NOAA TECHNICAL REPORTS

National Marine Fisheries Service, Special Scientific Report—Fisheries Series

The major responsibilities of the National Marine Fisheries Service (NMFS) are to monitor and assess the abundance and geographic distribution of fishery resources, to understand and predict fluctuations in the quantity and distribution of these resources, and to establish levels for optimum use of the resources. NMFS is also charged with the development and implementation of policies for managing national fishing organists, development and enforcement of domestic fisheries regulations, surveillance of foreign fishing off United States coastal waters, and the development and enforcement of international fishery agreements and policies. NMFS also assists the fishing industry through marketing service and economic analysis programs, and mortgage insurance and vessel construction subsidies. It collects, analyzes, and publishes statistics on various phases of the industry.

The Special Scientific Report Fisheries series was established in 1949. The series carries reports on scientific investigations that document long-term continuing programs of NMFS, or intensive scientific reports on studies of restricted scope. The reports may deal with applied fishery problems. The series is also used as a medium for the publication of bibliographies of a specialized scientific nature.

NOAA Technical Reports NMFS SSRF are available free in limited numbers to governmental agencies, both Federal and State. They are also available in exchange for other scientific and technical publications in the marine sciences. Individual copies may be obtained (unless otherwise noted) from D83, Technical Information Division, Environmental Science Information Center, NOAA, Washington, D.C. 20235. Recent SSRF's are:

Age and Size Composition of the Atlantic Menhaden, Brevoortia tyrannus, Purse Seine Catch, 1963-71, with a Brief Discussion of the Fishery

WILLIAM R. NICHOLSON'

ABSTRACT

The catch of Atlantic menhaden, Brevoortia tyrannus, estimates of numbers of fish caught by age, fishing effort, age and size distribution, and changes in the fishery are summarized and briefly discussed for the five areas of the Atlantic coast of the United States for 1963-71. Appended are tables of seasonal length frequency distributions and mean lengths by age and port and tables of monthly mean lengths by sex, age, and port. The purse seine fishery declined after 1962. North of Chesapeake Bay, plants closed or reduced fishing as fish became scarce. Of eight plants that processed menhaden in 1962 only two operated in 1971. The catch and catch per unit of effort in Chesapeake Bay declined as effort increased. South of Cape Hatteras, N.C. the fishery, which had been small compared to the fishery in other areas, showed little change. The average age and size of fish in the total catch declined as the fishery north of Chesapeake Bay, which mainly caught older and larger fish, declined. Age-1 and -2 fish, which constituted most of the catch from Florida to Chesapeake Bay, increased in average length and weight.

INTRODUCTION

In this report routine data collected from 1963 to 1971 on population dynamics of Atlantic menhaden, Brevoortia tyrannus, and major changes in the purse seine fishery are discussed. Included are length and weight statistics of individual age groups in samples taken at ports from Florida to New York, the annual catch, estimates of the number of fish caught at each age in the five divisions of the fishery, the number of vessel weeks (fishing effort), and catch per unit of effort.

Reports titled, "Age and size distribution of the Atlantic menhaden catch along the Atlantic coast of the United States, with a brief review of the fishery," have been published for the following years: 1952-55 (June and Reintjes 1959); 1956 (June and Reintjes 1960); 1957 (June 1961); 1958 (June and Nicholson 1964); 1959-62 (Nicholson and Higham 1964a, 1964b, 1965, 1966).

In previous reports data were summarized and discussed for five divisions of the fishery: the North, Middle, and South Atlantic areas; the Chesapeake Bay area; and the North Carolina fall fishery. These divisions described in the first report in the series (June and Reintjes 1959) have been retained, with one modification: the boundary between the Chesapeake Bay and South Atlantic areas has been changed from lat. 36°35'N to lat. 35°20'N because no vessels from South Atlantic ports fish above lat. 35°N (Fig. 1).

Some major changes in the format have been made.

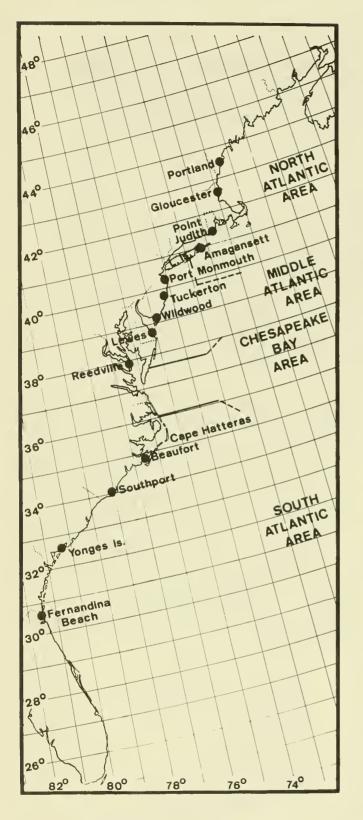

Length frequencies of each age group are summarized by port rather than by division of the fishery; mean lengths and total number of males and females of each age are shown instead of frequencies for each sex; mean lengths are shown by port and month rather than by area and season; and only mean weights of all ages combined for each port are shown. Because there is no suitable method of determining the amount of effort expended in each area by vessels from a particular port, the estimated numbers of fish of each age are summarized by port of landing rather than by area of capture, as in previous reports. The distribution and estimated numbers of purse seine sets have been omitted because this information has been discussed in another publication (Nicholson 1971).

To facilitate some text table and all appendix table headings, the following numeric codes are used for the various ports:

Fernandina Beach, Fla.	1
Southport, N.C.	2
Beaufort, N.C. summer fishery	3
Reedville and Cape Charles, Va.	4
Lewes, Del.	5
Wildwood, N.J.	6
Port Monmouth, N.J.	7
Amagansett, N.Y.	8
Point Judith, R.I.	9
North Carolina fall fishery	10

Plants at Yonges Island, S.C. and Portland, Maine did not operate and plants at Gloucester, Mass. and Tuckerton, N.J. were not sampled. In this report the North Carolina fall fishery, while technically not a port, is treated as one.

^{&#}x27;Atlantic Estuarine Fisheries Center, National Marine Fisheries Service, NOAA, Beaufort, NC 28516.

CHANGES IN THE FISHERY

Because landings in the North and Middle Atlantic areas after 1962 declined and many plants closed or reduced fishing, the fisheries are discussed as a single

Figure 1.—Location of plants and fishing areas, Atlantic menhaden fishery.

area rather than separately as in previous reports. In 1963 the 1958 year class, which had supported the fishery for 4 yr in the Middle Atlantic and for 3 yr in the North Atlantic, ceased to contribute substantially to the catch. Plants at Gloucester, Mass. and Pt. Judith, R.I. ceased processing menhaden from purse seiners in 1963 and 1964, respectively. By 1966 the number of vessels at Amagansett, N.Y. and Port Monmouth, N.J. had fallen to about 2% of the number in 1962. The Tuckerton, N.J. plant closed after the 1964 season. One plant at Lewes, Del. closed after the 1964 season and the other during the middle of the 1966 season. The plant at Wildwood, N.J. operated only a part of each season from 1964 to 1969 and closed in 1970. The Amagansett plant, which did not open in 1967, operated only two vessels in the following years and closed again in 1970. The Port Monmouth plant in 1970 processed only menhaden caught in pound nets or by small trawlers converted to purse seining until one regular purse seine vessel began fishing in early September.

While plants in the North and Middle Atlantic areas either closed or reduced fishing in the years following 1962, plants in the Chesapeake Bay area increased fishing effort through 1966, despite a downward trend in catches that continued through 1969. Consolidation and acquisition reduced the number of companies from four to two, although three to five plants continued to operate. The fishing season, which formerly ceased by mid-October, extended to late November by 1964 as larger and faster vessels, which could range farther from port, exploited migrating schools passing in ocean waters off the mouth of the bay. In many instances, fish which formerly would have been landed in the North Carolina fall fishery were transported to Virginia plants for processing.

In the South Atlantic area, one plant which had operated at Fernandina Beach, Fla. from 1948 to 1957 reopened in 1965 but fished only four seasons. A plant which operated at Southport, N.C. from 1952 to 1961 was sold in 1963. It processed only during the 1963 fall fishery, the 1964 summer and fall fishery, and May 1964. A large refrigerated vessel fished from the other plant at Southport, but otherwise the size and number of vessels operating from South Atlantic plants changed little from previous years.

TOTAL CATCH

In previous reports the estimated numbers of fish landed were broken down by areas of capture on the basis of the percentage of catch samples from different areas. Because of minor changes in estimating the number of fish caught, some of the numbers published in previous reports for 1955-62 have been revised and are included.

Table 1.--Percentages of Atlantic menhaden captured by purse seines in areas other than where ports were located.

Year	Chesapeake Bay	Middle Atlantic	North Atlantic	Year	Chesapeake Bay	Middle Atlantic	North Atlantic
1955	0.00	1.18	3.06	1964	0.00	7.16	24.41
1956	0.00	0.00	24.46	1965	0.00	2.67	55.24
1957	0.00	2.16	18.77	1966	0.00	7.27	0.00
1958	0.00	1.67	9.02	1967	2.75	10.37	
1959	2.79	1.03	11.40	1968	0.04	0.00	15.83
1960	0.00	1.68	18.89	1969	0.00	17.56	0.00
1961	0.07	2.60	12.25	1970	6.55	42.23	0.00
1962	0.09	3.54	24.68	1971	9.43	81.70	0.00
1963	0.00	5.71	13.59				

In this report the catch, in metric tons and in estimated millions of fish, is credited to the area in which the plants are located, even though the fish may have been caught in another area. The catch is reported this way because: 1) except for some years when catches for ports in the North and Middle Atlantic were exceptionally small, fish caught outside an area in which a plant is located constitute only a small percentage of the total catch (Table 1); 2) the area in which catches are made cannot always be identified; and 3) the units of fishing effort (vessel weeks) can be associated only with the total catch landed at a plant.

Vessels fished mainly in the area in which the plant was located, occasionally in adjacent areas, but never in areas not adjacent. Chesapeake Bay vessels occasionally fished in the Middle Atlantic; Wildwood and Lewes vessels sometimes fished in a portion of the coast included in the Chesapeake Bay area. Port Monmouth vessels often fished in the western end of Long Island Sound. Amagansett vessels fishing off the northern New Jersey coast accounted for the fish caught outside the North Atlantic. In some years after 1963, the catch landed at Chesapeake Bay plants in November included migrating fish caught either off the mouth of the bay or in North Carolina waters. Although these catches were more closely associated with the North Carolina fall fishery, there was no way

of identifying them. No fish landed in the South Atlantic or North Carolina fall fishery were taken in other areas.

Total landings dropped sharply in 1963 as the strong 1958 year class phased out of the fishery, and plants in the North and Middle Atlantic closed or reduced their amount of fishing (Table 2). After another sharp drop in 1964 to 269,000 metric tons, landings in the following years fluctuated between 162,000 and 273,000 metric tons.

The estimated total number of actual fish landed is shown for all areas combined and for each area, individually (Tables 3-8). For all areas combined, it continued to decline after 1962, reaching a low of 868.16 million in 1969 (Table 3). It increased to 1,399.87 million in 1970, partly as a result of a fairly strong 1969 year class, but declined again in 1971. Fish older than age 2 continued to decrease after 1962 as the strong 1958 year class phased out of the fishery and as the catches from the North and Middle Atlantic and the North Carolina fall fishery dwindled.

FISHING EFFORT

Because observed effort and effective effort are often confused, I wish to stress that in this report observed effort is the basis for all discussions of catch, effort, and catch per unit of effort. In the Atlantic menhaden fishery the observed unit of effort, the

Table 2.--Atlantic menhaden purse seine catch, in thousands of metric tons by year and area.

accounted for less than 4%. The decline reflected a decrease in the population of older fish which normally accounted for the major portion of the catch in both areas.

The estimated number of fish caught dropped sharply in 1964 and remained low thereafter (Tables 4, 5). Age-1 fish supplied a relatively large percentage of the catch in the Middle Atlantic up to 1965, and a relatively small percentage after 1965 as the Lewes and Wildwood plants, which landed mostly age-1 and -2 fish, closed or reduced fishing. Age-2 and -3 fish, which usually compose most of the Port Monmouth catches, accounted for a larger percentage as the Lewes and Wildwood catches declined.

Fishing effort was 961 to 1,254 vessel weeks per year prior to 1963. It had dropped to 166 by 1966 and reached a low of 19 in 1970 (Table 9). The largest reduction-551 vessel weeks-was in 1964 as the plant operators cut back in the numbers of vessels following the extremely low catch in 1963. Also, fish were so scarce in 1964 that those vessels which did not stop fishing in August quit by the beginning of October. In 1965 one plant at Lewes and the Tuckerton plant remained closed, while most Wildwood vessels shifted to plants in Chesapeake Bay. In 1966 the Port Monmouth plant, and the remaining Lewes plant, which has never reopened, closed in late July, and Wildwood vessels fished a total of only 12 calendar weeks in Middle Atlantic waters. Since 1966 three to five vessels have fished at Port Monmouth, except in 1970 when only one regular purse seiner operated a few weeks in September, and two to five vessels have fished at Wildwood for short periods each year as fish became available, except in 1970 and 1971 when the plant remained closed.

The CPUE (catch per unit of effort) from 1963 to 1970 was generally about 50% or less of the CPUE in years prior to 1963 (Table 10). Both effort and CPUE were exceptionally low in 1966, indicating the extreme scarcity of older fish that year. The increase in the CPUE in following years probably reflected a decrease in vessel competition rather than any significant increase in menhaden abundance. One or two vessels at Amagansett and three to four vessels at Port Monmouth divided the available fish between them, and two to three vessels operated at Wildwood only when fish became locally abundant.

Chesapeake Bay Area

Except for 1959, when the large 1958 year class entered the fishery, catches from 1954 to 1968 remained fairly steady, fluctuating between 91,000 and 155,000 metric tons. By contrast, catches from 1945 to 1953 fluctuated between 35,000 and 81,000 metric tons. The relatively large catches from 1954 to 1968 resulted primarily from an increase in fishing effort caused by increased fishing efficiency, more vessels, and a longer season. Following the poor season in 1969, catches in 1970 rose sharply as the relatively large 1969 year class entered the fishery.

Although age-1 and -2 fish continued to constitute the major part of the catch after 1962, age-0 and -3 fish provided a greater proportion of it than in

Table 4--Calculated numbers of Atlantic menhaden (in millions) caught by purse seime vessels fishing from North Atlantic plants, 1955-71.

previous years (Table 6). In some years age-0 fish began entering the fishery in July. The reasons for these age classes providing a greater share of the catch are not clear. Increased growth rate of juveniles, resulting from a decrease in numbers and a consequent decrease in competition for food, is one probable explanation for the increased catch of juveniles. The increase in age-3 fish is more difficult

to explain. Although fishing increased on migrating schools passing the mouth of the bay as the season was extended into November, age-3 fish did not compose a larger percentage of the catch than during the summer. A probable explanation is that greater numbers of age-3 remained in the bay as the total number of fish decreased and competition for food diminished.

Fishing effort, while declining in the Middle and North Atlantic areas after 1962, increased substantially in Chesapeake Bay. Increases resulted not only from increases in the number of vessels, but also from increases in the length of the season. From 1963 to 1967 effort fluctuated between 666 and 803 vessel weeks compared to 410 to 668 from 1955 to 1962. It

then dropped to about 500 vessel weeks in 1969-71, by which time larger, faster vessels had replaced nearly all of the older, smaller vessels, and the number of spotter planes was about double the number prior to 1963 (Nicholson 1971).

In 1962 the CPUE dropped sharply and until 1970 remained at the levels prevailing from 1945 to 1952

(Nicholson 1971). Although part of the decrease probably was due to a decrease in menhaden abundance, part also was due to the increase in the number of vessels and the concomitant increase in fishing effort and vessel competition. From 1955 to 1961 the number of vessels generally was less than 25 each year, but from 1962 to 1968 the number ranged from

25 to 38 and generally was greater than 31 (Nicholson 1971). Since vessel competition from 1963 to 1969 was intense (Nicholson 1972), fewer fish were apportioned among a greater number of vessels, and a drop in the catch per vessel week was inevitable.

The low CPUE in 1969, following a decline in effort to 500 vessel weeks, probably reflects a scarcity of fish,

Table 7.--Calculated numbers of Atlantic menhaden (in millions) caught by purse seine vessels fishing from North Atlantic plants, 1955-71.

while the high CPUE in 1970, with about the same amount of effort, reflects the relatively strong 1969 year class, which entered the fishery at age-1.

Part of the large increase in the CPUE in 1970 may have resulted from an increase in the number of age-2 fish (1968 year class). Usually a year class contributes the greatest number of fish at age-1, but the 1968 year class contributed 66 million fish to the Chesapeake Bay catch in 1969 and over 259 million in 1970. A large number of this 1968 year class, caught as age-2 fish in 1970, probably spent the 1969 season in the South Atlantic, where the catch of age-1 fish in 1969 was much greater than the catch of age-2 fish in 1970.

South Atlantic Area

The annual catch in metric tons from 1963 to 1971 was of about the same magnitude as in previous years and age-1 and -2 fish continued to supply over 99% of the catch (Table 7).

The number of vessel weeks, while fluctuating over

the years, showed no substantial change. Although vessel size did not increase, efficiency probably did, as more fish pumps, power blocks, aluminum purse boats, and nylon nets were employed after 1962 (Nicholson 1971).

With the exception of 1965 and 1966 the CPUE was greater from 1963 to 1971 than in previous years, and

Table 9.--Number of vessel weeks in the Atlantic menhaden purse seine fishery, by area, 1955-71.

N.C. fall North Middle Chesapeake South Atlantic Atlantic Year Atlantic 2,492 2.652 1,999 2.296 1.839 1.800 1.346 1,228 1.010

reached a record 244 metric tons per vessel week in 1970. Much of the increase probably was due to fewer vessels and greater efficiency rather than any increase in the abundance of fish.

North Carolina Fall Fishery

Landings from 1963 to 1968, while slightly smaller than landings from 1955 to 1962, were generally over 50,000 metric tons, but from 1969 to 1971 they dropped sharply, amounting to only 7,900 in 1971. The age composition of the catches also changed, with fish younger than age-3 composing an increasingly higher percentage after 1963. Age-4 and older fish practically disappeared from catch samples after 1964 (Table 8).

From 1964 to 1968 effort fluctuated between 212 and 259 vessel weeks, somewhat less than from 1955 to 1963, but greater than from 1969 to 1971. In recent years poor prospects for fish abundance have contributed to the decline in the number of vessels, and the failure of fish to appear until late November has contributed to a shortening of the season.

Because the amount of time a vessel can fish during the fall season is dependent on weather, which can be quite variable from year to year, the vessel week is not a particularly good measure of effort and the catch per vessel week is not as sensitive an index of abundance as it is in the major areas of the "summer" fishery. Nevertheless, the low CPUE in 1970 and 1971 reflects an unusual scarcity of fish. Weather during both years was ideal for fishing; yet on many days spotter pilots

reported no concentrations of fish and vessels never left the dock. Some vessel operators declined to fish on small age-0 fish that were temporarily abundant at various times.

LENGTH AND WEIGHT

Length statistics are presented for the years 1963-71 in Appendix tables 1-18. In Appendix tables 1-10 frequency distributions are omitted for ages that contain less than 20 fish, or less than 1% of the number of fish in the annual sample. The mean lengths and the number of fish in the monthly samples at each port are shown in Appendix tables 11-18.

Several significant changes indicate an increased growth rate since 1963. Age-0 fish that began appearing in Chesapeake Bay catches in 1964 have been larger than age-0 fish caught in previous years in the North Carolina fall fishery. Age-0 fish caught in the North Carolina fall fishery since 1964, while not averaging as large as those caught in Chesapeake Bay, have been larger than those caught in previous years. Age-1 and -2 fish, although showing no appreciable change in mean length in samples from South Atlantic ports, have shown an increase in mean length in samples from Chesapeake Bay and Middle Atlantic ports. Mean lengths of age-3 fish from Chesapeake Bay samples since 1963 have been 30-50 mm greater than they were prior to 1963. Mean length of age-3 and -4 fish from samples at Port Monmouth and Amagansett also have been greater since 1963. Fish older than

age-4 have been too scarce to permit meaningful conclusions to be drawn.

Mean lengths for all ages combined also reflect the increased growth rates (Tables 11, 12). There are slight increases for fish in samples at South Atlantic ports, but large increases for fish at Chesapeake Bay, Middle Atlantic, and North Atlantic ports. The largest increase in mean lengths is for fish in Chesapeake Bay samples. Mean length of fish from North Carolina fall fishery samples generally were smaller from 1965 to 1971 than from 1955 to 1962. This change has resulted from the decrease in the average age of fish in the catch. Since weight increases at a much greater rate than length for fish over 200 mm, the length increases for fish caught during the summer north of Cape Hatteras represent a relatively large increase in biomass.

YEAR CLASS STRENGTH

Relative strength of year classes can be inferred by following the catch of each year class as it passes through the fishery. Because of the age and size distribution of Atlantic menhaden, variation in fishing effort in different areas can distort the relative importance of different age groups in the catch and make assessments difficult. If only the Chesapeake Bay catch, which has accounted for the major share of the catch since 1964, and the combined catch of ages 0-4 from all areas are considered, some meaningful inferences can be drawn.

The 1951, 1953, 1955, 1956, and 1958 year classes appear to have been strong. Whether they were unusually stronger than year classes prior to 1951 is not certain. The 1958 year class, however, was certainly the most abundant since 1951 and may have been one of the largest ever produced, although there is no way of knowing.

Evidence of the strength of the 1959 year class is conflicting. Although the catch of age-1 fish was poor, the catch of ages 2 to 4 was relatively good. Perhaps the 1959 year class did not appear as abundant at age-1 because the catches were dominated by the age-2 fish of the super abundant 1958 year class. Also, 1960 was a year of poor market conditions, and Chesapeake Bay plants, which account for most of the age-1 catch, established quota restrictions on the catch.

All of the year classes from 1960 to 1970 appear to have been smaller than any from 1951 to 1958. Although the total number of fish from the first three age groups after 1959 was not much less than the total number from these age groups prior to 1960, the effort against these age groups was much greater. In Chesapeake Bay, effort nearly doubled from 1955 to 1964.

The 1964, 1966, and 1969 year classes appear to have been the largest produced between 1959 and 1970. Since fishing effort in Chesapeake Bay was exceptionally high, particularly from 1964 to 1968, these year classes were smaller than the catches indicate and probably did not equal the abundance of any of the year classes from 1951 to 1959.

The 1969 year class, while apparently stronger than any year class since 1958 did not appear nearly as strong as those prior to 1958. It provided enough age-1 fish in 1970 to sustain only the South Atlantic and Chesapeake Bay fisheries, and not nearly enough to sustain also a fishery from the Virginia Capes to Delaware Bay, where age-1 fish from strong year classes prior to 1959 were usually abundant. In 1971, where age-1 fish from the 1970 year class were not abundant, the 1969 year class supplied barely enough fish to sustain the Chesapeake Bay fishery, and not enough to support even a small fishery from Delaware Bay to northern New Jersey, where age-2 fish are usually the most important age group.

- 648 Weight loss of pond-raised channel catfish (Ictalurus punctotus) during holding in processing plant vats. By Donald C. Greenland and Robert L. Gill. December 1971, m + 7 pp., 3 figs., 2 tables. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 649. Distribution of forage of skipjack tona (Euthynnus pelomis) in the eastern tropical Pacific. By Maurice Blackborn and Michael Laurs. January 1972, iti + 16 pp., 7 figs., 3 tables. For sale by the Soperintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 650. Effects of some antioxidants and EDTA on the development of rancidity in Spanish mackerel (Scomberomorus maculatus) during frozen storage. By Robert N. Farragut. February 1972, iv + 12 pp., 6 figs., 12 tables. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 651. The effect of premortem stress, holding temperatures, and freezing on the hiochemistry and quality of skippack tuna. By Ladell Crawford. April 1972, in + 23 pp., 3 figs., 4 tables. For sale by the Superintendent of Documents, U.S. Government Printing Office. Washington, D.C. 20402.
- 653. The use of electricity in conjunction with a 12.5-meter (Headrope) Gulf-of-Mexico shrimp trawl in Lake Michigan. By James E. Ellis, March 1972, iv + 10 pp., 11 figs., 4 tables. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 654. An electric detector system for recovering internally tagged menhaden, genus Brevoortio, By R. O. Parker, Jr. February 1972, iii + 7 pp., 3 figs., 1 appendix table. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, O.C. 20402.
- 655. Immobilization of fingerling salmon and troot by decompression. By Doyle F. Sutherland. March 1972, iii + 7 pp., 3 figs., 2 tables. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 656. The calico scallop, Argopecten gibbus. By Donald M. Allen and T. J. Costelln. May 1972, iii. + 19 pp., 9 figs., 1 table. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 657. Making fish protein concentrates by enzymatic hydrolysis. A status report on research and some processes and products studied by NMFS. By Malcolm B. Hale. November 1972, v + 32 pp., 15 figs., 17 tables, 1 appendix table. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 2002.
- 658. List of fishes of Alaska and adjacent waters with a guide to some of their literature. By Jay C. Quast and Elizabeth L. Hall. July 1972, iv + 47 pp. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 659 The Southeast Fisheries Center bionumeric code. Part I: Fishes. By Harvey R. Bullis, Jr., Richard B. Roe, and Judith C. Gatlin. July 1972, xl + 95 pp., 2 figs. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402
- 660. A freshwater fish electro-motivator (FFEM)-its characteristics and operation. By James E. Ellis and Charles C. Hoopes. November 1972, iii + 11 pp., 9 figs.
- 661 A review of the literature on the development of skipjack tuna fisheries in the central and western Pacific Ocean. By Frank J. Hester and Tamio Otsu. January 1973, iii + 13 pp., 1 fig. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

- 662. Seasonal distribution of tunas and billfaftes in the Atlantic, By John P. Wise and Charles W. Davis, January 1973, iv + 24 pp., 13 figs., 4 tables, For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20492.
- 663. Fish larvae collected from the northeastern Pacific Ocean and Puget Sound during April and May 1967. By Kenneth D. Waldron. December 1972, in ± 16 pp., 2 figs., 1 table. 4 appendix tables. For sale by the Superintendent of Documenta, U.S. Government Printing Office, Washington, D.C. 20402.
- 664. Tagging and tag-recovery experiments with Atlantic menhaden, Brevoortio tyronnus By Richard L. Kroger and Robert L. Dryfoos. December 1972, iv + 11 pp., 4 ligs , 12 tables. For sale by the Superintendent of Documents, U.S. Government Printing Office. Washington, D.C. 20402
- 665. Larval fish survey of Humbolt Bay, California By Maxwell B. Eldridge and Charles F. Bryan. December 1972, iii + 8 pp., 8 figs., 1 table. For sale by the Superinteedent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 666. Distribution and relative ahundance of fishes in Newport River, North Carolina By William R. Turner and George N. Johnson. September 1973, iv + 23 pp., 1 fig., 13 tables For sale by the Superintendent of Documenta, U.S. Government Printing Office, Washington, D.C. 20402.
- 667. An analysis of the commercial lohster (Homorus oriericonus) fishery along the coast of Maine, August 1966 through December 1970. By James C. Thomas. Jone 1973, v + 57 pp., 18 figs., 11 tables. For sale by the Superintendent of Documenta, U.S. Government Printing Office, Washington, D.C. 20402.
- 668. An annotated bibliography of the cunner, Toutogolabrus adspersus (Walhaum) By Fredric M. Serchuk and David W. Frame. May 1973, 11 + 43 pp. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402
- 669. Suhpoint prediction for direct readout meteorological satellites. By L. E. Eber Augost 1973, iii + 7 pp., 2 figs., 1 table. For sale by the Soperintendent of Documents. U.S. Government Printing Office, Washington, D.C. 20402
- 670. Unharvested fishes in the U.S. commercial fishery of western Lake Erie in 1969. By Harry D. Van Meter. July 1973, iii + 11 pp., 6 figs., 6 tables. For sale by the Soperintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402
- 671. Coastal upwelling indices, west coast of North America, 1946-71. By Andrew Bakun, June 1973, iv + 103 pp., 6 figs., 3 tables, 45 appendix figs. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402
- 672. Seasonal occurrence of young Gulf menhaden and other fishes in a northwestern Florida estuary. By Marlin E. Tagatz and E. Peter H. Wilkins August 1973, iii + 14 pp., 1 fig., 4 tables. For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.
- 673. Abondance and distribution of inshore benthic fauna off southwestern Long Island, N.Y. By Frank W. Steimle, Jr. and Richard B. Stone. December 1973, iii \pm 50 pp., 2 figs., 5 appendix tables.
- 674 Lake Erie bottom trawl explorations, 1962-66, By Edgar W. Bowman, January 1974, iv. + 21 pp., 9 figs., 1 table, 7 appendix tables.
