allows the political process to check those decisions," New Mexico ex rel. Richardson v. BLM, 565 F.3d 683, 703-704 (10th Cir. 2009), the DEIS falls short of this goal. The Navy's alternatives amount to a presentation of only one true course of action: potential training and testing in all areas at all times. A. Failure to Identify Environmental Impact-Based Alternatives The Navy claims it "considers potential environmental impacts" while executing its responsibilities under federal law, including NEPA. DEIS at I-I. But the Navy's alternatives were not selected to "inform decision-makers and the public" of how the Navy could "avoid or minimize adverse impacts or enhance the quality of the human environment." 40 C.F.R. § 1502.1. Instead, as discussed in the DEIS and below, the Navy chose alternatives based on factors unrelated to the proposed action's environmental impacts.	
NRDC - 75	At no point in the OEIS does the Navy discuss how the alternatives pose different environmental choices for the public and decisionmakers. The DEIS fails entirely to comply with NEPA's regulations, requiring the Navy to "present the environmental impacts of the proposal and the alternatives in comparative form, thus sharply defining the issues and providing a clear basis for choice among options by the decisionmaker and the public." 40 C.F.R. § 1502.14. The Navy fails to sharply define the environmental issues applicable to each alternative and include these differences in a comparison of alternatives. There is simply no comparison of the risks and benefits of each alternative site showing what is and is not known and what species and habitats would be most at risk from each alternative	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration).
NRDC - 76	The two alternatives that meet the Navy's purpose and needs present no options for a decisionmaker wishing to reduce harms to the environment or for the public to hold decisionmakers accountable for their choices based on environmental impacts. For example, a decisionmaker wishing to choose the alternative that does less harm to sea turtles has nowhere to turn. Similarly, both of the Navy's alternatives result in the exact same impact to marine mammals from training with sonar - over 2.5 million takes per year. Violating NEPA's regulations, there is no presentation of an alternative that details a way forward that "avoid[s] or minimizes] adverse impacts or enhancers] the quality of	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	the human environment." /d.	Eliminated from Further Consideration).
NRDC - 77	The Navy Improperly Dismissed Alternatives Necessary to Provide a Well Reasoned Choice of Alternatives Several alternatives were recommended to the Navy during the scoping process that addressed this absence of environmental impact-based alternatives. However, the DEIS improperly dismisses all these suggestions. "While NEPA 'does not require agencies to analyze the environmental consequences of alternatives it has in good faith rejected as too remote, speculative, or impractical or ineffective,' it does require the development of 'information sufficient to permit a reasoned choice of alternatives as far as environmental aspects are concerned. "' New Mexico ex reI. Richardson v. BLM, 565 F.3d 683, 708-709 (10th Cir. 2009) quoting Colorado Envrl. Coalition v. Dombeck, 185 F.3d 1162, 1174 (lath Cir. 1999).	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration).
NRDC - 78	Dismissing the suggestions, the Navy fails to show how any of the alternatives are "too remote, speculative, or impractical or ineffective." For instance, while proximity to home ports and complexes might prove to be more convenient and even more cost effective, neither expense nor ease equates to the level of being too remote, speculative, or impractical or ineffective. See DEIS § 2.5.1.1 at 2-59 t060. These factors alone cannot dictate an agency's choice of alternatives to evaluate in an EIS.	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration).
NRDC - 79	"The primary purpose of the impact statement is to compel federal agencies to give serious weight to environmental factors in making discretionary choices." 1-291 Why? Ass'n v. Burns, 372 F.Supp. 233,247 (D. Conn. 1974). If an agency is permitted to consider and compare the environmental impacts of its proposed action with only equally convenient alternatives-and permitted to omit from such analysis any alternatives that are less convenient, no matter that they might result in significant environmental benefits-this purpose would be thwarted and the alternatives analysis loses its purpose entirely. An agency must discuss all reasonable alternatives-those that will accomplish the purpose and need of the agency and are practical and feasible-not simply those it finds most expedient. 40 C.F.R. § 1502.14. By improperly disregarding many alternatives, the Navy has failed to discuss all reasonable alternatives.	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration).
NRDC - 80	The Navy Must Identify Alternative Sites and Seasonal Restrictions The Navy's analysis is devoid of geographic alternatives and even minor seasonal restrictions. This omission is inappropriate in light of the strong consensus-at NOAA and in the scientific community-that spatial-temporal avoidance of high-value habitat represents the best available means to reduce the impacts of mid-frequency active sonar	As described throughout Chapter 2, geographic and seasonal flexibility is required to support evolving Navy training and testing requirements, which are linked to real world events. As described in Section 5.2.3.1 (Effectiveness Assessment) of the EIS/OEIS, a specific season, time of day, or geographic area must be important to the resource to

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	and certain other types of ocean noise on marine life.[62] 62 - Supra, Note 3. Protected areas should ordinarily be identified during the planning stage based on biological and oceanographic factors, rather than merely on the confirmed presence of marine animals in real time; and, indeed, the Naval Facilities Engineering Command, Atlantic undertook just such an analysis in the Navy's previous EIS for Atlantic Fleet Active Sonar Training. The Navy's detailed planning for certain training and testing exercises, particularly major exercises, such as RIMPAC, JTFEXs, COMPTUEXs, and USWEXs, provide an ideal opportunity to develop reasonable alternatives for the timing and siting of such activities based on biological and oceanographic factors.	determine whether the potential for establishing a mitigation area would be effective in avoiding or reducing a potential impact on a resource. In determining importance, special consideration will be given to those time periods or geographic areas having characteristics such as especially high overall density or percent population use, seasonal bottlenecks for a migration corridor, and identifiable key foraging and reproduction areas. The Navy proposes mitigation measures (a portion of which will include specific mitigation areas) on a case-by-case basis that would apply to all locations where a specified activity occurs. The balance between Procedural Measures and Mitigation Area measures provide a way for the Navy to mitigate potential impacts while maintaining its military readiness objectives. The proposed mitigation measures were developed in coordination with NMFS in order to avoid or reduce a potential impact on a particular resource.
NRDC - 81	Further spatial-temporal alternatives do not require large shifts in location, but rather can be very effective by simply carving out small areas of known biological importance. For instance, the Navy concedes in its mitigation analysis (DEIS at 5-45) the importance of the Humpback Whale National Marine Sanctuary off the coast of the Hawaiian Islands, designating a "cautionary area" that requires higher administrative approval for activities in the area during winter months. Despite this recognition, the Navy fails to identify other areas and develop an alternative based on avoiding a handful of biologically important areas. Instead, all of the alternatives propose yearround, unrestricted use without regard to seasonal variations in marine mammal and fish abundance. This is true despite the well-documented seasonal migrations of numerous endangered species and the identification of biologically important areas. Carefully siting the activities proposed to occur in the range to avoid concentrations of vulnerable and endangered species and high abundances of marine life is the most critical step the Navy can take in reducing the environmental impacts of this project. However, because the Navy has failed to undertake an alternatives analysis that allows it to make an informed siting choice, the DEIS is inadequate and must be revised.	As described throughout Chapter 2, geographic and seasonal flexibility is required to support evolving Navy training and testing requirements, which are linked to real world events. As described in Section 5.2.3.1 (Effectiveness Assessment) of the EIS/OEIS, a specific season, time of day, or geographic area must be important to the resource to determine whether the potential for establishing a mitigation area would be effective in avoiding or reducing a potential impact on a resource. In determining importance, special consideration will be given to those time periods or geographic areas having characteristics such as especially high overall density or percent population use, seasonal bottlenecks for a migration corridor, and identifiable key foraging and reproduction areas. The Navy proposes mitigation measures (a portion of which will include specific mitigation areas) on a case-by-case basis that would apply to all locations where a specified activity occurs. The balance between Procedural Measures and Mitigation Area measures provide a way for the Navy to mitigate potential impacts while maintaining its military readiness objectives. The proposed mitigation measures were developed in coordination with NMFS in order to avoid or reduce a potential impact on a particular resource. Please refer to Section 5.3.4.1.11 (Avoiding Marine Species Habitats) for further discussion of habitat avoidance.
NRDC - 82	Other Reasonable Alternatives The DEIS should also consider other reasonable alternatives which could fulfill the Navy's purpose while reducing harm to marine life and coastal resources. For example:	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	(1) The DEIS fails to include a range of mitigation measures among its alternatives. Many such measures have been employed by the U.S. Navy in other contexts, as discussed in Section IV; and there are many others that should be considered. Such measures are reasonable means of reducing harm to marine life and other resources on the proposed range, and their omission from the alternatives analysis renders that discussion inadequate. For instance, while safety zones are no substitute for geographic mitigation (which, as noted above, is the most effective means of reducing impacts on marine mammals), they do provide a form of last-recourse protection for any animals that are spotted near the array. The Navy must analyze safety zone enhancements outside critical points of its training and consider modifications in the safety zone provisions. We have noted several reasons in the past why expanding the safety zone would reduce the risk of near-array exposures: for example, (1) marine mammal groups are often spread out over a wide area, and animals may go undetected within the safety zone even if group members are only spotted outside; and (2) uncertainty remains over the thresholds and distances needed to cause hearing loss in some species. Given the Navy's defacto use of a wider safety zone in past exercises, it should consider how to provide for safety zone enhancements outside critical points of its training. In addition, the Marine Mammal Commission has repeatedly called for modifications in the safety zone provisions to allow sufficient time for animals to move out of the sound field. 63 MMC, Letter from Tim Ragen, Executive Director, Marine Mammal Commission, to P. Michael Payne, Chief, Permits Division, NMFS. Formal comments on MMPA proposed rulemaking, submitted Nov. 13,2008 (2008).(2) While we appreciate the Navy's plan to use range sensors and other passive acoustic platforms in limited instances, such efforts must be expanded. The Navy has failed to set forth an action plan and timeline in its EIS (and as part of its adaptive management under its current incidental take permits) to bring these sensors and platforms on line for purposes of more meaningful mitigation. Passive acoustic monitoring is one of the most effective available means of monitoring marine mammals in the vicinity of MFA sonar exercises and other sources of undersea noise.[64] Under the right conditions, it can significantly improve detectability of certain cryptic or deep-diving species. For example, while beaked whales are theoretically sightable only during the 8% of time that they are on the surface (and even then are unlikely to be spotted visually), some species vocalize over roughly 25% of their deep foraging dives.[65] NMFS, in its rulemakings, has repeatedly noted the mitigation potential of passive acoustic monitoring and the commitment of the Navy to technological development in support of this measure. 74 Fed. Reg. 3895.(3) The Navy's statement of purpose and need contains no language that would justify the limited set of alternatives that the Navy considers (or the alternative it ultimately prefers). Yet it is a fundamental requirement of NEPA that agencies preparing an EIS specify their project's "purpose and need" in terms that do not exclude full consideration of reasonable alternatives. 40 C.F.R. § 1502.13; City of Carmel-by-the-Sea v. United States Dep't of Transp. , 123 F.3d 1142, 1155 (9th Cif. 1997) (citing Citizens Against Burlington, Inc. v. Busey, 938 F.2d	detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration). The selection of an alternative by the decision-maker will be based on a review of all relevant facts, impact analyses, and comments received via the EIS/OEIS public participation process. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of numerous potential mitigation measures. Section 5.3.1.2.4.1 (Detection Probabilities of Marine Mammals in the Study Area) has a detailed discussion of available literature on the sightability of marine mammals. Note that Navy does not employ only visual monitoring and makes use of passive acoustic detection when available and appropriate. Also note that not all beaked whale species are small and for example, Baird's beaked whale can reach in excess of 40 feet in length and generally have a detection rate g(0) in excess of 0.90 in the Pacific. More importantly, however, the characterization that visual detection rates for marine mammals, "generally approach only 5" is not accurate. Specifically in reference to the citation in the comment, Barlow and Gisiner (2006) provide a description of typical marine mammal survey methods from ship and aircraft and then provide "a crude estimate" of the difference in detection of beaked whales between trained marine mammal observers and seismic survey mitigation, which is not informative with regard to Navy mitigation procedures for the following reasons. The authors note that seismic survey differs from marine mammal surveys in that, "(1) seismic surveys are also conducted at night; (2) seismic surveys are not limited to calm sea conditions; (3) mitigation observers are primarily searching with unaided eyes and 7x binoculars; and (4) typically only one or possibly two observers are searching." When the Navy implements mitigation for which adjustments to modeling output were made, the four conditions Barlow and Gisiner (2006) note are not representative of Navy procedures nor necessarily a difference in marine mammal line-transect survey procedures. The Navy accounts for reduced visibility (i.e., activities which occur at night, etc.) by assigning a lower value to the mitigation effectiveness factor. On Navy ships, hand-held binoculars are always available and pedestal mounted binoculars, very similar to those used in marine mammal

Commenter	Comment	Navy Response
	190, 196 (D.C. Cif. 1991). "The existence of a viable but unexamined alternative renders an· environmental impact statement inadequate," Idaho Conservation League v. Mumma, 956 F.2d 1508, 1519 (9th Cir. 1992), and an EIS errs when it accepts "as a given" parameters that it should have studied and weighed. Simmons v. U.S. Army Corps of Engineers, 120 F.3d 664, 667 (7th Cir. 1997).In sum, the DEIS shortchanges or omits from its analysis reasonable alternatives that might achieve the Navy's core aim of testing and training while minimizing environmental harm. For these reasons, we urge the Navy to revise its DEIS to adequately inform the public of all reasonable alternatives that would reduce adverse impacts to whales, fish, and other resources. 40 C.F.R. § 1502.1.	surveys, are generally available to Navy Lookouts on board vessels over 60'. Also like marine mammal observers, Navy Lookouts are trained to use a methodical combination of unaided eye and optics as they search the surface around a vessel. The implication that marine mammal surveys only occur in "calm sea conditions" is not accurate since the vast majority of marine mammal surveys occur and data is collected in conditions up to sea states of Beaufort 5. The specific g(0) values analyzed by Barlow and Gisiner (2006) were derived from survey data for Cuvier's and Mesoplodon beaked whale that were detected in sea states of Beaufort 0-2 during daylight hours. However, marine mammal surveys are not restricted to sea states of Beaufort 0-2, many species g(0) values are based on conditions up to and including Beaufort 5 and, therefore, the conclusions reached by Barlow and Gisiner (2006) regarding the effect of sea state conditions on sightability do not apply to other species. Finally, when Lookouts are present, there are always more than the "one or two personnel" described by Barlow and Gisiner (2006) observing the area ahead of a Navy vessel (additional bridge watch personnel are also observing the water around the vessel). Finally, Navy's reliance on visual mitigation has been demonstrated to be effective over the seven years of monitoring associated with Navy training and testing at sea in publically available reports submitted to NMFS since 2006 and accessible on the NMFS Office of Protected Resources website. The Navy has revised the mitigation zones used during training and testing activities as described in Section 5.3.2 (Mitigation Zone Procedural Measures).
NRDC – 83	The Navy Fails to Analyze the Impacts on Wildlife Viewing Interests and Recreation. Just as it fails to consider the direct, indirect, and cumulative impacts of increased training in the HSTT Study Area on the region's marine mammals and other fish and wildlife, the DEIS does not adequately consider the effects on wildlife viewing and other wildlife-dependent recreational interests. The DEIS makes no mention of the value lost from the harm to marine mammals that attract a number of our organizational members and members of the public to the potentially affected areas of Southern California and Hawaii. Nor does it address the potential economic value lost from decreased tourism (e.g., whale watching, cruise ships, etc.), particularly those areas centered on observing whales and other marine mammals in their natural habitats. One of NEPA's explicit purposes is to "assure esthetically and culturally pleasing surroundings," 42 U.S.C. 433 1(b)(2), and courts have made clear that an agency must adequately consider such recreational impacts in its NEPA analysis. See, e.g., Lujan v. NWF, 497 U.S. 871, 887	As stated in the approach to analysis (see Section 3.0.5 [Overall Approach to Analysis]), indirect impacts result when a direct impact on one resource induces an impact on another resource (referred to as a secondary stressor). If there is no direct impact on a resource, then indirect impacts are not foreseeable. Section 3.9 (Fish) concluded no long-term impacts to fish populations. The analysis in Marine Mammals (Section 3.4) and Socioeconomic Resources (Section 3.11) screened for any impacts on other resources that might create secondary impacts. Because the EIS/OEIS concluded there would be no impacts to fish populations, reduced catch rates and prey base were not addressed for Marine Mammals (Section 3.4) or Socioeconomic Resources (Section 3.11). The biological resources sections (3.4 through 3.9) determined there would be no long-term

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	(1990) ("no doubt that recreational use and aesthetic enjoyment are among the sorts of interests NEPA [was] specifically designed to protect"); LaFlamme v. FERC, 852 F.2d 389, 401 (1988) (because "there were substantial questions raised regarding whether the project may significantly affect recreational use in the project area, and that FERC failed to explain or discuss" these impacts, the court found that "this record reflects a decision which is neither 'fully informed or well-considered,'" and therefore concluded the agency's decision not to prepare an EIS was unreasonable).	impacts to populations, therefore not reaching the level of "harm" as to impact tourism activities.
NRDC - 84	Project Description and Meaningful Public Disclosure Disclosure of the specific activities contemplated by the Navy is essential if the NEPA process is to be a meaningful one. See, e.g., LaFlamme v. F.E.R.C., 852 F.2d 389, 398 (9th Cir. 1988) (noting that NEPA's goal is to facilitate "widespread discussion and consideration of the environmental risks and remedies associated with [a proposed action]"). For meaningful public input, the Navy must describe source levels, frequency ranges, duty cycles, and other technical parameters relevant to determining potential impacts on marine life. The DEIS provides some of this information, but it fails to disclose sufficient information about active sonobuoys, acoustic device countermeasures, training targets, or range sources that would be used during the exercises. And the DEIS gives no indication of platform speed, pulse length, repetition rate, beam widths, or operating depths-that is, most of the data that the Navy used in modeling acoustic impacts.	Information regarding source levels, frequencies, duty cycles, and other technical parameters have been provided in consideration of that which is necessary to conduct the analysis, and in consideration of protection of classified information. For more information on sonar system parameters, see Chapter 2 (Section 2.3.7, Classification of Acoustic and Explosive Sources). For descriptions of specific activities and the sources used for each activity, see Appendix A (Navy Activities Descriptions).
NRDC – 85	The Navy-despite repeated requests-has not released or offered to release CASS/GRAB or any of the other modeling systems or functions it used to develop the biological risk function or calculate acoustic harassment and injury.	The CASS/GRAB program is classified and not available for public release; however, approximate results can be obtained using other mathematical models commonly available to those with the technical expertise to utilize those tools. See the Criteria and Thresholds for U.S. Navy Acoustic and Explosive Effects Analysis Technical Report and the Determination of Acoustic Effects on Marine Mammals and Sea Turtles Technical Report which can be found at www.hstteis.com, for details on the development of the Navy Acoustic Effects Model and Criteria.
NRDC – 86	In addition, the Navy has also ignored repeated Freedom of Information Act requests regarding information and reports cited in the DEIS. These models, reports, and requests for information must be made available to the public, including the independent scientific community, for public comment to be meaningful under NEPA and the Administrative Procedure Act. 40 C.F.R. §§ 1502.9(a), 1503.1(a) (NEPA); 5 U.S.C. § 706(2)(0) (APA). In addition, guidelines adopted under the Data (or Information) Quality Act also require their disclosure. The Office of Management and Budget's guidelines require agencies to provide a "high degree of transparency" precisely "to facilitate reproducibility of such information by qualified third parties" (67 Fed. Reg. 8452, 8460 (Feb. 22,2002»; and the Defense Department's own data quality guidelines mandate that	No reference has been provided and the Navy is unaware of any Freedom of Information Act requests on this topic that have not been responded to. Navy takes its regulatory responsibilities seriously and when a request is submitted, it is acted upon.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	"influential" scientific material be made reproducible as well. We encourage the Navy to contact us immediately to discuss how to make this critical information available.	
NRDC - 87	Compliance With Other Applicable Laws A number of other statutes and conventions are implicated by the proposed activities. Among those that must be disclosed and addressed during the NEPA process are the following: (l) The Marine Mammal Protection Act ("MMPA"), 16 U.S.C. § 1361 et seq., which requires the Navy to obtain a permit or other authorization from NMFS or the U.S. Fish and Wildlife Service prior to any "take" of marine mammals. The Navy must apply for an incidental take permit under the MMPA, and NRDC will submit comments regarding the Navy's application to NMFS at the appropriate time. (2) The Endangered Species Act, 16 U.S.C. § 1531 et seq., which requires the Navy to enter into formal consultation with NMFS or the U.S. Fish and Wildlife Service, and receive a legally valid Incidental Take Permit, prior to its "take" of any endangered or threatened marine mammals or other species, including fish, sea turtles, and birds, or its "adverse modification" of critical habitat. See, e.g., IS36(a)(2); Romero-Barcelo v. Brown, 643 F.2d 835 (1st Cir. 1981), rev'd on other grounds, Weinberger v. Romero-Careeto, 456 U.S. 304, 313 (1982). Given the scope and significance of the actions and effects it proposes, the Navy must engage in formal consultation with NMFS and the U.S. Fish and Wildlife Service over the numerous endangered and threatened species that will be harmed from its activities. (3) The Coastal Zone Management Act, and in particular its federal consistency requirements, 16 U.S.C. § 1456(c)(1)(A), which mandate that activities that affect the natural resources of the coastal zone-whether they are located "within or outside the coastal zone"-be carried out "in a manner which is consistent to the maximum extent practicable with the enforceable policies of approved State management programs." The Navy must fulfill its CZMA commitments along the California and Hawaii coasts. (4) The Magnuson-Stevens Fisheries Conservation and Management Act, 16 U.S.C. § 1801 et seq. ("MSA"), which requires federal agencies to "consult with the Secretary [of Commerce] with respect to any action authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken" that "may adversely affect any essential fish habitat" identified under that Act. 16 U.S.C. §1855 (b)(2). In turn, the MSA defines essential fish habitat as "those waters and substrate necessary to fish for spawning, breeding, feeding or growth to maturity." 16 U.S.C. § 1802 (10). The HSTT Study Area contains such habitat. As discussed at length above, anti-submarine warfare exercises alone have the significant potential to adversely affect at least the waters, and possibly the substrate, on which fish in these areas depend. Under the MSA, a thorough consultation is required.(5) The Marine Protection, Research and Sanctuaries Act, 33 U.S.C. § 1401 et seq., which requires federal agencies to consult with the Secretary of Commerce if their actions are "likely to destroy, cause the loss of, or injure any sanctuary resource." 16 U.S.C. § 1434(d)(l). Since the Navy's exercises would cause injury and mortality of	The Navy has addressed all of these statutes and conventions. Please see Section 3.0.1 (Regulatory Framework) for a complete list of Federal Statues and Executive Orders addressed in Chapter 3 (Affected Environment and Environmental Consequences) and Chapter 6 (Additional Regulatory Considerations). The Clean Water Act was addressed in Section 3.1 (Sediments and Water Quality) and the Clean Air Act was addressed in Section 3.2 (Air Quality). As part of this process, the Navy has consulted under the Marine Mammal Protection Act, Endangered Species Act, and Magnuson-Stevens Fishery Conservation Management Act. The Proposed Action did not warrant consultation under the Marine Protection, Research and Sanctuaries Act or the Migratory Bird Treaty Act. The Navy has submitted Determinations to California and Hawaii in compliance with the Coastal Zone Management Act. Chapter 6 (Additional Regulatory Considerations) has thoroughly addressed Marine Protected Areas (Section 6.1.2) under Executive Order 13158.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	species, consultation is clearly required if sonar use takes place either within or in the vicinity of the sanctuary or otherwise affects its resources. Since sonar may impact sanctuary resources even when operated outside its bounds, the Navy should indicate how close it presently operates, or foreseeably plans to operate, to such sanctuary and consult with the Secretary of Commerce as required. In addition, the Sanctuaries Act is intended to "prevent or strictly limit the dumping into ocean waters of any material that would adversely affect human health, welfare, or amenities, or the marine environment, ecological systems, or economic potentialities" (33 U.S.C. § 1401 (b», and prohibits all persons, including Federal agencies, from dumping materials into ocean waters, except as authorized by the Environmental Protection Agency. 33 U.S.C. §§ 1411,1412(a). The Navy has not indicated its intent to seek a permit under the statute.(6) The Migratory Bird Treaty Act, 16 U.S.C. § 703 et seq. ("MBTA"), which makes it illegal for any person, including any agency of the Federal government, "by any means or in any manner, to pursue, hunt, take, capture, [or] kill" any migratory birds except as permitted by regulation. 16 U.S.C. § 703. After the District Court for the D.C. Circuit held that naval training exercises that incidentally take migratory birds without a permit violate the MBTA, (see Center for Biological Diversity v. Pirie, 191 F. Supp. 2ei 161 (D. D.C. 2002) (later vacated as moot», Congress exempted some military readiness activities from the MBTA but also placed a duty on the Defense Department to minimize harms to seabirds. Under the new law, the Secretary of Defense, "shall, in consultation with the Secretary of the Interior, identify measures-- (1) to minimize and mitigate, to the extent practicable, any adverse impacts of authorized military readiness activities on affected species of migratory birds; and (2) to monitor the impacts of such military readiness activities on affected species of migratory birds." Pub.L. 107-314, § 315 (Dec. 2,2002). As the Navy acknowledges, many migratory birds occur within the HSTT Study Area. The Navy must therefore consult with the Secretary of the Interior regarding measures to minimize and monitor the effects of the proposed range on migratory birds, as required.(7) Executive Order 13158, which sets forth protections for marine protected areas ("MPAs") nationwide. The Executive Order defines MPAs broadly to include "any area of the marine environment that has been reserved by Federal, State, territorial, tribal, or local laws or regulations to provide lasting protection for part or all of the natural and cultural resources therein." E.G. 13158 (May 26,2000). It then requires that "[e]ach Federal agency whose actions affect the natural or cultural resources that are protected by an MPA shall identify such actions," and that, "[t]o the extent permitted by law and to the maximum extent practicable, each Federal agency, in taking such actions, shall avoid harm to the natural and cultural resources that are protected by an MPA." Jd. The Navy must therefore consider and, to the maximum extent practicable, must avoid harm to the resources of all federally- and state-designated marine protected areas. The proposed activities also implicate the Clean Air Act and Clean Water Act as well as other statutes protecting the public health. The Navy must comply with these and other laws.	

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 88	Conflicts with Federal, State and Local Land-Use Planning NEPA requires agencies to assess possible conflicts that their projects might have with the objectives of federal, regional, state, and local land-use plans, policies, and controls. 40 C.F.R. § 1502.16(c). The Navy's training and testing activities may affect resources in the coastal zone and within other state and local jurisdictions, in conflict with the purpose and intent of those areas. The consistency of Navy operations with these land use policies must receive more thorough consideration.	The Navy has prepared Coastal Zone Management Act consistency determinations to ensure consistency with the enforceable policies of the applicable Coastal Zone Management Programs. Additionally, the Draft EIS/OEIS was submitted to each state adjacent to the Study Area for comment.
NRDC - 89	Appendix B – Impacts of Sonar	The issues addressed in this appendix were responded to directly within the NRDC comments above.
NRDC - 90	Appendix C – CRITIQUE OF THE NAVY'S ACOUSTICS ANALYSIS CRITIQUE OF THE RISK ASSESSMENT MODEL EMPLOYED TO CALCULATE TAKES IN THE HAWAII RANGE COMPLEX SUPPLEMENTAL DRAFT ENVIRONMENTAL IMPACT STATEMENT David E. Bain, Ph.D. Abstract Rather than using a fixed received level threshold for whether a take is likely to occur from exposure to mid-frequency sonar, the Navy proposed a method for incorporating individual variation. Risk is predicted as a function of three parameters: 1) a basement value below which takes are unlikely to occur; 2) the level at which 50% of individuals would be taken; and 3) a sharpness parameter intended to reflect the range of individual variation. This paper reviews whether the parameters employed are based on the best available science, the implications of uncertainty in the values, and biases and limitations in the model. Data were incorrectly interpreted when calculating parameter values, resulting in a model that underestimates takes.	The analytical methodology used in this EIS/OEIS was developed in close coordination with NMFS for the Hawaii Range Complex EIS/OEIS finalized in 2009. Past actions also included rulemaking by NMFS and issuance of a five year Letter of Authorization under the Marine Mammal Protection Act using the methodology presented in that previous EIS/OEIS. The "Appendix C – Critique" presented in these most recent comments is almost a verbatim repeat of the same critique presented in 2008 and so the following responses are also necessarily repetitive of the responses provided previously. As noted previously, the analysis presented in the HSTT EIS/OEIS represents the best available and most applicable science with regard to analysis of effects to marine mammals from sound sources. While recognizing there is incomplete and unavailable information with regard to behavioral impacts on marine mammals (see Section 3.4.3, Environmental Consequences), the response function curve extends to 120 dB sound pressure level specifically to encompass uncertainty and the potential for behavioral reactions in marine mammal species that may be affected by sounds perceived at levels just above ambient.
NRDC - 91	Errors included failure to recognize the difference between the mathematical basement plugged into the model, and the biological basement value, where the likelihood of observed and predicted takes becomes non-negligible; using the level where the probability of take was near 100% for the level where the probability of take was 50%; and extrapolating values derived from laboratory experiments that were conducted on trained animals to wild animals without regard for the implications of training; and ignoring other available data, resulting in a further underestimation of takes.	NMFS, as a cooperating agency and in its role as the MMPA regulator, reviewed all available applicable data and determined there were specific data from three data sets that should be used to develop the criteria. NMFS then applied the response function to predict exposures that resulted in exposures that NMFS may classify as harassment. NMFS developed two risk curves based on the Feller adaptive risk function, one for odontocetes and pinnipeds and one for mysticetes, with input parameters of B = 120dB, K = 45, 99 percent point = 195 dB, 50 percent point = 165 dB.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 92	In addition, uncertainty, whether due to inter-specific variation or parameter values based on data with broad confidence intervals, results in the model being biased to underestimate takes.	The commenter provides no specifics on why the takes would be underestimated. There is much conservativeness (overestimation) built into the modeling process (refer to Finneran and Jenkins [2012]). Additionally, NMFS, as a cooperating agency and in its role as the MMPA regulator, reviewed all available applicable data and determined there were specific data from three data sets that should be used to develop the criteria. NMFS then applied the risk function to predict exposures that resulted in exposures that NMFS may classify as harassment. NMFS developed two risk curves based on the Feller adaptive risk function, one for odontocetes and pinnipeds and one for mysticetes, with input parameters of B = 120dB, K = 45, 99 percent point = 195 dB, 50 percent point = 165 dB.
NRDC - 93	The model also has limitations. For example, it does not take into account social factors, and this is likely to result in the model underestimating takes. This analysis has important management implications.	The commenter was concerned that if one animal is "taken" and leaves an area then the whole pod would likely follow. The model does not operate on the basis of an individual animal, does account for average group size, and quantifies the exposures NMFS may classify as takes based on the summation of fractional marine mammal densities. Because the model output does not consider the many mitigation measures that the Navy utilizes when it is using mid-frequency active sonar, to include mid-frequency active sonar power down and power off requirements should mammals be spotted within certain distances of the ship, if anything, it overestimates the amount of takes.
NRDC - 94	First, not only do takes occur at far greater distances than predicted by the Navy's risk model, the fact that larger areas are exposed to a given received level with increasing distance from the source further multiplies the number of takes. This implies takes of specific individuals will be of greater duration and be repeated more often, resulting in unexpectedly large cumulative effects. Second, corrections need to be made for bias, and corrections will need to be larger for species for which there are no data than for species for which there are poor data.	Modeling accounts for exposures NMFS may classify as takes at distances up to 180 kilometers as described in the Final EIS/OEIS Section 3.4.3 (Environmental consequences) and the Determination of Acoustic Effects on Marine Mammals and Sea Turtles for the Hawaii-Southern California Training and Testing EIS/OEIS technical report. These clearly demonstrate the modeling was conducted over a wide range of bathymetry, sound velocity profiles, and bottom classes. Using these sound propagation characteristics, modeling resulted in less than 1 percent of the exposures that NMFS may classify as a take occurring between 120 dB and 140 dB. Risk function data sets and the parameters, such as the basement values, were chosen to account for uncertainties and for species for which there was less or no data regarding hearing thresholds. The area encompassed by this sound propagation, as determined by NMFS for exposures that may constitute harassment, avoids a bias toward underestimation because the response function parameters were designed with this in mind.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 95	Third, the greater range at which takes would occur requires more careful consideration of habitat-specific risks and fundamentally different approaches to mitigation. The value of the model is that it provides a focus for future research on the effects of noise on marine mammals. In particular, the sensitivity analysis indicates the primary need for data is determining response probabilities of a wide range of species when exposed to received levels near the level at which 50% of individuals respond.	Section 5.3.4 (Mitigation Measures Considered but Eliminated) of the Final EIS/OEIS evaluates alternative or additional mitigations, specifically, as they relate to potential mitigation approaches. The examples of the fundamentally different approaches noted in the comment were addressed in this section of the Final EIS/OEIS. In addition, NMFS has identified general goals of mitigation measures. These goals include avoidance of death or injury, a reduction in the number of marine mammals exposed to received levels when these are expected to result in takes, a reduction in the number of times marine mammals are exposed when these are expected to result in takes, a reduction in the intensity of exposures that are expected to result in takes, and a reduction in adverse effects to marine mammal habitat. As discussed below, NMFS and Navy have identified mitigation measures that are practicable and reasonably effective. For example, the safety zones reduce the likelihood of physiological harm, the number of marine mammals exposed, and the intensity of those exposures. The Navy has determined that mitigation measures will likely prevent animals from being exposed to the loudest sonar sounds or explosive effects that could potentially result in temporary threshold shift or permanent threshold shift and more intense behavioral reactions (Final EIS/OEIS, Section 5.3, Mitigation Assessment). Mitigation measures that are practicable involve those that reduce direct physiological effects within the temporary threshold shift and permanent threshold shift thresholds.
NRDC - 96	The Navy distinguishes two types of takes: Level A, in which there is immediate injury or death; and Level B, in which there is no immediate injury, but cumulative exposure may lead to harm at the population level. However, in certain contexts, Level B harassment may lead to Level A takes through indirect mechanisms. The population effects of Level A takes on populations are relatively easy to assess, as individuals that are killed are obviously removed from the population, and those that are injured are more likely to die whenever the population is next exposed to stress.	This comment is a complete mischaracterization of the analysis presented in the EIS/OEIS. Navy does not anticipate any mortality from its activities. Though the model estimates the potential for mortality based on very conservative criteria, with the implementation of proven mitigation and decades of historical information from conducting training and testing in the study area, the likelihood of mortality is near zero and would not impact populations. Additionally, there is no evidence that the type of injuries that could potentially occur (fully recoverable or limited permanent threshold shift) have or will result in follow on mortality.
NRDC - 97	Temporary Threshold Shifts in captive marine mammals are commonly used as an index of physical harm (e.g., Nachtigall et al. 2003, Finneran et al. 2002 and 2005, Kastak et al. 2005). Limiting experimental noise exposure to levels that cause temporary effects alleviates ethical concerns about deliberately causing permanent injury. However, repeated exposure to noise that causes temporary threshold shifts can lead to	The vast majority of these level B takes are short term behavioral responses to relatively short–term activities. The population level impacts are fully discussed in the EIS/OEIS; see Sections 3.0 and 3.4 for the overall discussion, and Sections 3.0.5.7.1 and 3.4.3 for specifics.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	permanent hearing loss. In fact, chronic exposure to levels of noise too low to cause temporary threshold shifts can cause permanent hearing loss.	
NRDC - 98	Changes in behavior resulting from noise exposure could result in indirect injury in the wild. A variety of mechanisms for Level B harassment to potentially lead to Level A takes have been identified.	In prior rulemakings, NMFS established that exposures resulting in Level A and B harassment cannot be considered to overlap, otherwise the regulatory distinction between the two criteria would be lost and the required quantification of takes would be ambiguous. To facilitate the regulatory process, the Final EIS/OEIS maintained a clear and distinct division between Level A and Level B Harassment as required by NMFS.
NRDC - 99	Captive cetaceans Studies of captive marine mammals provide an excellent setting for identifying direct effects of sound. E.g., one of the datasets employed by the Navy consists of studies relating short-term exposure of bottlenose dolphins and belugas to high levels of noise to Temporary Threshold Shifts. The Navy (Dept. Navy 2008b, p 3-7) noted aggressive behavior toward the test apparatus, suggesting stress was another consequence of the test (see also Romano et al. 2004). Such effects would be unconditional results of noise exposure. However, extrapolation of the level at which aggression was observed to the level at which behaviorally mediated effects might occur in the wild is problematic, as this depends on how well trained the subjects were. For example, the Navy has been a leader in training dolphins and other marine mammals to cooperate with husbandry procedures. Tasks like taking blood, stomach lavage, endoscopic examination, collection of feces, urine, milk, semen and skin samples, etc. once required removing individuals from the water and using several people to restrain them. With training, painful and uncomfortable procedures can be accomplished without restraint and with a reduction in stress that has significantly extended lifespans of captive marine mammals (Bain 1988).	The Navy and NMFS relied upon best available science to derive the behavioral response function. The data used were based on one captive animal study and two studies that involved observations of wild animals exposed to sonar or sonar-like signals.
NRDC - 100	12. Right whales exposed to alerting devices consistently responded when received levels were above 135 dB re 1 µPa. Due to the small sample size (six individuals), it is unclear whether this is close to the 50% risk, the 100% risk level, or both. These data do not allow identification of B, as lower exposure levels were not tested. In mysticetes exposed to a variety of sounds associated with the oil industry, typically 50% exhibited responses at 120 dB re 1 µPa. Thus right whales may be similar to killer whales.	Results of the research by Nowacek et al. (2004) indicated that right whales reacted to multiple "alert stimuli" which were developed specifically to elicit a response. These stimuli had a limited similarity to Navy sonar systems. In addition, Nowacek et al. was one of three primary references used to derive the risk function curve which accounts for effects down to 120 dB sound pressure level. Navy disagrees that there is any science indicating that "mysticetes exposed to a variety of sounds associated with the oil industry, typically 50% exhibited responses at 120 dB re 1 µPa." If in reference to Malme et al. (1983, 1984) as cited elsewhere in the critique, then those studies in fact indicated that for migrating whales, a 50-percent probability of response occurred at 170 dB for a continuous, low frequency sound source.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC – 101	See Table 1: Bain Appendix H Datasets not considered The Navy incorrectly concludes that additional datasets are unavailable. In addition to the other killer whale datasets mentioned above, data illustrating the use of acoustic harassment and acoustic deterrent devices on harbor porpoises illustrate exclusion from foraging habitat (Laake et al. 1997, 1998 and 1999, Olesiuk et al. 2002). Data are also available showing exclusion of killer whales from foraging habitat (Morton and Symonds 2002), although additional analysis would be required to assess received levels involved. The devices which excluded both killer whales and harbor porpoises had a source level of 195 dB re 1 ~a, a fundamental frequency of 10kHz, and were pulsed repeatedly for a period of about 2.5 seconds, followed by a period of silence of similar duration, before being repeated. Devices used only with harbor porpoises had a source level of 120-145 dB re 1 Pa, fundamental frequency of 10 kHz, a duration on the order of 300 msec, and were repeated every few seconds. Harbor porpoises, which the Navy treats as having a B+K value of 120 dB re µPa (with A large enough to yield a step function) in the AFAST DEIS (Dept. Navy 2008a), 45 dB lower than the average value used in the HRC SDEIS, may be representative: of how the majority of cetacean species, which are shy around vessels and hence poorly known, would respond to mid-frequency sonar. Even if harbor porpoises were given equal weight with the three species used to calculate B+K, including them in the average would put the average value at 154 dB re 1 µPa instead of 165 dB re 1 µPa.	The data sources these comments present as requiring such consideration involve contexts that are neither applicable to the proposed actions nor the sound exposures resulting from those actions. For instance, the comments' citation to Lasseau et al. involve disturbance to a small pod of dolphins exposed to 8,500 whale-watching opportunities annually. This is nothing like the type or frequency of action that is proposed by the Navy for the HSTT Study Area. Navy training involving the use of active sonar typically occurs in situations where the ships are located miles apart, the sound is intermittent, and the training does not involve surrounding the marine mammals at close proximity. Furthermore, suggestions that affect from acoustic harassment devices and acoustic deterrent devices, which are relatively continuous, high frequency sound sources (unlike mid-frequency active sonar) and are specifically designed to exclude marine mammals from habitat, are also fundamentally different from the use of mid-frequency active sonar. Finally, reactions to airguns used in seismic research or other activities associated with the oil industry are also not applicable to mid-frequency active sonar, since the sound or noise source, its frequency, source level, and manner of use is fundamentally different.
NRDC – 102	14. An important property of the model is that the biologically observed basement value is different than the mathematical basement value. The Navy proposes using 120 dB re 1 µPa as the basement value. They indicate the selection of this value is because it was commonly found in noise exposure studies. 15. For example, many looked at changes in migration routes resulting from noise exposure, and found that 50% of migrating whales changed course to remain outside the 120 dB re 1 µPa contour (Malme et al. 1983, 1984). These results might be interpreted in several ways. They could be seen as minor changes in behavior, resulting in a slight increase in energy expenditure. Under this interpretation, they would not qualify as changes in a significant behavior, and are irrelevant to setting the basement value. They could be interpreted as interfering with migration, even though the whales did not stop and turn around, and hence 120 dB would make an appropriate B+K value rather than B value. Third, the change in course could have been accompanied by a stress response, in which case the received level at which the course change was initiated rather than the highest level received (120 dB re 1 µPa) could be taken as the biological basement value.	These comments are factually inaccurate. The single citation provided for the repeated assertion that 50 percent of marine mammals will react to 120 db re 1uPa is Malme et al. (1983, 1984). Malme et al. (1983, 1984) in fact indicated that for migrating whales, a 50-percent probability of response occurred at 170 dB for a continuous, low frequency sound source that is very different from mid-frequency active sonar. Additionally, based on recent work at the Atlantic Undersea Test and Evaluation Center and SOCAL (Southall et al. 2007 and Tyack et al. 2011), with the exception of beaked whales there is no evidence to suggest the 120 dB basement value is incorrect, and for beaked whales a 140 dB receive level step function criteria was chosen.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
NRDC - 103	See Table 2: Bain Appendix Take numbers are based on Alternative 3 in the Hawaii Range Complex SDEIS (Dept. Navy 2008b), which in turn is based on the No Action Alternative, Table 3.3.1-1. Where the number of takes approaches the size of the population, the actual number of takes will be smaller than shown in the table. However, individuals will be taken multiple times and the duration of takes will be longer than if the calculated number of takes were small. Presumably, longer and more frequent takes of individuals will have more impact on the population than takes due to single exposures. See Table 3: Bain Appendix H Table 3. Sensitivity analysis based on a model with spherical spreading for 2 km followed by cylindrical spreading.	The vast majority of these level B takes are short term behavioral responses to relatively short term activities. The population level impacts are fully discussed in the EIS/OEIS. See Sections 3.0 and 3.4 for the overall discussion, and Sections 3.0.5.7.1 and 3.4.3 for specifics.
Ocean Conservation Research-01 (Written)	Please include the following comments into the record for both the HSTT DEIS and the AFTT DEIS. In preparing, this critique we have had the opportunity to review the comments from our colleagues at the Natural Resources Defense Council (NRDC) to both the HSTT and AFFT DEIS's. We find them thorough, thoughtful, comprehensive, and complete. Rather than overlap their efforts, let it stand that we fully endorse their work on these reviews. We always appreciate the opportunity to review and comment on proposed activities of the US Navy, although we find that the concurrent issuance and simultaneous closure of the public comment period for the Hawaii-Southern California Testing and Training (HSTT) and the Atlantic Fleet Training and Testing (AFTT) DEIS places a significant and we believe unreasonable burden on the resources of those of us who have made it our work to review, comment, and inform the public about how their tax dollars are spent.	The Navy has complied with all NEPA notification requirements under 40 C.F.R. § 1506. NEPA regulations require that agencies not allow less than 45 days for comments on a Draft EIS/OEIS. Please note that public comments are very important to the NEPA process. The Navy included an extra 15 days for review of this document for an extended comment period of 60 days total.
OCR-02	As always we have concerns about the impacts of the proposed activities, and in the case of both of the HSTT and AFTT DEIS we are particularly concerned, given that the estimated take numbers are so extremely high. In reviewing these documents we found that the numbers were high because the drafters of the documents dug deeply into the literature and presented their estimations based on both more thorough as well as more current peer reviewed literature. This is a breath of fresh air from our previous experiences in reviewing US Navy DEIS documents wherein the peer-reviewed papers substantiating the positions in the documents were either outdated, based on questionable premises, and/or the assumptions made about impacts were short-sighted or woefully inadequate. We congratulated this new candor in the HSTT- DEIS to our community on its original release, figuring that the Navy N-45 Environmental Preparedness Group was coming to terms with the fact that mitigating for bad public opinion was more costly than "'doing the right thing." This was particularly in light of the recent US Navy Public Relations sobriquet of "A force for good."	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 (Affected Environment and Environmental Consequences) of the EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy implements practical, effective, and safe mitigations in the context of impacts to the proposed activity.
OCR-03	That being said, upon deeper review of the documents our concerns are redoubled, because while there is more overall candor in the document, the assumptions that	The Navy is committed to protecting the marine environment during the conduct of its training and testing activities. As described in

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	destroying so much marine life for the expediency of the perceived Navy mission is completely unacceptable. While it may be arguable in the regulatory setting of the Marine Mammal Protection Act that "Level B" behavioral adaptations to proposed activities would be disruptive but recoverable, there is absolutely no justification for biological damage indicated in a "Level A" harassment. Even short-term "recoverable" assaults such as temporary threshold shift (TTS) are barbaric. Asking the National Marine Fisheries Service or the Marine Mammal Commission to issue "Incidental Harassment Authorizations" or "Take Permits" for "Level A" harassment is the apex of institutional hubris. If someone were to apply to the Department of Health and Human Services for a permit to yell in someone else's ear, or spill spent ordinance in their salad they would be watched cautiously and put on some "security risk list." So why is the US Navy encouraged to apply for permission to damage animals? It is patently unethical to damage an animal unless you are going to eat it, or it is going to eat you.	Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy has used extensive measures to protect the marine environment while training and testing for nearly a decade. All mitigation measures are designed to reduce or avoid potential impacts to marine resources, taking into account national security interests, the best available science, and regulatory requirements (including the MMPA and ESA). Additional information on the development of mitigation measures can be found in Section 5.2.2, (Overview of Mitigation Approach). Furthermore, the Navy has invested a significant amount of funding and support for marine mammal research.
OCR-04	We understand the need for a robust military to defend our shores and guard against unlawful international activities on the high seas. We also understand that we do not want to send our military personnel into harm's way without assuring their utmost safety. But the US military- particularly the Navy - is the most powerful fighting force on the planet, unparalleled by even the combined forces of the next eight global military powers - many of which are current allies. Of course it is always the desire for a military force to be "invincible." But invincibility should always be framed in the context of the scale of the threats, in the the costs to society, and increasingly in terms of the cost to our global environment. It should also be weighed in terms of the effectiveness and costs of the alternatives. Because in addition to the hefty costs of over-blown military invincibility, the risk is that it easily becomes a rationale for the military action to become the "action of choice," overshadowing less costly alternatives for conflict resolution such as diplomacy, or social and economic pressures. If there remains the chance that our military personnel will suffer or die in an action, there then remains a high incentive to engage in diplomacy or socio-political actions. If our military can just "pound our perceived threats into oblivion" it will then fall upon our own citizens to attempt to stop the carnage. This is a very ineffective strategy for democratic engagement because we have repeatedly seen that in the heat of perceived conflict the voices of our citizens fade behind the roar of war. I need not point any further than our reckless engagement with Iraq in 2002 based of false assumptions with the huge collateral costs to our economy and the destabilization of global security as an example. While we are not military strategists, nor are we privy to the long-term political objectives of our government, we are as citizens qualified to add our philosophical voice to this discussion. This is particularly in light of the fact that we find the assumptions used to justify the continuous expansion of US Navy warfare training ranges throughout US sovereign waters so egregious, short sighted, and reckless as to almost not warrant any further comment, except to say the since the decommissioning of the US Training Range in Vieques, Puerto Rico, that the	The Alternatives carried forward meet the Navy's purpose and need to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The discussion of interaction with commercial fisheries is included in the description of the baseline as an essential component used to inform a complete discussion on the status and threats to species. The Navy activities are compared against this baseline.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	US Nave has been making the entire US Sovereign waters a "Warfare Training Range." The HSTT-DEIS and AFTT-DEIS are further evidence of this relentless expansion and begs philosophical feedback because aside from the scientific candor in estimated take levels, there is an assumption that this is "OK." One of the arguments used in the DEIS to justify the high take levels is the comparison implied throughout the entire "Affected Environment" Sections 3 as well as in the executive summaries that commercial fisheries interactions through entanglements and by-catch exact much higher impacts on marine mammals, fish, invertebrates, and turtles than the proposed military actions as to render the military actions insignificant. This is a hollow argument; while the take numbers may indicate that the military actions are the "lesser of two evils," it does not justify any of the deliberate carnage of marine life by the Navy. The determinations of "acceptable" take numbers are predicated on the assumption that given the various population densities of the subject animals, that an "incidental, but not intentional, taking by citizens while engaging in that activity within that region of small numbers of marine mammals of a species or population stock [is allowed] if the Secretary ... finds that the total of such taking during each five-year (or less) period concerned will have a negligible impact on such species or stock."[3] This regulatory framework defined in the Marine Mammal Protection Act (MMPA) was modified to accommodate "military readiness activity [with] a determination of "least practicable adverse impact on such species or stock."	
OCR-05	This accommodation is not an exemption or release from the MMPA, rather it is an opportunity to evaluate the proposed actions in the context of "personnel safety, practicality of implementation, and impact on the effectiveness of the military readiness activity."[5] This clause provides for deeper consideration of the environmental costs of the action with the safety and effectiveness of the desired outcomes in mind. It is through this that the US Navy's "Force for Good" could really shine, because the US Navy through its resources and funded studies of ocean physics, chemistry, marine habitat and biology has developed a broad palate to examine the potential impacts of their actions. This is an opportunity that is not being taken the HSTT and AFTT OBIS's. While the evaluations reveal a new candor, the proposed alternatives don't express responsiveness to the estimated impacts. Nor do they reflect anthropogenic impacts that we know about, that are increasingly becoming evident, but are just recently entering into of the literature.	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes the chosen alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration). The selection of an alternative by the decision-maker will be based on a review of all relevant facts, impact analyses, comments received via the EIS/OEIS public participation process, and the requirements of the Navy in order to fulfill its mission. The EIS/OEIS uses best available science as described in Section 3.0.5 (Overall Approach to Analysis).
OCR-06	For example: while the synergistic and cumulative impacts of human activities are beginning to make way into the Environmental Impact Statement discussions, so far	The Navy used the best available science and a comprehensive review of past, present and reasonably foreseeable actions to develop

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	there is no metric examining the intermediate and long term health effects induced by our ever increasing agonistic activities on marine life. It is quite clear that we are compromising marine habitats through chemical pollution. Animals at the top trophic levels are becoming toxic to the point that a stranded whale or dolphin runs the possibility of being an Environmental Protection Agency-rated "toxic waste site," and food animals once considered 'delectable' are no longer safe for human consumption. A similar concern lies in the impacts of noise pollution. Even when the impacts are not mortal or "permanent" we are inducing noise-related stress on marine animals[6] that most probably compromises their ability to survive and proliferate. Much of this is pointed out in the Sections 3 "Affected Environment" and particularly in the Sections 3.4 Marine Mammal sections where the more recent papers on behavioral impacts of noise exposures are sited. It is clear from the more recent work that behavioral impacts occur at much lower levels and at greater distances than what is used as the threshold for MMPA "Level B" exposure.	a robust Cumulative Impacts analysis (Chapter 4).
OCR-07	It is clear that we are compromising their habitat, increasing stress levels, displacing them from preferred feeding, social, and breeding areas, and compromising their ability to communicate, navigate, proliferate, and ultimately survive by the short-sighted priorities of our military-industrial and commercial economy. In this context we should not be doing a comparative analysis on whether fishing, shipping, or Naval warfare training has a greater impact on marine habitat, rather we need to examine how the additional disruptions further compromise an already stressed environment.	The discussion of general threats to resources is included in the description of the baseline as an essential component used to inform a complete discussion on the status and threats to species. The Navy activities are compared against this baseline.
OCR-08	If more "biological bandwidth" is required to assure our national security and health of our marine food supply, the Navy is in the best place to promote less impactful marine technologies, and enforce regulations that decrease unlawful commercial and industrial impacts on the habitat. Throughout my 20 year experience of reviewing and critiquing US Navy and other agency Draft Environmental Impact Statements I have taken the allotted public comment period to comb through the proposals, examining the assumptions, deconstructing the models, and evaluating the supporting documentation. Typically I have offered comments on the shortcomings, obfuscations, deceptions, and programmatic deceits set into the agencies' responses to their NEPA mandated requirements to explore the environmental impacts of their proposed actions.	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 (Affected Environment and Environmental Consequences) of the EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy implements, to the maximum extent practicable, mitigation measures during its training and testing activities.
OCR-09	This case is different, largely due to the comprehensive and thorough examination of the literature in the two DEIS. While I find it annoying that these were let out concurrently I do appreciate the "candor" of the drafts. What I find extremely troubling is that with all of the facts, models, and assumptions presented in the documents that the Navy is not paying heed to what they have concluded: that millions of marine mammals and countless fish and marine invertebrates will be maimed, poisoned, or killed by the proposed actions. They have not considered that over the intermediate to long term the	The HSTT EIS/OEIS analyses and conclusions are based on best available science and do not support your comment. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 (Affected Environment and Environmental Consequences) of the EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation,

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	practices of the US Navy proposed in the HSTT and AFTT DEIS's will contribute significantly to the collapse of marine ecosystems. And they have not conceded that these environmental compromises will have a significantly deeper negative impact on global security. In our review of the HSTT and AFTT DEIS we find profound evidence that the economic and environmental costs are excessive, particularly in a time when both the US economy and the ocean environment are under deep duress. We advise that in both the Hawaii Southern California Training and Testing and the Atlantic Fleet Training and Testing areas that the "No Action" alternative be selected.	and Monitoring) of the EIS/OEIS, the Navy implements, to the maximum extent practicable, mitigation measures during its training and testing activities. Though the intensity of training and testing will increase, the events are of relatively short duration. Based on the analysis of potential impacts and associated mitigation measures, the Navy does not anticipate long-term, population level impacts to marine animals. The Navy used the best available and most applicable science to analyze potential environmental impacts to every resource. The Navy is studying the long-term population effects of sonar as stated in Section 5.5 (Monitoring and Reporting). Additionally, Navy has been conducting these types of training activities for decades and there is no evidence to support this comment.
Save the Whales-01 (Electronic)	I am outraged that the U.S. Navy would go ahead with sonar testing that could kill and harm marine mammals 2.8 million times a year over a five year period. The proposed training and testing activities off the coasts of Hawaii, Southern California, the Atlantic seaboard and the Gulf States from 2014 to 2019 gives these figures in your Draft Environmental Impact Statements. The Navy's projected damage to whales and dolphins is astounding. It is a vast increase over previous estimates of potential harm for the same regions. The numbers for far-reaching harm that will be inflicted on marine mammals during these testing activities is staggering: over 5,000,000 instances of temporary hearing loss, 16,000 instances of permanent hearing loss, almost 9,000 lung injuries, and over 1,800 deaths. An estimated 11,200 whales and dolphins will be deafened. What is unstated is that whales and dolphins depend on sound to navigate, communicate and survive. What is not presented in your analysis are reasonable alternatives to reduce the unprecedented damage to marine animals. Your mitigation plan, based on the ability of lookouts to detect whales and dolphins, will not achieve a significant reduction in damage to marine life.These same plans have been found by Federal courts to be inadequate and ineffective. Visual surveillance may be impaired at sea and unsuitable for distinguishing deep-diving species that spend little time at the surface. If fully effective, it would only protect species from the most serious injuries. I call on the Navy to please identify and set aside areas of high marine mammal density which is acknowledged to be the most effective means of reducing marine mammal injury. If the United States and its Navy wish to be seen as a leader in saving marine life, it must significantly reduce the levels of death and injury to whales, dolphins and other marine life involved in these plans.	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 (Affected Environment and Environmental Consequences) of the Draft EIS/OEIS. The Navy is proposing to implement several mitigation measures within pre-defined habitat areas in the Study Area. For the purposes of this document, the Navy will refer to these areas as “mitigation areas.” As described throughout this section, these recommended mitigation areas may be based off endangered species critical habitats, endangered species reproductive areas, or bottom features. The size and location of certain habitat areas, such as the critical habitats, is subject to change over time; however, the Navy’s effectiveness and operational assessments and resulting mitigation recommendations are entirely dependent on the mitigation area defined in this document. Therefore, it is important to note that the Navy is recommending implementing mitigation measures only within each area as described in this document. Applying these mitigations to additional or expanded areas could potentially result in an unacceptable impact on readiness. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Draft EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf].
Save the Whales-02	I understand that for safety & security purposes ship hulls need to be tested for strength. However, believe if we can send men to the moon & can have humans orbit our planet on a space station, we can find a way to test ships without causing harm to the ocean-life we've not yet exterminated. I'm from a NASA town & grew up in a NASA family so I know our government has the know-how. Perhaps funding could be diverted from the testing to find out why monkeys fling their poop. Don't laugh, this is listed as a current legitimate budget expense of our government. We can't keep killing off these amazing creatures in our	The Navy is constantly evaluating and funding research to assess improved technologies that will achieve Navy mission goals while protecting resources on land and at sea. Evaluation of these technologies continues to be a Navy focus as is research into all technologies that will protect and defend the United States.
Sierra Club (Bigger)-01 (Written)	INTRODUCTION Thank you for the opportunity to comment on this very comprehensive document. We also appreciate the efforts of the Navy to engage the public in review of this document, including the hosting of public open house public meetings at various locations throughout the affected region. We recognize and appreciate the contributions of our armed services personnel, including the U.S. Navy, in providing for the security of our homeland under increasingly complex conditions. That includes the difficult task of seeking to balance the duties of providing such security while also fulfilling their responsibilities as environmental stewards. As citizens of the United States, we value our freedom and security. We also value our relationships with whales, dolphins, sea turtles, sea birds, and other creatures with which we share the Planet. They are more than just "natural resources." Strong, adequate, measures are necessary to avoid or minimize risks the Navy's training and testing activities pose to marine species and their habitats, as they also face increasing stresses in coming years from climate change impacts -- including rises in sea levels, and increases in sea temperatures and ocean acidification-- and from the cumulative impacts of increased uses of coastal waters for wind energy projects, oil and gas exploration, and other human activities.	The Navy is committed to protecting the marine environment during the conduct of its training and testing activities. As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy has used extensive measures to protect the marine environment while training and testing for nearly a decade.
Sierra Club (Bigger)-02	GENERAL COMMENTS We are quite concerned over the potential toll the planned Testing and Training activities described in this DEIS could exact on marine mammals, sea turtles, other species and their habitats. Unfortunately, we do not consider the mitigation measures described in this DEIS to be sufficiently strong or adequate.	As described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS, the Navy evaluated the effectiveness and practicability of a number of potential mitigation measures. Through consultation and the permitting process with NMFS and USFWS, the Navy refined the mitigation measures, which are now presented in Chapter 5 of this Final EIS/OEIS.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
Sierra Club (Bigger)-03	In addition to our own study of this document, we have reviewed and endorsed the comments on this DEIS submitted by the National Resources Defense Council (NRDC). We agree with their conclusion that this DEIS must be revised as necessary to comply with NEPA requirements, including development of alternatives that incorporate spatial and temporal mitigation measures. The DEIS shows in considerable detail that either Alternative I and Alternative 2 (the Preferred Alternative) would constitute very large increases in the, scope, scale, and impacts of activities compared to the baseline levels of the No Action Alternative. In particular the DEIS projects large increases in "takes" under the provisions of the Marine Mammal Protection Act (MMPA) and the Endangered Species Act (ESA). Ultimately, the National Marine Fisheries Service will need to establish take limits through authorization letters in compliance with the MMPA and the ESA. As the DEIS notes, NMFS may require additional mitigation measures as conditions for issuing an MMPA (and, presumably, ESA) letter of authorization: "In order to make the findings necessary to issue an MMPA Letter of Authorization, it may be necessary for NMFS to require additional mitigation measures or monitoring beyond those contained in this Draft EIS/OEIS. These could include measures considered, but eliminated in this EIS/OEIS, or as yet undeveloped measures. The public will have an opportunity to provide information to NMFS through the MMPA process, both during the comment period following NMFS' notice of receipt of the application for a letter of authorization, and during the comment period following publication of the proposed rule. NMFS may propose additional mitigation measures or monitoring in the proposed rule." (ES-12) While this quote suggests that NMFS might require more stringent measures than contained in this DEIS, we concur with NRDC that the DEIS itself should identify such measures as alternatives to be considered.	The Alternatives carried forward meet the Navy's purpose and need (see Section 1.4 [Purpose and Need for Proposed Military Readiness Training and Testing Activities]) to ensure that it can fulfill its obligation under Title 10. See Section 2.5 (Alternatives Development) for more detailed information on the development of alternatives. The Navy complied with NEPA requirements in the development and consideration of alternatives. This EIS/OEIS analyzes all alternatives in Section 2.5.2 (Alternatives Carried Forward) and explains why the Navy has eliminated other alternatives in Section 2.5.1 (Alternatives Eliminated from Further Consideration). The selection of an alternative by the decision-maker will be based on a review of all relevant facts, impact analyses, comments received via the EIS/OEIS public participation process, and the requirements of the Navy in order to fulfill its mission.
Sierra Club (Bigger)-04	2. Inadequacy of Visual Detection as a Mitigation Measure Use of lookouts and other visual detection methods as mitigation measures may be necessary, but are not sufficient in the case of numerous species whose presence is difficult to detect visually. For example, under either Alternative 1 or Alternative 2, the Hawaiian stock of Cuvier' s beaked whale is projected to receive 52,110 Behavioral exposures out of a total of 112,752 for all Hawaiian stock species. This equates to 46%, almost half, of the total. The study area abundance for this species is 15,242, so these impacts are very significant as a percentage of the total population. The Occurrence in the Study Area is described as "Year-round occurrence but difficult to detect due to diving behavior "6 The Dwarf sperm whale accounts for 20,569 out of a total of 30,292 TTS exposures -- 67% of the total. It accounts for 60 out of 63 PTS exposures- 95% of the total. The study area abundance for this species is 17,519, so these impacts are also very significant as a percentage of the total population. It appears that the population, or at least a portion of the population, will be subject to multiple exposures at levels affecting their auditory functions. The Occurrence in the Study Area is described as "Stranding numbers	The Navy acknowledges the limitations of visual shipboard monitoring and uses aerial monitoring and passive acoustic monitoring for multi-faceted monitoring where practical. The EIS/OEIS, Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring), presents the U.S. Navy's mitigation measures, outlining steps that would be implemented to protect marine mammals and Federally listed species during training events. In general, there are usually more ships and more observers present on Navy ships, and additional aerial assets engaged in exercise events than used during trackline detection during a survey, thereby increasing the potential to detect marine mammals during a Navy activity. Section 3.4.3.1.8.4 (Model Assumptions and Limitations) in the Final EIS/OEIS provides a more robust discussion on marine mammal sightability and the inclusion of implementing mitigation measures to reduce the effects of sound exposures on marine mammals. Section 3.4.3.2 (Analysis of Effects on Marine Mammals) has been revised to account for the Navy's mitigation

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	suggest this species is more common than infrequent sightings during survey (Barlow 2006) indicated." This suggests that even trained scientists seeking to assess population sizes have difficult spotting this species visually. Cuvier's beaked whale and the Dwarf sperm whale are both "cryptic" species difficult to spot" because they are not very active at the surface and do not have a conspicuous blow)."7 It is clear that the use of lookouts or other visual detection methods are not sufficient for the populations most affected by Training activities in the Hawaiian Area Complex. As disturbingly high as these exposures are, they are likely understated since they do not include exposures from Testing or other activities. We have not had sufficient time to perform the required calculations, which require compiling exposure data from two, and possibly more, separate tables scattered throughout the DEIS. Nor should reviewers such as us- or, ultimately, NMFS -- have to perform such additional steps in order to get useful information out of the huge amounts of fragmented data contained in this DEIS. The revised, reissued, version of this DEIS must contain tables showing total impacts per species from all sources as well as ratios of exposures to total population sizes. Such tables would be necessary for determining what levels of take would be acceptable under the MMPA or ESA, and would direct decision makers to the areas requiring additional or more effective mitigation measures.	measures and marine mammal behavioral responses to sound in the water to more accurately reflect the predicted potential effects on marine mammals. In addition, for species-specific take requests permitted under MMPA for activities covered by the HSTT EIS/OEIS, please see the complete Letter of Authorization at the NMFS website: http://www.nmfs.noaa.gov/pr/permits/incidental.htm#applications
Sierra Club (Bigger)-05	3. Concerns over impacts to Gray whale populations in SOCAL The DEIS shows high estimated exposures for the Gray whale population, including considerable instances of PTT relative to the population size. As stated in the DEIS, the "Population migrates through SOCAL, with the occurrence in SOCAL described as "Transient during seasonal migrations. "8 According to the DEIS, the Gray whale population is estimated at I 8,813. Combined Training and Testing exposures under the No Action Alternative are estimated to be 1,077 Behavioral, 1,401 ITS, and 0 PTS. Those impacts relative to the population size are 6%, 7%, and 0% respectively. Combined Training and Testing exposures under Alternative 1, are 3,816 Behavioral 7,358 TTS, and 25 PTS. Those impacts relative to the population size are 21%, 39%, and 0.1% respectively. The increases relative to the No Action Alternative are 359% for Behavioral and 525% for ITS. Combined Training and Testing exposures under Alternative 2, are 3,911 Behavioral 7,645 TTS, and 25 PTS. Those impacts relative to the population size are 21%, 41%, and 0.1% respectively. The increases relative to the No Action Alternative are 363% for Behavioral and 546% for TTS. Clearly, use of a temporal closure for at least key portions of the SOCAL area appears warranted for reduction of impacts to the Gray whale population transiting the SOCAL.	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 (Affected Environment and Environmental Consequences) of the Draft EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Draft EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf].
Sierra Club National Marine Action	Aloha, my name is Dave Raney, and I am Team Leader of the Sierra Club's National Marine Action Team. The Sierra Club is soliciting comments from our affected Chapters and will submit written comments on this DEIS, and the Atlantic Fleet Training and	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from active sonar and explosives were analyzed in Chapter 3 of the Draft EIS/OEIS. Also, as described in Chapter 5

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
Team-01 (Written)	Testing DEIS. This evening I will make a few preliminary comments. First, we recognize and appreciate the contributions of our armed services personnel, including the U.S. Navy, in providing for the security of our homeland under increasingly complex conditions. That includes the difficult task of seeking to balance the duties of providing such security while also fulfilling their responsibilities as environmental stewards. We value our freedom and security. As Pacific Islanders in particular, we also value our relationships with whales, dolphins, sea turtles, sea birds, and other creatures with which we share the Planet. They are more than just "natural resources" and we ask your help in protecting them from risks your training and testing activities may pose, as they also face increasing stresses in coming years from climate change impacts -- including rises in sea levels, and increases in sea temperatures and ocean acidification. You have invited our help in improving this DEIS. Here are two suggestions: 1. Use coastal and marine spatial planning tools, as promoted by the National Ocean Policy, to address the conflicts this DEIS attempts to address. NOAA and the Navy have a broad array of applicable tools, including a geographic information system data base showing the densities of marine mammal and sea turtle species found in specific areas. Avoiding areas of high population densities through the use of spatial planning, or zones, such as the National Marine Fisheries service proposed monk seal critical habitat, would be much more effective than the heavy reliance the DEIS currently places on the use of lookouts and limited area mitigation zones.	(Standard Operating Procedures, Mitigation, and Monitoring) of the Draft EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities. Based on the analysis in the EIS and monitoring conducted during actual training events, the proposed training will not pose a risk to whales, fish, and other wildlife given that these same activities have been conducted for many years here and in other Range Complexes with no indications of broad-scale impacts that are either injurious or of significant biological impact to marine mammals, fish, or wildlife at those locations. Please see the recent results supporting this as presented in training ranges monitoring reports available at available at: [http://www.nmfs.noaa.gov/pr/pdfs/permits/hrc_socal_report.pdf]. Regarding the use of simulation, as described in Section 2.5.1.3 (Simulated Training and Testing) of the Draft EIS/OEIS, "Today's simulation technology does not permit anti-submarine warfare training with the degree of fidelity required to maintain proficiency. While simulators are used for the basic training of sonar technicians, they are of limited utility beyond basic training. A simulator cannot match the dynamic nature of the environment, such as bathymetry and sound propagation properties, or the training activities involving several units with multiple crews interacting in a variety of acoustic environments." Coastal and marine spatial planning is a tool under development by the National Ocean Council (NCO) which includes all federal agencies and is co-chaired by the CEQ Chair and Director of Office, Science, Technology and Policy. CMSP is a team effort by the NOC and its staff in coordination with all the NOC members. Navy continues working with the NOC Staff and other members to implement the National Ocean Policy in accordance with Executive Order 13547. Additional information on the status of the National Ocean Policy can be obtained at http://www.whitehouse.gov/administration/eop/oceans/policy. The DoD has been and will continue to be actively involved in the National Ocean Policy process. The mitigation measures listed in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the Final EIS/OEIS are the result of the consultation with NMFS and USFWS. The Navy proposes to implement both area-specific mitigations and activity-specific mitigations. For a discussion of area-specific mitigations, please see Section 5.3.3 (Mitigation Areas) of the Draft and Final EIS/OEIS. To supplement the Navy's proposed Mitigation Areas, activity-specific procedural mitigation measures (see Section 5.3.1, Lookout Procedural Measures and Section 5.3.2,

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
		Mitigation Zone Procedural Measures) will apply year round at each activity location. The balance between Procedural Measures and Mitigation Area measures provide a way for the Navy to mitigate potential impacts while maintaining its military readiness objectives. Refer to Chapter 4 (Cumulative Impacts) for a discussion of the additive effects of all projects in the Study Area.
Sierra Club National Marine Action Team-02	2. Abandon the SINKEX program of sinking obsolete ships in our waters. We note that each of the three alternatives includes the possible sinking of up to six ship hulks in the Hawai'i Range Complex through use of the SINKEX project. We urge the Navy to abandon the wasteful and environmentally threatening practice of sinking ships that still contain remnant amounts of PCBs even after meeting what we consider to be inadequate cleanup standards required by the EPA. This DEIS rules out several potential mitigation measures because they would make a training practice "unrealistic." The use of SINKEX involves sinking a large, unarmed, stationary vessel incapable of attempting evasive maneuvers or employing electronic countermeasures. This fails the requirement for realism, just as shooting a grazing cow would not adequately prepare one for duck hunting. SINKEX has provided a small percentage of trainees the experience of watching live weapons send very large ships to the bottom of the ocean. That experience passes with time, while the ship that was sunk permanently joins what has become the underwater equivalent of an elephant's graveyard on our seabed. There are more than a dozen such ships sunk within the Hawai'i Range Complex, most of them due north of the island of Kaua'i. Surely this is not an acceptable environmental legacy for the Navy, and we urge that you abandon the use of SINKEX from this time forward.	The SINKEX is an essential component of the suite of training activities to ensure that Sailors and Marines are ready to deploy in real world operations. The Navy must comply with the Office of the Chief of Naval Operations (OPNAV) Instruction 1541.5, which limits SINKEXs to those required to satisfy specific requirements for ship survivability or weapons lethality evaluation (required by Title 10, Section 2366 for major system or munitions programs), major joint or multi-national exercises, or the evaluation of new multi-unit tactics or tactics and weapons combination. Environmental preparation of SINKEX vessels is in accordance with EPA permits and additional guidance. As stated in Section 1.4.2 (Fleet Readiness Training Plan), the Fleet Readiness Training Plan outlines the training activities required for military readiness that prepares Navy personnel for any conflict or operation. The Navy's building-block approach to training is cyclical and qualifies its personnel to perform their assigned missions. The value of a SINKEX goes beyond engaging a maneuvering target and the lessons learned are passed to other members of the fleet.
Sirius Institute and Planet Puna (Oral)	Okay. Well, thank you for letting me speak here. I hope my input can have some value. Star Newland and I, through the Sirius Institute and Planet Puna, have been studying mostly the effects of birth and general birth and water birth on the constitution of humans. And one of the major experts in underwater birth and birth in general is a French medical doctor named Dr. Michel Odent. And he points out that nearly all cultures have messed around with the birth imprint or the birthing process. For example, some cultures will express the mother's colostrum and throw it away to make sure that the baby never has it in spite of the fact it's the most helpful thing it could get right at birth. Other cultures would put sand, salt, bread, sugar, rice, anything other than milk as the first taste for an infant. So we have planet-wide messed up the process of birth. Recently -- well, not recently but over the last decades, they've been using more and more synthetic Oxytocin, Pitocin, and it's causing great fetal distress, but it also messes up the bonding and the suckling between the mother and infant. So we are rapidly losing the ability to give birth properly. The punchline of this is when you do this to an infant, since the type of life they have is dependent on their birth imprint, you end up -- if you interfere with birth in a major way like we've been doing, you end up with people that have missed connecting with their mothers, with the Earth, and they are great warriors,	Thank you for participating in the NEPA process.

Table E.3-3: Responses to Comments from Organizations (continued)

Commenter	Comment	Navy Response
	and they are traumatized. They're enraged, and they're ready to kill at some point because we have messed up their birth imprint. So we have fallen into this, and that might be one of the major reasons why we have such a warlike planet. So fortunately the Navy has agreed to partner with Star Newland and the Sirius Institute for domestic harmony, and so we're here to talk to them about that. And we hope that the Navy can start this process that one could imagine, for example, Navy wives giving birth in the water with the service dolphins that the Navy already has. One can imagine the service dolphins helping the returning veterans with their traumas and post-traumatic stress disorders and so on. And this could lead to a much more harmonious planet, which is consonant with the Navy goals right now, that they will pursue humanitarian efforts to avoid or reduce conflict before they will choose to attack and to do other things like that. So we're very proud that the Navy wants to do that, and we're hoping they'll continue, and we're here to help in any way to reverse this trend on the planet. Thanks.	
Surfrider Foundation (Labedz) (Oral)	Hi, I'm Gordon LaBedz. I'm here representing The Surfrider Foundation, and you're taking notes. In 2006 the Surfrider Foundation, the Kauai Chapter, sued the Navy over RIMPAC. And the law that we used with NEPA, National Environmental Protection Act, and the judge agreed with us that RIMPAC needed an environmental impact statement. And the Navy appealed, and the appeal judge agreed with us, too. And our view towards this EIS is that this does not work. A blanket, We want to do whatever we want to do for the next five years as far as testing and training in one booklet, is just not in the spirit of the National Environmental Protection Act that each bad thing that the Navy does needs to be looked at separately. And a blanket umbrella EIS it appears to us is illegal. And that's the most important thing that needs to be commented on this draft EIS, and we are talking to our attorneys. Thank you.	The Navy shares your concern for marine life. All of the reasonably foreseeable effects from Navy training and testing activities were analyzed in Chapter 3 (Affected Environment and Environmental Consequences) of the EIS/OEIS. Also, as described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the EIS/OEIS, the Navy implements, to the maximum extent possible, mitigation measures during its training and testing activities. The EIS/OEIS is prepared by the Department of the Navy in compliance with the National Environmental Policy Act (NEPA), the Council on Environmental Quality, the Department of the Navy procedures for implementing NEPA, and Executive Order 12114 (Environmental Effects Abroad of Major Department of Defense Actions). The selection of an alternative by the decision-maker will be based on a review of all relevant facts, impact analyses, comments received via the EIS/OEIS public participation process, and the requirements of the Navy in order to fulfill its mission.
