Table S2. Individual lengths (in mm). Upon identification and count, individuals were re-frozen for length measurements at a later time. For the six species selected in this study, the plan was to take length measurements for (nearly) all individuals in the species if found in sufficient quantity in both the marsh and seagrass habitats for adequate comparison of individual length between the habitats (i.e., individuals present consistently in the habitat throughout the sampling period in sufficient quantity to allow for adequate statistical power in the comparison of individual length between the habitats). For those species without sufficient individuals for adequate individual length comparison between the habitats, the plan was to simply measure the length of a subset of the individuals captured taken randomly to obtain a representative idea of their size range. Given this, we measured individual length for nearly all captured individuals of blue crab, brown shrimp, and white shrimp, but only for a subset of captured individuals of American silver perch, pinfish, and spotted sea trout. However, upon further consideration, we realized the results of the individual length comparisons between the habitats could be confounded by the different gear used in the comparison and, thus, discarded those comparisons.

Blue Crab
