ABSTRACT

The Alaska Fisheries Science Center (AFSC) of the United States and the Pacific Research Institute of Fisheries and. Oceanography (TINRO) of the Union of Soviet Socialist Republics (U.S.S.R.) conducted a cooperative bottom trawl survey of the Bering Sea aboard the Russian research vessel Novokotovsk during May-July 1990. The primary purpose of this survey was to assess the distribution, abundance, and biological condition of groundfish resources, in both the eastern and western Bering Sea continental shelf. A separate and completely {independent trawl survey of the central and southeastern Bering Sea continental shelf was also conducted. by the AFSC during this period aboard, two U.S. research vessels.

Results summarizing geographic distribution, abundance estimates, and size composition are, presented for the principal species of fish encountered. The distribution and relative abundance of the commercially important crab species-are also shown. Results of the cooperative survey are compared to the results of the separate 1990 U.S. survey from the areas commonly fished in the eastern Bering Sea. The appendices include station and catch information, detailed abundance, size, and age data.

CONTENTS

INTRODUCTION

The Resource Assessment. and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC) and the Pacific Research Institute of Fisheries, and Oceanography (TINRO) of the Union of Soviet Socialist Republics (U.S.S.R.) conducted a cooperative bottom trawl survey of the Bering Sea during May-July' 1990 . In addition to this cooperative survey, which was conducted aboard a Russian research vessel. an independent U.S. bottom trawl survey was conducted aboard two U.S. chartered fishing vessels from June through August. The U.S. vessels sampled the central and southeastern Bering Sea continental shelf waters, whereas the Russian vessel surveyed the northwestern portion of the shelf and northern Bering Sea in addition to the area sampled by the U.S. vessels. Seven U.S. scientists participated in survey operations conducted aboard the Russian. vessel.

Systematic bottom trawl surveys of crab and fish species in the eastern portion of the Bering Sea have been conducted by the United' States annually since the early 1970s. The primary purpose of these surveys has been to provide informationon the abundance and biological conditionof the crab and groundfish resources for management purposes and the fishing industry, as well as for scientific studies. Initial surveys were limited in area to Bristol Bay and the central portion of the eastern Bering Sea. However, during 1975 and 1979-92 the survey region was expanded to cover the major portion of the eastern. Bering Sea.

Two agencies of the Soviet Union (now a part of the Russian Federation), TINRO and the All-Union Scientific Research Institute of Marine Fisheries and Oceanography (VINRO), have conducted fisheries research in the, Bering Sea since 1958 under a program called the "Bering Sea Comprehensive Scientific-Commercial Expedition" (Moiseev 1963). These surveys usually have had multiple objectives including bottom trawl sampling for groundfish, hydroacoustic-midwater trawl surveys of spawning concentrations of walleye pollock (Theragra chalcogramma), and ichthyoplankton surveys for pollock and other groundfish species.

The AFSC has participated in 8 of the 16 Russian groundfish surveys conducted between 1980 and 1990 by placing fisheries scientists aboard the Russian research vessels or in some cases by coordinating the survey activities of Russian and U.S. research vessels.

Coordination between U.S. and Russian survey activities have beenlimited primarily because U.S. scientists and Russian scientists have used different methods for collecting station data and processing and biological sampling of the survey catches. Differences in sampling methods between nations (Hirschberger 1985) have resulted in data sets that are not completely compatible. In addition, navigational equipment available on the Russian vessels has not always provided precise position and station data which are essential for calculating fishing area and deriving abundance estimates from average catch rates using area swept methods. Comparisons of data between U.S.

and Russian surveys conducted in recent years have shown. significant differences, primarily in abundance estimates and size distribution of many fish species. The biomass estimates for many groundfish species derived from Russian survey data have been consistently lower in comparison to estimates from U.S. surveys.

The design and configuration of the Russian bottom sampling trawls used during these surveys have varied between survey years and there has been little information available to assess their fishing efficiency and bottom-tending characteristics. Side-by-side comparative fishing experiments between U.S. and Russian research vessels in l982, 1988, and 1989, however, indicate that the Russian trawls were less efficient than the U.S. sampling trawl for some groundfish species closely associated with the sea floor.

Even though there are differences in sampling methods and Russian survey trawls over the years, these cooperative efforts are beneficial in assessing the relative distribution. of some groundfish species at other seasons of the year and in the western portion of the Bering Sea. The cooperative surveys conducted aboard Russian vessels during September and November 1980 and from January to May 1984 have provided data to describe the distribution of groundfish through the fall and spring months when survey activity by the AFSC has been limited (Raymore 1988). In the summer of 1982 the Russian, bottom trawl survey expanded the sampling area westward of the eastern Bering Sea shelf across

the U.S.-U.S.S.R. Convention Line of 1867 to the Siberian coast. Information collected during that survey has been valuable in understanding the distribution of groundfish populations that inhabit both U.S. and Russian waters.

An attempt was made to standardize U.S. and Russian data sets during the 1990 cooperative U.S. -Russian bottom trawl survey of the Bering Sea shelf. Prior to the beginning of the survey, the AFSC installed a Loran-C navigation system aboard the Russian vessel in an effort to standardize the collection of accurate position and distance-fished data. Net mensuration equipment was also provided to evaluate the configuration and fishing characteristics of the Russian trawl. Standard sampling methods used to collect station and catch data were consistent with those used aboard the U.S. vessels.

This report describes the survey and analytical methodology used and summarizes the results of the U.S.-Russian cooperative survey conducted during the summer of 1990. Complete results of the 1990 U.S. survey of the eastern Bering Sea are presented in Armistead and Nichol (1992).

The specific objectives of this report are to

1. Describe the geographical distribution of important living demersal resources in the eastern and western Bering Sea during the survey period;
2. Describe biological characteristics and relative abundance of commercially or ecologically important. species and;
3. Compare the results and findings of the cooperative survey with the results of the U.S. survey from the areas commonly sampled in the eastern Bering Sea.

SURVEY METHODS

Survey Area and Sampling Design

The survey area sampled by the Russian research vessel is shown in Figure l. This area was subdivided into three major regions for analytical, comparative, and reporting purposes. These included: the standard U.S. shelf which encompassed the combined areas of the central and southeastern Bering Sea continental shelf; the northern shelf; and the western shelf. The standard U.S. shelf, also sampled several weeks later by the two U.S. vessels, included eastern Bering Sea shelf waters from Bristol Bay west to the 200 m isobath and north to approximately St. Matthew Island. The north continental shelf area encompassed the waters between St. Matthew Island to St. Lawrence Island and from the Alaska mainland to the U.S.-U.S.S.R. Convention Line of 1867. The study region also extended into the western Bering Sea which included the shelf area from the Gulf of Anadyr west to Cape Olyutorski. These three regions were further divided into geographical subareas (Fig. 2) delineated by the 50 m, 100 m, and 200 m isobaths. These subareas define general oceanographic domains and characterize distributionpatterns of many bottom dwelling species. These subareas for the three main regions are numbered as follows: standard U.S. shelf (subareas l-6), northern shelf (subareas 7-9), and western shelf (subareas 14-16). Detailed bathymetric information was unavailable to accurately determine depth zones in the westernsubareas 14 and 16 (Gulf of Anadyr and Cape Navarin to Cape Olyutorski). Subsequently the

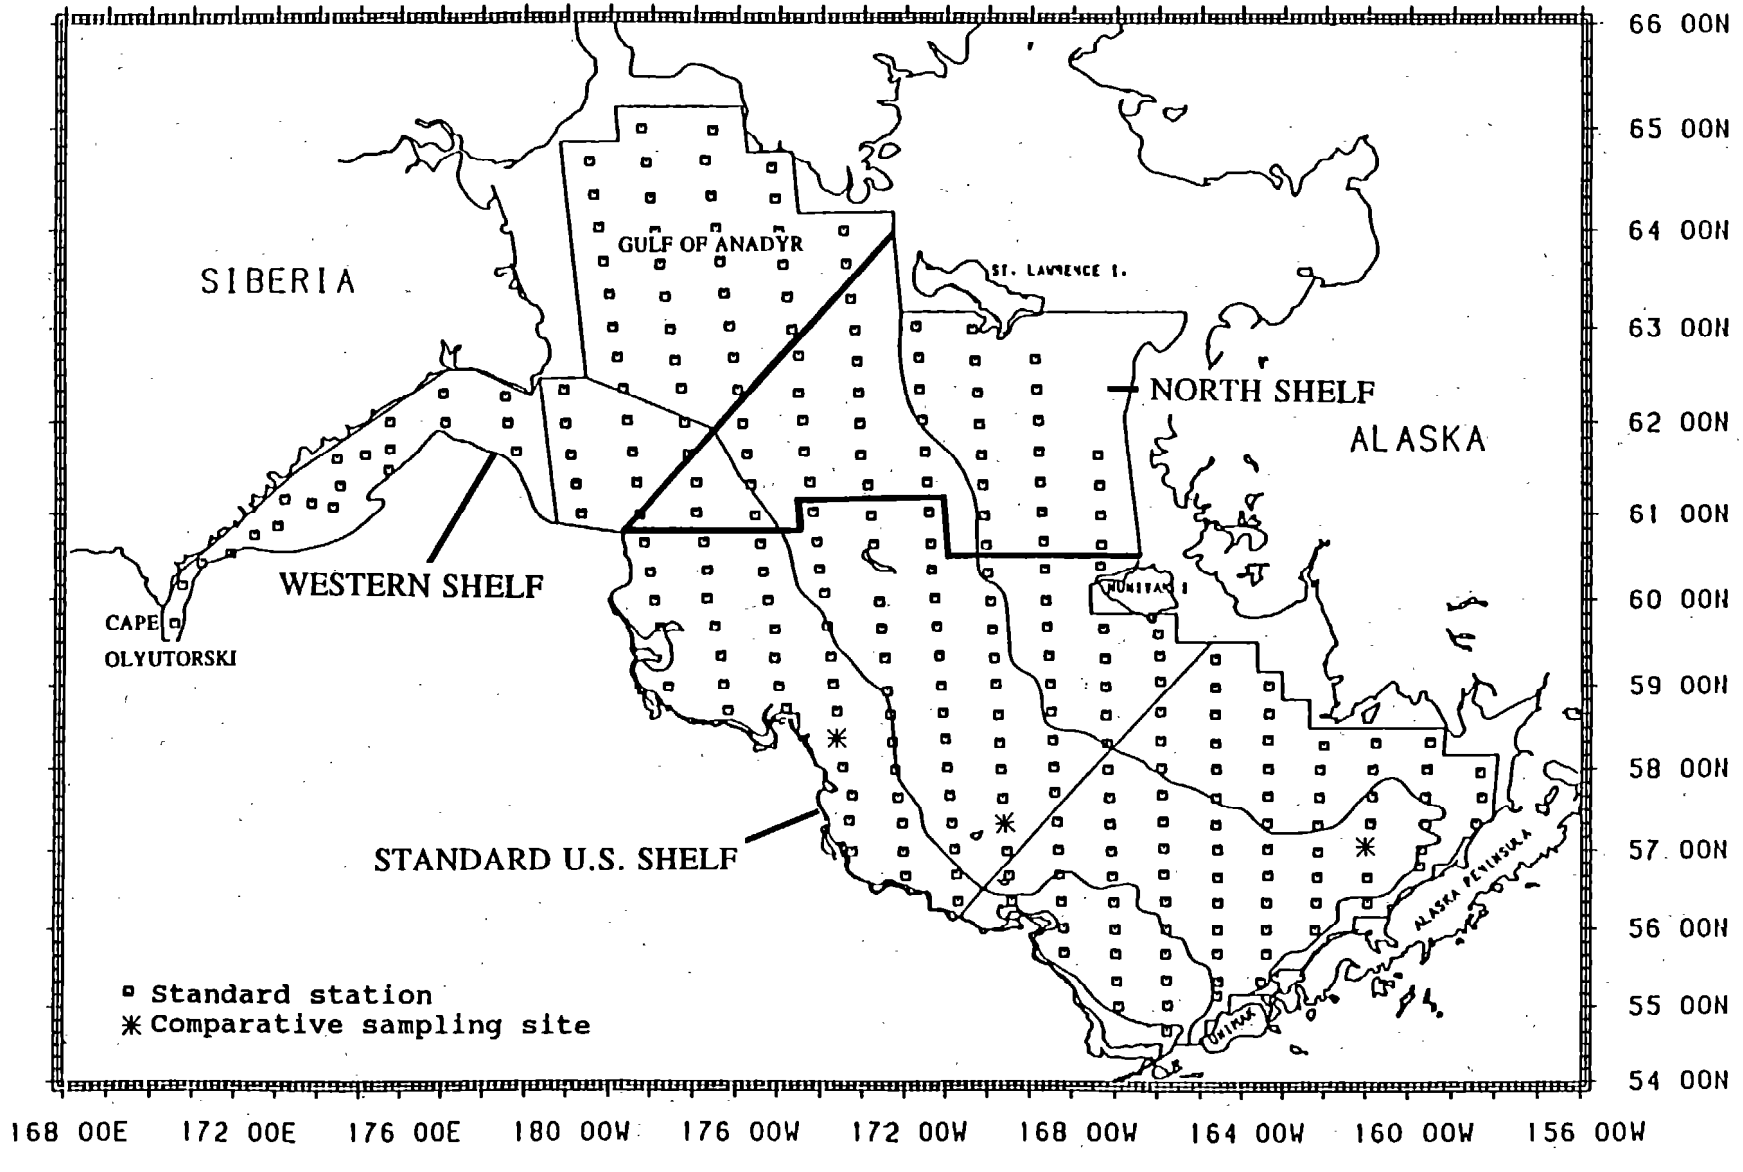

Figure 1. --Station locations sampled by the Novokotovsk during the 1990 cooperative U.S.-Russian bottom trawl-survey of the Bering Sea shelf.

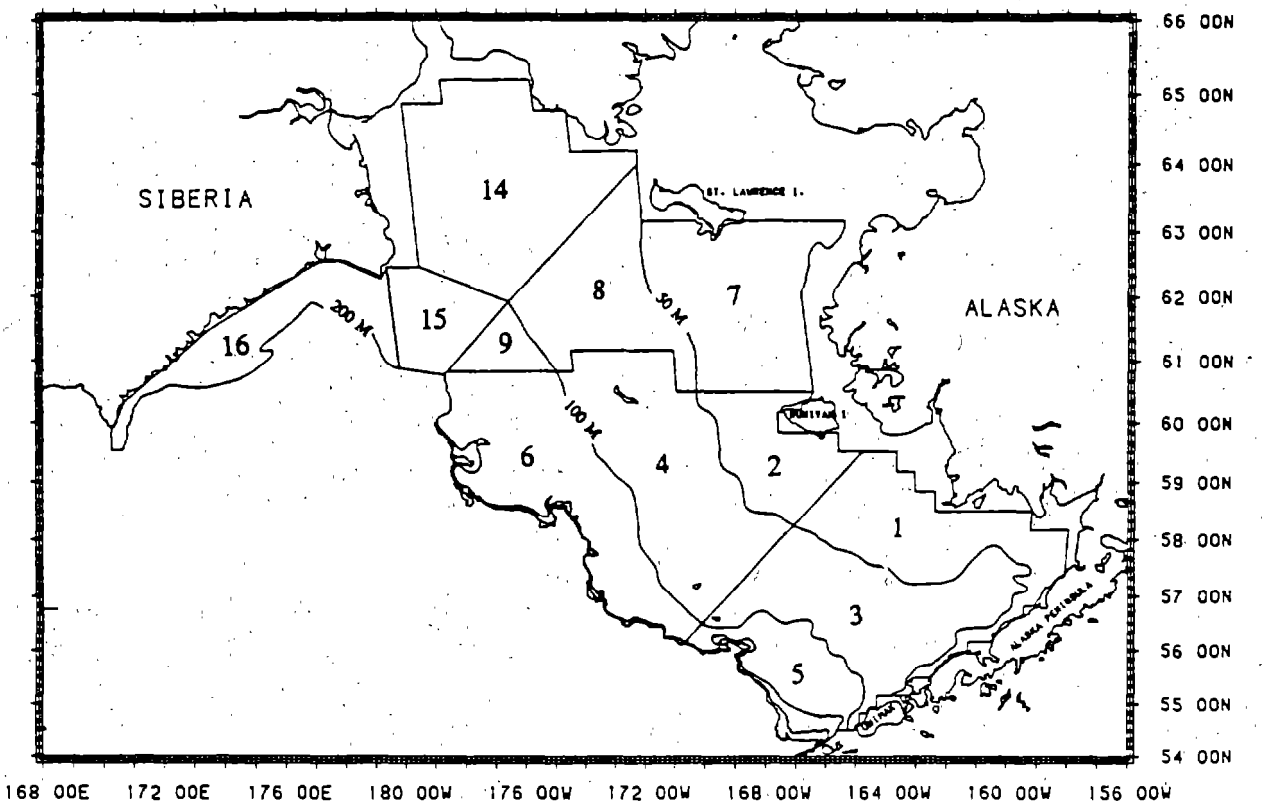

Figure 2. --Survey stratification used for the analysis of the 1990. cooperative U.S. -Russian bottom trawl survey of the Bering Sea shelf.

analysis and reporting of-data recorded from these strata combined all informationcollected at depths less than 100 m in subarea 14 and less than 200 m in subarea 16.

The overall survey area encompassed approximately 757,400 km^2, (Table l). The standard U.S. shelf accounted for 61% of the total area surveyed while the northern shelf (19%) and western shelf area (20%) were nearly equal in size.

The overall sampling intensity was one station sampled for every 2,744 km^2. (Table l). Sampling density was highest in the 'western shelf area at one sample Site for every 2,438 km^2 and

lowest in the northern shelf at one station completed for each 3,191 km^2.

Total survey	757,423	1.000	276	2,744

Standard sampling site locations were based on a schematic 20 x 20 nautical mile grid system that was established during early U.S. bottom trawl surveys in the 1970s. One sampling station was identified in the center of each grid cell. Because of time limitations the Russian research vessel fished alternate

transects columns spaced 40 nmi apart. All transect column stations were later sampled by U.S. vessels in the standard U.S. survey area. Fishing operations began in Bristol: Bay and proceeded westward completing north/south transect columns.

A total of 6 days for comparative. fishing experiments were scheduled to evaluate fishing efficiencies between the Russian sampling net and the standard U.S. 83-112 bottom trawl. Three different sampling sites were identified in the survey area to assess trawl catchability differences for varied species assemblages (Fig. 1). A total of 10 parallel comparative trawl sets, approximately 0.1 nmi apart, were conducted by the Russian vessel at each of the three sampling sites. Two days were spent at each sampling location. The Russian net was fished along the transects the first day and the following day the U.S. 83-112 trawl was used. All tows were 30 minutes in duration. Each transect pair was sampled at approximately the same time of day with each net to reduce the effects of potential daytime variations in species availability. Catches at each location were sorted, weighed, and enumerated.

Vessel and Fishing Gear

Survey activities were conducted aboard the Russian-research vessel Novokotovsk, a 101.6 m stern trawler using the Russian 35/41 bottom trawl. The U.S. 83-112 bottom trawl (used by the AFSC during U.S. groundfish surveys of the eastern Bering Sea since 1982) was-also fished by the Novokotovsk during the

comparative fishing experiments. Attributes of these sampling trawls are described in Table 2. The Russian 35/41 trawl had a longer headrope (35.0m) and footrope (49.0 m) when compared to the U.S. net (25.3 m and 34.l m respectively). Approximately 17 m of anchor chain weighing 250 kg was used on the footrope of the Russian trawl. The U.S. net used 0.6 m chain extensions between the lower dandyline and footrope to enhance bottom-tending characteristics. Roller gear was not used on either bottom trawl.

Table 2. --Description of bottom trawl sampling equipment used by the research vessel Novokotovsk during the 1990 cooperative U.S. -Russian bottom trawl survey of the Bering Sea shelf.

Trawl type	Headrope length (m)	Footrope length (m)	Opening		Mesh sizes				Accessory gear	
			horz. (m)	vert. (m)	Wing (mm)	Square (mm)	Belly (mm)	Codend (mm)	Doors (m)	Dandyline length(m)
Russian 35/41	35.0	49.0	17-20	4-6	100	70	50	30	6[2]	75
U.S. 83-112	25.3	34.1	14-16	2-3	102	102	89	89	1.8 x 2.7	50

Trawl configuration and variations in wing spread and headrope opening height were monitored using a SCANMAR[1] net mensurationsystem. Only 62 net measurements were obtained during the trawling operations because of mensuration equipment failure. These data indicated that the horizontal opening of the Russian net ranged between 17 and 20 m with a vertical opening of

[1]Reference to trade names does not imply endorsement by the National Marine Fisheries Service, NOAA.

4-6 m. The US. -83-112 net ranged from 14 to 16 m and from 2 to 3 m for horizontal and vertical openings, respectively. Position and distance fished information were collected using a Loran C navigational system. The haul began as soon as the net and trawl cable had been deployed and ended 30 minutes later when the retrieval of the net began. Beginning and ending haul positions were used to calculate distances fished at each sampling site.

Collection and Processing of Samples

An attempt was made to maintain a constant towing speed of 3.0 nmi/hr at each sampling site. Trawling operations were restricted to daylight hours to eliminate possible variation in catch rates for various species resulting from vertical diurnal migration or differential day/night net-avoidance behavior.

Sampling procedures used aboard the Novokotovsk were consistent with those established during U.S. groundfish surveys and are described in detail by Wakabayashi et al. (1985). A 30-minute bottom trawl was conducted at each designated sampling site. Catches weighing less than the capacity of the sampling table (approximately l,OOO kg) were completely processed. Catches over 1,800 kg were weighed with an electronic scale and released onto the deck. A random subsample was then transferred to the sorting table for processing. Species or species groups were sorted into baskets, weighed, then enumerated. Subsample weights and numbers were later expanded by the total catch to subsampled weight ratio.

The following fish species were further processed for size composition data:

1. Walleye pollock (Theragra chalcogramma)
2. Yellowfin sole (Pleuronectes asper)
3. Rock sole (Pleuronectes bilineatus)
4. Pacific cod (Gadus macrocephalus)
5. Flathead sole (Hippoglossoides elassodon)
6. Bering flounder (Hippoglossoides robustus)
7. Arrowtooth flounder (Atheresthes stomias)
8. Kamchatka flounder (Atheresthes evermanni)
9. Alaska plaice (Pleuronectes quadrituberculatus)
10. Pacific halibut (Hippoglossus stenolepis)

When possible, subsamples of approximately 150-200 individuals were randomly selected from the catches. Each subsample was first sorted by sex then measured to the nearest centimeter from the tip of the snout to the middle of the caudal ray fork of the tail. Pacific halibut were measured live and returned to the sea as soon as possible to ensure maximum survival rate. Halibut weights were later calculated using a length-weight relationship provided by the International Pacific Halibut Commission (IPHC). That relationship is

$$Weight_{(lbs)} = (9.204 * 10^{-6}) * L(cm).^{3.42}$$

The AFSC and TINRO methods for collecting length composition data differed. U.S. scientists routinely collect length data rounded to the nearest whole centimeter. As an example, fish measuring between 9.5 and 10.5 cm were recorded as 10 cm fish on U.S. vessels. TINRO scientists, however, recorded fish lengths between 10 and 11 cm as 11 cm fish. In order to make size

composition data comparable with those collected onboard the U.S. research vessels, length data from the Novokotovsk were-adjusted. Each, length was randomly assigned either the originally recorded length, or the original length decreased by 1 cm.

Age structures were collected from walleye pollock in the western shelf area to determine age composition. Five otoliths per sex-centimeter size category were, collected and stored in a 50% alcohol solution for subsequent evaluation by the Age and Growth Unit of the Resource Ecology and Fisheries Management Division at the AFSC. Otoliths were also collected in-the standard U.S. continental shelf aboard the U.S. vessels. Growth rates and age-length keys for walleye pollock from the standard U.S. shelf are presented in Armistead and Nichol (1992). Age-length keys were constructed separately for the western shelf and standard U.S. shelf otolith collections. Age structures were not collected for the north shelf area. Age composition was estimated by proportioning the computed population length-frequency distribution to ages using the respective western shelf or standard U.S. shelf age key.

Data Analysis

Methods -and procedures used in the analysis of the data collected during the 1990 survey are summarized below. A more complete description of the analytical methods used are provided in Wakabayashi et al. (1985).

During the sorting of the catch from each station, scientists attempted to identify (time permitting) all fish and invertebrates to the lowest possible taxon. However for some of the species encountered it was difficult to make positive identifications with the amount of time available between hauls. Arrowtooth flounder (Atheresthes stomias) and Kamchatka flounder (Atheresthes evennanni) are very similar in appearance and may not have been completely separated during the sorting. process, especially when the catch was subsampled. Catch and length data for these two species were subsequently grouped together and are reported here as Atheresthes spp. Similarly, flathead sole (Hippoglossoides elassodon) and the closely related Bering flounder (Hippoglossoides robustus) were also grouped and are presented in this report as Hippoglossoides spp.

Catch per unit effort (CPUE) was calculated in terms of weight (kg) and numbers caught per hectare (1 ha = 10,000 m^2) trawled as described by Alverson and Pereyra (1969). The mean CPUE value for the entire survey area was derived from the sum of the mean CPUE of each subarea weighted by the size of that subarea. Biomass and population numbers were calculated for each subarea as the product of the mean subarea CPUE and the area contained in that subarea. Total biomass and population numbers were calculated by summing the component subarea values.

The number of Individuals by size and sex category was estimated by expanding the length-frequency subsample to the total number of fish at each sampling site. These expanded

numbers were subsequently combined to represent the size composition in each subarea and then applied to the population estimate to produce population at size.

Age composition in terms of biomass for walleye pollock was estimated by first calculating biomass at length using the, equation: $B_L = P_L * \{A *-(L^B)\}$, where

B_L = biomass at length L in grams,
= population number at length L,
L = fork length in mm, and
A and B = constants based on regressions of previous species-specific length-weight data obtained from the RACE eastern Bering Sea database.

Values used for the constants A and B for walleye pollock are as follows:

	A	B
Male	0.0000081670	2.963988
Female	0.0000063161	3.010031
Unsexed	0.0000029701	3.167916

After converting weight in grams to metric tons (t), B_L was then apportioned to biomass at age using the age-length keys for each area.

Growth characteristics of walleye pollock were described with von Bertalanffy (1938) growth, curves fitted to age-length data.

The relative fishing efficiencies of the Russian bottom sampling net and the standard U.S. 83-112 sampling net were evaluated by comparing the CPUE trawled for each species caught.

One net was determined to have a different catchability coefficient than the other when the distribution of CPUE values were found to be statistically different-based on a Bayesian approach described by Geisser and Eddy (1979).

RESULTS OF THE SURVEY

The Novokotovsk completed 345 trawl hauls including 60 comparative trawl sets. In addition to standard haul, position, catch, and sea water temperature information, approximately 52,000 length measurements were recorded from fish species of interest (Table 3). Approximately 550 pollock otolith pairs were collected and preserved.

Table 3.--Number of length frequencies collected aboard the Novokotovsk by species and area during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

Species	Region			Total
	Standard U.S. shelf	Northern shelf	Western shelf	
Walleye pollock	15,781	1,411	3,477	20,669
Pacific cod	1,812	205	954	2,971
Yellowfin sole	11,306	2,026	67	13,399
Hippoglossoides spp.	4,585	369	1,004	5,958
Pacific halibut	523	6	44	573
Alaska plaice	3,789	1,424	297	5,510
Atheresthes spp.	2,692	0	0	2,692
Misc. species[a]	116	180	0	296
Total	40,604	5,621	5,843	52,068

[a] Includes rex sole, northern rockfish, and saffron cod.

Environmental Conditions

During May-June, sea water surface temperatures ranged from 0.8° C to 10.1° C in the survey area. Surface temperatures were

generally lowest in the shallow waters of the Alaska mainland inshore area and increased westward as the survey proceeded (Fig 3). The warmest sea surface temperatures were observed off the southern waters of the Siberian coast during mid-July when the survey was completed.

Bottom temperatures ranged from -1.8° C to 4.8° C with the warmest waters located in Bristol Bay, the southeastern Bering Sea, and the far western area off the coast of Siberia (Fig. 4). A large mass of subzero water was encountered in the northern portion of the study region extending from the Gulf of Anadyr south through the central portion of the eastern Bering Sea. The overall mean bottom temperature was 1.0° C. The standard U.S. shelf had the warmest bottom temperaturesaveraging 1.7° C while the north shelf was coldest at -0.6" C. The combined western subareas were also relatively cold with a mean bottom temperature of 0.2° C primarily due to the cold water mass located in subareas 14 and 15.

Comparative Trawl Experiment

The Novokotovsk completed 30 paired comparative sets using the Russian sampling net and the standard U.S. 83-112 bottom trawl. Ten comparative sets were conducted at each of three sampling sites in the southeastern Bering Sea (Fig. 1).

Comparison of the catch rates (standardized to kg/ha trawled) between sampling nets indicated that the U.S. 83-112 sampling net was more effective in capturing Pacific cod

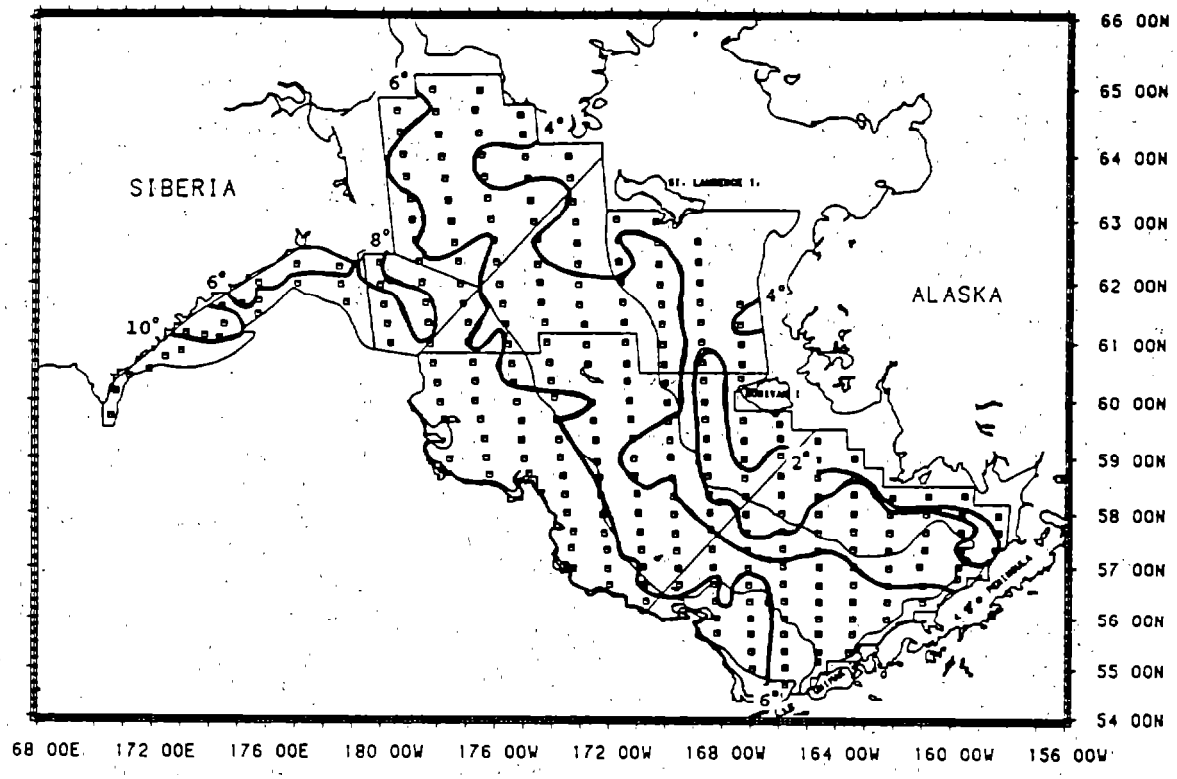

Figure 3. --Distribution of surface water temperatures (°C) observed during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

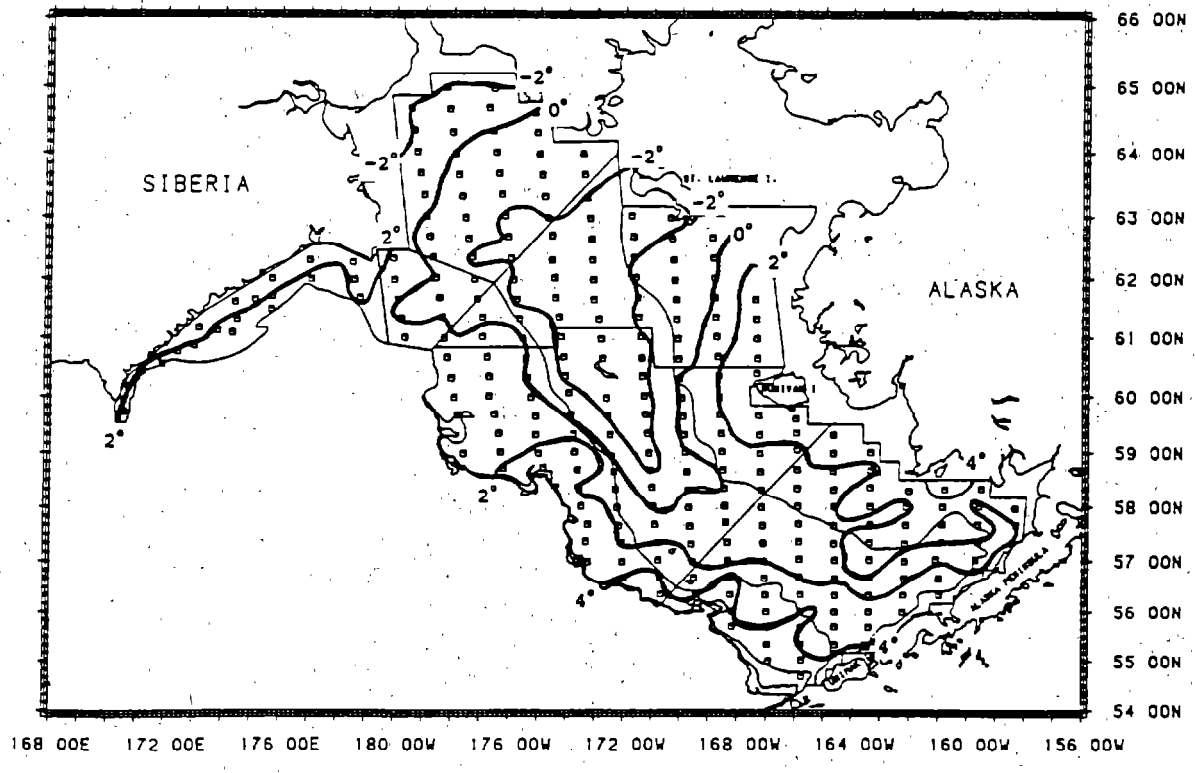

Figure 4. --Distribution of bottom water temperatures (°C) observed during the 1990 cooperative U.S. -Russian bottom trawl survey of the Bering Sea shelf.

(G. macrocephalus), Tanner crabs (Chionoecetes bairdi and c. opilio), blue king crab (Paralithodes platypus), starfish, and most other invertebrates. The catch efficiency for invertebrates was probably increased by the 0.61 m footrope chain extensions that enhanced the 83-112 trawl's ability to tend bottom and therefore improved the sampling efficiency for species situated directly on the seabed. The Russian net was not equipped with these extensions and apparently did not tend bottom as well. Although results showed similarities in catch efficiencies between these sampling nets for many species, adjustments to catches were not made primarily because of the relatively small number of comparative tows at each sampling site. They do, however, suggest strong similarities in fishing efficiencies between sampling nets when used aboard the Novokotovsk for some species as shown in Table 4. It should be noted that the R/V

*Geisser and Eddy (1979) test indicates a significant difference between sampling net CPUE.

Novokotovsk is over 3 times larger than the vessels used in the U.S. bottom trawl survey. Differences in fishing efficiencies using the 83-112 bottom trawl aboard the Novokotovsk and the smaller U.S. survey vessels is unknown. Vessel logistics and time limitations prevented conducting side-by-side trawling experiments between the U.S. and Russian vessels.

Relative Importance of Major Taxonomic Groups

During the 1990 cooperative survey, 95 fish species representing 20 families were consistently identified (Table 5). Forty-six invertebrate species were identified from the catches. Some invertebrate species were not completely sorted and identified during the sampling procedure because of time limitations. Many invertebrates were subsequently grouped in broader taxonomical categories such as family, order, and phylum or recorded as "other invertebrates." As a result, some of the more specific invertebrate categories may be underestimated.

The total biomass of fish and invertebrates combined in the overall survey area was estimated at 16.5 million t (Tables 6 and. 7). Of this, nearly 74% (12.3 million t) of the biomass occurred in the standard U.S. shelf, 8% (1.3 million t) in the north shelf area, and 18% (3.0 million t) in the western area.

Fish--The total biomass of all fish species sampled was estimated at 11.6 million t and accounted for 69.1% of the total catch of fish and invertebrates combined (Table 6). Total fish catch rates. frequently exceeded 400 kg/ha trawled in the standard

Table 5. --Mean CPUE (kg/ha) of fish species encountered during the 1990 U.S.-Russian cooperative groundfish survey of the Bering Sea.

[a]Rounding accounts for minor discrepancies between sums of subareas and total survey area, and between sums of taxonomic subgroups and major groups.
[b]Proportion of total estimated biomass, fish and invertebrates combined, for the total survey area (Total estimated biomass = 16,539,353 t).
[c]Biomass for pagurids, crustaceans, gastropods, pelecypods, and echinoderms may be underestimated since some were classified as other invertebrates during the sampling procedures.

U.S. area and were generally less than 125 kg/ha in the north shelf area (Fig. 5) Fish were also found in relatively low levels of abundance in the Gulf of Anadyr region of the western shelf. About 83% (9.6 million t) of the total fish biomass was located in the standard U.S. shelf. Another 6% (0.7, million t) were present in the north shelf area and 11% (1.3 million t) in the western area. Six fish families including Pleuronectidae (47.6%), Gadidae (45.0%), Rajidae (2.6%), Cottidae (2.4%), Clupeidae (0.8%), and Zoarcidae (0.6%) contributed 99% of the total estimated fish biomass.

Invertebrates --The combined invertebrate biomass accounted for 30% or nearly 5.0 million t of the total estimated biomass of fish and invertebrates (Table 7). Members of the phylum Echinodermata were the most frequently encountered invertebrate category with an estimated biomass of approximately 2.4 million t or nearly-one-half of the overall invertebrate biomass and about 14% of the combined fish and invertebrate biomass. Starfish were the major component of the echinoderm assemblage. Sea urchins were the second most abundant echinoderm group with highest concentrations located in the western shelf area. Crustaceans, primarily represented by tanner crab, comprised 28.5% of the total estimated invertebrate biomass. The molluscs, ascidians, and coelenterates combined comprised about 2.3% of the total invertebrate biomass. Gastropods were the most often encountered members of the phylum Mollusca. Gastropods and other members of the phylum Mollusca were likely the most undersampled because many species in this phylum tend to burrow into the sea bottom below the effective path of the sampling trawl.

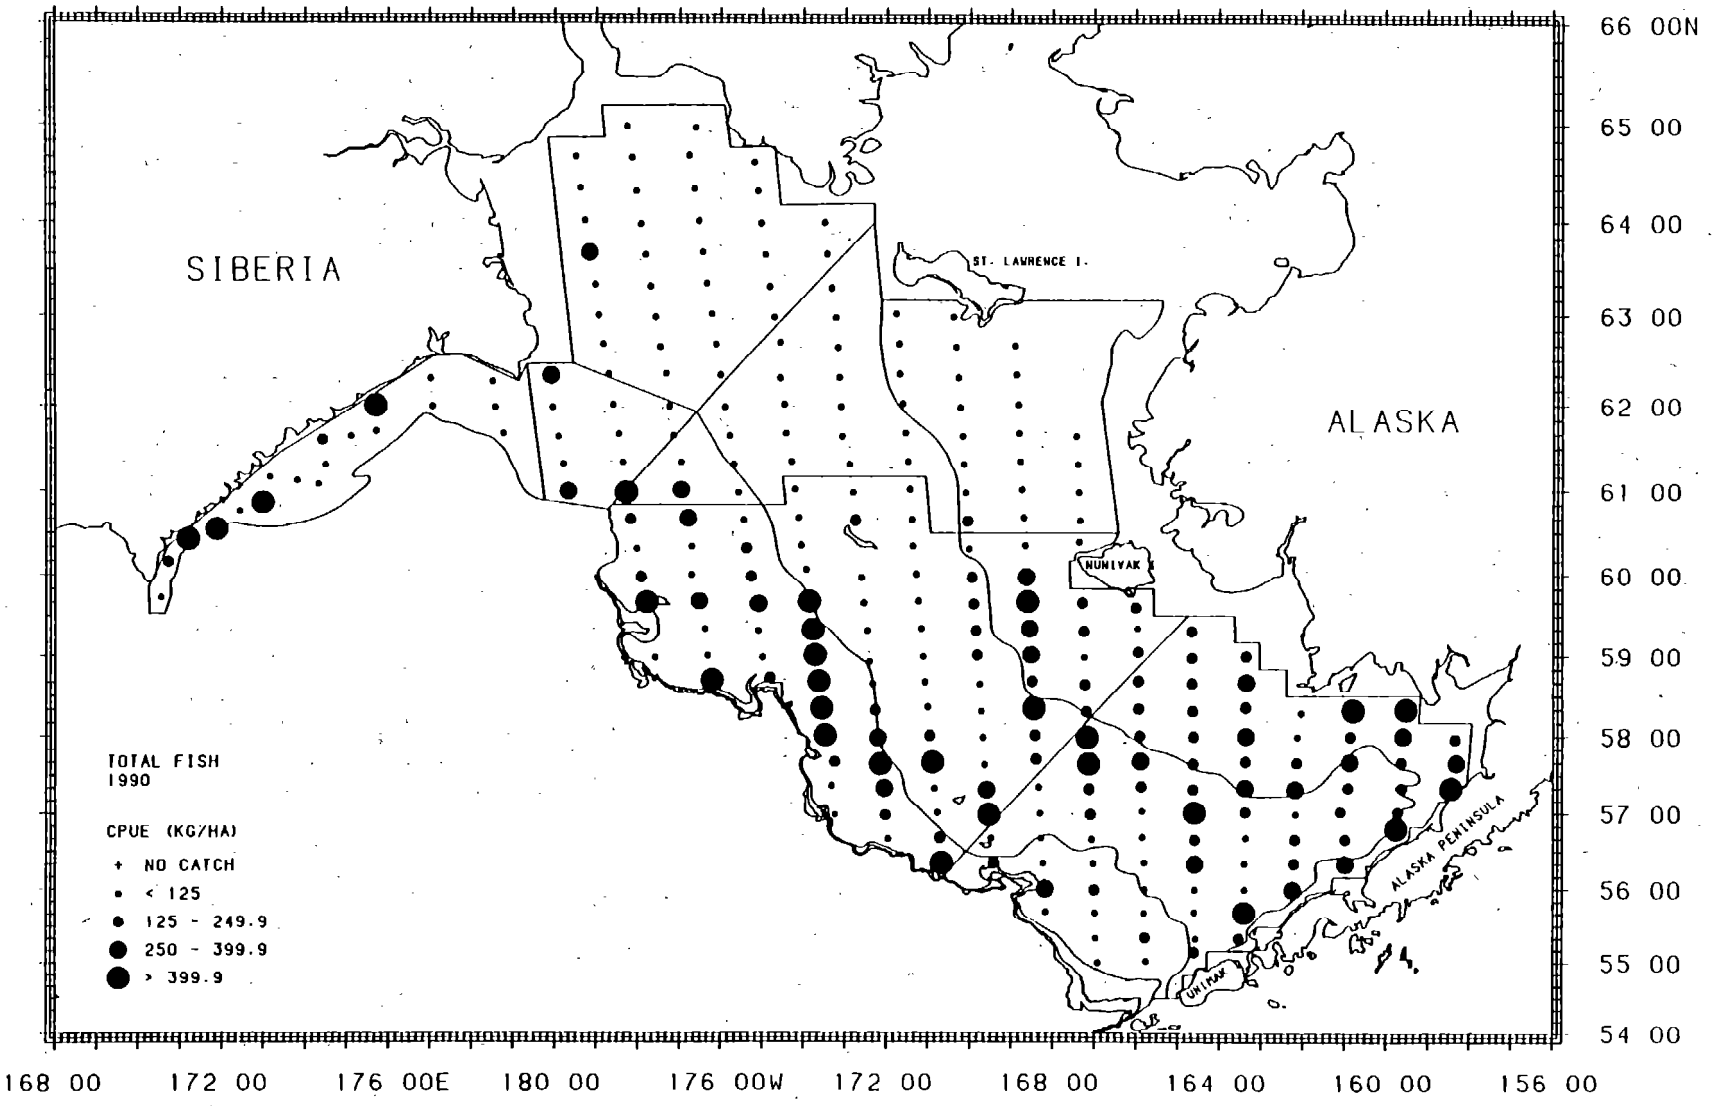

Figure 5.--Distribution and relative abundance in kg/ha of total fish sampled during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

Fish Groups

Pleuronectidae (flatfishes)

Fifteen species of flatfish were identified during the survey (Table 5). They accounted for 5.5 million t or 48% of the entire estimated fish biomass. Approximately 94% of the total flatfish biomass was located in the standard U.S. shelf area with 4% in the north shelf area and 2% in the western area (Table 6). Yellowfin sole was the major component of this group comprising 46% of the total flatfish biomass estimate. Yellowfin sole were primarily concentrated in the standard U.S. shelf area. Rock sole was the second most abundant species accounting for 24% of the flatfish biomass estimate followed by Alaska plaice (15%), Hippoglossoides spp. (7%), and Atheresthes spp. (5%).

Gadidae (codfishes)

The family Gadidae was represented by four species with a combined estimated biomass of 5.2 million t. This group was widely distributed throughout the survey area with approximately 73% (3.8 million t) located in the standard U.S. shelf area, 8% (0.4 million t) found in the north shelf area, and the remaining 19% (1 million t) located in the western shelf region (Table 6). Walleye pollock was by far the most abundant gadid species comprising 80% by weight of this family followed by Pacific cod (19%): Arctic cod (Boreogadus saida) and saffron cod (Eleginus gracilis) comprised the remaining 1% with highest catch rates encountered in the north shelf area (Table 5).

Rajidae (skates)

Four species of skates were identified during the survey (Table 5). The Alaska skate (Bathyraja parmifera) was the most commonly encountered skate species in the standard U.S. and western areas and was the only skate species recorded in the north shelf area. Skates were most abundant in subareas 5 and 6 at depths greater than 100 m (Fig. 6). Skates were the third most abundant fish group (following the gadids and pleuronectids) and had an estimated biomass of nearly 300,000 t. Ninety percent of the entire skate biomass was located in the standard U.S. shelf.

Cottidae (sculpins)

The family Cottidae was the most diverse fish group encountered with 24 species identified (Table 5). Sculpins were broadly distributed throughout the survey area and were encountered at most sampling sites (Fig. 7). This group accounted for approximately 2% (282,000 t) of the total estimated fish biomass. Members of the genus Myoxocephalus accounted for most (62%) of the sculpin biomass.

Other fishes

Sixteen additional families were encountered in the survey area (Table 5). Together these families accounted for 272,000 t or 2% of the entire estimated fish biomass (Table 6). The dominant families included the Clupeids (herring), Zoarcids (eelpouts), Osmerids (smelts), and Agonids (poachers) (Figs. 8-11).

Abundance, Distribution, and Size Composition of Principal Fish Species

Walleye pollock

Distribution and abundance--Walleye pollock was the most abundant fish species encountered occurring at 269 (98%) of the stations sampled (Fig. 12). Walleye pollock comprised 25% of the total combined biomass estimate of fish and invertebrates and 36% of the total. fish biomass (Table 6). The overall mean catch rate was nearly 55.0 kg/ha trawled (Table 8). Concentrations were greatest in the 100-200 m depth zone in subareas 6 and 9 with mean CPUE values of 223.9 kg/ha and 268.3 kg/ha, respectively. Pollock were also encountered in relatively high abundance in western shelf subarea 16 at 110.4 kg/ha trawled. Catch rates were lowest in north shelf subareas 7 and 8, averaging 3.3 kg/ha and 0.9 kg/ha, respectively. Although juvenile walleye pollock (< 20 cm fork length) were encountered throughout the survey, they were most abundant in subarea 6 at water temperatures about 0° C with catches exceeding 100 kg/ha trawled (Fig,. 13).

The total biomass of walleye pollock was estimated at 4,162,000 t with population numbers exceeding 12.6 billion fish (Table 8). Approximately 3,153,000 t or 76% of the total biomass was located in the standard U.S. shelf region. Nearly 51% of the overall biomass was located in subarea 6. The north shelf area accounted for 340,000 t (8%) of the remaining biomass with the western shelf containing 669,000 t (16%).

[a]Differences in totals and sums of biomass and population numbers by subarea are due to rounding.

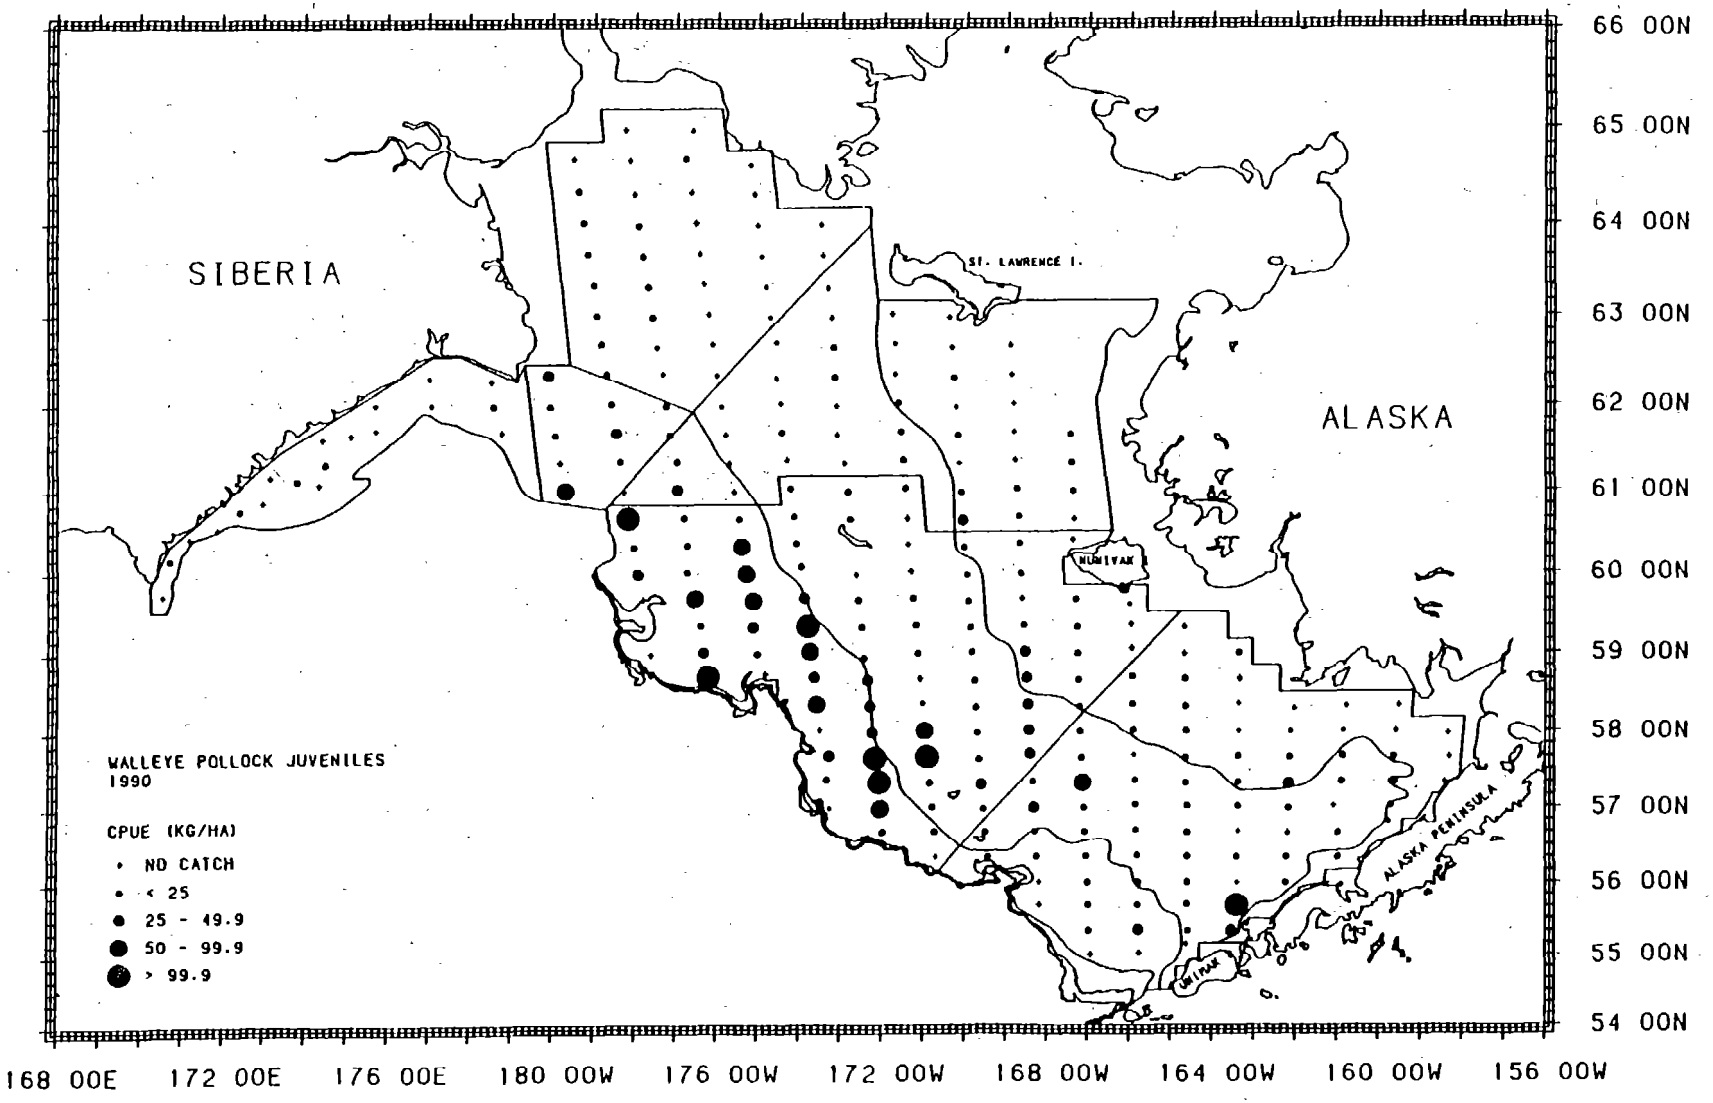

Figure 13. --Distribution and relative abundance in kg/ha of juvenile walleye pollock (<20 cm) sampled during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

Size composition--Walleye pollock measured during the survey ranged in size from 6 cm to 85 cm in length. The mean length of waileye pollock for the total survey area was 27.6 cm (Fig. 14). The standard U.S. area was characterized by a bimodal length distribution with a high proportion (51%) of young fish in the 9 cm to 15 cm size range. Most of the remaining population sampled in the standard U.S. shelf were composed of adults ranging from 40 cm to 55 cm in length. The portion of the population in the north shelf area was primarily composed of juveniles with an overall mean-size of 22.7 cm. Nearly 50% of the pollock sampled in the north shelf area were less than 10 cm in length. The overall mean size in the western shelf area was 33.9 cm with no pronounced modes. Relatively few juveniles were encountered in the combined western shelf subareas where approximately 70% of the fish measured were over 20 cm in length. Juvenile walleye pollock were abundant in subareas 2, 4, 7, and 8 accounting for over 80% of the estimated population in those areas (Fig. 15). Few juveniles were encountered in subareas 9 and 16 where they represented less than 6% of the estimated population.

Age composition--The mean age for pollock sampled in the standard U.S. shelf was 3.7 years compared to 4.5 years in the western shelf. Over 50% of the pollock population numbers in the standard U.S. shelf were comprised of fish aged 0-1 (Fig. 16). A high proportion (nearly 30%) of the fish in the western shelf

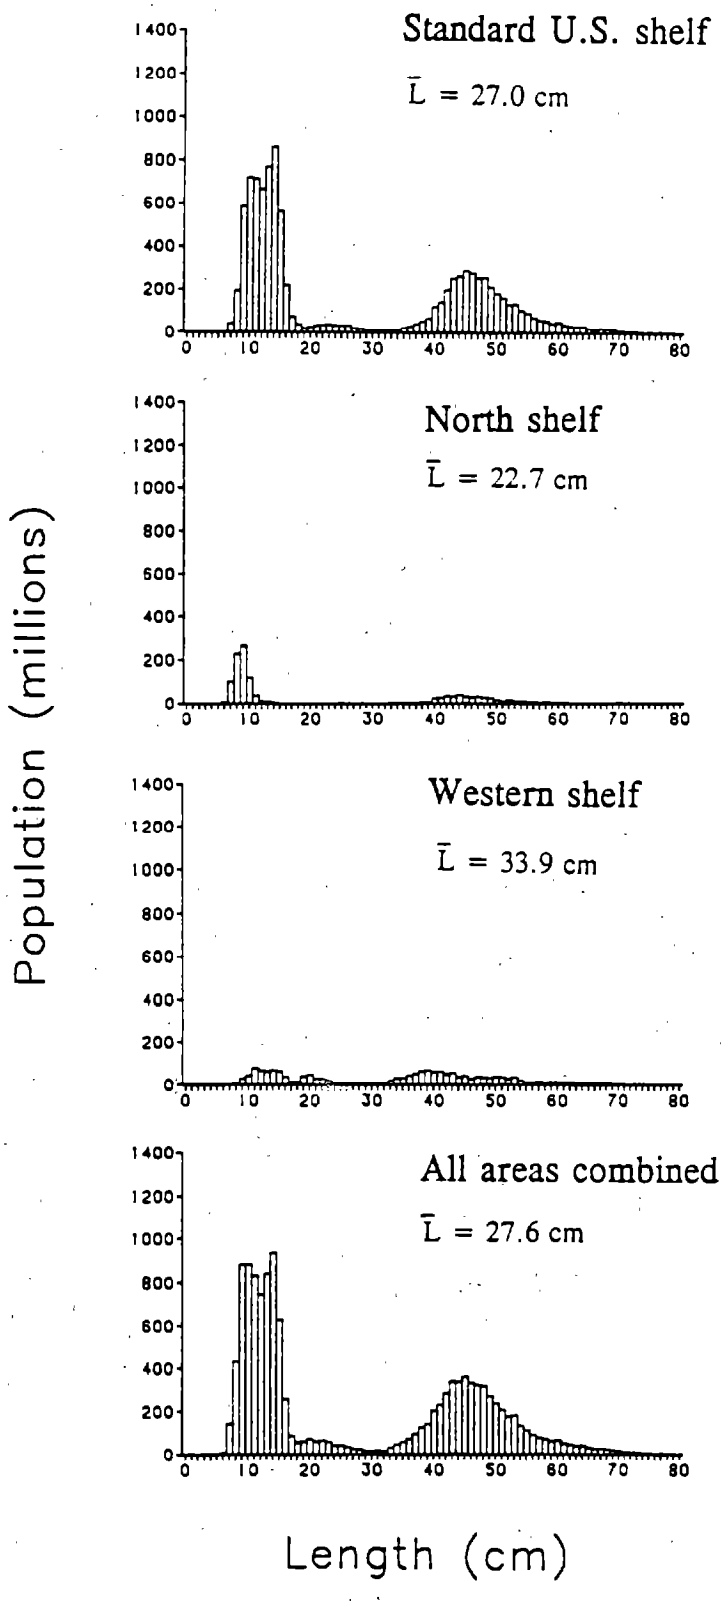

Figure 14.--Estimated size composition of walleye pollock by region during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

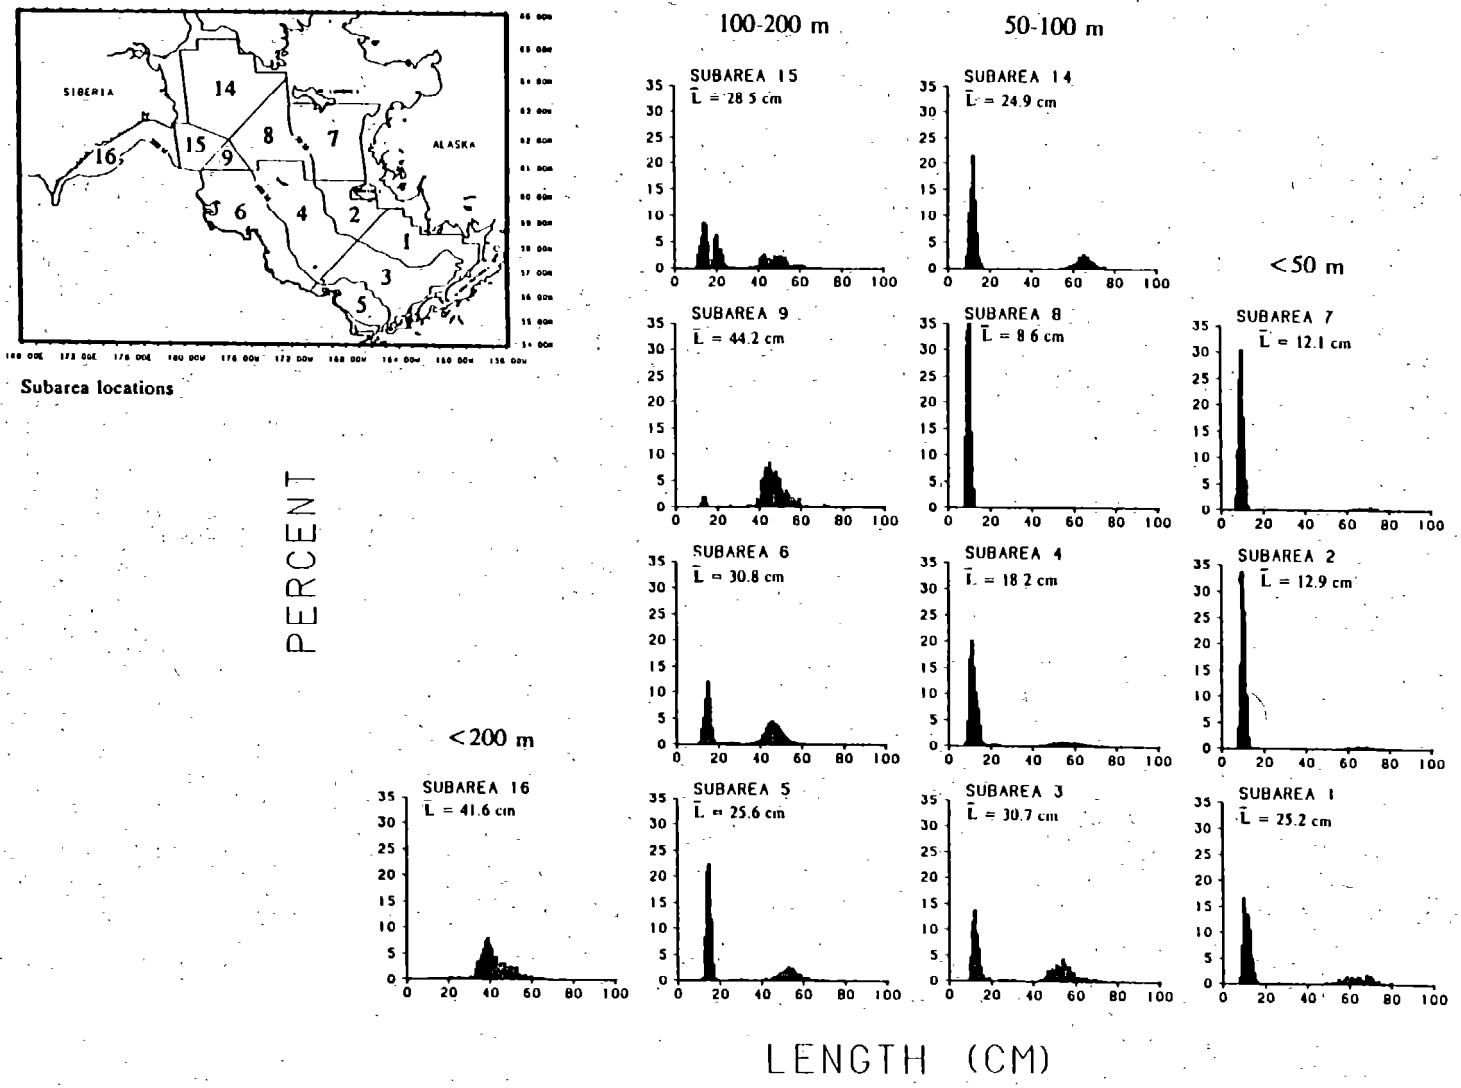

Figure 15.--Estimated relative size composition of walleye pollock (sexes combined) by subarea during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

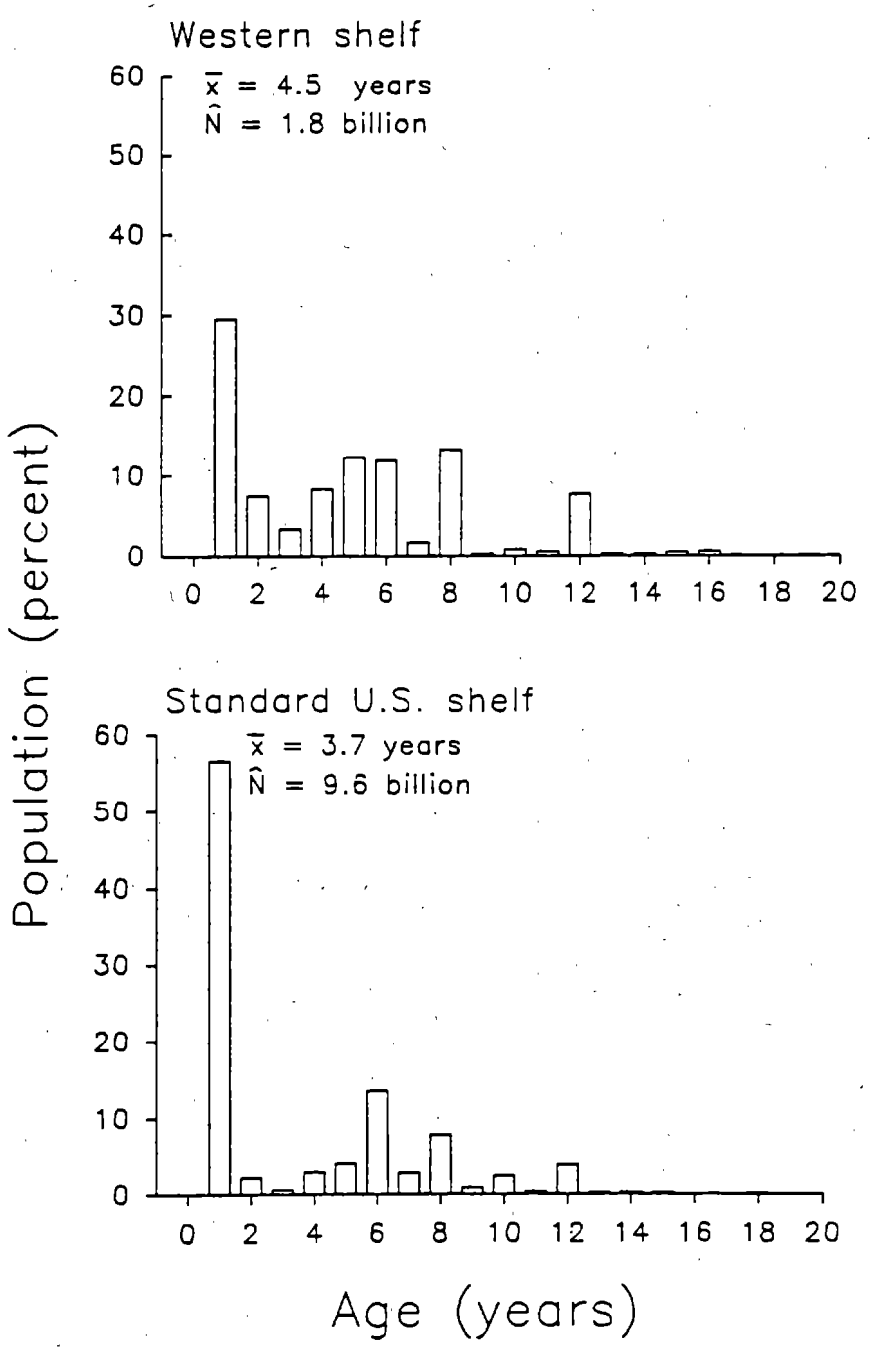

Figure 16.--Relative age composition of walleye pollock in the western shelf and standard U.S. shelf areas during the 1990 cooperative bottom trawl survey. Age-length keys were constructed from data collected by the Novokotovsk in the western shelf and AFSC age data collected in the standard U.S. shelf. These keys were applied to Novokotovsk length data from the respective areas.

area were also age 1 or less. Fish ages 6, 8, and 12 corresponding to the 1984, 1982, and 1978 year classes, respectively, were prominent on the standard U.S. shelf. These three year classes comprised 62% of the biomass of walleye pollock in this area (Fig. 17). These age classes were also prominant in the western shelf region in terms of biomass although fish 4 and 5. years old were also relatively abundant.

Growth--Von Bertalanffy growth curves fitted to age data for walleye pollock from the western shelf area indicated similar growth between sexes. Growth completion rates (K) were nearly equal although the asymptotic length was slightly higher for females (Fig. 18 and Table 9). Growth rates were similar between pollock. from the western shelf and the standard U.S. shelf.

Table 9. --Parameters of the von Bertalanffy growth curves for walleye pollock by sex from data collected in the western shelf area during the 1990 cooperative U.S.-Russian bottom trawl survey and from data collected during the independent 1990 AFSC bottom trawl survey of the standard U.S. shelf.

Sex	Number of age readings	Age range	Length range (cm)	Parameters L_∞	K	t_o

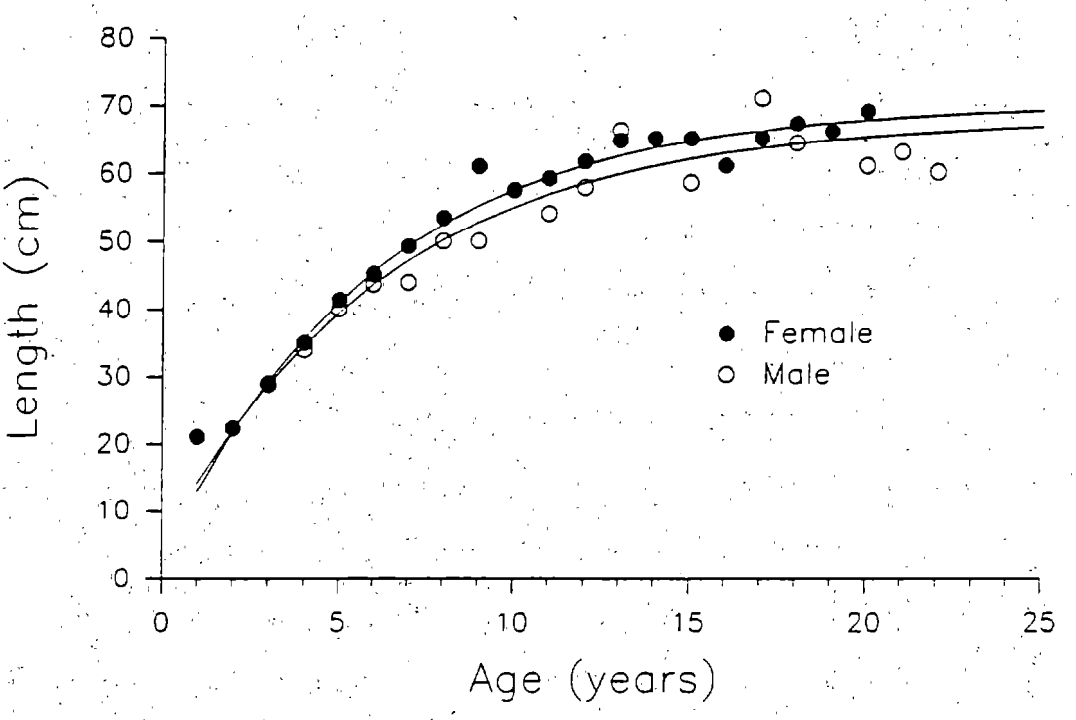

Figure 18. --Von Bertalanffy growth curves for male and female walleye pollock, in the western shelf area as shown by age data collected aboard the R/V Novokotovsk during the 1990 cooperative U.S. -Russian bottom trawl survey of the Bering Sea shelf.

Pacific cod

Distribution and abundance--Pacific cod were recorded at 223 stations. Largest catches (>49.9 kg/ha trawled) primarily occurred at water depths greater than 50 m as shown in Figure 19. The overall mean catch rate was nearly 13.3 kg/ha trawled (Table 10). Greatest densities of Pacific cod were encountered in the western shelf area (20.7 kg/ha) followed by the standard U.S. shelf (14.2 kg/ha). Pacific cod were least abundant in the north shelf area with catch rates averaging 2.1 kg/ha.

The total Pacific cod biomass was estimated at l,000,000 t with 65% of the biomass located in the standard U.S. area and 32% in the western shelf. The north shelf area accounted for only about 3% of the total biomass. Approximately 515,000 (51%) of the total estimated biomass was located in subareas 3, 4, and 6 combined. The total population of Pacific cod was estimated at 655.7 billion fish.

Size composition --The mean size of Pacific cod sampled in the entire survey area was 43.7 cm (Fig. 20). A much higher percentage (23%) of young fish less than 20 cm were found in the standard U.S. shelf compared to the western Bering Sea (5%). Pacific cod averaged 44.5 cm in length in the north shelf area. The length composition of Pacific cod by depth zone and subarea are summarized in Figure 21. The mean size increased with increasing depth. In the standard U.S. shelf area, mean size increased from 35.2 cm at depths less than 50 m (subareas 1 and 2) to 40.5 cm between 50 and 100 m (subareas 3 and 4) and 56.1 cm at depths greater than 100 m (subareas 5 and 6).

Yellowfin sole

Distribution and abundance--Yellowfin sole were the second most abundant fish species caught during the survey and were encountered at 158 stations (Fig. 22). The major portion of the sampled population was located in the inner shelf waters of the standard U.S. shelf area. Relatively few yellowfin sole were taken in the north shelf and western area. The overall mean catch rate for this species was 33.5 kg/ha trawled (Table 11). Mean CPUE values varied considerably between the standard U.S. shelf (52.4 kg/ha), north shelf (7.68 kg/ha), and the western shelf area (0.13 kg/ha). Greatest concentrations were observed at depths less than 50 m in subarea 1 (147.9 kg/ha) and subarea 2 (114.7 kg/ha).

The yellowfin sole biomass for the entire survey area was estimated at 2,539,000 t. Nearly 96% of, this total estimated biomass or 2,429,000 t was located-in the standard U.S. shelf with 45% in subarea 1 alone. Approximately 4% of the biomass was located in the north shelf area with less than 1% of the biomass in the western area. The total population of yellowfin sole in the survey area was estimated, at l0.6 billion fish.

Size composition--Yellowfin sole measured during the survey had an overall mean length of 25.8 cm (Fig. 23). Yellowfin sole were largest in the western shelf area averaging 32.1 cm in length and smallest in the north shelf area with a mean size of 23.3 cm. Yellowfin sole averaged 25.9 cm in the standard U.S. shelf where most of the population occurred. Mean size increased

with increasing depth, ranging from 23.3 cm to 25.4 cm at depths less than 50 m (subareas 1, 2, and 7) to over 28.0 cm at depths of 50-100 m in subareas 3 and 4 (Fig. 24). Juveniles less than 20 cm were most abundant in subareas less than 50 m in the standard U.S. shelf while few juveniles were encountered in the western shelf.

Rock sole

Distribution and abundance--Rock sole were widely distributed throughout the survey area but were most highly. concentrated in the shallow portion of the standard U.S. shelf in Bristol Bay and around the Pribilof Islands (Fig. 25). The overall mean CPUE value was 17.5 kg/ha trawled (Table 12). Highest catch rates were observed in the standard U.S. shelf at 28.4 kg/ha with much lower catch rates occurring in the-north shelf area (0.2 kg/ha) and the western area (1.3 kg/h&). Major. concentrations were observed in the standard U.S. shelf at depths less than 100 m with CPUE values ranging from 59.8 kg/ha in subarea 1 to 22.5 kg in subarea 2. Rock sole abundance decreased sharply at depths over 100 m.

The biomass of rock sole for the entire survey area was estimated at 1,327,OOO t (Table 12). Nearly 98% of the estimated. biomass was located in the standard U.S. shelf, primarily in the combined subareas of 1, 3, and 4. The total rock sole population in the survey area was estimated at 6.8 billion fish.

[b] Differences in totals and sums of biomass and population numbers by subarea are due to rounding.

Size composition--Rock sole ranged in size from 6 cm to 50 cm in length. The mean size of rock sole over all areas was 22.7 cm (Fig. 26). Two moderate length modes were observed in the standard U.S. shelf at approximately l4 cm and 29 cm. The largest percentages of juveniles were observed at depths less than 50 min the standard U.S. shelf (subarea 1 and 2) (Fig. 27).

Hippoglossoides spp.

Distribution and abundance--Two species of Hippoglossoides were broadly distributed throughout the survey area occurring at 79% of the stations sampled (Fig. 28). Flathead sole (H. elassodon) was predominant in the catches from the southern waters of the standard U.S. shelf through the central shelf waters, whereas Bering flounder (H. robustus) predominate in catches from the north shelf and western area. Largest concentrations of thisgenus were located in the southern portion of the standard U.S. area at depths greater than 50 m. Catch rates of Hippoglossoides averaged 4.9 kg/ha trawled over the entire survey area (Table 13). CPUE was greatest in the standard U.S. area averaging 7.2 kg/ha and was lowest in the north shelf area at 0-6 kg/ha. Subareas 3 and 5 contained the highest concentrations with mean catch rates of 15.2 kg/ha and 13.0 kg/ha, respectively.

The total biomass of Hippoglossoides spp. was estimated at 371,400 t (Table 13). Nearly 90% of the estimated biomass (333,000 t) was located in the, standard U.S. shelf. The western

[b]Differences in totals and sums of biomass and population numbers by subarea are due to rounding.

area accounted for 8% of the total biomass with only 2% (7,900 t) found in the north shelf area. The majorportion of the estimated biomass was located in subarea 3, which comprised a little over 42% of the entire survey area biomass estimate.

A total of 1.7 billion fish were estimated for the overall survey area. The population distribution differed from the biomass distribution. Approximately 72% of the population was located in the standard U.S. area compared to 90% of the biomass. The western region contained 23% of the total population number, yet only 8% of the estimated biomass.

Size composition--Lengths for Hippoglossoides spp. averaged 26.1 cm across the entire survey area (Fig. 29). Fish were largest in the standard U.S. shelf averaging 28.1 cm and smallest in the western shelf at 20.0 cm. Size distributions by subarea are shown in Figure 30. Members of this genus were largest in the 50-100 m depth zones of subareas 3 and 4 with mean lengths of 33.2 cm and 28.0 cm, respectively.

Alaska plaice

Distribution and abundance--Alaska plaice were frequently encountered throughout the survey, with the exception of subarea 5 (Fig. 31). The total area CPUE of Alaska plaice averaged 11.0 kg/ha (Table 14). Catch rates were highest in the standard U.S. shelf (14.7 kg/ha) followed by the north shelf area (7.2 kg/ha) and the western area (3.4 kg/ha). Alaska plaice were most abundant at depths less than 100 m.

[a]0 indicates fishing but no catch; - indicates no sample or insufficient data.
[b]Differences in totals and sums of biomass and population numbers by subarea are due to rounding.

The estimated biomass for the entire survey area was 832,000 t (Table 14). The major portion of the estimated biomass was located in the standard U.S. area (82%). An additional 12% was found in the north shelf area, primarily in subarea 7, with the remaining 6% in the western shelf region. The population for the total survey area was estimated at 1.3 billion fish. The abundance distribution of the population was similar to the biomass distribution with 81% of the estimated population located in the standard U.S. shelf.

Size composition--Alaska plaice ranged in size from 9 cm to 61 cm with an overall mean size of 35.2 cm (Fig. 32). Two modes in the size composition were evident in the standard U.S. shelf with a prominent peak at about 35 cm and one peak less pronounced at about 43 cm. This variation was primarily due to the differences in mean length between males and females. Mean length was greatest (35.8 cm) in the standard U.S. shelf and lowest (31.9 cm) in the north shelf region. Juvenile Alaska plaice (< 20 cm) were most abundant at depths less than 50 m in subarea 1 but were also encountered in subarea 16 (Fig. 33). Few juveniles were found in waters greater than 50 m.

Atheresthes spp.

Distribution and abundance--The two species of Atheresthes, arrowtooth flounder (A. stomias) and Kamchatka flounder (A. evermanni) were primarily distributed in the standard U.S. shelf at depths greater than 100 m (Fig. 34). The overall CPUE

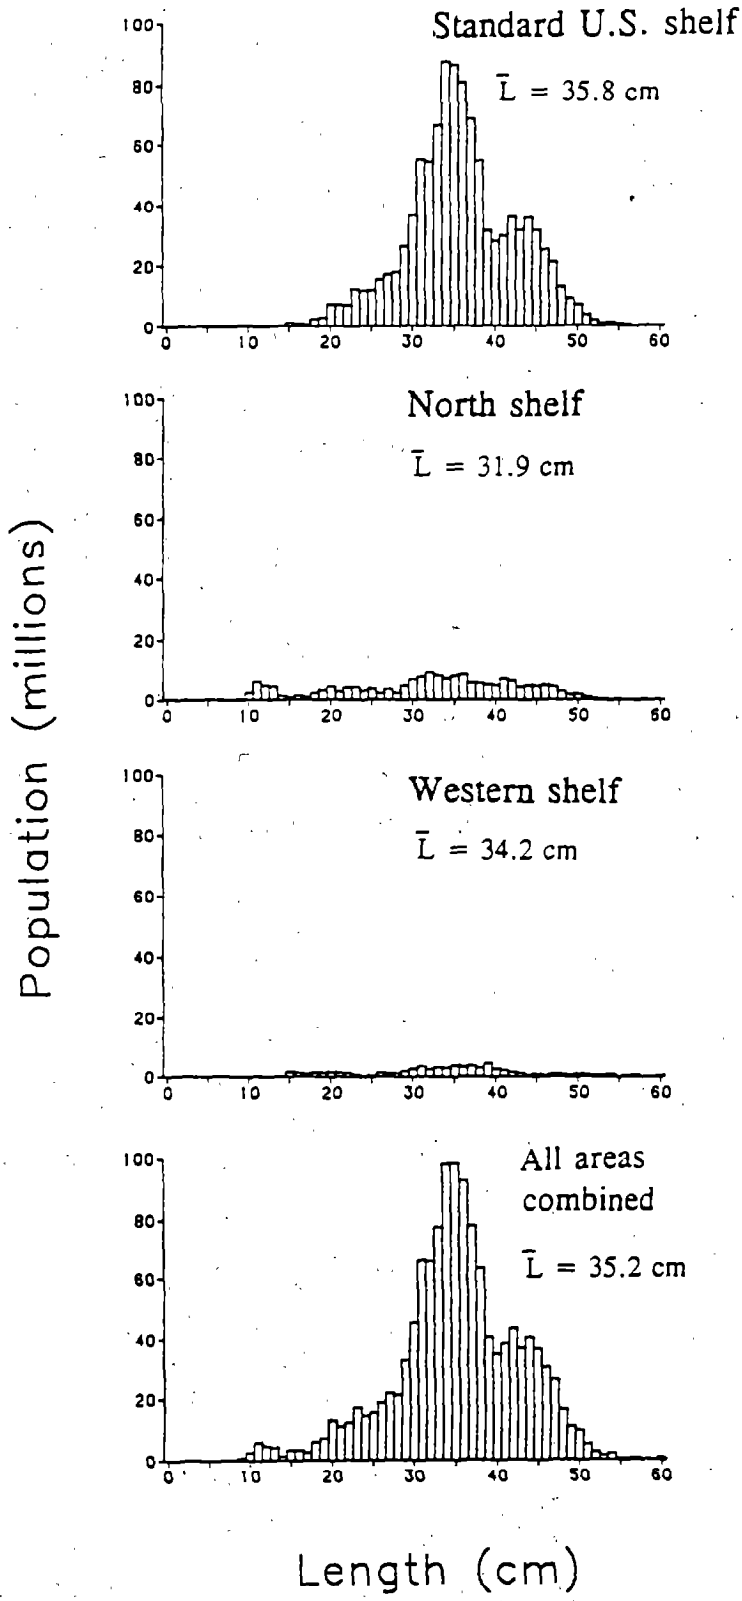

Figure 32.--Estimated size composition of Alaska- plaice by region during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

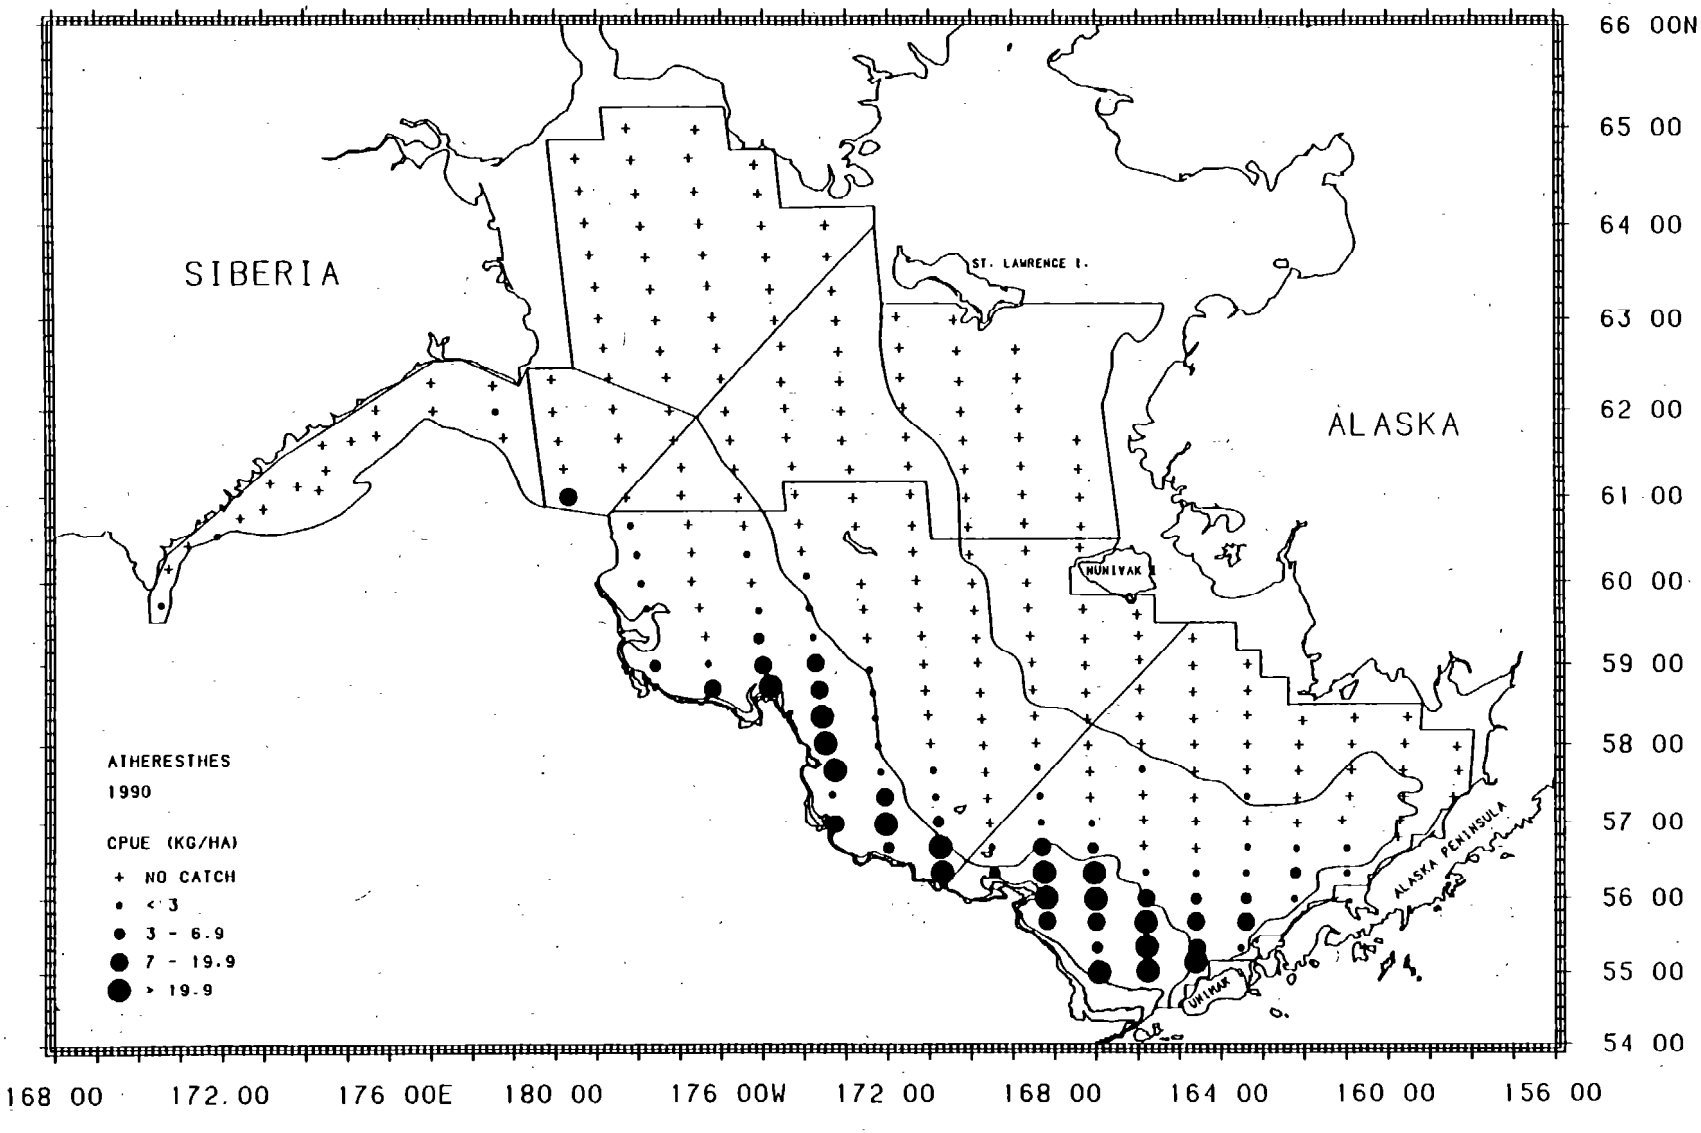

Figure 34.--Distribution and relative abundance in kg/ha of Atheresthes spp. sampled during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

was 3.4 kg/ha with mean catch rates highest in subareas 5 (31.9 kg/ha) and 6 (10.0 kg/ha) (Table 15). Atheresthes spp. were not encountered in the north shelf area and only trace amounts were found on the western shelf.

The biomass of Atheresthes SPP. over the entire survey area was estimated at 258,000 t (Table 15). Over 99% of the estimated biomass was located in the standard U.S. shelf, primarily in the l00-200 depth zone of subareas 5 and 6. The remainder of the biomass (1%) was located in subareas 15 and 16 of the western shelf region. The total survey area population was estimated at 625.1 million fish (Table 15).

Size composition--Size compositiondata for Atheresthes spp. was limited to the standard U.S. shelf. The mean size of Atheresthes spp. measured in the standard U.S. shelf was 32.6 cm (Fig. 35). Mean size varied little between subareas and depth zones ranging from 31.8 cm in subarea 3 to 33.0 cm in subarea 6 (Fig. 36).

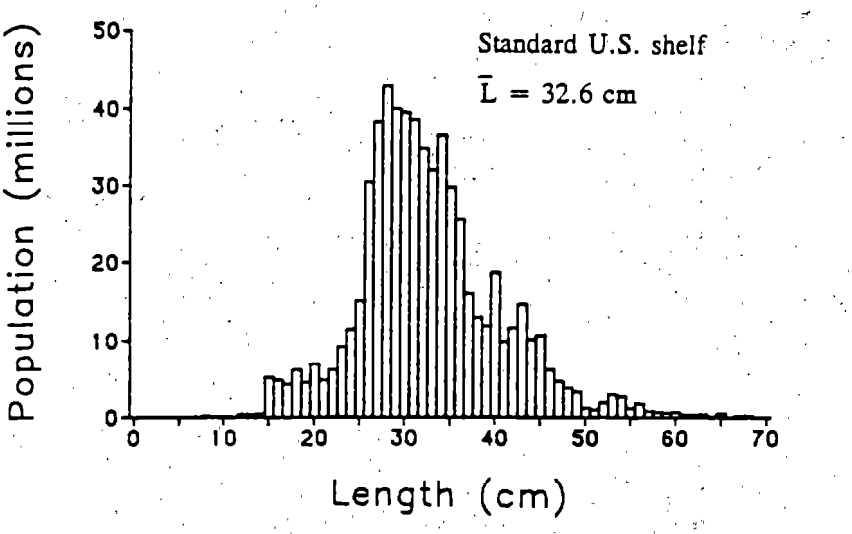

Figure 35.--Estimated-size composition of Atheresthes spp. for the standard U.S. shelf during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

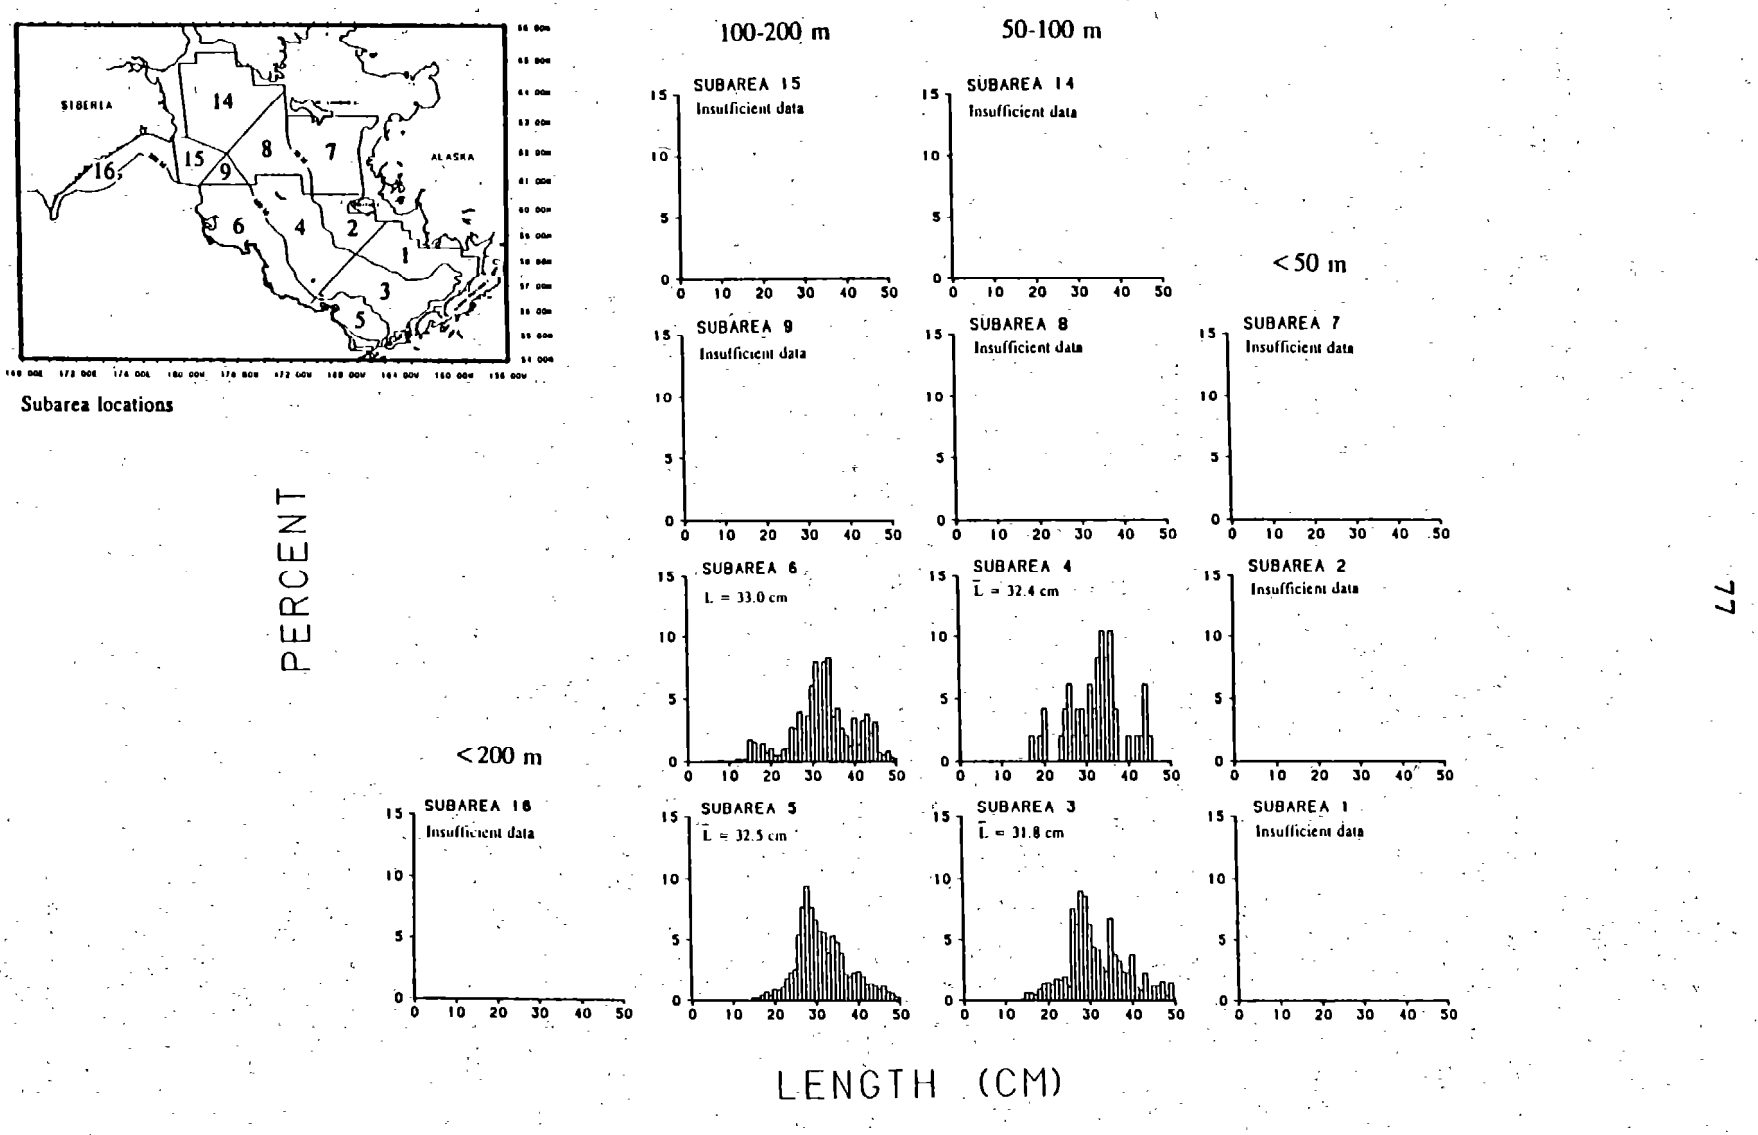

Figure 36.--Estimated relative size composition of <u>Atheresthes</u> sp. (sexes combined) by subarea during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

Pacific halibut

Distribution and abundance--Pacific halibut were encountered in all subareas with the exception of subarea 8 (Fig. 37). The mean CPUE for the entire survey area was 1.4 kg/ha trawled (Table 16). Mean catch rates ranged from 2.15 kg/ha in the standard U.S. shelf to 0.6 kg/ha in the western area and less than 0.1 in the north shelf area. Pacific halibut were most abundant in subarea 3 with catches averaging 3.4 kg/ha.

The biomass for Pacific halibut in the total survey area was estimated to be 109,000 t (Table 16). Almost 92% of the total biomass (99,800 t) was located in the standard U.S. shelf with most of the remaining biomass (8%) found in the western area. Less than 1% of the estimated biomass was located in the north shelf area. Population abundance totaled 89.3 million fish with 86.5 million (97%) located in the standard U.S. shelf.

Size composition--Pacific halibut averaged 39.4 cm in length over all areas (Fig. 38). They were largest in the western shelf area averaging 65.6 cm and smallest in the standard U.S. shelf (39.0 cm). A pronounced size mode was apparent at about 30 cm in the standard U.S. shelf. Mean length increased with increasing depth from 28.8 cm in subarea 2 (< 50 m depth zone) to 74.5 cm in subarea 6 (100-200 m depth zone) as shown in Figure 39.

Greenland turbot

Distribution and abundance--Greenland turbot (Reinhardtius hippoglossoides) were encountered at relatively low levels of abundance and occurred at only 20% of the stations (Fig. 40). The overall mean catch rate was less than 0.1 kg/ha (Table 17). They were most abundant at depths of 100-200 m in subareas 6, 9, and 15 with mean CPUE values of 0.29 kg/ha, 0.35 kg/ha, and 1.19 -kg/ha, respectively. Greenland turbot biomass over all areas was estimated at 7,200 t. Nearly 81% of the biomass was

therefore-size composition information is not available. However, based on mean weight data, the largest fish were found in the western shelf area, averaging 0.3-2 kg (Table 17). Greenland turbot were-smallest in the north shelf area with a mean weight of 0.15 kg.

Abundance and Distribution of Major Crab Species

The Russian bottom trawl appeared to have sampled invertebrates poorly based on the results of the comparative trawl experiment. However, since the survey data may provide some insight on the relative distribution and relative abundance of snow crab and king crab, it is summarized here. Snow crab. (C. opilio and C. bairdi combined) was the dominant commercial crab group comprising 7.7% of the total-biomassof fish and

invertebrates combined (Table 7). They were encountered in all subareas at an average catch rate of 16.7 kg/ha. Red and blue king crab were encountered less frequently and had a combined overall catch rate of 0.8 kg/ha trawled.

Tanner crab (Chionoecetes opilio)

Distribution and abundance --Opilio Tanner crab were broadly distributed throughout the survey region (Fig. 41). Largest catches (> 83 kg/ha trawled) generally occurred at bottom water temperatures of 1° C and colder in the northern and central portion of the Bering Sea. The overall mean CPUE for opilio Tanner crab was 14.7 kg/ha (Table 18). The north shelf area had the greatest mean catch rate at 17.5 kg/ha. Catch rates were lowest in the western shelf area at 11.4 kg/ha.

The total biomass and population number of opilio Tanner crab was estimated at 1.1 million t and 21.5 billion crabs, respectively. The distribution of population numbers was markedly different than the biomass distribution. Approximately 62% of the total estimated biomass and 35% of the population numbers were located in the standard U.S. shelf while 22% of the biomass and over one-half (52%) of the population were found in the north shelf region. This was due to the large number of small crab in north shelf subareas 7 and 8. The western shelf area accounted for 15% of the total biomass and nearly 13% of the population number.

[a]Differences in totals and sums of biomass and population numbers by subarea are due to rounding.

Tanner crab (C. bairdi)

Distribution and abundance--Bairdi Tanner crab were primarily found in areas where-water temperatures was 2° C or warmer in the southern portion of the standard shelf and in western shelf subarea 16 (Fig. 42). This species was not encountered in the north shelf area or subarea 14 of the western shelf. The overall CPUE was 1.5 kg/ha with highest mean catch rates located in subarea 3 at 5.3 kg/ha (Table 19). Bairdi Tanner crab were least abundant in subareas 2 and 15 averaging 0.4 kg/ha.

The biomass of bairdi Tanner crab was estimated at 115,911 t with population numbers totaling 596 million crabs. Eighty-six percent of the biomass was located in the standard U.S. shelf with the remaining 14% in the western shelf region. Mean individual crab weights were highest in the western shelf region with an average weight of 0.36 kg compared to 0.18 kg in the standard U.S. shelf.

Red king crab

Distribution and abundance--Red king crab (Paralithodes camtschatica) occurred at 33 stations. Their distribution was limited to the southeastern portion of the survey area although they were observed in one haul in the western shelf area (Fig. 43). This species was not encountered at depths greater than 100 m. The overall average catch rate was 0.6 kg/ha (Table 20).

[b]Differences in totals and sums of biomass and population numbers by subarea are due to rounding.

Red king crab were most abundant in standard U.S. shelf subarea 3 with a mean CPUE of 3.5 kg/ha.

Nearly 100% of the estimated biomass of 45,253 t was located in the standard U.S. shelf with 79% of the total biomass in subarea 3. Estimated population abundance totaled 36.6 million crab over the entire survey area.

Blue king crab

Distribution and abundance--Blue king crab, were infrequently encountered during the survey (Fig. 44). The overall CPUE value averaged 0.22 kg/ha with the highest mean catch rate occurring in the western shelf area at 0.98 kg/ha (Table 21). Catches were lowest in the north shelf region at 0.01 kg/ha. Blue king crab were most abundant in subarea 16 at 2.7 kg/ha. The total area biomass of blue king crab was/estimated at 16,943 t with 92% located in subarea 16. The standard U.S. shelf accounted for 6% of the total biomass while the north shelf area contributed the remaining 2%. Population numbers of blue king crab were estimated at 25.2 million crab for the total survey area.

DISCUSSION

The comparison of results from past U.S. and U.S.-Russian cooperative bottom trawl surveys of the standard U.S. shelf have revealed major differences in abundance estimates. For example, biomass estimates derived from U.S. data for most major fish species sampled in both 1988 and 1989 were significantly greater than estimates derived from data collected aboard Russian research vessels (Table 22). Biomass estimates from the

Table 22. --Biomass estimates (t) for major fish species from the standard U.S. shelf commonly fished during separate U.S. and, cooperative U.S.-Russian bottom trawl surveys conducted during 1988, 1989, and 1990.

	1988		1989		1990	
Species	U.S.	Cooperative U.S.-Russian	U.S.	Cooperative U.S.-Russian	U.S.	Cooperative U.S.-Russian
Walleye pollock	6,922,000	2,052,455	5,921,600	2,922,284	7,656,972	3,153,303
Pacific cod	959,500	531,407	962,500	794,960	744,337	656,577
Yellowfin sole	2,854,600	1,230,268	2,831,800	1,431,121	2,182,822	2,492,097
Rock sole	1,903,500	742,108	1,318,200	988,743	1,410,582	1,304,064
Hippoglossoides spp.	557,500	194,020	523,200	266,947	652,488	333,121
Alaska plaice	936,800	434,279	599,400	369,183	529,387	679,443
Greenland turbot	11,600	3,963	8,900	5,431	14,371	3,156
Atheresthes spp.	306,400	105,841	410,700	170,760	467,522	255,855
Pacific halibut	138,200	50,413	77,100	85,518	89,936	99,754

1988 and 1989 U.S.-Russian cooperative survey data were over 60% lower for many flatfish species when compared to independent U.S. survey estimates. These results most likely reflect a greater fishing efficiency by the U.S. standard 83-112 bottom trawl for

many bottom species relative to the efficiency of the several different Russian trawls used in the cooperative surveys. The Russian sampling net used in 1988 had a 69 m headrope and 85 m footrope with a reported horizontal opening of 29 m and a vertical opening of 5 m. The net used during the 1989 cooperative survey had a 35 m headrope and a reported 22 m horizontal and 12 m vertical opening. There is little information available to fully evaluate these net's bottom-tending characteristics or fishing efficiencies.

Discrepancies in within-year biomass estimates between U.S. and U.S.-Russian cooperative surveys may have also resulted from bias created by navigational equipment. Starting and ending positions aboard the Russian vessels in 1988 and 1989 were generated through a Russian satellite navigation system. This system updated the ship's position at irregular intervals that did not necessarily correspond to the actual beginning and ending times of the haul and resulted in imprecise distance-fished information. Comparisons between survey results are further complicated because the U.S.-Russian cooperative trawl surveys in 1988-1990 started about 2 weeks earlier than the independent U.S. survey. This difference in sampling time may have allowed some portion of the groundfish assemblage to move into or out of the survey area. Such movement may have accounted for some of the differences observed in biomass estimates and population parameters between the two surveys although it is extremely

unlikely to have created the magnitude of differences observed for many species during 1988 and 1989.

The comparison of estimates between the two 1990 surveys showed greater within-year consistency relative to comparisons of the surveys conducted in 1988 and 1989 (Table, 22). Reasons- for such an improvement include: 1) the Russian bottom trawl used during 1990 appears to have tended bottom much better than those used during earlier surveys and 2) the use of the Loran-C navigational system improved the precision of the haul distance actually transected. Percent differences in biomass estimates from the two 1990 surveys were much smaller- for some fish species, including Pacific cod(± 12%), yellowfin sole (± 12%), rock sole (± 8%), and Alaska plaice (+ 22%) than differences seen in earlier years.

Overall mean lengths of flatfish sampled in the standard U.S. shelf during both surveys conducted in 1990 were nearly identical for yellowfin sole, Alaska plaice, and Pacific halibut (Fig. 45). The mean length of rock sole was somewhat smaller (19.5 cm) from the independent U.S. survey compared to the cooperative Russian survey (22.9 cm). The greatest differences in size composition for any species were observed with walleye pollock with a mean length of 41.9 cm using the U.S. survey data and 27.0 cm using the cooperative survey data (Fig. 46). The Russian trawl was apparently much more efficient in capturing juvenile walleye pollock while the U.S. 83-112 trawl appeared more effective in sampling the-adult portion of the population.

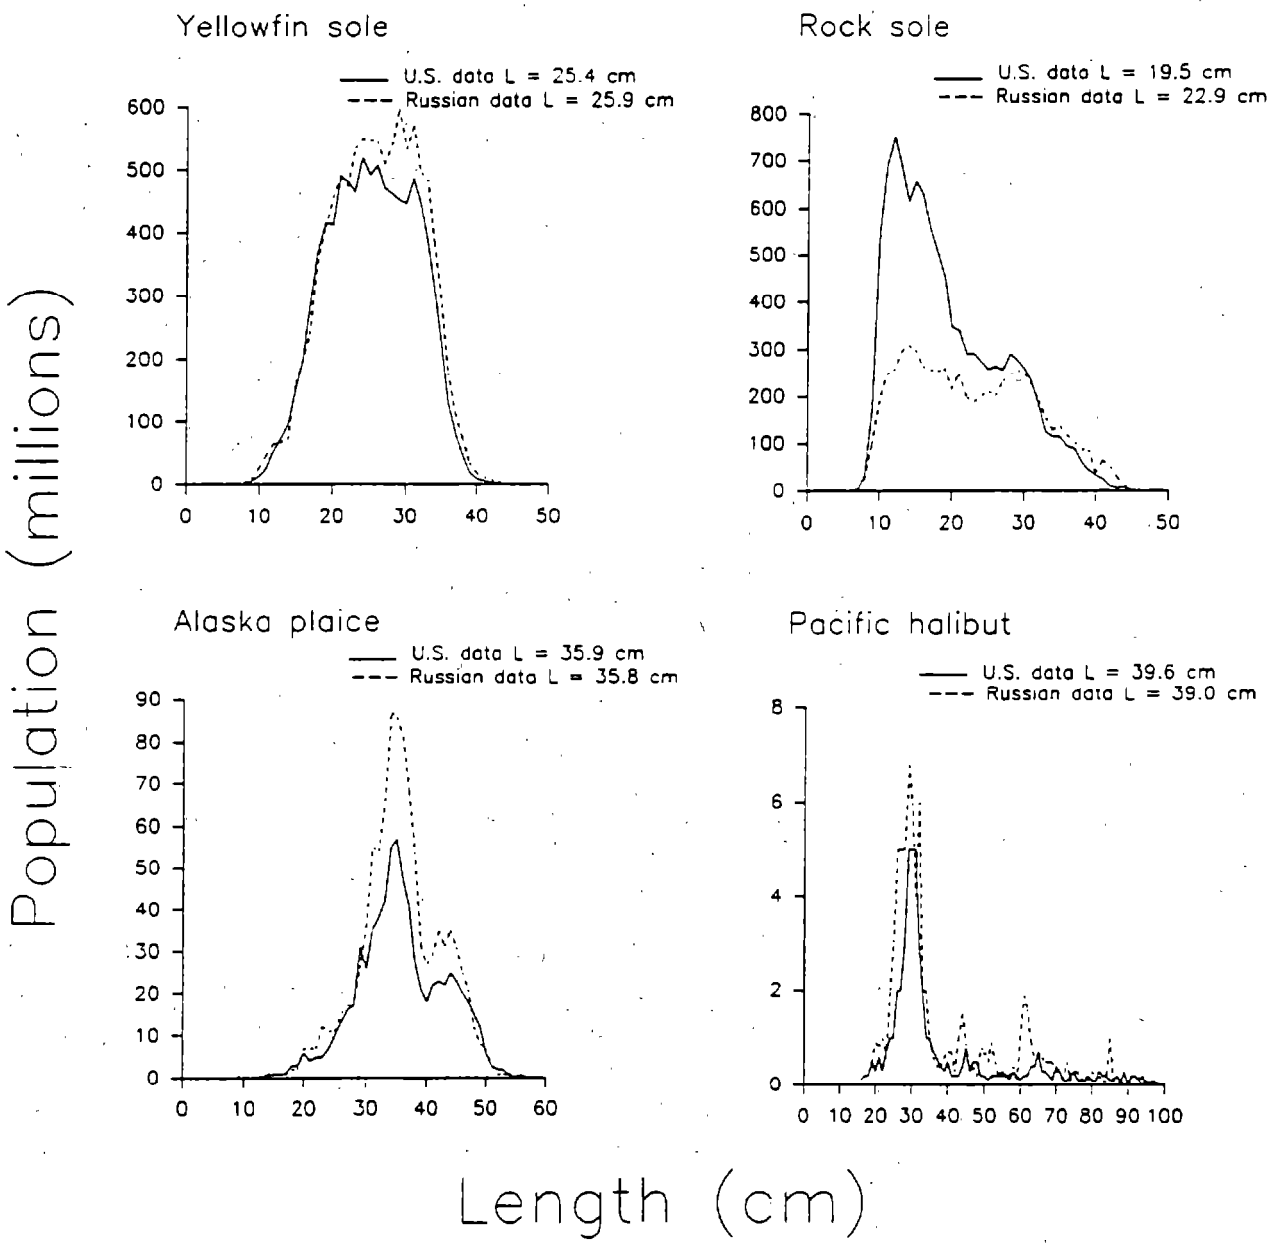

Figure 45. --Length composition of yellowfin sole, rock sole, Alaska plaice, and Pacific halibut during the 1990 independent US. bottom trawl survey and-the 1990 cooperative U.S.-Russian bottom trawl survey. Data is from the standard U.S. area commonly fished during both surveys.

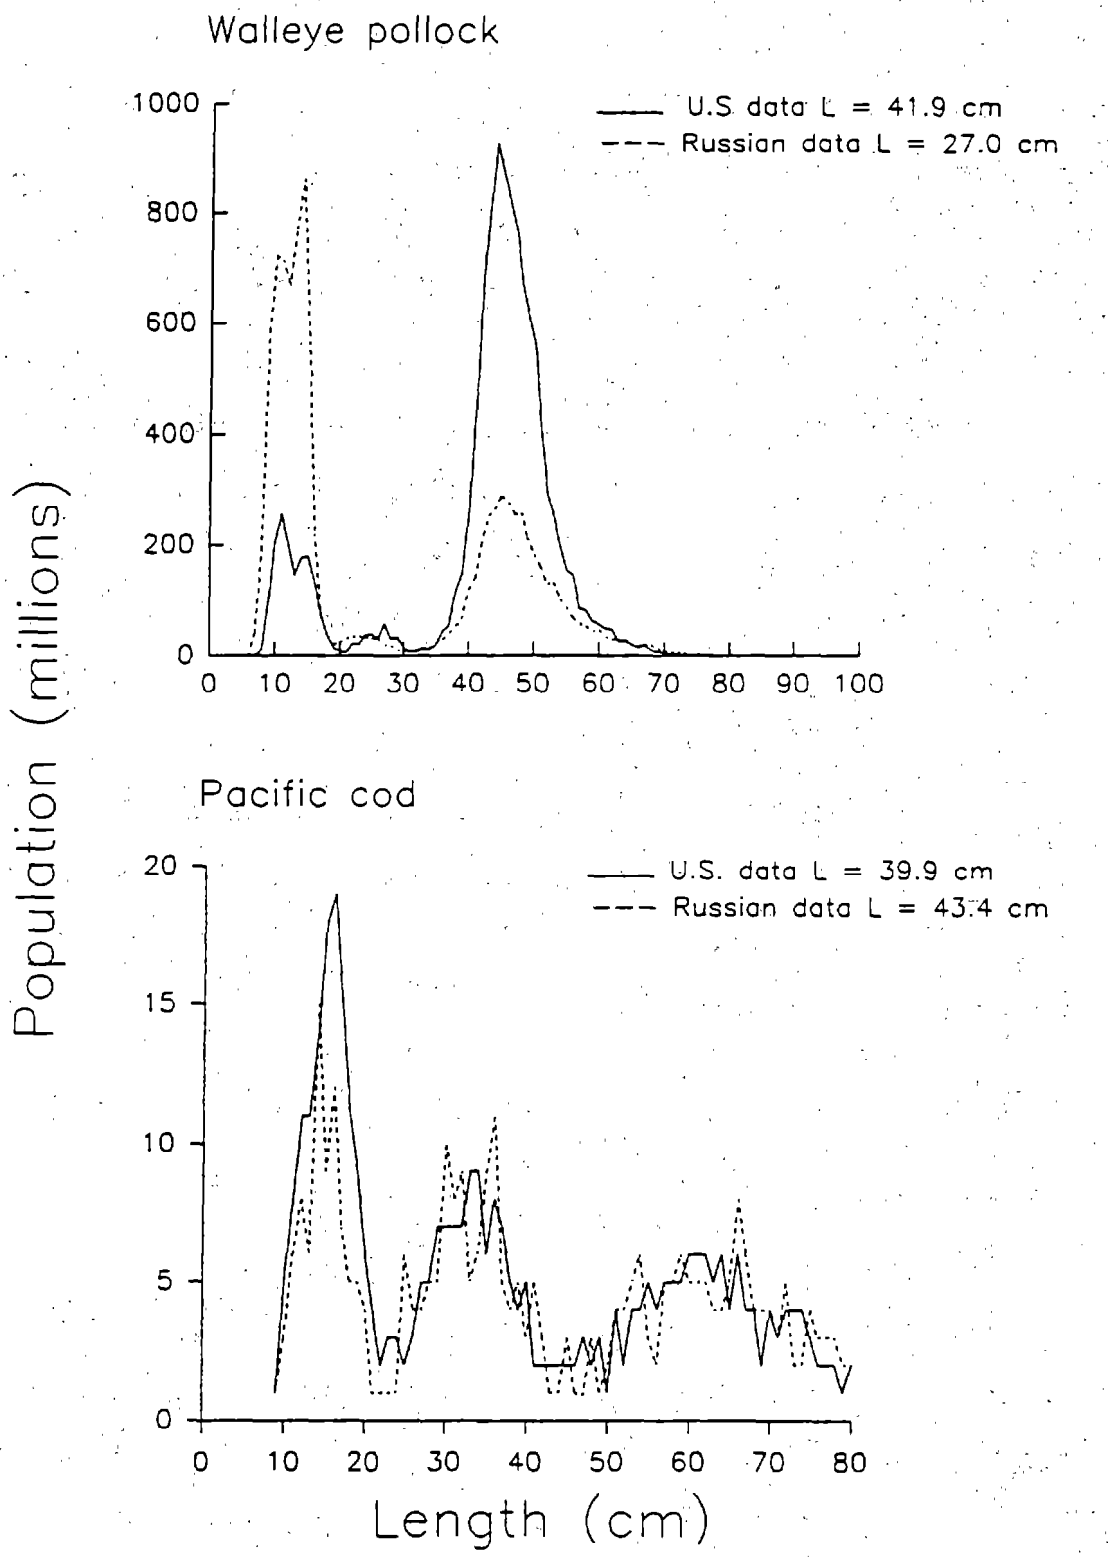

Figure 46.--Length composition of walleye pollock and Pacific cod during the 1990 independent U.S. -bottom trawl survey and the 1990 cooperative U.S.-Russian bottom trawl survey. Data is from the standard U.S. area commonly fished during both surveys.

The size distribution of Pacific cod was similar between data sets although the independent U.S. survey data indicated a somewhat smaller mean length of 39.9 cm compared to the cooperative survey estimate of 43.4 cm.

Information obtained during the 1990 cooperative U.S.-Russian survey has provided U.S. scientists the most complete set of contiguous data to assess the relative distribution, abundance, and biological characteristics of some groundfish and invertebrate species in both the eastern and western portions of the Bering Sea continental shelf. However, biomass and population estimates derived from the 1990 cooperative U.S.-Russian bottom trawl survey. should be considered in relative terms, not absolute terms. Potential bias due to survey timing, sampling density, differences in sampling trawls used between survey years, as well as bottom trawl efficiency can not be fully evaluated in the Russian data sets.

Acknowledgments

The authors wish to express their gratitude to Russian scientist Dr. V. M. Paschenko, the specialists, and crew of the Novokotovsk that participated in this survey. Our appreciation is also extended to U.S. scientists Dennis Benjamin, Doyne Kessler, David Roetcisoender, Pierre Dawson, Ray Baxter, and John Bowerman who assisted in the onboard collection of the data presented in this report.

APPENDIX A

Station, Haul, and Catch Data

Appendix A contains computer listings of stationand catch data for all successfully completed standard stations used in the analysis of the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf. The listing begins with haul number 51. Hauls 1 through 50 were made during an ichthyoplankton survey just prior to the beginning of the bottom trawl survey and are not listed here. Missing haul numbers indicate either unsatisfactory or comparative tows. Station locations by haul number are shown in Figure A-1.

Latitudes and logitudes are in degrees, minutes, and tenths of minutes. Gear depths are in fathoms and catch weights, are in kilograms. Tow duration is in tenths of hours. Distance fished is in nautical miles.

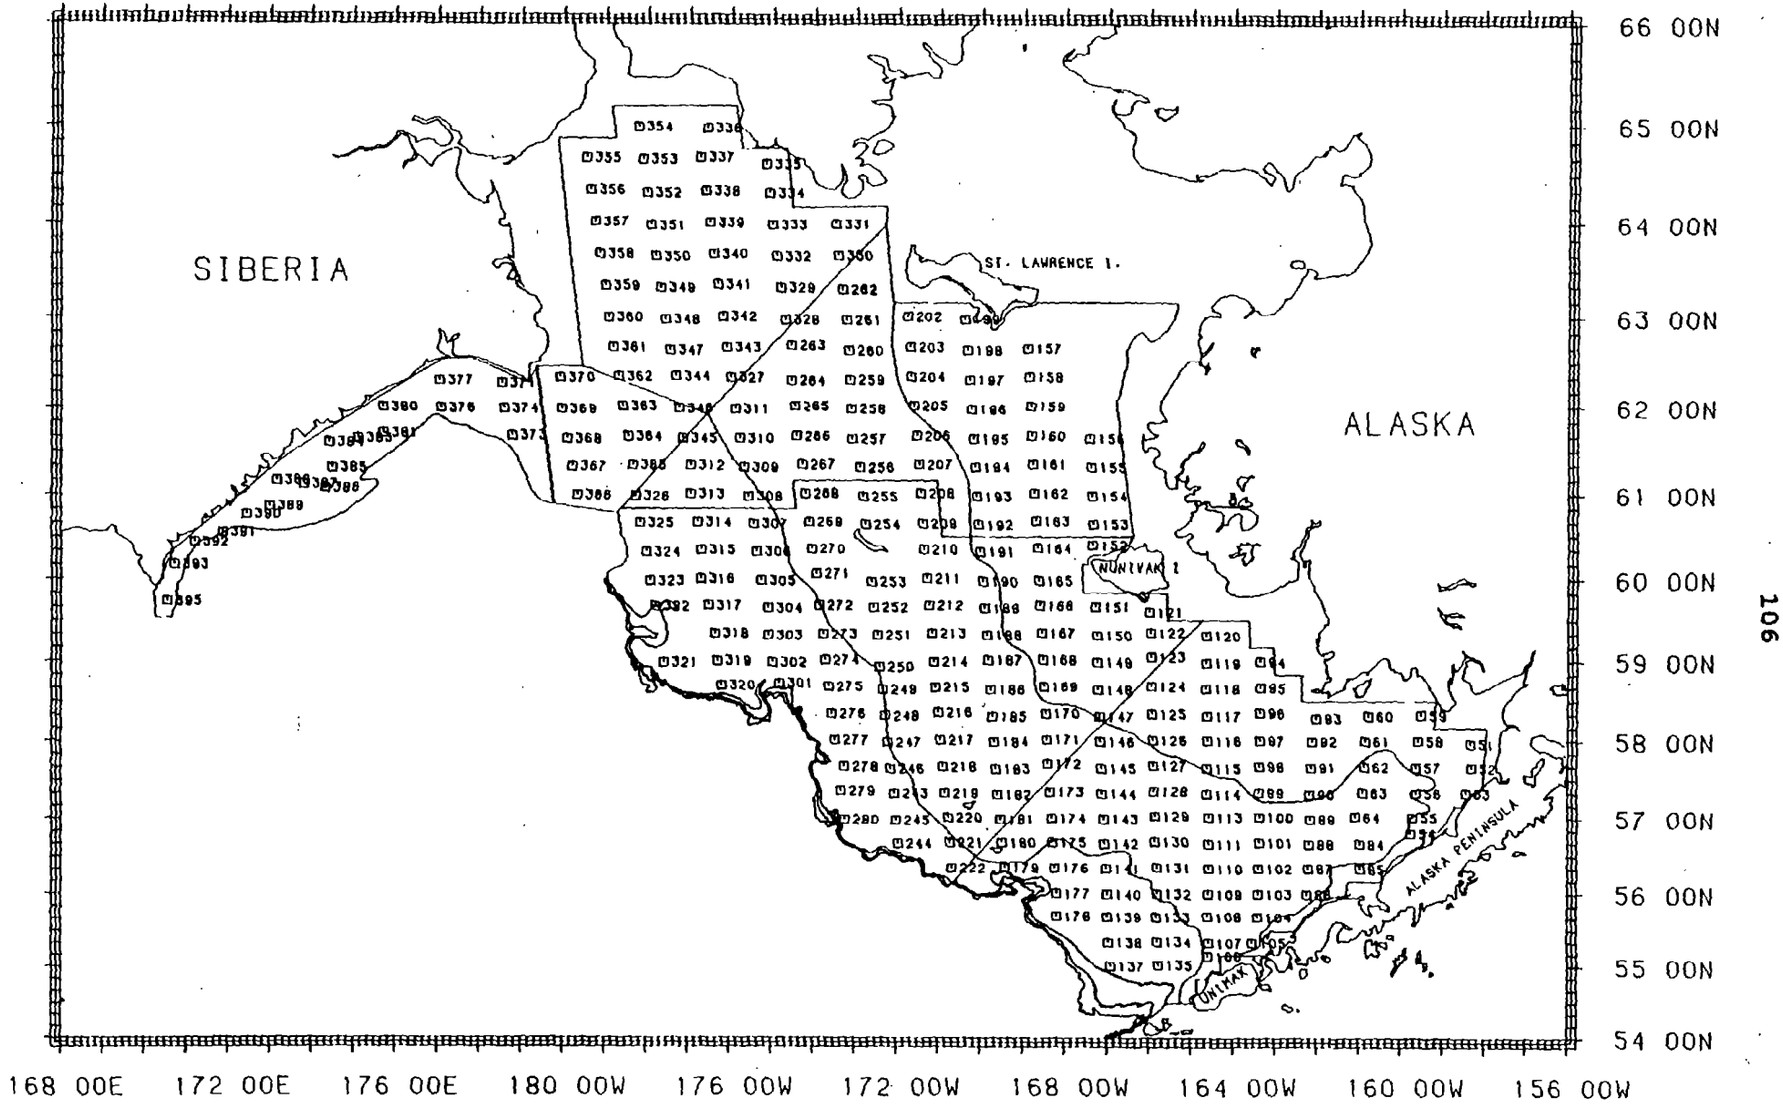

Figure A1.--Sampling sites by haul number from the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

APPENDIX B

Abundance Estimates for Principal Fish Species

Appendix B presents estimates of population size in terms of number of individuals and. biomass estimates in metric tons with confidence intervals for the principal species of fish sampled during the 1990 cooperative-survey. Estimates are given by subarea, standard U.S. area (SA), north shelf (NS), western shelf (WS), and for all areas combined.

APPENDIX C

Population Estimates by Sex and Size Groups for Principal Fish Species

Appendix C presents population estimates for principal fish species by sex-centimeter interval. Estimates are given for the standard U.S. shelf area, north shelf area and, western shelf area.

Table C-l. --Population estimates by sex and size groups for Walleye pollock from the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.

APPENDIX D

Age-Length Keys for Walleye Pollock

Appendix D presents age length keys forwalleye pollock by sex and both sexes combined from the western shelf area collected during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf. Lengths are in millimeters. Asterisks indicated fish lengths for which ages have been interpolated.

List of Tables

Table D-1.--Age-length keys for walleye pollock from age and length data collected during the 1990 cooperative U.S.-Russian bottom trawl survey of the Bering Sea shelf.
