NOAA Technical Memorandum NWS NHC-31

Updated February 1992

THE DEADLIEST, COSTLIEST, AND MOST INTENSE
UNITED STATES HURRICANES OF THIS CENTURY
(AND OTHER FREQUENTLY REQUESTED HURRICANE FACTS)

Prepared by:

Paul J. Hebert, WSFO, Miami, Florida
Jerry D. Jarrell, NHC, Miami, Florida
Max Mayfield, NHC, Miami, Florida

National Hurricane Center
Coral Gables, Florida
February 1992

PREFACE

This version of the Deadliest, Costliest, and Most Intense United States Hurricanes of This Century is an update through the 1991 hurricane season. Hurricane Bob, with about \$1.5 billion damage to the United States East Coast has caused some of the damage tables to be revised. Also, 1990 Census figures have influenced several sections of the text. This is, nevertheless, a fairly minor update of work done by Hebert, Taylor and Case (1984).

THE DEADLIEST, COSTLIEST, AND MOST INTENSE
UNITED STATES HURRICANES OF THIS CENTURY
(AND OTHER FREQUENTLY REQUESTED HURRICANE FACTS)

by

Paul J. Hebert, Weather Service Forecast Office
Jerry D. Jarrell & Max Mayfield, National Hurricane Center
National Weather Service
Miami, Florida.

ABSTRACT

Lists of United States hurricanes which have caused 25 or more deaths and more than one hundred million dollars in damages (unadjusted) during this century have been compiled from all data sources available at the National Hurricane Center (NHC). In addition, all major¹ hurricanes which have made landfall in the United States during this century are listed. Some additional statistics on United States hurricanes of this century and tropical cyclones in general are also presented.

1. INTRODUCTION

Numerous requests are received at the National Hurricane Center for statistical information on deaths, damages, and severity of hurricanes which have affected the United States. Various reference materials gave different estimates of these statistics so that decisions had to be constantly made as to which information should be given out by NHC as "official" from the National Hurricane Information Center (another function of NHC). Requests to other Weather Service Offices posed the same dilemma. These lists are being published in the hope of presenting a single source of the best currently available estimates of deaths, damages, and intensity of major U.S. hurricanes which have made landfall in this century. In some instances, data in these lists present revised estimates for individual hurricanes based on more complete information received after earlier published values, including the previous versions of this technical memorandum. There are other frequently asked questions about hurricanes. What is the average number of hurricanes per year? What year(s) had the most and least hurricanes? What hurricane had the longest life? When did the earliest and latest hurricane occur? What was the most intense Atlantic hurricane? What was the largest number of hurricanes in existence on the same day? When was the last time a major hurricane or any hurricane hit a given community directly²? Answers to these and several other questions are provided in Section 3.

¹ A major hurricane is a category 3, 4, or 5 on the Saffir/Simpson Hurricane Scale (see Table 1), and is comparable to a Great Hurricane in other publications.

² A direct hit means experiencing the core of strong winds and high tides of a hurricane.

Table 1. Saffir/Simpson Hurricane Scale Ranges.

Scale Number (Category)	Central Pressure (Millibars)	OR (Inches)	Winds (Mph)	OR (Feet)	Surge	Damage
1	≥ 980	≥ 28.94	74-95	4-5	Minimal	
2	965-979	28.50-28.91	96-110	6-8	Moderate	
3	945-964	27.91-28.47	111-130	9-12	Extensive	
4	920-944	27.17-27.88	131-155	13-18	Extreme	
5	< 920	< 27.17	> 155	> 18	Catastrophic	

2. CRITERIA

The statistics in most of the tables and figures in this publication depend directly on the criteria used in preparing another study, Hurricane Experience Levels of Coastal County Populations-Texas to Maine (Hebert, Taylor, and Case, 1984). The primary purpose of that study was to demonstrate, county by county, the low hurricane experience level of a large majority of the population. Statistics show that the largest loss of life and, for the most part, property occur in locations experiencing the core of a category 3 or higher hurricane. Unless a given population has experienced this core, or direct hit, with its very strong winds and high tides, it would defeat the primary purpose of the study on hurricane experience levels to so categorize it.

The central pressure ranges of hurricanes on the Saffir/Simpson scale will usually agree quite well with the wind ranges in that category. In the absence of other information, this is normally the best estimate of a hurricane's winds. However, some hurricanes which have developed from winter-type or subtropical low pressure systems occasionally have a minimum central pressure lower than the corresponding observed winds would suggest. In this instance, the wind criteria are used.

On the other hand, the surge is strongly dependent on the slope of the continental shelf (shoaling factor). This can change the height of the surge by a factor of two for a given central pressure and/or maximum wind.

Heavy rainfall associated with a hurricane is not one of the criteria for categorizing it.

The subjective determination of which category number to assign to a hurricane, as well as its direct or indirect effect, is made on a county by county basis with the intent of the study on hurricane experience levels foremost in mind.

As with the assignment of scale numbers, a certain amount of subjectivity was inescapable at times in determining which counties received direct or indirect hits during the various hurricane situations. However, certain arbitrary guidelines for these classifications as used in Hurricane Experience Levels, etc., are indicated below:

Direct Hit - When the innermost core region or "eye" moved over a county, it was counted as a direct hit. Using "R" as the radius of maximum winds in a hurricane (the distance in miles from the storm's center to the circle of maximum winds around the center), all or parts of counties falling within approximately 2R to the right and R to the left of a storm's landfall point were considered to have received a direct hit. (This assumes an observer at sea looking toward the

shore). On the average, this direct hit zone extended about 50 miles along the coastline ($R \approx 15$ miles). Of course, some hurricanes were smaller than this and some, particularly at higher latitudes, were much larger. Cases were judged individually, and many borderline situations had to be resolved.

Indirect Hit - These were based primarily on a hurricane's strength and size, and on the configuration of the individual county coastline. Here again, much subjectivity was necessary in many cases which were complicated by storm paths and geography. Generally, those areas on either side of the direct hit zone which received at least wind gusts of hurricane force and/or tides of 4 to 5 feet or more above normal were considered to have had an indirect hit.

It is realized that the effect of an indirect hit by a large category 4 hurricane might be greater than that of a small category 1 affecting the same county. However, trying to account for these differences would hopelessly complicate the use of this system.

The study by Simpson and Lawrence (1971) gives climatological probabilities of the total number of storms and hurricanes to affect the U.S. coastline by fifty-mile wide coastal segments, as well as only hurricanes, and major (or great) hurricanes. While this 50 miles approximates that of the "core" used for direct hits, there are some differences. In the Simpson and Lawrence study, a storm/hurricane/great hurricane was counted in the segment where it crossed the coast plus the next segment to the right. As indicated earlier, the "core" used in Hebert, Taylor, and Case (1984) can be smaller or larger than 50 miles, and could also affect one of the segments in Simpson and Lawrence to the left of a coastline crossing which that study would not count.

The foregoing two studies and their associated criteria are climatological with their primary purpose being for use in assessing risk based on past experience. On the other hand, the National Weather Service's Hurricane Probability Program has as its purpose the assessment of risk based on a present hurricane threat to the United States coastline. It does this by arbitrarily defining a "strike" as the center of a hurricane moving through a zone within approximately 50 nautical miles to the right or 75 nautical miles to the left of the site of interest (Sheets, 1984). The asymmetry is to allow for the strongest winds in a hurricane frequently being further to the right of the center than the left - a consideration reflected also in the earlier studies discussed. This 125 nautical mile diameter circle approximates the region of hurricane force winds for a "typical" hurricane. It will usually be larger than the "core", and is fixed, like the segments in Simpson and Lawrence. **HURRICANE STRIKE PROBABILITIES HAVE NO RELATION TO HURRICANE INTENSITY.** Users of these probabilities must take this into account when assessing risk, based on the forecast time before landfall and strength. The reader is urged to refer to The

National Weather Service Hurricane Probability Program (Sheets, 1984) for a more thorough explanation of forecast probabilities.

Statistics on total storm/hurricane activity in the North Atlantic Ocean (which includes the Gulf of Mexico and the Caribbean Sea) can be found in Neumann, et al (1987). A detailed breakdown of hurricanes by category which have affected coastal counties of the Gulf of Mexico and North Atlantic Ocean both directly and indirectly can be found in Hebert, Taylor, and Case (1984), which has been updated where necessary for this technical memorandum. The best source of how a hurricane affected individual localities or states can be found in the annual articles on the hurricane season in the Monthly Weather Review (1990 for example), the Diagnostic Report of the National Hurricane Center (1991 for example) and Storm Data (1990 for example).

3. DISCUSSION

Part I

- (1) What have been the deadliest hurricanes of this century in the United States?

Table 2 lists the 31 deadliest hurricanes to strike the U.S. in this century. Although technically incorrect, we have included 1900 in "this century". Three hurricanes prior to 1900 as well as a tropical storm which affected southern California in 1939 are listed as an addendum because of their large death tolls.

- (2) What have been the costliest hurricanes of this century in the United States?

Table 3 lists the 32 costliest hurricanes to strike the U.S. in this century. Figures are unadjusted for inflation. Table 3a re-orders some of these plus several other hurricanes after adjusting to 1990 dollars³.

- (3) What have been the most intense hurricanes to strike the United States during this century?

Table 4 lists the 60 major hurricanes which have struck the U.S. during this century. Hurricanes are ordered by the lowest estimated central pressure and/or highest category to affect the United States at time of landfall.

A look at the lists of deadliest and costliest hurricanes of this century reveals several striking facts: (1) The twelve deadliest hurricanes were all the equivalent of a category 4 or higher, if the excessive forward speed is considered as raising the category of a hurricane by one. (2) Large death totals were primarily a result of the 15 to 20 feet or more rise of the ocean (storm surge) associated with many of these major hurricanes. All but four of the thirty-one deadliest hurricanes were major hurricanes. Two of the four were the inland flood-producing hurricanes Agnes and Diane. (3) A large portion of the damage in three of the twelve costliest tropical cyclones (Table 3) resulted from inland flooding caused by torrential rainfall in mountainous areas. (4) Nearly three-fifths of the deadliest hurricanes were the equivalent of a category four or higher, but only two-fifths of the costliest hurricanes (Table 3) met this criterion. (5) Only one of the deadliest hurricanes has occurred during the past twenty years in contrast to about half of the costliest hurricanes.

³ Adjusted to 1990 dollars on basis of U.S. Department of Commerce composite construction cost indexes.

DIRECT HITS BY HURRICANES
U.S. GULF & ATLANTIC COASTS
1900-1991

Category 5:	2
4:	14
3:	44
2:	35
1:	57
<u>TOTAL</u>	<u>152</u>

Major hurricanes (categories 3,4,5): 60

This means that during the period 1900-1991, an average of 2 major hurricanes every 3 years made landfall somewhere along the U.S. Gulf or Atlantic coast. (All categories combined average about 5 hurricanes every 3 years for the same period.)

One of the greatest concerns of the National Weather Service's (NWS) hurricane preparedness officials is that the statistics in tables 1-4 will mislead people into thinking that no more large loss of life will occur in a hurricane because of our advanced technology. Dr. Robert Sheets, spokesman for the NWS hurricane warning service and Director of NHC, as well as former Director, Dr. Neil Frank, have repeatedly emphasized the great danger of a catastrophic loss of life in a future hurricane if proper preparedness plans for vulnerable areas are not formulated.

The study by Hebert, Taylor, and Case (1984), now being updated with 1990 census data, shows that 85% of U.S. coastal residents from Texas to Maine have never experienced a direct hit by a major hurricane. Many of those 45 million residents had moved to coastal sections during the past twenty-five years. Even the landfall of Hugo has not lessened an ever increasing concern brought by the continued increase in coastal populations.

A look at Table 5 which lists hurricanes by decades in this century shows that during the twenty year period 1960-1979 both the number and intensity of landfalling U.S. hurricanes decreased sharply! Based on 1900-1959 statistics from the same study, the expected number of hurricanes and major hurricanes during the period 1960-1979 was 36 and 15, respectively. In fact, only 27 or 75% of the expected number of hurricanes struck the U.S. with only 10 major hurricanes or 67% of that expected number. The decade of the eighties showed little change to this trend.

Hurricane Hugo became the first category 4 or 5 hurricane to strike the U.S. since Camille in 1969, a period of 20 years. On the average a category 4 or greater hurricane strikes the U.S. once every 6 years.

Fewer hurricanes do not necessarily mean a lesser threat of disaster, however. The 1919 hurricane which was both the third deadliest and third most intense of this century to strike the U.S. occurred in a year which had a total of only three storms/hurricanes. The most intense U.S. hurricane of record in 1935 and the eighth costliest in 1965 (Betsy) occurred in years which had a total of only six storms/hurricanes.

The conclusions are obvious. A large death toll in a U.S. hurricane is still possible. The decreased death totals in recent years may be as much a result of lack of major hurricanes striking the most vulnerable areas as they are of any fail-proof forecasting, warning, and observing systems. Continued coastal growth and inflation will almost certainly result in every future major landfalling hurricane (and even weaker hurricanes and tropical storms) replacing one of the current costliest hurricanes. If warnings are heeded and preparedness plans developed, the death toll can be reduced, but, in the absence of a change of attitude or laws restricting building near the ocean, large property losses are inevitable.

Table 5. Number of hurricanes of various categories to strike the United States each decade. Updated from Hebert and Case (1990).

DECADE	CATEGORY					ALL	MAJOR
	1	2	3	4	5	1,2,3,4,5	3,4,5
1900-1909	5	5	4	2		16	6
1910-1919	8	3	5	3		19	8
1920-1929	6	4	3	2		15	5

1900-1991	57	35	44	14	2	152	60

Note: Only the highest category to affect the U.S. has been used.

Part II

In addition, to information about U.S. hurricanes, this section will also include statistics on total tropical storm and hurricane activity.

- (1) What is the average number of hurricanes per year?

Table 6 gives the average number of tropical cyclones which reached storm strength and hurricane strength for various time periods. A total of ten tropical cyclones reaching storm strength with six of these becoming hurricanes appears to be the best averages to use based on the past 40 to 50 year time period. The averages of eight tropical cyclones and five hurricanes for the longer 106-year period is a reflection of less detection and fewer actual storms prior to 1930.

- (2) What year(s) have had the most and least hurricanes?

Table 7 shows the years of maximum and minimum tropical cyclone and hurricane activity for the entire Atlantic Ocean. The only years when a hurricane failed to strike the U.S. coast were 1902, 1905, 1907, 1914, 1922, 1927, 1930, 1931, 1937, 1951, 1958, 1962, 1973, 1978, 1981, 1982 and 1990. Note that only twice has the U.S. gone as long as two years without a hurricane. The most hurricanes to strike the U.S. in one year were six in 1916 and 1985. There were five in 1933, and four in 1906, 1909, and 1964. Three hurricanes have struck the U.S. in one year a total of fifteen times. Ten of these fifteen times occurred during the sixteen years from 1944 to 1959! A chronological list of all hurricanes to strike the U.S. during this century through 1982 including month, category by states affected, and minimum sea level pressure at landfall can be found in Hebert, Taylor, and Case (1984). That publication is targeted for updating during 1992.

Table 6. Average number of tropical cyclones which reached storm strength and hurricane strength for various time periods. Updated from Neumann, et al (1987).

PERIOD	NUMBER OF YEARS	AVERAGES (PER YEAR)	
		TROPICAL CYCLONES	HURRICANES
1886-1991	106	8.4	4.9
1942-1991	50	9.8	5.7
1952-1991	40	9.7	5.6
1962-1991	30	9.6	5.4
1972-1991	20	9.4	5.1
1977-1991	15	9.5	5.3
1982-1991	10	9.2	4.8

Includes subtropical storms after 1967.

Table 7. Years of maximum and minimum tropical cyclone and hurricane activity in the North Atlantic Ocean, Caribbean Sea, and Gulf of Mexico during the period 1871-1991 (from Neumann, et al, 1987).

MAXIMUM ACTIVITY

TROPICAL CYCLONES ¹		HURRICANES ²	
NUMBER	YEAR(S)	NUMBER	YEAR(S)
21	1933	12	1969
18	1969	11	1916, 1950
17	1887	10	1887, 1893, 1933
16	1936	9	1955, 1980

MINIMUM ACTIVITY

TROPICAL CYCLONES ¹		HURRICANES ²	
NUMBER	YEAR(S)	NUMBER	YEAR(S)
1	1890, 1914	0	1907, 1914
2	1925, 1930	1	1890, 1905, 1919, 1925
		2	1895, 1897, 1904, 1917, 1922, 1930, 1931, 1982

¹ Includes subtropical storms after 1967. See Neumann, et al (1987).

² After 1885.

- (3) When did the earliest and latest hurricane occur?

The hurricane season is defined as June 1 through November 30. An early hurricane can be defined as occurring in the three months prior to the start of the season, and a late hurricane can be defined as occurring in the three months after the season. With these criteria the earliest observed hurricane in the Atlantic was on March 7, 1908, while the latest observed hurricane was on December 31, 1954. The earliest hurricane to strike the U.S. in this century was Alma which struck northwest Florida on June 9, 1966. The latest hurricane to strike the U.S. was late on November 30, 1925 near Tampa, Florida.

- (4) What were the longest-lived and shortest-lived hurricanes?

Ginger in 1971 holds the record for both the most number of days as a hurricane (20) and tropical cyclone (31). There have been many tropical cyclones which attained hurricane intensity for periods of 12 hours or less.

- (5) What were the strongest and weakest Atlantic hurricanes? To strike the United States?

In terms of central pressure (and probably winds) the strongest observed hurricane in the Atlantic basin was Gilbert in 1988 with a pressure of 888 millibars while located in the northwest Caribbean. The 1935 Labor Day hurricane in the Florida Keys with a pressure of 892 millibars was the strongest hurricane to strike the U.S. Numerous hurricanes have reached only the minimum wind speed near 74 miles per hour and struck the U.S.

- (6) How many hurricanes have there been in each month?

Table 8 adapted from Neumann, et al (1987) shows the total and average number of tropical cyclones and those which became hurricanes by months for the period 1886-1991. In addition, the monthly total and average number of hurricanes to strike the U.S. in this century (updated from Hebert and Case, 1990) are given.

Table 8. Total and average number of tropical cyclones and hurricanes in the North Atlantic Ocean, Caribbean Sea, and Gulf of Mexico by month of origin for the period 1886-1991 (from Neumann, et al, 1987), and for hurricanes striking the U.S. coast in this century (updated from Hebert and Case, 1990).

MONTH	TROPICAL CYCLONES ¹		HURRICANES		U.S. HURRICANES ²

¹ Includes subtropical storms after 1967. See Neumann, et al (1987) for details.

² 1900-1991.

* Less than 0.05.

- (7) What was the largest number of hurricanes in existence in the Atlantic Ocean at the same time?

According to information on the current version of the master data file of Neumann, et al (1987), there have never been four hurricanes in existence in the North Atlantic at the same time in this century. On August 22, 1893 four hurricanes co-existed, one of them being the hurricane which killed an estimated 2,000 people in Georgia-South Carolina several days later. On September 11, 1961 three hurricanes and possibly a fourth existed. The only other years in this century with three hurricanes on the map at the same time were 1950 and 1967.

- (8) How many direct hits by hurricanes of various categories have affected each state?

Table 9, updated from Hebert and Case (1990), shows the number of hurricanes (direct hits) affecting the U.S. and individual states. The table shows that on the average close to two hurricanes per year strike the U.S., while two major hurricanes cross the U.S. coast somewhere every three years. Other noteworthy facts, updated from Hebert and Case (1990), are: 1.) Thirty-six percent of all U.S. hurricanes hit Florida; 2.) Sixty-nine percent of category 4 or higher hurricanes have hit either Florida or Texas; 3.) Along the middle Gulf coast, southern Florida, and New York and southern New England, approximately one out of every two hurricanes is major one.

Table 9. Number of hurricanes (direct hits) affecting the U.S. and individual states 1900-1991 according to Saffir/Simpson scale (updated from Hebert and Case, 1990).

AREA	CATEGORY NUMBER					ALL	MAJOR HURRICANES (≥3)

Maine	5	0	0	0	0	5	0

*. Indicates all hurricanes in this category were moving greater than 30 mph.

Note: State totals will not equal U.S. totals and Texas and Florida sectional totals will not necessarily equal state totals.

- (9) When are the major hurricanes likely to strike given areas?

Table 10 shows the incidence of major hurricanes by months for the U.S. and individual states. For the United States as a whole, September has had more major hurricanes than all other months combined. However, three of the most devastating hurricanes did not occur in September--AUDREY (June 1957), CAMILLE (August 1969), and HAZEL (October 1954). Only in Texas and Louisiana are major hurricanes in August and September almost an equal threat. Most major October hurricanes occur in southern Florida.

- (10) How long has it been since a major hurricane directly hit a given community? Any hurricane? Indirectly?

Table 11 summarizes the occurrence of the last major hurricane or of any hurricane to directly hit the more populated coastal communities from Brownsville, Texas to Eastport, Maine. In addition, if a hurricane indirectly affected a community after the last direct hit, it is listed in the last column of the table.

Perhaps the most illustrative example of the uncertainty of when a hurricane might strike a given locality is Pensacola, Florida. Although Dunn (1967) listed Pensacola as the city with the second highest frequency of hurricane force winds in the United States (1 in 10), it has been more than 60 years since any hurricane directly struck Pensacola!

In order to obtain the same type of information listed in Table 11 for the remaining coastal communities, the reader is referred to Hebert, Taylor, and Case (1984).

- (11) What is the total United States damage (unadjusted and adjusted) and death toll for each year of this century?

Table 12 summarizes this information. Tables 12a-c rank the years. In most years the death and damage totals are usually the result of a single, major hurricane. Gentry (1966) gives damages adjusted to 1957-59 costs as a base for the period 1915-1965. For the most part, death and damage totals for the period 1915-1965 were taken from Gentry's paper, and for the remaining years from the Monthly Weather Review. Adjusted damages were calculated to 1990 dollars by the same factors as used in Table 3a.

Table 10. Incidence of major hurricanes (direct hits) by months to affect the United States and individual states (1900-1991) according to the Saffir/Simpson Scale (updated from Hebert and Case, 1990).

² Considered too high in 1915 reference.

³ Using 1915 cost adjustment base - none available prior to 1915.

(12) Are there hurricane cycles?

Figures 1 through 10 show the landfalling portion of the tracks of major hurricanes which have struck any portion of the United States during this century.

The reader might note the tendency of the major hurricanes to cluster in certain areas during certain decades. Another interesting point is the general tendency for this clustering to occur in the latter half of individual decades in one area and in the first half of individual decades in another area. During the very active period of the thirties this clustering is not apparent.

A comparison of twenty-year periods beginning in 1900 indicates that the major hurricanes tended to be in the western Gulf Coast states at the beginning of the century, shifting to the eastern Gulf Coast states and Florida during the next twenty years, then to Florida and the Atlantic Coast states during the forties and fifties, and back to the western Gulf Coast states in the sixties and seventies. Do figures 9 and 10 indicate a shift to the eastern Gulf Coast state Florida, and the Atlantic Coast states in the eighties and nineties?

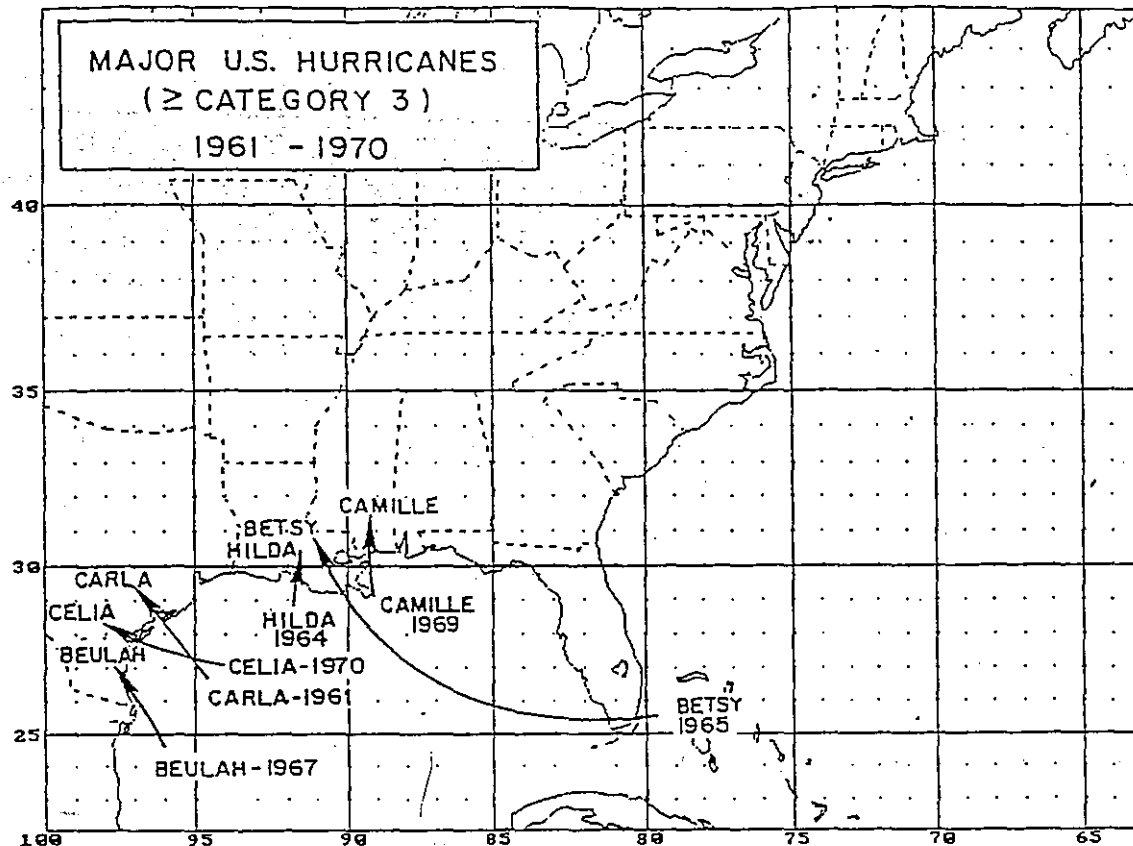

Figure 7. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1961-1970.

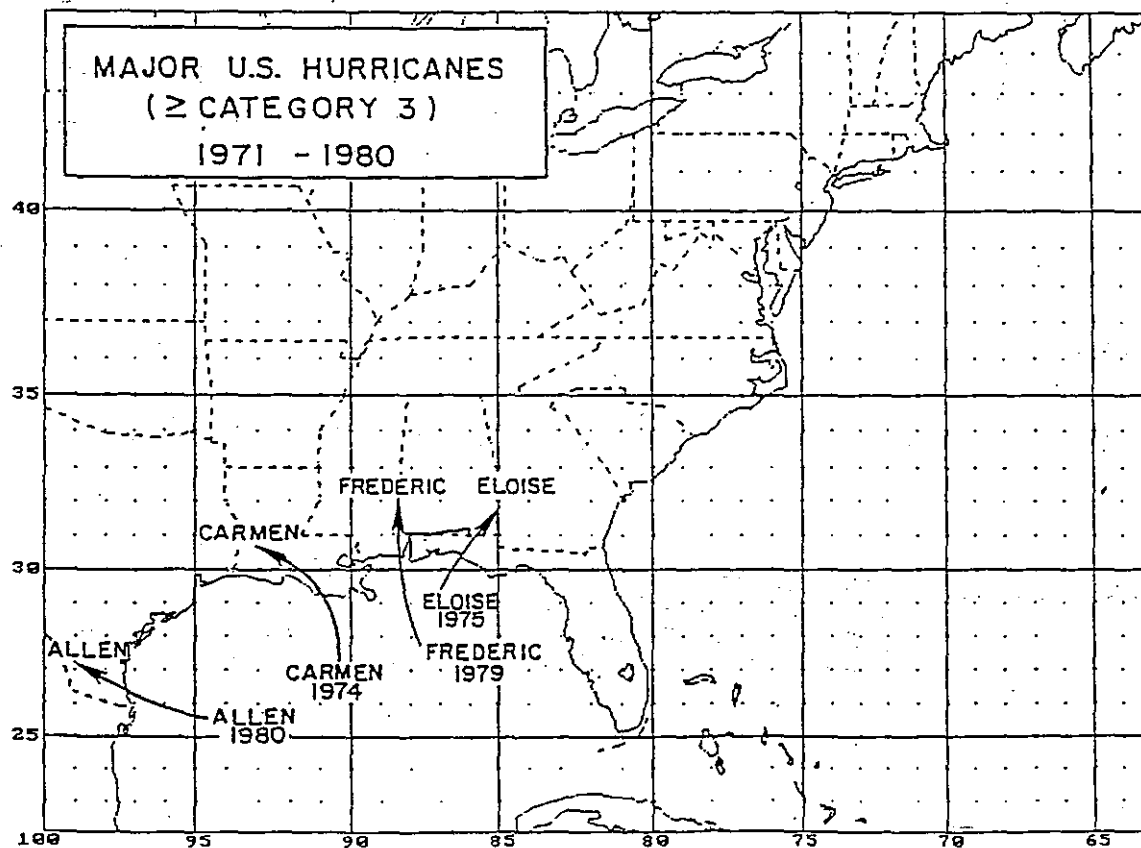

Figure 8. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1971-1980.

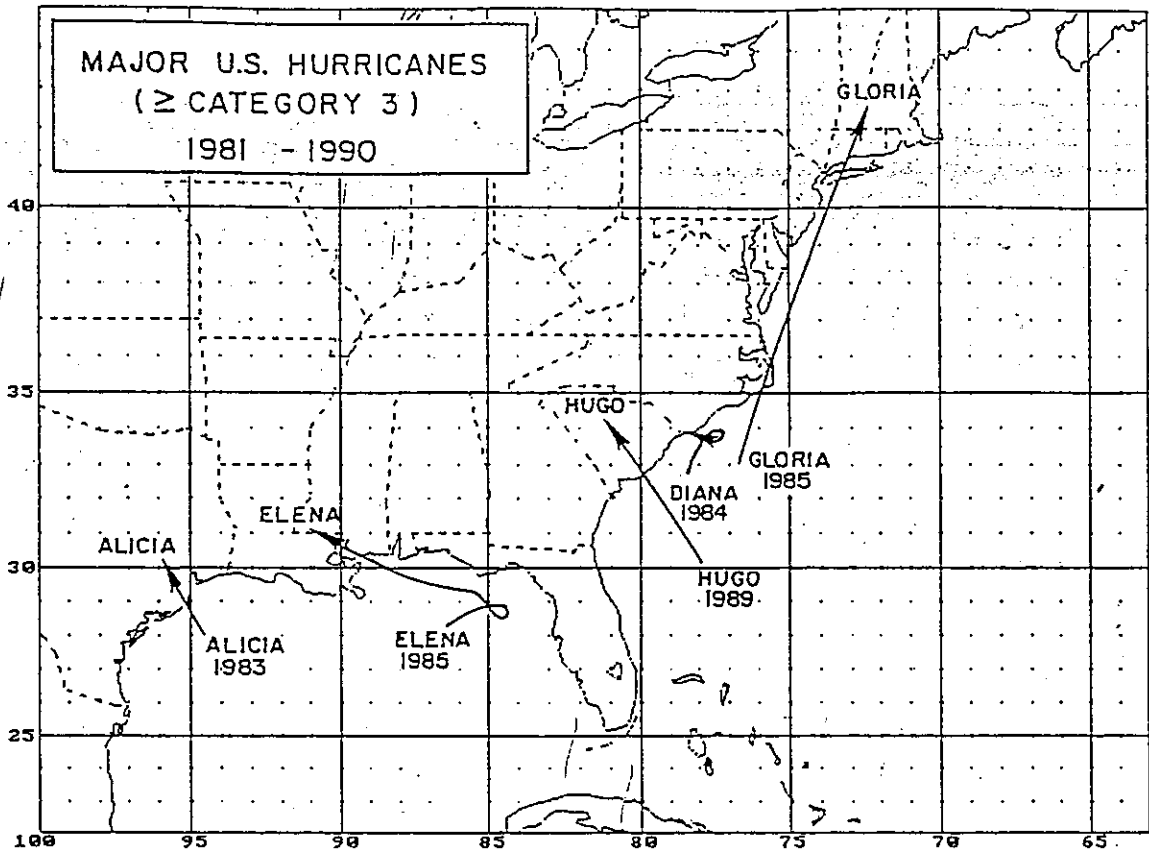

Figure 9. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1981-1990.

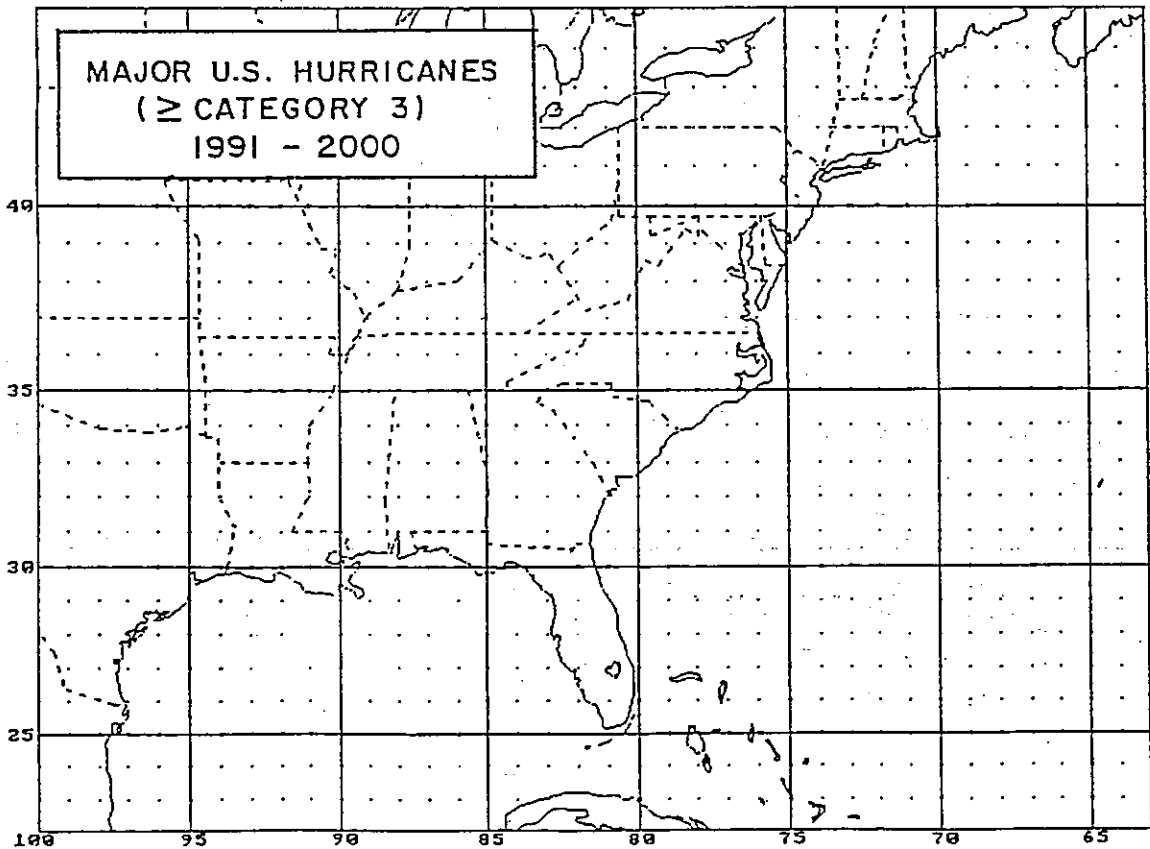

Figure 10. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1991-2000.

(13) Are there hurricane cycles evident in certain years regardless of category or geographical area?

Table 13 gives a tabulation of hurricanes of all categories to affect the U.S. by individual years within each decade.

Table 13. Major and all category landfalling hurricanes in the United States by individual years.

	<u>MAJOR HURRICANES</u>										
	00	01	02	03	04	05	06	07	08	09	Total
1900-09	1						2			3	6
1910-19	1					2	2	1	1	1	8
1920-29		1					2		1	1	5
1930-39			1	3	1	1	1		1		8
1940-49		1	1		2	1		1	1	1	8
1950-59	2				3	2		1		1	9
1960-69	1	1			1	1		1		1	6
1970-79	1				1	1				1	4
1980-89	1			1	1	2				1	6
TOTAL	7	3	2	4	9	10	7	4	4	10	60
1990-99		1									

	<u>ALL HURRICANES</u>										
	00	01	02	03	04	05	06	07	08	09	Total
1900-09	1	2		2	1		4		1	4	15
1910-19	2	2	2	2		3	6	1	1	1	20
1920-29	2	2		1	2	1	3		2	2	15
1930-39			2	5	2	2	3		2	1	17
1940-49	2	2	2	1	3	3	1	3	3	3	23
1950-59	3		1	3	3	3	1	1		3	18
1960-69	2	1		1	4	1	2	1	1	2	15
1970-79	1	3	1		1	1	1	1		3	12
1980-89	1			1	1	6	2	1	1	3	16
TOTAL	14	12	8	16	17	20	23	8	11	22	151
1990-99		1									

Figures 1 through 10 certainly support the existence of a cyclical nature of major hurricanes affecting given regions. Table 13 is also suggestive of preferred periods. However, it is left to the reader to decide what weight should be given to these statistics.

SUMMARY

In virtually every coastal city of any size from Texas to Maine, both present National Hurricane Center Director, Dr. Robert Sheets, and former Director, Dr. Neil Frank, have stated that the United States is building toward a hurricane disaster. The population growth versus low hurricane experience levels indicated in Hebert, Taylor, and Case (1984), together with updated statistics presented in the discussion section of this paper, form the basis for their statements. Stated simply, the areas of the United States where 9 out of 10 persons have lost their lives by drowning from the storm surge during hurricanes (along the immediate Gulf of Mexico and Atlantic shorelines) are the very areas where the most dramatic increases in population have occurred in recent years. This situation, in combination with continued building on low coastal elevations, will lead to serious problems for many areas in future hurricanes. Since it is likely that people will always live along the immediate shoreline, a pleasant way of life, the solution to the problem lies in education and preparedness.

The message to coastal residents is this: Become familiar with what hurricanes can do, and when a hurricane threatens your area, increase your chances of survival by moving away from the water until the hurricane has passed! Unless this message is clearly understood by coastal residents through a thorough and continuing preparedness effort, a future disaster is inevitable.

Acknowledgements: The work of J.G. Taylor and R.A. Case, co-authors of previous versions of this paper, contributed much. Joan David drafted the figures. Linda Kremkau provided the 1990 census data.

NOAA SCIENTIFIC AND TECHNICAL PUBLICATIONS

NOAA, the *National Oceanic and Atmospheric Administration*, was established as part of the Department of Commerce on October 3, 1970. The mission responsibilities of NOAA are to monitor and predict the state of the solid Earth, the oceans and their living resources, the atmosphere, and the space environment of the Earth, and to assess the socioeconomic impact of natural and technological changes in the environment.

The six Major Line Components of NOAA regularly produce various types of scientific and technical information in the following kinds of publications:

PROFESSIONAL PAPERS—Important definitive research results, major techniques, and special investigations.

TECHNICAL REPORTS—Journal quality with extensive details, mathematical developments, or data listings.

TECHNICAL MEMORANDUMS—Reports of preliminary, partial, or negative research or technology results, interim instructions, and the like.

CONTRACT AND GRANT REPORTS—Reports prepared by contractors or grantees under NOAA sponsorship.

TECHNICAL SERVICE PUBLICATIONS—These are publications containing data, observations, instructions, etc. A partial listing: Data serials; Prediction and outlook periodicals; Technical manuals, training papers, planning reports, and information serials; and Miscellaneous technical publications.

ATLAS—Analysed data generally presented in the form of maps showing distribution of rainfall, chemical and physical conditions of oceans and atmosphere, distribution of fishes and marine mammals, ionospheric conditions, etc.

Information on availability of NOAA publications can be obtained from:
