## Abstract

Sauger (*Sander canadensis*) and walleye (*Sander vitreus*) are closely related North American fish species that are often managed by fishery agencies throughout their ranges. However, genotyping resources for sauger are presently limited to a small set of microsatellite loci. We evaluated whether primers in an existing walleye genotyping-in-thousands panel could amplify single nucleotide polymorphism loci (SNPs) in sauger. We identified 71 primer pairs that amplify 118 SNPs in both species. Allele frequency differences were large enough to confidently distinguish the species and identify hybrids. Additionally, we identified 41 loci with observed heterozygosity  $>0.1$  in sauger; these markers may be useful for simple population genetic analyses and parentage analysis when few contributors are present and for differentiating highly structured populations.

**Keywords** Amplicon genotyping · GT-seq · Sauger · Walleye · Stocking assessment

Sauger (*Sander canadensis*) and walleye (*Sander vitreus*) are closely related North American freshwater fish species. While both species have supported substantial recreational and commercial fisheries in parts of their ranges (Pegg et al. 1996; Radomski 2003; Schmalz et al. 2011), they are increasingly targets of restoration due to abundance declines associated with habitat fragmentation, overharvest, and climate change (Hoff 2001; Jaeger et al. 2005; Gillenwater et al. 2006; Hansen et al. 2017; Hartman et al. 2019). Given the species' dual roles as targets of both rehabilitation and harvest, they are often closely managed by natural resource agencies (e.g., Loukmas 2013; Gelwicks et al. 2014).

Amplicon genotyping panels provide a cost-efficient means of collecting genetic data at hundreds of loci that can inform research of conservation interest (Meek and Larson 2019). A genotyping-in-thousands (GT-seq; Campbell et al. 2015) panel was recently developed for walleye with loci selected to both quantify population structure and inform parentage analyses (Bootsma et al. 2020). This panel consists of 436 primer pairs that generate ~ 140 bp amplicons, permitting genotyping on single-end 150 bp sequencing platforms. Given their taxonomically close relationship and capacity to hybridize (saugeye; Graeb et al. 2010; Quist et al. 2010), we expected a subset of loci from the existing walleye panel to amplify and be polymorphic in sauger. A genotyping panel applicable to both species could have conservation and management applications, including species identification, identification of saugeye (*Sander canadensis* X *S. vitreus*), and assessment of stocking success via parentage-based tagging.

To identify loci with utility for both sauger and walleye, we first genotyped 351 sauger from Wisconsin's Lake Winnebago using a 400-locus subset of the Bootsma et al. (2020) walleye GT-seq panel with demonstrated consistent amplification. Genomic DNA was extracted from ethanol-preserved fin clips using a chelating resin-based procedure

(Campbell et al. 2015; Bootsma et al. 2020). PCR amplifications used 1.5 µl of the primer pool at 0.5 µM per primer pair and involved initial denaturing at 95 °C for five min, five touchdown amplification cycles (95 °C for 30 s, 5% ramp down, 57 °C for 2 min, 72 °C for 30 s), 10 additional amplification cycles (95 °C for 30 s, 65 °C for 30 s, 72 °C for 30 s), a final extension at 72 °C for 5 min, and a 4 °C hold. A barcoding PCR was then performed by combining 5 µl 2x Qiagen Multiplex PCR Plus master mix with 1 µl of 10 µM Illumina TruSeq i7 barcoding primer, 2 µl of 5 µM Illumina TruSeq i5 barcoding primer, and 2 µl 3:40 diluted PCR product. Barcoding amplifications involved initial denaturing at 95 °C for 5 min, 10 amplification cycles (95 °C for 10 s, 65 °C for 30 s, 72 °C for 30 s), a final extension at 72 °C for 5 min, and a 4 °C hold. PCR product was then normalized with SequalPrep normalization kits with an elution volume of 20 µl per well, followed by pooling 10 µl per well. The plate-specific 960 µl pools were concentrated to 100 µl with a QIAquick PCR purification and gel extraction kit. Eluates were purified with 0.9x AMPure XP beads and eluted in 40 µl TLE. We then performed a final purification via gel extraction. Libraries were quantified with Qubit high sensitivity assays and sequenced using MiSeq 2×150 runs. Sequence reads were then genotyped using GTscore v1.3 (McKinney et al. 2020).

Genotypes were filtered to remove SNPs with >10% missing data and individuals with >50% missing data. We used two walleye datasets to make comparisons to the sauger data; each genotyped according to Bootsma et al. (2020). First, we calculated locus-specific observed and expected heterozygosity and minor allele frequency using data from 254 walleye from a single population in Fox Lake, Wisconsin. Second, we used a random subsample of 351 walleye (i.e., the same number of sauger analyzed) drawn from a larger dataset of 45 walleye populations across Minnesota and Wisconsin to demonstrate differences in allele frequencies between the two species using a principal component analysis (PCA). Using multiple walleye populations allowed inter-specific variation to be assessed relative to intra-specific variation. Additionally, we used the hybridize function of the Adegenet (Jombart 2008) R package to simulate sauger x walleye genotypes to evaluate the panel's capacity to detect saugeye. PCA was performed on species-specific allele frequency data using the dudi.pca function of the R package ade4 (Dray and Dufour 2007; Thioulouse et al. 2018). Individuals with >5% missing data were removed from the PCA to limit bias caused by the necessary substitution of missing data with the average values of observed data.

Seventy-two primer pairs amplified 118 SNPs that were shared among sauger and walleye (1–7 SNPs per amplicon; Table 1). Two overamplifying loci (83,046 and 85,954) were

identified, which could be removed from the genotyping panel to improve evenness of sequencing depth across loci (Table 1). Locus-specific measures of genetic diversity often differed substantially between the species (Table 1). Inter-specific allele frequency differences resulted in adequate power to distinguish the species and their hybrid along the first principal component axis (Fig. 1), with additional axes summarizing intraspecific variation (maximum 2.2% variation explained). These 118 SNPs may help inform future conservation genetic analyses of sauger, with the added benefit of enabling direct comparison to walleye.

**Table 1** Locus IDs, SNP IDs, alleles, and primer sequences for 118 sauger (SAU; *Sander canadensis*) and walleye (WAE; *Sander vitreus*) primer pairs, along with proportion of reads attributable to each proper pair (Prop. reads), measures of genetic diversity, deviation from Hardy-Weinberg proportions for each SNP amplified by the listed primers

| Locus  | Pos | Forward primer          | Reverse primer            | T <sub>M</sub> For |      | T <sub>M</sub> Rev | Prop. | H <sub>obs</sub> | H <sub>exp</sub> |      | MAF   | HW p-value |      |      |

Pos: position within locus; T<sub>M</sub>For: forward primer melting temperature; T<sub>M</sub>Rev: reverse primer melting temperature; H<sub>obs</sub>: observed heterozygosity; H<sub>exp</sub>: expected heterozygosity; MAF: Minor allele frequency; HW p-value: exact test for Hardy-Weinberg proportion deviation p-value

**Fig. 1** Density plot of principal component analysis (PCA) axis 1 indicating divergence in allele frequencies between sauger (*Sander canadensis*), walleye (*Sander vitreus*), and simulated sauger×walleye at 118 SNP loci

**Acknowledgements** We thank the members of the Wisconsin Department of Natural Resources and Walleyes for Tomorrow for collecting samples used in this research. Any use of trade, firm, or product names is for descriptive purposes only and does not imply endorsement by the U.S. Government.

**Author contributions** All authors contributed to the study conception and design. Data collection was performed by Paul Albosta. Analyses were performed by Jared J. Homola. The first draft of the manuscript was written by Jared J. Homola and all authors commented on subsequent versions of the manuscript. All authors read and approved the final manuscript.

**Funding** This work was supported by funding from the Wisconsin Department of Natural Resources.

**Data Availability** Coauthor and data author, Paul Albosta, has made the GTscore primer-probe file and genotypes for walleye, sauger, and simulated saugeye available in an archived GitHub repository

at [https://github.com/palbosta/Winnebago\\_sauger\\_parentage](https://github.com/palbosta/Winnebago_sauger_parentage) (DOI <https://doi.org/10.5281/zenodo.7683147>). Questions about the data can be directed to the data author, Paul Albosta at [palbosta@uwsp.edu](mailto:palbosta@uwsp.edu).

## Declarations

**Competing interests** The authors have no relevant financial or non-financial interests to disclose.
