24 **Abstract**

25 The crustacean hyperglycemic hormone (CHH) neuropeptide family has multiple
26 functions in the regulation of hemolymph glucose levels, molting, ion, and water balance and
27 reproduction. In crab species, three neuroendocrine tissues: the eyestalk ganglia (medulla
28 terminalis X-organ and -sinus gland= ES), the pericardial organ (PO), and guts synthesize a
29 tissue-specific isoforms of CHH neuropeptides. Recently the presence of the mandibular organ-
30 inhibiting hormone (MOIH) was reported in the stomatogastric nervous system (STNS) that
31 regulates the rhythmic muscle movements in esophagus, cardiac sac, gastric and pyloric ports
32 of the foregut. In this study, we aimed to determine the presence of a tissue-specific CHH
33 isoform in the Jonah crab, *Cancer borealis* using PCR with degenerate primers and 5', 3' rapid
34 amplification of cDNA ends (RACE) in the ES, PO, and STNS. The analysis of CHH sequences
35 shows that *C. borealis* has one type of CHH isoform, unlike other crab species. We also isolated
36 the cDNA sequence of molt-inhibiting hormone (MIH) in the ES and MOIH in the ES and STNS.
37 The presence of CHH, MOIH and MIH in the sinus gland of adult females and males is
38 confirmed by using a dot-blot assay with the putative peaks collected from RP-HPLC and anti-
39 *Cancer* sera for CHH, MIH, and MOIH. The present of crustacean female sex hormone (CFSH)
40 in the sinus gland of adult females was examined with a dot-blot assay with anti-*Callinectes*
41 CFSH serum. Levels of CHH, MOIH, and MIH in the sinus gland and their expressions in the
42 eyestalk ganglia are estimated in the adult males, where CHH is the predominant form among
43 these neuropeptides.

50

51 **1. Introduction**

52 Crustacean hyperglycemic hormone (CHH) is commonly found in all the crustaceans,
53 since its first structural isolation from the sinus gland of the European green crab, *Carcinus*
54 *maenas* [23]. CHH neuropeptides form the CHH neuropeptides family together with molt-
55 inhibiting hormone (MIH), and mandibular organ-inhibiting hormone (MOIH), and vitellogenesis
56 or gonad-inhibiting hormone (V/GIH) [2, 5]. CHH family neuropeptides possess similar primary
57 structures, and their number of amino acid residues range from 71 to 78 amino acids, containing
58 three intradisulphide bridges. Based on the putative amino acid sequence of an open reading
59 frame (ORF) of cDNA either with or without CHH-precursor related peptide (CPRP), the CHH
60 family is further divided into two subgroups: the first subgroup with CHH neuropeptides with
61 CPRP and the other with MIHs and MOIHs without CPRP. Moreover, depending on a species, it
62 appears that the CHHs are subject to post-translational modification processes including
63 cyclization at N-terminus, isomerization of F₃ from L to D amino acid and amidation at C-
64 terminus [9, 13, 23, 31], resulting in multiple isoforms of CHH neuropeptides in the sinus gland.

65

66 The structural isoforms of CHH neuropeptides are found in eyestalk (ES) and pericardial
67 organs (PO) of several crab species while they are also present in fore- and hindguts in crab
68 species which are possibly derived from alternative splicing of CHH gene(s) [3, 8, 17, 18]. The
69 two isoforms of CHH neuropeptides (1 and 2) present in the sinus gland or the PO are derived
70 from the post-translational modification, cyclization at N-terminus from Q to <Q, respectively [9,
71 18]. The levels of conversion from Q to <Q of N terminus of CHH is not complete to be a 100 %;
72 hence, there are always two forms of CHH1 and CHH2 present in the sinus gland and the PO.
73 In any case, both CHH1 and CHH2 are present in the hemolymph [9], while CHH2 being the
74 primary form having 4 -5 times more than CHH1 [15] is referred to as the ES-CHH.

75

76 The function of a hormone is intimately associated with its presence in hemolymph,
77 while the levels of expression are indicative of the amounts of a protein. The expression of ES-
78 and PO-CHH is molt-stage independent [10, 14], whereas the gut-CHH is exclusively present
79 during premolt stage [8]. The full-length cDNA of CHH is encoded in four exons, the first two of
80 which are common in the CHHs of three tissues, while the third is alternatively spliced in a
81 tissue-specific manner [17].

82

83 The eyestalk that shows exhibiting the presence of these hormones first in the
84 embryonic stages [11, 32], is considered as the primary tissue source for CHH neuropeptides
85 family. CHHs and MIHs are also found in ventral nerve cord of *Metapenaeus ensis* [20]. The ES
86 also serves for the source of MOIH as the primary structural isolation of MOIH is first reported in
87 the sinus gland of *C. pagurus* [39]. The intense immunostaining with anti-MOIH serum in the
88 stomatogastric nervous system (SNTS) of *C. productus* [21] suggests that STNS may be an
89 additional site of these CHH neuropeptides.

90

91 Most hormones transduce their signals at the optimal concentration throughout the life
92 cycle, as seen in the case of molting hormone ecdysteroid levels in the hemolymph of three
93 different sized juvenile and adult females of *C. sapidus* [6]. Despite the size variation, the
94 ecdysteroid levels are kept at the tight range of 230-330 ng/ml. Hence, it is plausible to infer that
95 the larger size of *C. borealis* may produce more neuropeptides or hormone to achieve the
96 optimal concentration as they grow. The information regarding how the hormone levels vary
97 during the life cycle of a species, especially, by size is still missing in general. The levels of CHH
98 neuropeptide expression in the eyestalk ganglia and of the corresponding proteins in the sinus
99 gland may differ by size.

100

101 In the present study, we aimed to isolate the cDNA sequences of CHH family members
102 including CHH, MIH and MOIH from ES, CHH and MOIH from STNS, and CHH from PO of
103 intermolt stage adult male *C. borealis*. To this end, PCR with degenerate primers and 5', 3' rapid
104 amplification of cDNA ends (RACE) were employed. The presence of the neuropeptides in the
105 sinus gland was examined using an RP-HPLC combined with dot-blot assays. We then
106 measured the expression levels of these neuropeptides in the ES of adult males using qPCR
107 assays and the corresponding neuropeptide contents in the sinus gland of the same animals
108 using a reversed phase-high performance liquid chromatography (RP-HPLC). For the first time
109 in decapod crustaceans, we have isolated a CHH isoform from the STNS. Interestingly *C.*
110 *borealis* may have only one type of CHH in the tissues examined, unlike other portunid crab
111 species.

112

113 **2. Methods and Materials**

114 *2.1 Dissection and cDNA synthesis*

115 Adult male *C. borealis* were purchased from a local crabber (Maine) and kept in a flow-
116 through natural seawater system at 10°C and fed mussels (5% of body weight) twice a week.
117 Tissues (eyestalk ganglia, STNS and PO) were dissected from the ice-chilled animals for total
118 RNA extraction using a stereo dissection microscope. Tissues: ES, PO, and STNS were
119 dissected from the ice-chilled *C. borealis* and immediately processed for total RNA or mRNA
120 extraction using total RNA extraction kit or Oligotex mRNA mini kit, respectively (Promega). The
121 quantity of RNAs was estimated using a NanoDrop spectrometer (Fishersci).

122

123 *2.2 Profiles of CHH neuropeptides in the sinus gland of different sized adult males*

124 The extract of sinus glands that were dissected from individual adult males with $111.9 \pm$
125 3.0 mm CW (n=9) was separated on a Jupiter C18 column (4.6 x 150 mm, 5 μ m, Phenomenex),
126 connected to a RP-HPLC (HP1100) using a gradient 30-70% B over 60 min (A= 0.1% in 100%

127 water and B= 0.11% TFA in 60% acetonitrile and 40% water). The flow rate was 0.6 ml/min. The
128 absorption was monitored using a photodiode array detector and the chromatogram was
129 extracted at 210 nm and presented. The peaks were manually collected for dot-blot assay. The
130 peak area (milli-Absorption Units*sec =mAU*s) was used for comparing the relative amount of
131 each neuropeptide/sinus gland after normalizing the initial peak area of the all the
132 neuropeptides to the size of CHH.

133

134 *2.3 Dot blot analysis of neuropeptides*

135 As alluded to earlier, the peaks that were manually collected and dried in a SpeedVac
136 were re-dissolved in 100 µl of 2 M acetic acid. One microliter of each peak was spotted on a
137 nitrocellulose membrane and air-dried. Then, the membranes were incubated with the following
138 antisera at a final dilution of 2,000 in 5% NFM in PBST for overnight at 4°C: rabbit anti-*Cancer*
139 CHH, MOIH, and MIH sera [21] and anti-*Callinectes* CFSH [44]. After washing the membranes
140 with 5% non-fat milk in the PBS containing 0.5% Tween 20 (PBST) three times for 5 min each,
141 the membranes were incubated with an horseradish peroxidase (HRP)-conjugated anti-rabbit
142 IgG at the final dilution of 2000 in 5% NFM in PBST for an hour at room temperature. Stable
143 3,3'-Diaminobenzidine (DAB) was used to develop the membranes after repeating the washing
144 step as above.

145

146 *2.4 PCR cloning with degenerate primers and 5', 3' rapid amplification of cDNA ends (RACE)*

147 The degenerate primers were generated based on the conserved regions of CHH, MIH,
148 and MOIH sequences that were identified using Clustal W (www.genome.ad.jp). 5' and 3' RACE
149 cDNAs were synthesized using SMART cDNA synthesis kit (BD Biosciences) by following the
150 manufacturer's instructions.

151 The first touchdown (TD) PCR was carried out with Advantage Taq (BD Bioscience) and
152 a combination of CHHdF1 (5'TGYAARGGNGTNTAYGA3'), MIHdF1 (5'

153 GNGTNATHAAYGAYGA3') or MOIHdF1 (5' TGYCARAAYTTYATHGGNAA 3') and Universal
154 Primer (UMP, BD Biosciences). The TD-PCR product once 20-fold diluted in water was served
155 for the nested PCR with the dF2 and dR1 primers of CHH, MIH, and MOIH (listed in Table 1).
156 The nested PCR products were run on a 1.5% agarose gel and the band located approximately
157 ~140 bp was excised for DNA extraction using the Qiagen gel extraction kit (Qiagen). The
158 purified DNA was then inserted into a TOPO-TA vector for cloning and sequencing analysis.
159 Based on the initial sequence of CHH, MIH, and MOIH, gene-specific primers (listed in Table 1)
160 were generated for 5', 3' RACE. Two-step PCRs were first employed using a procedure similar
161 to that previously described [7]. *C. borealis* gene-specific primers listed in Table 1 as stated
162 above. The sequencing results were compared to the Non-redundant protein sequences (nr)
163 database using blastx (<http://blast.ncbi.nlm.nih.gov/Blast.cgi>) and the encoded protein
164 sequences were aligned by ClustalW (www.genome.ad.jp) employing the default parameters.
165 The ORF sequence of CHH, MIH, and MOIH was verified by cloning of the PCR product that
166 was amplified with the start and end primer. The accession number of the sequences are as
167 follows: MN382372 ES-crustacean hyperglycemic hormone (CHH); MN382373 ES-Molt-
168 inhibiting hormone (MIH); MN382374 ES-Mandibular organ-inhibiting hormone (MOIH);
169 MN382375 PO-crustacean hyperglycemic hormone (CHH); MN382376 STNS-crustacean
170 hyperglycemic hormone (CHH)-ES type mRNA;
171 MN382377 STNS-crustacean hyperglycemic hormone (CHH)-PO type mRNA; and MN382378
172 STNS-Mandibular organ-inhibiting hormone (MOIH) mRNA.

173

174 *2.5 Sequence analysis*

175 The ORF was found using ORF finder (www.ncbi.nlm.nih.gov/orffinder/). The putative signal
176 peptide of CHH, MIH, and MOIH was examined using Signal P 5.0
177 (<http://www.cbs.dtu.dk/services/SignalP/>).

178

179 *2.6 Expression analysis*

180 The cDNA samples of eyestalk ganglia obtained from adult males sized with 111.9 ± 3.0
181 mm carapace width (CW, n=9) assayed were assayed for CHH, MOIH, and MIH expression.
182 These animals at the intermolt stage and sexually matured (i.e., presence of spermatophores in
183 the testis and vas deferens) that were obtained from a commercial crabber were caught off the
184 Rhode Island area (US) in April 2019. The animals were shipped overnight to the Institute of
185 Marine and Environmental Technology (IMET, Baltimore, MD) and acclimated in 30 ppt artificial
186 seawater for two weeks at 10°C. The animals were fed as described above. The samples were
187 assayed in duplicate with each gene standard ranging 2E6 to 2E2 copies. The data were
188 presented as mean \pm 1 SE (n) copies/ μ g eyestalk total RNA.

189

190 *2.7 Statistical analysis*

191 Statistical analyses were carried out with SPSS 17.0 software. Data were tested for
192 normality (Kolmogorov-Smirnov test) and homogeneity of variances using the Levene's test.
193 Non-parametric one-way analysis of variance (ANOVA, Kruskal-Wallis test) was used to
194 determine the statistical significance. Statistical differences at $P < 0.05$ were indicated with
195 letters.

196

197 **3. Results**

198 *3.1 Neuropeptide profiles of a single sinus of adult males and females by RP-HPLC*

199 The chromatograms were obtained from the separation of neuropeptides present in
200 single sinus gland of adult males and females (Figs. 1A and B). Dot blot analysis using
201 corresponding *C. pagurus* anti-MOIH, CHH, and MIH sera showed that four peaks collected
202 from male and female SG and noted to 1 to 4 were identified as MOIH, CHH1, CHH2, and MIH.

203 In adult female SG, the presence of crustacean female sex hormone (CFSH) that was noted “**”
204 in Fig. 1B was confirmed using *C. sapidus* anti-CFSH serum.

205

206 3.2 CHH sequences from eyestalk ganglia (ES), pericardial organs (PO), and stomatogastric 207 nervous system (STNS)

208 The sequences of CHH obtained from ES, PO and STNS are shown in Fig. 2A. ES and
209 PO had the same CHH ORF sequences. The ORF of ES and PO cDNAs (140 amino acids)
210 consists of the signal peptide, CPRP, a dibasic cleavage site and CHH at C terminus with
211 amidation site and tribasic cleavage site in this order. The first 24 putative amino acid sequence
212 (MLTTRTLLLGVMCVYLSTLPYVHA, boxed in solid black line) was identified as the signal
213 peptide using Signal P 5.0 ($P= 0.947$). The dibasic cleavage site (KR) was flanked between 38
214 amino acid of CPRP and 72 amino acid of CHH which started with Q and ended with amidation
215 site, G₁₃₇ and triple cleave site, KKK₁₃₈₋₁₄₀ (squared in red in Fig. 2A).

216 The signal peptide of STNS-CHH cDNAs was not predicted ($P= 0.0071$, Signal P 5.0),
217 while the rest of sequence of ORF sequence showed the presence of the same CPRP, dibasic
218 cleavage site and CHH sequence with the amidation site G₁₃₇ but dibasic cleave site, KK₁₃₈₋₁₃₉.

219 The cDNA sequences of *C. borealis* CHH were aligned with those isolated from *C.*
220 *productus* (Fig. 2B). The Cab-ES- and PO- CHH signal peptides were three amino acid
221 residues shorter than Cap-CHHs. Interestingly, the sequences of CPRP and CHH vary greatly
222 in their C-terminal regions, compared to N-terminal regions.

223

224 3.2 MIH and MOIH sequences from ES

225 MIH cDNA was found only in the ES. The ORF of MIH cDNA sequence was aligned with
226 *C. pagurus* MIH sequence (Fig. 3A) and consisted of 113 amino acids starting with 35 amino
227 acids comprising the signal peptide ($P= 0.9827$, Signal P 5.0) and 78 amino acids of MIH
228 starting with R₁ and ending with K₇₈.

229 Two MOIH cDNAs were isolated from the ES and STNS. Both sequences were identical
230 and shared the same ORF sequences shown as Fig. 3B. The ORF sequence consisted of a 34-
231 amino acid signal peptide (P= 0.784) and 78 amino acid MOIH.

232

233 *3.3 Neuropeptide levels in the sinus gland and their expression in the eyestalk ganglia of adult*
234 *males*

235 Fig. 4A shows the relative peak area of the following neuropeptide present in the sinus
236 gland of the adult males: CPRP, MOIH, CHH1, CHH2 and MIH in the order of RP-HPLC elution.
237 CPRP and CHH2 are predominant, followed by CHH1, MIH and MOIH. The ratio CHH1: CHH2
238 was 0.275 ± 0.019 (n=9).

239 The expression levels of these neuropeptides in the eyestalk ganglia (Fig. 4B) were
240 similar to neuropeptides (Fig. 4A). CHH expression was the greatest with $2.6 \pm 0.4E8$ copies/ μ g
241 total RNA (n=9), followed by MIH with $7.5 \pm 1.0 E7$ copies/ μ g total RNA (n=9) and MOIH with
242 $5.3 \pm 0.75 E7$ copies/ μ g total RNA (n=9).

243

244 **4. Discussion**

245 The present study describes the isolation of cDNA sequences of neuropeptides: CHH,
246 MIH and MOIH in the eyestalk ganglia, CHH from the PO, and STNS and MOIH from STNS of
247 the Jonah crab, *C. borealis*, together with the presence of the sinus gland neuropeptides: CHH,
248 MIH, and MOIH. The expression levels of CHH, MOIH, and MIH are in agreement with the
249 neuropeptide levels in the sinus gland.

250

251 We employed PCR with degenerate primers and 5', 3' RACE cloning to isolate CHH
252 cDNAs from ES, PO, and STNS of the Jonah crab, *C. borealis*. A notable finding was the
253 presence of CHH in the STNS, in addition to the previous report stating STNS exhibited MOIH-
254 like substance using immunohistochemistry [21]. The sequence identity between the CHHs of

255 ES, PO, and STNS is unexpected, particularly the amino acid position 41- to the end, which
256 contrasts to the previous reports of the crustacean hyperglycemic hormone in other crab
257 species [14, 18]. Overall, as expected, *C. borealis* CHHs show the highest identity (>90%) with
258 ES-CHH of *C. pagurus* and *C. productus* [13, 22].

259

260 In the sinus gland of adult *C. borealis*, four peaks are common in both genders. Females
261 show another peak, identified as CFSH using *Callinectes* CFSH antiserum [44], suggesting that
262 the CFSH presence in females of crab species may be a common feature [25]. Two structural
263 isoforms of CHH are present as two peaks that are cross-reacted to *Cancer* CHH antiserum.
264 This suggests that CHH2, the largest peak is derived from post translational modification at the
265 N-terminus same as in the other crab species [7, 9, 13, 14, 38, 41]. *C. borealis* has one MOIH
266 form which differs from *C. pagurus* with two structural isoforms: CapMOIH 1 and CapMOIH 2:
267 K₃₂ to Q₃₂ [39].

268

269 Two brachyuran species show the tissue specific isoforms of CHH in ES and PO the
270 sequences of which only share ~ 60-70% identity [14, 18, 23]. This major difference is located in
271 the last ~ 30 residues of amino acids that are encoded in the third exon. To our surprise, the
272 CHH sequences obtained from the different tissues of *C. borealis* exhibits 100% sequence
273 identity, contrasting to the finding of *C. productus* where CHH polymorphism is observed at
274 individual levels [22]. Our finding of one CPRP form (type II based on the sequence reported
275 [19] contrasts to the earlier report of the presence of four CPRP sequences in the pooled sinus
276 gland extracts (n=30) of *C. borealis* using nanoscale liquid chromatography tandem mass
277 spectrometry [19]. However, we observed one CPRP peak from the sinus gland of an individual
278 animal.

279

280 Both the MIH and MOIH of all three *Cancer* species exhibit higher sequence identity
281 than CHHs. The putative MIH sequences of three *Cancer* species including *C. borealis* show
282 the highest identity as only four aa of 113 aa encompassing the entire ORF differ in the main
283 MIH neuropeptide [28, 37]. The MOIH sequences of these animals also differ by four aa of 112
284 aa of the entire ORF region (two aa in the signal peptide and the other two in MOIH
285 neuropeptide region).

286

287 MOIH is found only in the crabs belonging to the genus *Cancer* and *Metacarcinus* [21,
288 39]. It is unknown why the brachyuran crabs belonging to the family Cancridae including genus
289 *Cancer* and *Metacarcinus* possess the MOIH. Since MIH is found in all crab species, MOIH
290 could be a product of gene duplication of MIH. In the family Cancridae, MOIH has acquired a
291 separate function for the inhibition of mandibular-organ activity i.e., suppressing the synthesis of
292 methyl farnesoate [39] that stimulates vitellogenesis [33, 34]. Hence, MOIH acts as a VIH in
293 this animal group. The other crab species do not have a separate neuropeptide form of the
294 MOIH; for example, in the spider crab *Labinia emarginata*, CHH with hyperglycemic action
295 exhibits MOIH action [26, 27].

296

297 Eyestalk ganglia developing in early embryonic stages of decapod crustaceans are the
298 hub of the most important endocrine tissues. Lobster, crayfish, and shrimp have multiple
299 isoforms of CHH peaks, while crab species exhibits two types of CHH neuropeptides: CHH type
300 with CPRP and the other MIH and MOIH without CPRP. It is noted that the sinus gland of all
301 crab species contains fewer neuropeptide peaks than those of shrimp and lobster species,
302 where each of these peaks are assigned to a specific type of a neuropeptide with a respective
303 function. Two peaks are two isoforms of CHH together with one or multiple forms of CPRP and
304 MIH while *Cancer* species display additional one or two forms of MOIH [7, 9, 13, 40]. In the tiger
305 prawn, *Metapenaeus japonicus* and the whiteleg shrimp, *Litopenaeus vannamei*, the sinus

306 gland reveals the presence of 6-7 neuropeptides that are all related to the CHH type, with each
307 showing the activity of hyperglycemic, molt-inhibiting, or vitellogenin-inhibiting hormone
308 functions [35, 36, 43] . For example, the sinus gland of the American lobster, *Homarus*
309 *americanus*, contains at least three CHH neuropeptide types with each showing two isoforms [4,
310 31]: a predominant peak with hyperglycemic activity; the other two with MIH activity and
311 VIH/GIH activity. On the other hand, shrimp and lobsters contain VIHs that structurally differ
312 from CHHs [16, 36].

313

314 Though little is known about the CHH gene arrangement, relatively high sequence
315 homology among CHH neuropeptides suggests that CHH gene is well-conserved among the
316 arthropods. *C. borealis* has most extensively used for studying decapod neuromodulation [1, 24,
317 29, 30]. It will be interesting to examine if the STNS of other decapod crustaceans may produce
318 a tissue-specific isoform of CHH. The STNS-CHH sequence does not contain a signal peptide,
319 indicating presumably it is not released. The functional significance of CHH present in the STNS
320 needs to be studied in terms of the role of STNS in two central pattern-generating networks
321 controlling feeding behaviors in crustaceans.

322

323 The distribution and isoform of CHH neuropeptides vary by species. Whilst MIH is
324 predominantly present in the eyestalk ganglia of crab species, MOIH is also found in eyestalk
325 ganglia and STNS [21]. A tissue-specific isoform of CHH is found in ES, PO, and fore- and
326 hindgut of *C. maneus* [8, 9, 18]. Interestingly, this is the first time we report that in *C. borealis*,
327 the same form of CHH is found in multiple tissues including ES, PO, and STNS.

328

329 The sinus gland functions as the storage and release site of neuropeptides (CHH, CPRP,
330 and MIH) produced by neurosecretory cells of eyestalk ganglia of decapod crustaceans. The
331 translation of CHH mRNA encoding one CPRP and CHH yields the equal amount of these

332 neuropeptides. The post-translational modification is incomplete; the sinus gland always
333 contains two CHHs: 1 and 2 with CHH2 as the major form [7, 13, 14]. The ratio of CHH1: CHH2
334 (~0.27) could reflect the efficiency of Q_1 to $<Q_1$ at the N-terminus and translation rate.

335

336 The presence of CPRP in the hemolymph predisposes its release from the sinus gland
337 [42]. Notably, a 1:1 stoichiometric ratio of CHH and CPRP release is noted in *C. pagurus* [42].
338 Thus, it is plausible to suggest that the sinus gland should have contained the same amount of
339 these two neuropeptides. In *C. borealis*, the ratio of CPRP and CHH1 and CHH2 present in the
340 sinus gland is skewed at 1.0: 1.6, suggesting that these peptides may have been differentially
341 released. The function of CPRP remains to be defined. However, the sinus gland with the
342 amounts of CPRP less than those of CHH suggesting the higher amounts of CPRP secretion,
343 together with the longer half-life of CPRP ($t_{1/2} = \sim 60$ min) in hemolymph than CHH ($t_{1/2} = \sim 5-10$
344 min) [12, 42] indicates the presence of a high concentration of this peptide in hemolymph,
345 which points out the importance of an additional study.

346

347 Overall, the expression of each of these CHH neuropeptides reflects the neuropeptide
348 levels in the sinus gland: highest expression of CHH, supporting the predominant CHH, and
349 CPRP levels in the sinus gland. The adult animals > 110 mm CW are used for this study. We
350 are currently investigating to examine if there is a relationship between the size and
351 neuropeptide levels in ES (both transcripts and protein).

505 **Figure legends**

506
507

508 Figure 1. The neuropeptide profiles of sinus gland obtained from adult female (A) and male (B)
509 by RP-HPLC analysis. Two sinus gland extract was separated on a Gemini column (4.6
510 x 250 mm, 5 µm particle size with 100 Å) using a gradient: 30-70% B over 60 min at the
511 flow rate of 0.6 ml/min. The chromatogram is shown with the absorption at 210 nm. 1:
512 MOIH; 2: CHH1; 3: CHH2; 4: MIH. * = CFSH. Peaks identified using dot blot assays with
513 specific antisera are noted with 'black dot'.
514

515 Figure 2. Clustal W alignment of the putative amino acid sequence of CHHs deduced from the
516 ES, PO, and STNS cDNA sequences of *C. borealis*, together with Cap ES-CHH.
517 Consensus amino acids are shown with '*'. Signal peptides of ES- and PO-CHH are
518 boxed. Dibasic cleavage site, KR, precedes CHH sequences. Putative amidation site (G)
519 and tribasic cleavage site (KKK) are boxed in red, respectively.
520

521 Figure 3. Clustal W alignment of putative amino acid sequence deduced from ES-MIH (A) and
522 ES- and STNS-MOIH (B) cDNA sequences, together with Cap-ES-MOIH 1 and 2.
523 Consensus amino acids are shown with '*'. Signal peptide is boxed.
524

525 Figure 4. Relative quantification of neuropeptide levels in the sinus gland of the adult males (A).
526 Single or two sinus glands were separated on a C18 column with a gradient condition of
527 30-70% B (0.1% TFA in 60% acetonitrile + 40% water) over 60 min at 0.6 ml/min flow
528 rate. The detection was at 210 nm wavelength that monitors peptide bonds. To compare
529 the amount of each neuropeptide, the relative peak areas shown in Fig. 4A were derived
530 by normalizing the initial values to the size of CHH1 and CHH2 (72 aa). (B) Expression
531 levels of CHH and MIH in eyestalk ganglia of adult males. The data were presented as
532 mean ± 1 SE copies/µg eyestalk total RNA. Each cDNA sample was assayed in triplicate.
533 The data are presented as mean ± 1SE (n). Non-parametric one-way analysis of
534 variance (ANOVA) (Kruskal-Wallis test) was used to determine the statistical
535 significance. Statistical differences at $P < 0.05$ were indicated with letters.
