NOAA Technical Memorandum NMFS

The National Marine Fisheries Service's Alaska Fisheries Science Center uses the NOAA Technical Memorandum series to issue informal scientific and technical publications when complete formal review and editorial processing are not appropriate or feasible. Documents within this series reflect sound professional work and may be referenced in the formal scientific and technical literature.

The NMFS-AFSC Technical Memorandum series of the Alaska Fisheries Science Center continues the NMFS-F/NWC series established in 1970 by the Northwest Fisheries Center. The NMFS-NWFSC series is currently used by the Northwest Fisheries Science Center.

ABSTRACT

The results of the 2014 Underwater Camera Survey of the Eastern Bering Sea slope and outer shelf are presented here. The 2014 survey was the first comprehensive underwater camera survey of coral and sponge on the Bering Sea slope and outer shelf conducted by the National Marine Fisheries Service. Two-hundred fifty transects were successfully completed during the survey, which extended north from Bering Canyon to Pervenets Canyon. Transects were randomly selected between Unalaska Island and Pervenets Canyon. Each transect was assigned to one of eight geographical regions. Demersal populations of corals, sponges, sea whips, fishes, and crabs were sampled by drifting a stereo drop camera for 15 minutes at each transect. Survey results presented in this report include fish and crab composition and density, coral, sponge and sea whip density and height, and substrate composition for each transect. The Appendix lists start position, distance towed, swath, mean depth, and mean temperature for each transect completed.

INTRODUCTION

The fish and crab resources of the eastern Bering Sea slope and outer shelf are widely utilized by commercial fisheries in Alaska. It is an area of enhanced primary and secondary productivity (the "Bering Sea Greenbelt"). Physical processes at the shelf break enhance productivity, attracting large numbers of fishes, seabirds, and marine mammals (Springer et al. 1996). About 40% of U.S. commercial fisheries catch originates from the eastern Bering Sea, including the slope and outer shelf. The eastern Bering Sea slope contains five major canyons each of which incises the outer shelf (Fig. 1). In 2012, the North Pacific Fishery Management Council (NPFMC) received testimony from environmental organizations suggesting management measures to provide Essential Fish Habitat (EFH) protection to coral, sponge and other benthic habitat of fish and crab species for two of the largest eastern Bering Sea canyons (Pribilof and Zhemchug).

Based on this testimony, the NPFMC requested the Alaska Fisheries Science Center (AFSC) conduct an analysis to determine whether or not the Bering Sea canyons are unique coral and sponge habitats and if the fish and invertebrate assemblages make the canyons vulnerable to the effects of commercial fishing. An analysis of existing data was conducted and presented to the NPFMC in 2013 (Sigler et al. 2013; Sigler et al. 2015). The conclusions of that analysis were that although there are some physical characteristics that distinguish the canyons from the surrounding slope and outer shelf areas, there are no unique features about the biology that distinguish Pribilof or Zhemchug Canyons from the surrounding slope areas. The major variables structuring the biological communities on the eastern Bering Sea slope and outer shelf are depth and latitude (Sigler et al. 2015, Hoff et al. in review).

As part of the follow-up to the 2013 analyses, the NPFMC requested that the AFSC conduct an underwater camera survey at transects along the eastern Bering Sea slope and outer shelf. This survey was designed to verify predictions of benthic invertebrate presence or absence, assess species associations between fishes and invertebrates, and document any evidence of fishing activity that was observed. The objective of this report is to present detailed data collected from the underwater camera survey, as well as images and summaries from each transect.

METHODS

Study Area

The eastern Bering Sea is dominated by a broad, shallow continental shelf that stretches east to west from the Alaska mainland to the shelf break roughly 700 km away (Fig. 1). The eastern Bering Sea shelf is commonly divided into three domains based on bathymetry and oceanographic fronts: the inner shelf (0 to 50 m), the middle shelf (50 to 100 m) and the outer shelf (100 to 180 m) (Coachman 1986). The shelf break is typically at 180 to 200 m depth, except at the northern edge of Bering Canyon, where the shelf break is at 500 m (Sigler et al. 2015). The eastern Bering Sea slope and outer shelf are made up of five major canyons (Bering Canyon, Pribilof Canyon, Zhemchug Canyon, Pervenets Canyon and Navarin Canyon) with an inter-canyon area between each (Fig. 1). There are also multiple smaller canyons along the shelf break, but none incise the shelf to the degree of the five largest. This report covers seven

regions (canyon and between canyons) along the continental slope and the outer region of the eastern Bering Sea shelf.

Survey Design and Field Sampling

Two-hundred fifty of 300 randomly selected transects were successfully completed from 8 August to 6 September 2014 (Fig. 2; Appendix A). Due to poor weather and time constraints the majority of unsampled transects were north of Zhemchug Canyon. Transects were chosen on a regularly-spaced grid overlayed on the eastern Bering Sea outer shelf and slope with 100 m by 100 m sides. Random transects were chosen in two stages. For the first stage, 10 transects were chosen randomly from each of the nine individual canyon and between canyon areas (n = 90) to ensure that there was adequate spatial coverage of the entire area. For the second stage, 210 transects were randomly chosen throughout the nine slope areas and the outer shelf based on the probability of coral presence from the bottom-trawl model of coral distribution (Sigler et al. 2015). Thus, areas with a higher probability of coral presence (such as Pribilof Canyon and the adjacent area to the north) received more allocated transects (Fig. 2).

A stereo drop camera system (Williams et al. 2010) was used as the primary sampling tool. The system is designed to be towed or drifted continuously along a linear transect at or near the seafloor. Two machine-vision cameras spaced approximately 30 cm apart in underwater housings were connected via ethernet cables to a computer also in an underwater housing. One of the paired cameras recorded 1.45 megapixel monochromatic still images, while the other camera collected 1.73 megapixel color still images. Lighting was provided by four strobe lights constructed of four Bridgelux® BXRA LED arrays capable of producing 1,300 lumens at 10.4 W. The computer, cameras, and lights were powered by a 28 V NiMH battery pack. Synchronous images were collected from each of the cameras at a frequency of one image per second and written to a hard drive on the computer. Additionally, images were taken (but not written to the hard drive) from the monochrome camera at a rate of four images per second. These images were viewed in real time on a monitor at the surface. This allowed the height of the camera to be actively controlled to keep it just above the seafloor using a quick response electric winch. A 3/16-inch diameter coaxial cable provided the video connection from the drop camera system to the winch at the surface and allowed image viewing in real time.

At each occupied transect, the camera was deployed at the center of the grid cell and lowered to the seafloor. Once seafloor contact was made, the drop camera was drifted along the bottom for 15 minutes. During each deployment, the drop camera system was drifted through the water column in the direction of the prevailing current a speed of 0.48 to 3.34 km/hr (0.26 to 1.8 knots) approximately 1 to 2 m above the substrate with the cameras pointed slightly downward at an angle of approximately 35° off parallel to the seafloor. The research vessel's global positioning system (GPS) was used to determine the position of the camera throughout the deployment. A concentrated effort was made to keep the deployment cable as near to vertical as possible. The distances traveled during deployments ranged from 27 m to 839 m (mean = 362 m, SE = 8.8). Area (m^2) was calculated by multiplying distance the camera drifted (m) by swath of the camera field of view (m).

Image Analysis

Each image pair collected during each deployment was viewed using stereo image processing software developed in the Python programming language (Kresimir Williams, AFSC-RACE Division, unpublished software). Substrates were classified by a commonly used seafloor substratum classification scheme (Stein et al. 1992, Yoklavich et al. 2000). The classification consists of a two-letter coding of substratum type denoting a primary substratum with > 50% coverage of the seafloor bottom and a secondary substratum with 20% - 49% coverage of the seafloor (Table 1). There were eight identified substratum types: mud/silt (M, distinguished from sand by presence of silt clouds), sand (S, grains often visible, no silt clouds), gravel (G, diameter < 6.5 cm), mixed coarse material (MC), cobble (C, 6.5 < diameter < 25.5 cm), boulder (B, diameter > 25.5 cm), exposed low relief bedrock (R), and exposed high relief bedrock, and rock ridges (K). By this classification, a section of seafloor covered primarily in cobble, but with boulders over more than 20% of the surface, would receive the substratum code Cobble.boulder (Cb) with the secondary substratum indicated by the lower-case letter. Substratum codes were changed if a substratum encompassed more than 10 consecutive images.

All fishes and commercially important crabs were identified to the lowest taxonomic level possible and counted for each image pair. Species identification for fishes was based on Butler (2012), Mecklenburg (2002), and J. W. Orr (AFSC pers. comm.). Structure-forming invertebrates (corals, sponges, and sea whips) were also identified to the lowest possible taxonomic level and counted for each image pair. Species identification for corals and sponges were based on Cairns (2011), Stone et al. (2011), Stone (2014), R. Stone (AFSC pers. comm.), Taylor et al. (2013), and Wing and Barnard (2004). Demospongiae were too numerous to count on four transects. A random subsample of 135 paired frames was obtained and all individuals were counted. Sponges less than 10 cm in height were difficult to discern from other small white or yellow items on the seafloor, so these were not included in the counts or analyses. Individual taxon densities were calculated by dividing counts by area swept (distance observed x path width observed).

Vertical habitat was defined as structure-forming invertebrates such as corals, sponges, and sea whips. Heights were obtained when the base and tip of the invertebrate could be clearly identified in both images. Sea whips with bent tips were measured to their highest point above the seafloor. For transects where sponge or sea whip counts exceeded 500, a random subsample of 135 paired images were selected to obtain approximately 200 height measurements.

Image analysis resulted in densities of fishes, crabs, and structure-forming invertebrates (no./m^2) for each of the 250 transects, fish lengths for each species that could be measured, heights of structure forming invertebrates and the proportions of each type of substrate found on the transect. Densities of individual taxa were calculated by dividing counts by the area swept (distance observed x path width observed). The image analysis software provided a range, in centimeters, from the camera to each individual target that was identified in an image pair. The path width was estimated from the median of this range for each transect. The median range of all objects counted on a transect was assumed to be the distance from the camera where 100% of fishes and invertebrates were detected for that transect. The viewing angle for each camera is known (and fixed by the camera lens). Using the median range and the known viewing angle, a horizontal line in front of the camera can be calculated using formulae for sizing

triangle components. Since we have an angle (viewing angle) and the adjacent side of a triangle (range) for each camera, the length of the opposite side can be calculated. This opposite side is the viewing path width at the median range for each transect. This width was calculated for each transect and used as the path width in density estimation. The mean path width across all transects was 3.08 m (SE = 0.05), with a minimum of 1.55 m and a maximum of 5.51 m for any individual transect.

RESULTS

For the purpose of this report, transects were grouped into eight regions: Bering Canyon, Bering Canyon to Pribilof Canyon, Pribilof Canyon, Pribilof Canyon to Zhemchug Canyon, Zhemchug Canyon, Zhemchug Canyon to Pervenets Canyon, Pervenets Canyon, and Outer Shelf. Two-hundred fifty transects were successfully occupied between Bering Canyon and Pervenets Canyon. Depths ranged from 91 m to 756 m, with the shallowest (90.6 m) transect occurring in Pribilof Canyon and the deepest (776.8 m) between Pribilof Canyon and Zhemchug Canyon. Thirty-six different fish and crab species or taxonomic groupings are presented in this report (Table 2). These were dominated by eelpouts (Zoarcidae) and *Chionoecetes* crabs. However, grenadiers (Macrouridae) and rockfishes (*Sebastes* sp., especially Pacific ocean perch, *S. alutus*) were also common. Most of the species that were found in high abundance tended to be small benthic dwelling fishes such as eelpouts, snailfishes (Liparidae), sculpins (Cottidae, Hemitripteridae, Psychrolutidae), and poachers (Agonidae). Vertical habitat consisted of over 70,000 structure-forming invertebrates (Table 3). These were comprised of about 53% Demospongiae and 38% sea whips. Only 2% (< 1,500 individuals) of the total invertebrates observed were corals.

Corals occurred on 32 of the 250 survey transects. They were identified into five taxonomic groups, including three families (Primnoidae, Plexauridae, and Isididae), and two genera (*Plumarella* sp. and *Swiftia* sp.). The most common corals were *Plumarella* sp. and *Swiftia* sp. The median depth at which coral occurred was 451 m (range = 201 – 770 m), much deeper than the median depth of samples (276 m). Corals occurred at 50% of the survey transects in Pribilof Canyon and about 18% of the transects in the area between Pribilof and Zhemchug Canyons. Corals were present at one transect on the Outer Shelf and one transect in Zhemchug Canyon.

Sponges occurred on 113 of the 250 survey transects. They were identified into three classes: Hexactinellida, Demospongiae, and Calcarea. The median depth at which sponges occurred was 311 m, and they covered almost the entire depth range of sampling from 111 m to 781 m. Sponges were widely distributed and occurred in all of the sampled regions.

Sea whips (Pennatulacea) were also widely distributed both in terms of depth and region. They occurred at depths from 91 m to 700 m (median = 266 m) at 105 of the 250 transects surveyed. At least two different species of sea whip were observed, *Halipteris willemoesi* and an unidentified *Halipteris* species. Sea whips occurred in all regions.

Thirty-five different substrate combinations were identified. Substrate composition for each transect is presented in the site summaries as "Primary.secondary" (i.e., Sand.mud) unless primary and secondary substrates are identical (i.e., Sand).

Evidence of fishing was identified in 32 transects. Trawl gear, longline gear, and trawl tracks were recorded (Table 4; Fig. 3).

Survey results are presented in eight sections according geographical regions. Each section contains a map of transect locations and coral, sponge and sea whip distributions as well as summary tables of species composition, density, and height data. For each transect, we provide date, location (decimal degrees), area (m^2), mean depth (m), mean temperature (°C), fish and crab composition; coral, sponge, and sea whip density and height; substrate composition; images; and a summary description.

ACKNOWLEDGMENTS

Recognition and appreciation are extended to Tim Cosgrove, Landon Mavar, Al Mavar and Gordy Mendez of the FV *Vesteraalen*. Their cooperation, expertise, and goodwill made this survey possible. Appreciation is also extended to Jerry Hoff, Jay Orr, Duane Stevenson and Bob Stone of the AFSC, and Steve MacLean of the NPFMC. Finally, appreciation is extended to Rebecca White for graphics support, and Kim Rand, Mike Levine, Denise McKelvey, and Jennifer Cahalan for their technical support, comments, and suggestions.

Funding for this project was provided by the NMFS Cooperative Research Program, the AFSC Habitat and Ecological Processes Research Program, and NOAA's Deep Sea Research and Technology Program.

Ten transects were completed in Bering Canyon. Depths ranged from 168 m to 691 m. Seventeen taxa of fishes and crabs were identified (Table 6). Vertical habitat was dominated by *Halipteris* sp. (Table 7). Heights ranged from 5.1 cm to 75.0 cm (Table 8).

Bering Canyon

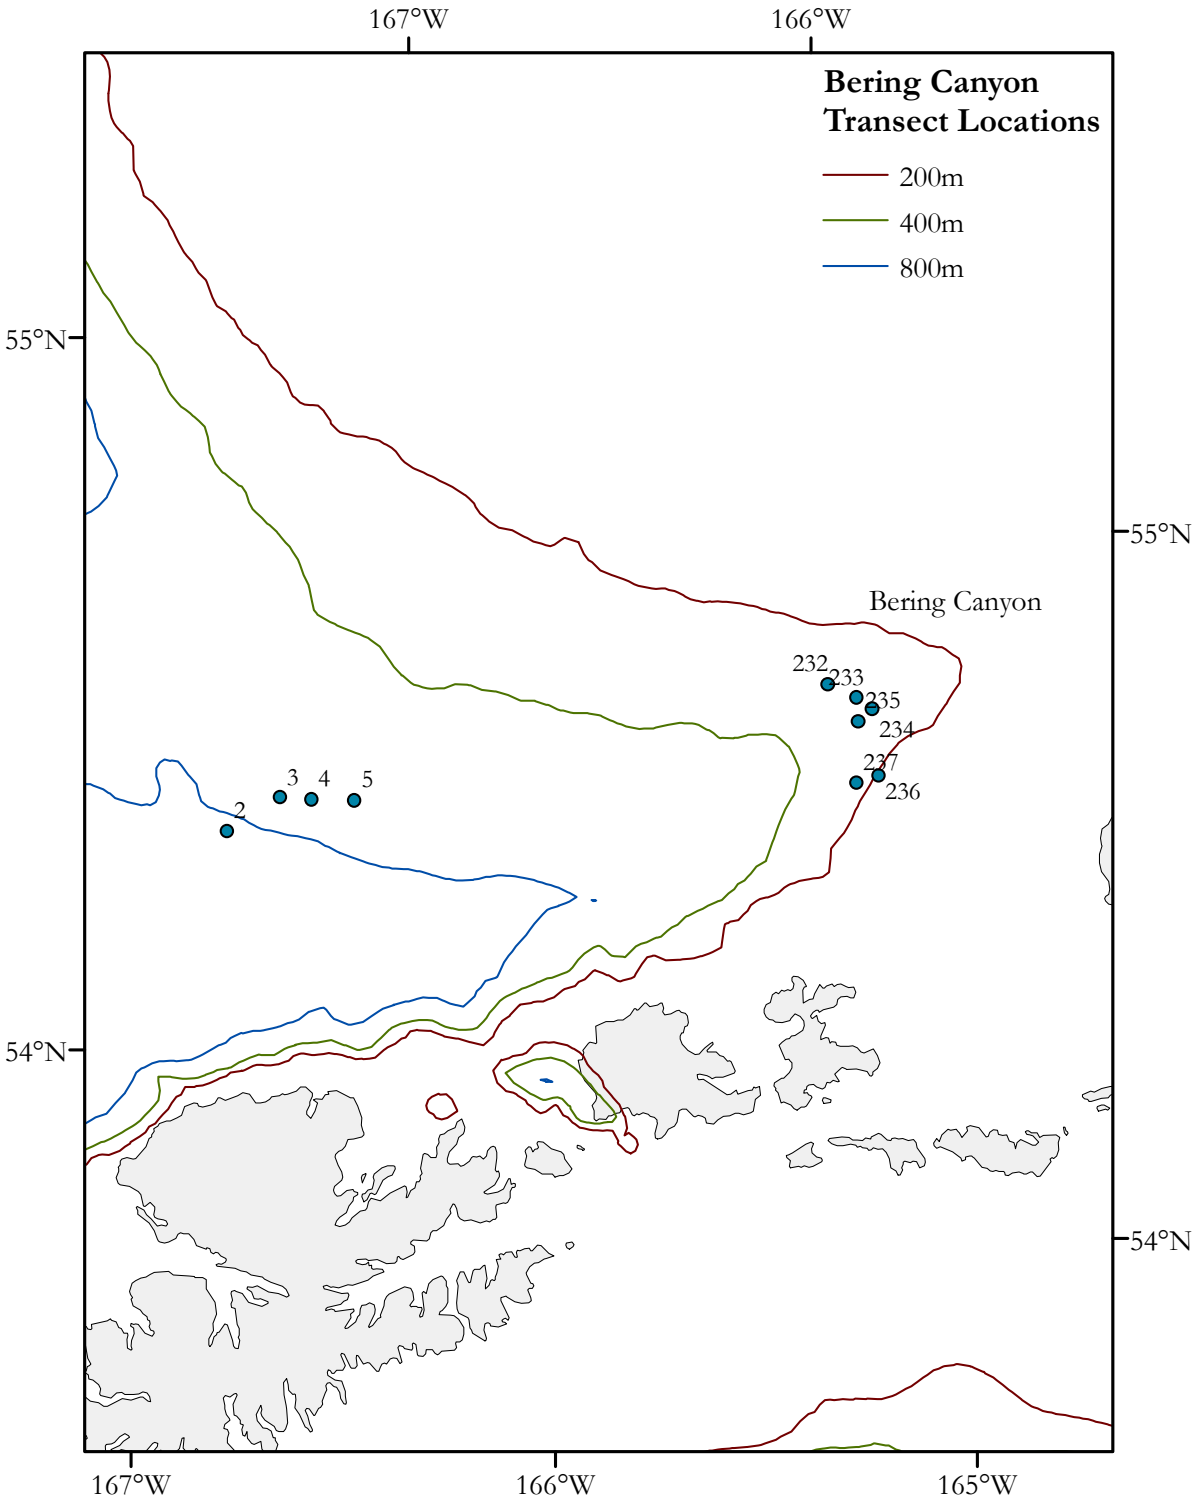

Figure 4. -- Survey transect locations, Bering Canyon.

SITE SUMMARY: Bering Canyon

Bering Canyon is the southernmost canyon in the Bering Sea. It has an estimated volume of 4,300 km^3 (Karl et al. 1996). Bering Canyon may be the longest submarine canyon in the world, extending 400 km across the outer shelf and slope (Karl et al. 1996). Unlike all of the other canyons in the Bering Sea, it consists of only one channel.

Sand was the primary substrate at 9 of the 10 transects (Table 5). Mud was the primary and secondary substrate at the remaining transect. For each of the transects in Bering Canyon the primary and secondary substrates were unchanging throughout the observations.

Eelpouts, snailfishes, giant grenadiers, and poachers comprised 68% of the fish and crab observations (Table 6). Two species of crab were identified, *Chionoecetes* sp. and golden king crab.

Vertical habitat primarily consisted of *Halipteris* sp., which only occurred at transects 232, 233, and 237 (Figs. 5-6). Ninety-six percent of the *Halipteris* occurred on a sandy substrate at Transect 233 where the mean depth was 271 m. Demospongiae were identified at five of the transects while Hexactinellida were only identified at two (Table 7, Fig. 6).

Table 5. -- Summary of substrates identified at transects (n = 10) in Bering Canyon.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observations
Sand*	229 - 298	4	40%
Sand.mud	542 - 691	4	39%
Mud*	271 - 271	1	11%
Sand.gravel	168 - 168	1	11%

*Primary and secondary substrates were the same.

Table 6. -- Summary of fishes and crabs identified at transects (n = 10) in Bering Canyon.

Species/Grouping	Number of occurrences	Number of transects with occurrences	Mean transect depth range (m)	Mean density (individuals/m^2)

Images

Summary - description of transect

Transect 237: Primary and secondary substrates consisted entirely of sand. Density for this transect was < 0.01 individuals/m^2 with two fish groups (skate, flatfish) and Pacific cod identified. One damaged *Halipteris* sp. was identified but not measured. No other corals or sponges were found.

Bering Canyon to Pribilof Canyon

Eighteen transects were completed between Bering Canyon and Pribilof Canyon. Depths ranged from 143 m to 753 m. Twenty-three taxa of fishes and crabs were identified (Table 10). Vertical habitat was dominated by *Halipteris* sp. (Table 11). Sponge and sea whip heights ranged from 2.4 cm to 266.3 cm (Table 12).

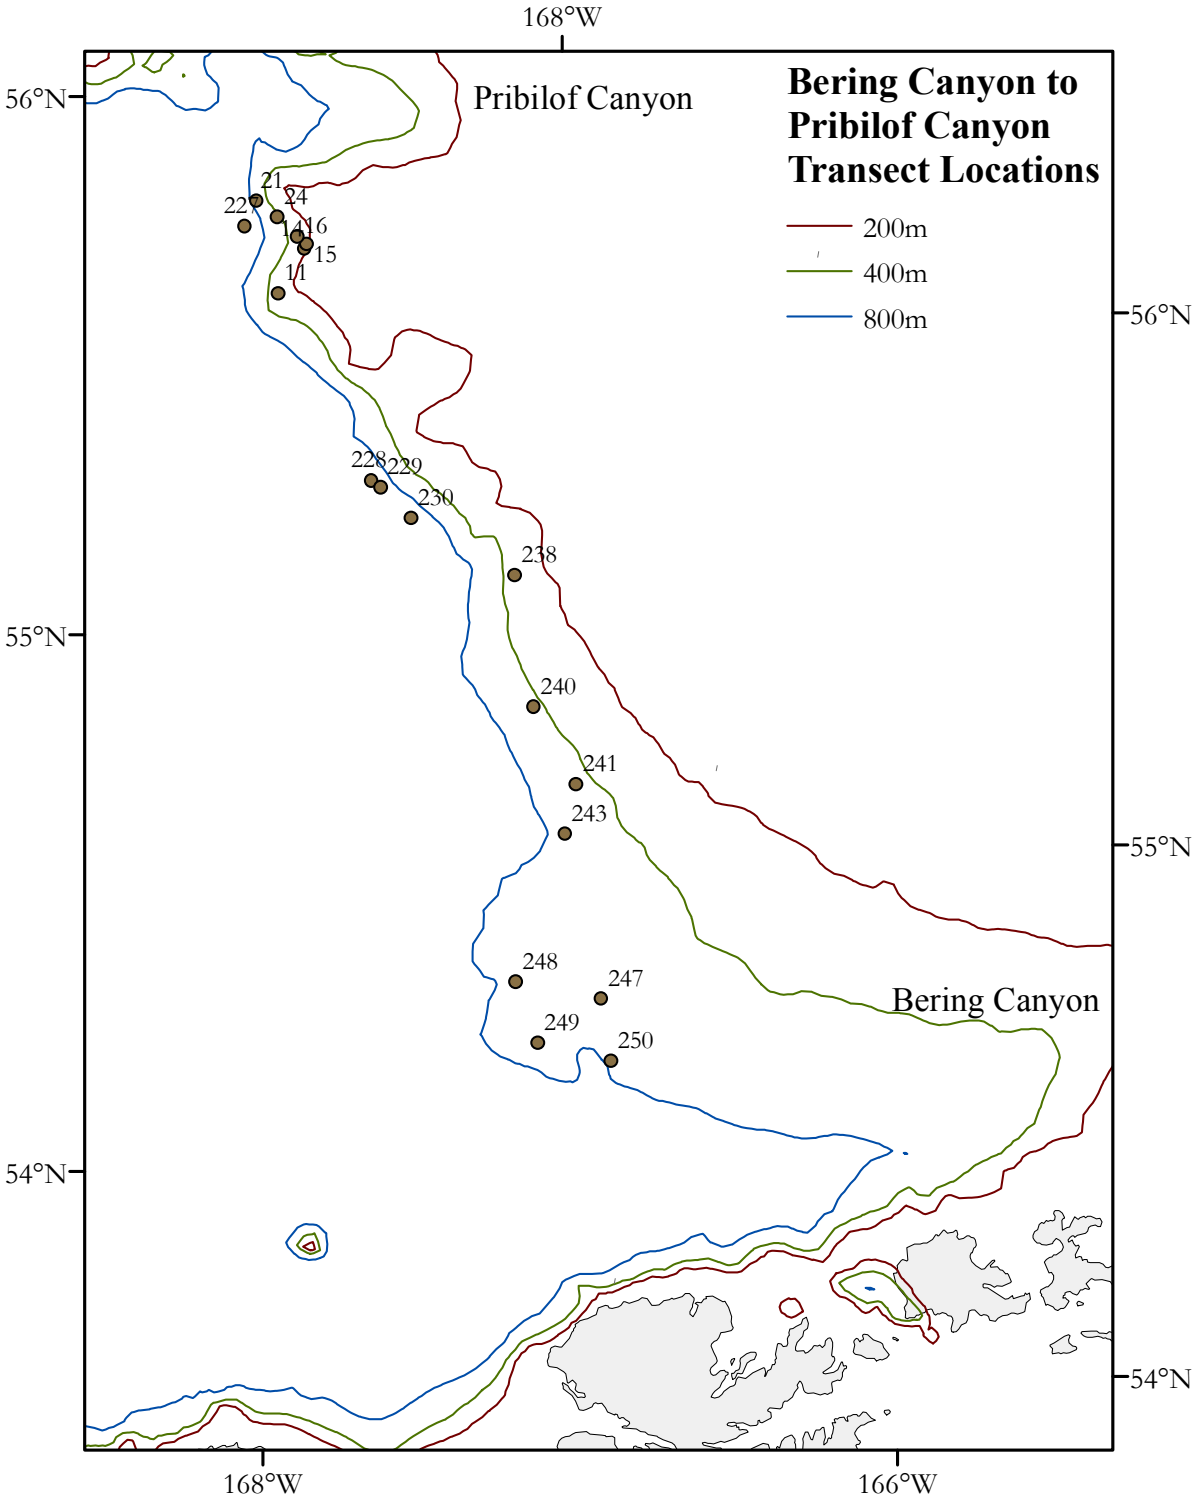

Figure 7. -- Survey transect locations, Bering Canyon to Pribilof Canyon.

SITE SUMMARY: Bering Canyon to Pribilof Canyon

The substrate between Bering Canyon and Pribilof Canyon was consistently mud or sand and mud. Substrates at 17 of the 18 transects contained mud (Table 9). Transect 238 was the only transect where both the primary and secondary substrates were identified as sand.

Of the fish and crab species identified eelpouts, *Chionoecetes* sp., and snailfishes were most frequently observed (Table 10).

Vertical structures consisted of *Halipteris* sp. (98%), Demospongiae (1%), and Hexactinellida (< 1%) (Table 11). *Halipteris* sp. occurred at all depths but was most abundant at transect 238 (Fig. 8). Damaged *Halipteris* sp. were identified at 4 of the 9 transects. *Halipteris* heights ranged from 12.3-266.3 cm with the taller *Halipteris willemoesi* occurring at transects 16, 21, 24, and 238 (Table 12). Demospongiae was identified at the southern and northern boundaries of the inter-canyon region. Only one Hexactinellida was observed at transect 21 along the outer edge of Pribilof Canyon (Fig. 9).

Table 9. -- Summary of substrates observed at transects (n = 18) between Bering Canyon and Pribilof Canyon.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observations
Mud*	346 - 753	11	64%
Sand.mud	143 - 226	6	30%
Sand*	217 - 217	1	6%

*Primary and secondary substrates were the same.

Summary - description of transect

Transect 248: Primary and secondary substrates consisted entirely of mud. Only three fish were identified in this transect; an eelpout, poacher, and popeye grenadier. As a result, species density for the transect was very low (0.01 individuals/m^2). No corals or sponges were identified.

Summary - description of transect

Transect 250: Primary and secondary substrates consisted entirely of mud. Only 7 fish were identified resulting in a low density (0.01 individuals/m^2). Vertical habitat was largely absent with only three Demospongiae identified, and one measured (11.3 cm). No corals were identified.

Thirty-five transects were completed in Pribilof Canyon. Depths ranged from 93 m to 761 m. Twenty-nine taxa of fishes and crabs were identified (Table 14). Vertical habitat was dominated by Demospongiae (Table 15). Heights ranged from 2.1 cm to 61.6 cm (Table 16).

Pribilof Canyon

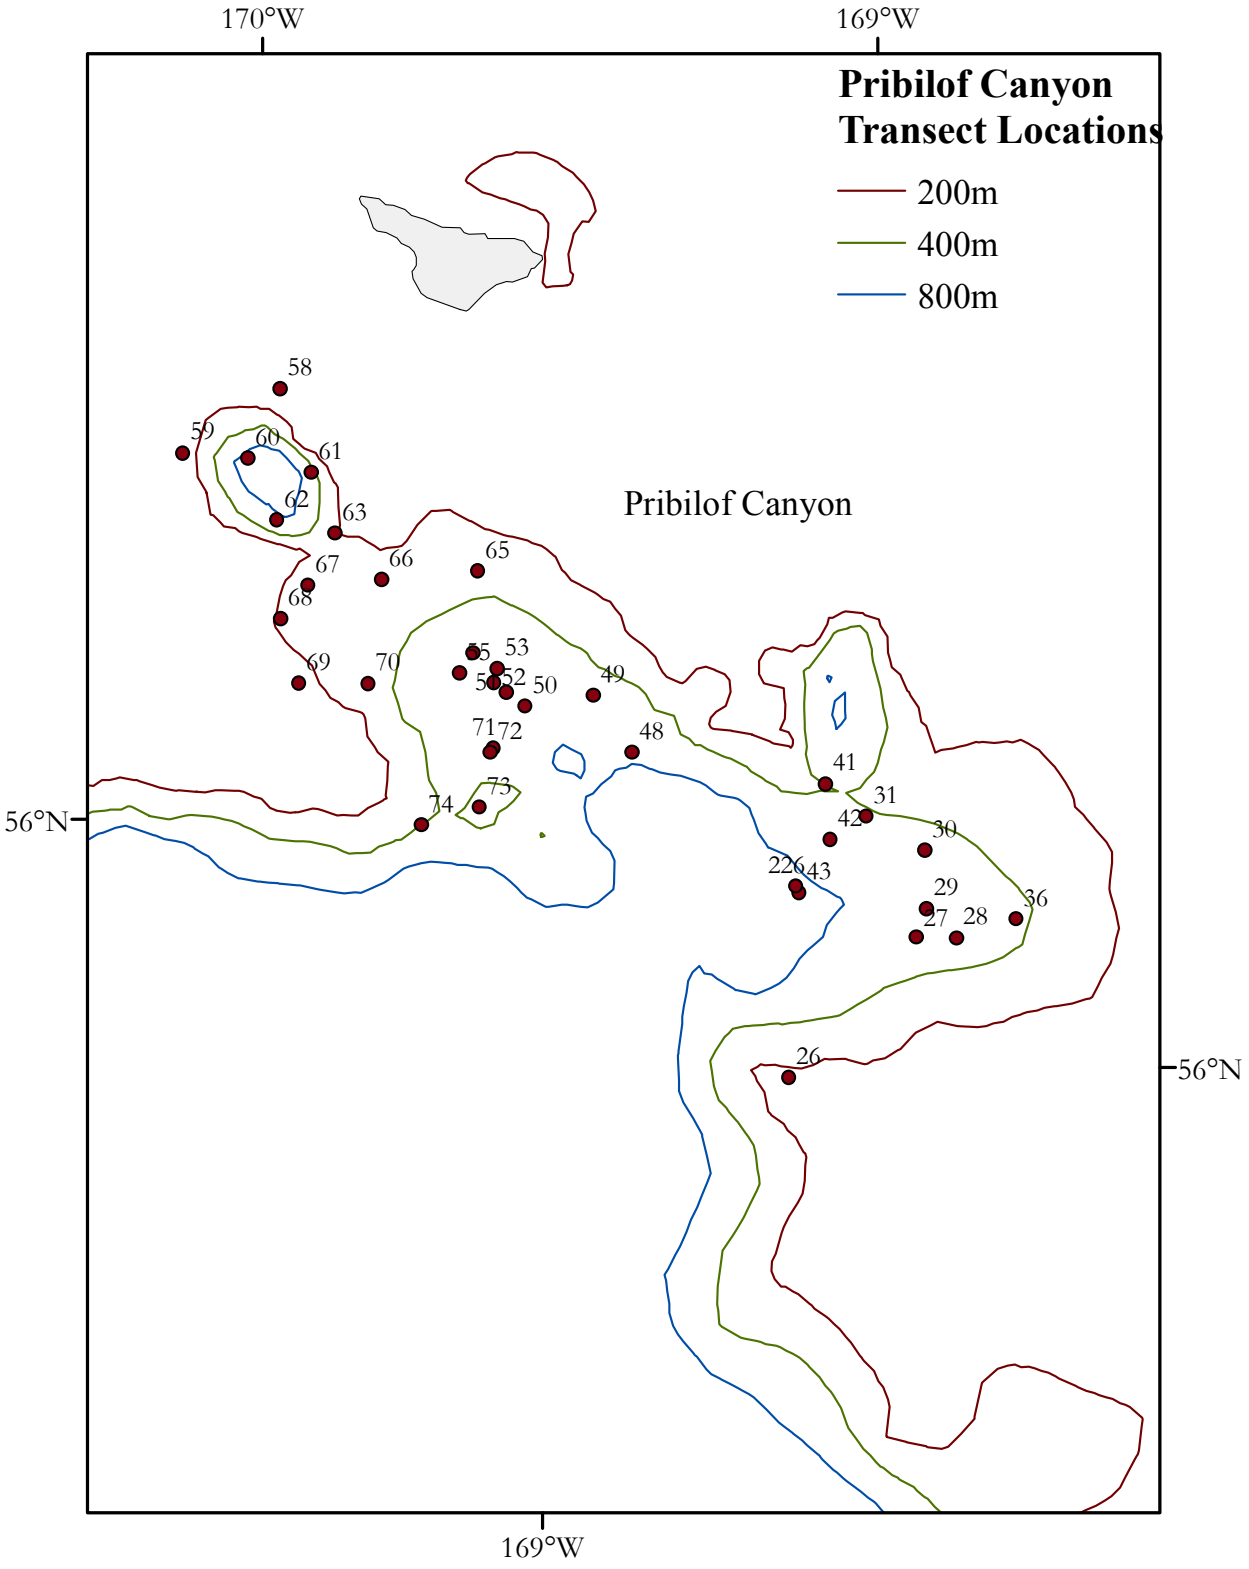

Figure 10. -- Survey transect locations, Pribilof Canyon.

SITE SUMMARY: Pribilof Canyon

Pribilof Canyon is an elongated canyon that runs parallel to the continental shelf. It is approximately 45 km wide at the shelf break with a 1,600 m relief. There are two branches in the canyon that merge at 1,500 m where the canyon turns 90 degrees and eventually merges with Bering Canyon (Karl et al. 1996).

The substrates in Pribilof Canyon were more diverse than Bering Canyon or the inter-canyon area. Over seventy percent of the observations were sand with mud or mixed coarse (Table 13). The remaining substrates were a mix of cobble, boulder, and gravel.

Golden king crabs ($n = 712$) were by far the most frequently observed species of crabs or fishes (Table 14). Ninety percent ($n = 640$) of the golden king crabs were identified in transect 54. Eelpouts, snailfishes, and *Chionoecetes* were the next most abundant. Rockfishes made up 6% of the species composition.

Twelve taxa of corals, sponges, and sea whips were identified (Table 15), more than any other region surveyed. Sponges were the most abundant with Demospongiae ($n = 4,436$) occurring at 24 of the 35 transects. Seventy-one percent of observed Demospongiae were present in transect 54. *Plumarella* and *Swiftia* were the most plentiful of the corals. Isididae were identified at three transects (53, 54, 73) in the deep water at the northwestern edge of the central canyon.

The tallest vertical structure was Demospongiae (Table 16). *Plumarella* had the largest range in heights, 3.6-52.7 cm. Corals were evenly distributed throughout the canyon (Fig. 12), while sea whips were only found in the northwest (Fig. 11). Demospongiae were also evenly distributed but Hexactinellida was only identified in the northwest and Calcarea was only seen in the southeast (Fig. 13).

Table 13. -- Summary of substrates observed at transects (n = 35) in Pribilof Canyon.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observations
Sand.mud	93 - 761	20	47%
Mixed coarse	188 - 760	14	33%
Sand*	502 - 717	4	11%
Sand.gravel	215 - 659	3	3%
Mixed coarse.cobble	201 - 446	4	3%
Sand.mixed coarse	399 - 399	1	2%
Mixed coarse.boulder	188 - 532	7	1%
Sand.cobble	181 - 659	3	<1%
Cobble*	188 - 435	2	<1%
Cobble.boulder	188 - 435	2	<1%
Cobble.mixed coarse	435 - 760	2	<1%
Sand.boulder	181 - 659	2	<1%
Mixed coarse.low bedrock	532 - 532	1	<1%
Boulder.mixed coarse	532 - 532	1	<1%
Gravel.mixed coarse	394 - 394	1	<1%
Mixed coarse.gravel	524 - 524	1	<1%

*Primary and secondary substrates were the same.

Summary - description of transect

Transect 27: Primary and secondary substrates consisted predominantly of sand. Small patches of sand/boulder and mixed coarse were seen as well. Fish and crab density was 0.04 individuals/m^2. Eelpouts ($n = 13$) and snailfishes ($n = 13$) were the dominant taxa (60%). Vertical habitat consisted of eight Primnoidae (4 *Plumarella* sp.) as well as two *Swiftia* sp. In addition, 58 Demospongiae and 32 Hexactinellida were identified. Four *Plumarella* sp. were measured and their mean height was 20.1 cm. One unidentified primnoid measured 29.1 cm. The mean heights for 11 Demospongiae and 9 Hexactinellida were 16.4 cm and 19.9 cm, respectively. The vertical habitat density for the transect was 0.09 individuals/m^2. No sea whips were found.

Summary - description of transect

Transect 28: Primary and secondary substrates were almost entirely mixed coarse. Only 10 fish were found and snailfishes made up 40% of them. Fish density was low (0.01 individuals/m^2). Coral density was < 0.01 individuals/m^2, and consisted of 7 *Swiftia* sp. The vertical habitat also contained 223 sponges (12 unknown, 8, Calcarea, 178 Demospongiae, 25 Hexactinellida). Sponge density was 0.26 individuals/m^2. Measurements were collected from 21 Demospongiae, 6 Hexactinellida, 2 unknown sponges, and 1 Calcarea. Correspondingly, mean heights were 13.5 cm, 12.6 cm, 14.3 cm, and 18.2 cm. No sea ships were identified.

Summary - description of transect

Transect 226: Primary and secondary substrates consisted entirely of sand (63%). The remaining 37% of the frames were off bottom with no visual input received. Overall fish and crab density was very low, 0.01 individuals/m^2. Only 3 individuals in 2 taxa were identified. No vertical habitat was observed.

Sixty-eight transects were completed between Pribilof Canyon and Zhemchug Canyon. Depths ranged from 130 m to 796 m. Thirty-five taxa of fishes and crabs were identified (Table 18). Vertical habitat was dominated by *Halipteris* sp. and hexactinellids (Table 19). Heights ranged from 2.2 cm to 205.6 cm (Table 20).

Pribilof Canyon to Zhemchug Canyon

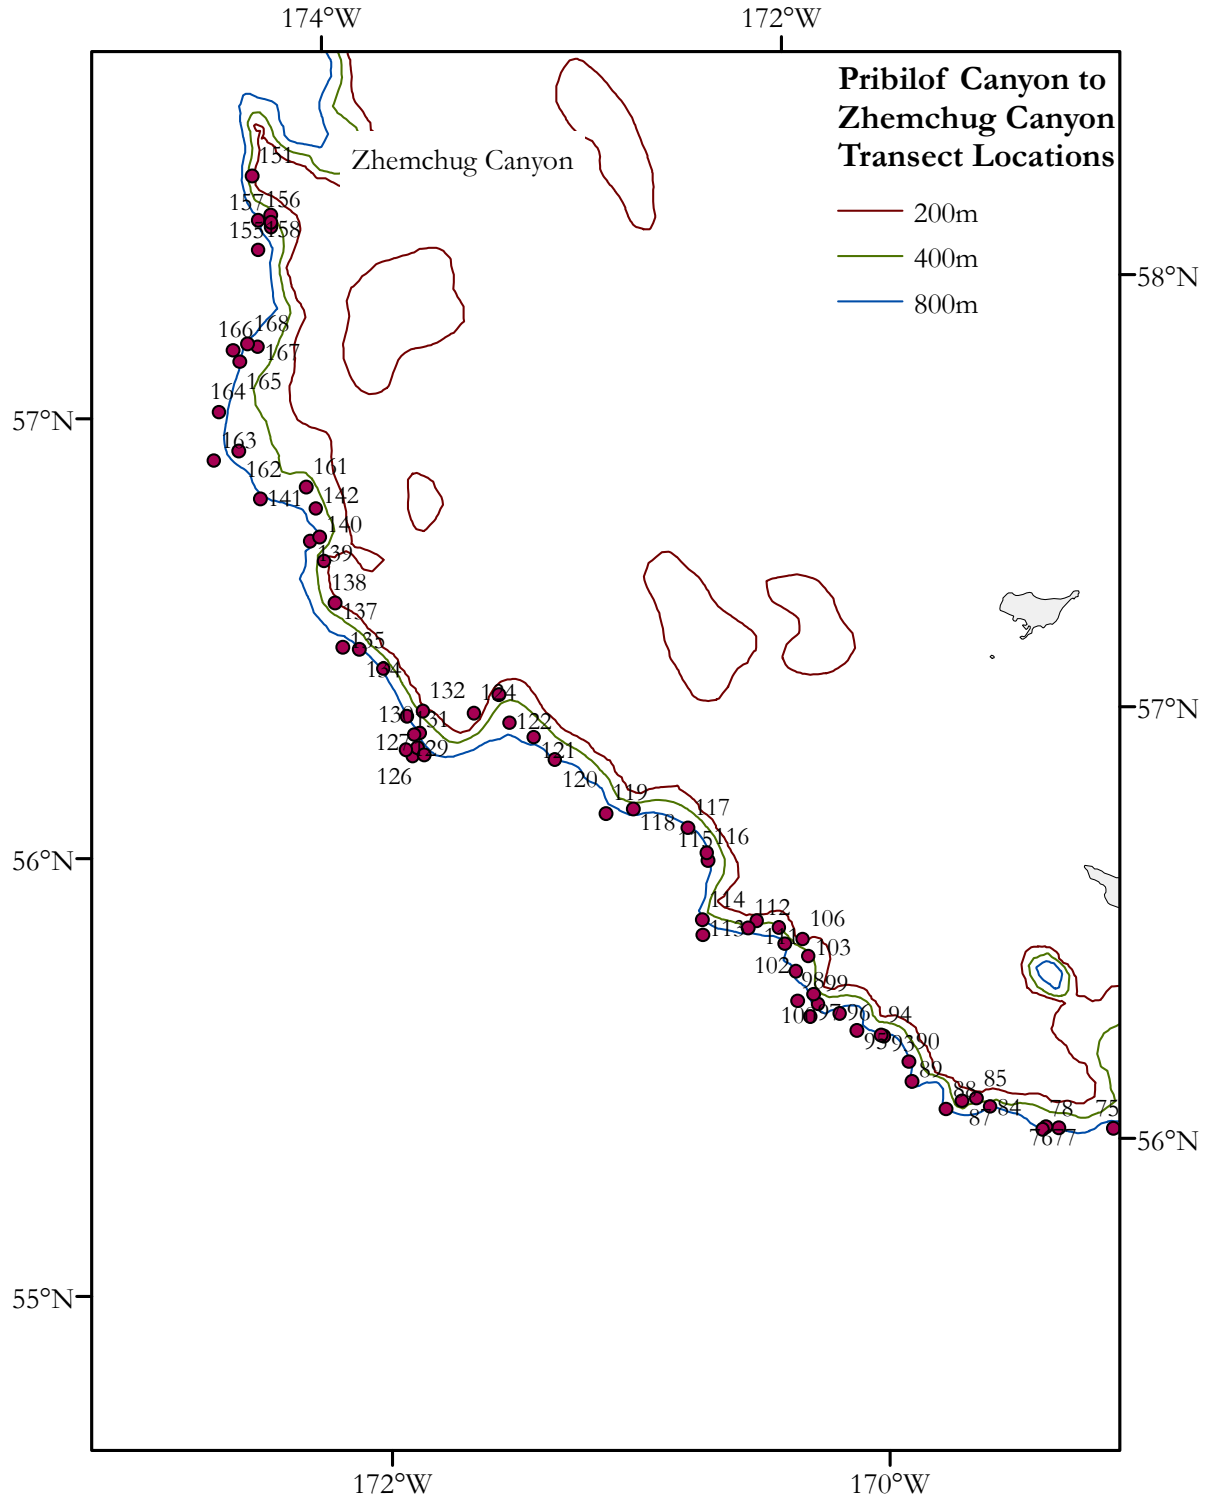

Figure 14. -- Survey transect locations, Pribilof Canyon to Zhemchug Canyon.

SITE SUMMARY: Pribilof Canyon to Zhemchug Canyon

Nineteen different substrates were identified between Pribilof Canyon and Zhemchug Canyon (Table 17). The majority of the observations were sand and mud, with sand being identified as the primary substrate over 75% of the time. Boulders were seen at 25 of the transects.

Fishes and crabs were plentiful and diverse (Table 18). More fish and crab taxa (35) were identified in the Pribilof-Zhemchug inter-canyon region than anywhere else. Popeye grenadier, sculpins, and eelpouts were the most abundant followed by Pacific ocean perch. Rockfishes (n = 514) comprised 19% of the species composition.

Halipteris (n = 14,977) far outnumbered all of corals and sponges, occurring at 31 transects and at all depths observed (Table 19). Demospongiae was the next most abundant (n = 6,047) also occurring at all depths. Hexactinellida was identified at 30 transects. Isididae (n = 60) was the most abundant coral but only occurred at depths greater than 400 m. *Plumarella* (n = 49) the next most abundant coral was seen at four transects with depths ranging from 207-474 m.

Coral, sponge, and sea whip heights ranged from 2.2 cm to 204.4 cm with *Halipteris* sp. being the shortest and *Halipteris willemoesi* being the tallest (Table 20). The tallest Hexactinellida (205.6 cm) of the survey was seen in this region at transect 97.

Sea whips, corals, and sponges were found in fifty-two of the sixty-eight transects. Sea whips and sponges were found throughout the region (Figs. 15, 17). Primoidae and Isididae were only identified in the southern transects (Fig. 16).

Table 17. -- Summary of substrates observed at transects (n = 68) between Pribilof Canyon and Zhemchug Canyon.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observations
Sand.mud	130 - 770	52	61%
Mud*	367 - 796	7	11%
Mixed coarse	167 - 474	11	9%
Sand.mixed coarse	142 - 770	15	9%
Sand*	133 - 491	6	5%
Mixed coarse.cobble	218 - 455	3	1%
Mixed coarse.boulder	188 - 760	6	1%
High bedrock	759 - 760	2	1%
Sand.cobble	340 - 760	5	1%
Sand.boulder	142 - 770	12	<1%
Sand.gravel	455 - 770	3	<1%
Cobble.mixed coarse	285 - 285	1	<1%
Boulder.cobble	455 - 455	1	<1%
Cobble.sand	474 - 474	1	<1%
Boulder*	137 - 759	2	<1%
Mixed coarse.sand	474 - 474	1	<1%
Mixed coarse.mud	474 - 474	1	<1%
Gravel.mud	148 - 148	1	<1%
Mixed coarse.gravel	455 - 455	1	<1%

*Primary and secondary substrates were the same.

Summary - description of transect

Transect 89: Primary and secondary substrates consisted of mixed coarse(68%), mixed coarse and boulders (< 1%), sand and cobble (< 1%), and sand and mud (32%). Overall fish and crab density was 0.03 individuals/m^2. Shortspine thornyheads accounted for 26% of the enumerated taxa. The next most abundant taxa were blackspotted rockfishes and golden king crabs at 17% each%. Vertical habitat consisted of Demospongiae (n = 19) and Hexactinellida (n = 3), with a density of 0.02 individuals/m^2. Demospongiae heights (n = 4) ranged from 14.5 cm to 21.5 cm with a mean of 17.4 cm. Only one Hexactinellida was measured, with a height of 15.1 cm. No corals were observed.

Summary - description of transect

Transect 168: Primary and secondary substrates consisted entirely of mud. Overall fish and crab density was 0.03 individuals/m^2. Eelpouts accounted for 30% of the enumerated taxa. The next most abundant taxa were poachers, snailfishes, and *Chionoecetes* sp., at 61% combined. No vertical habitat consisted was observed.

Zhemchug Canyon

Twenty-five transects were completed in Zhemchug Canyon. Depths ranged from 121 m to 744 m. Thirty-one taxa of fishes and crabs were identified (Table 22). Vertical habitat was dominated by sponges (Table 23). Heights ranged from 1.7 cm to 134.5 cm (Table 24).

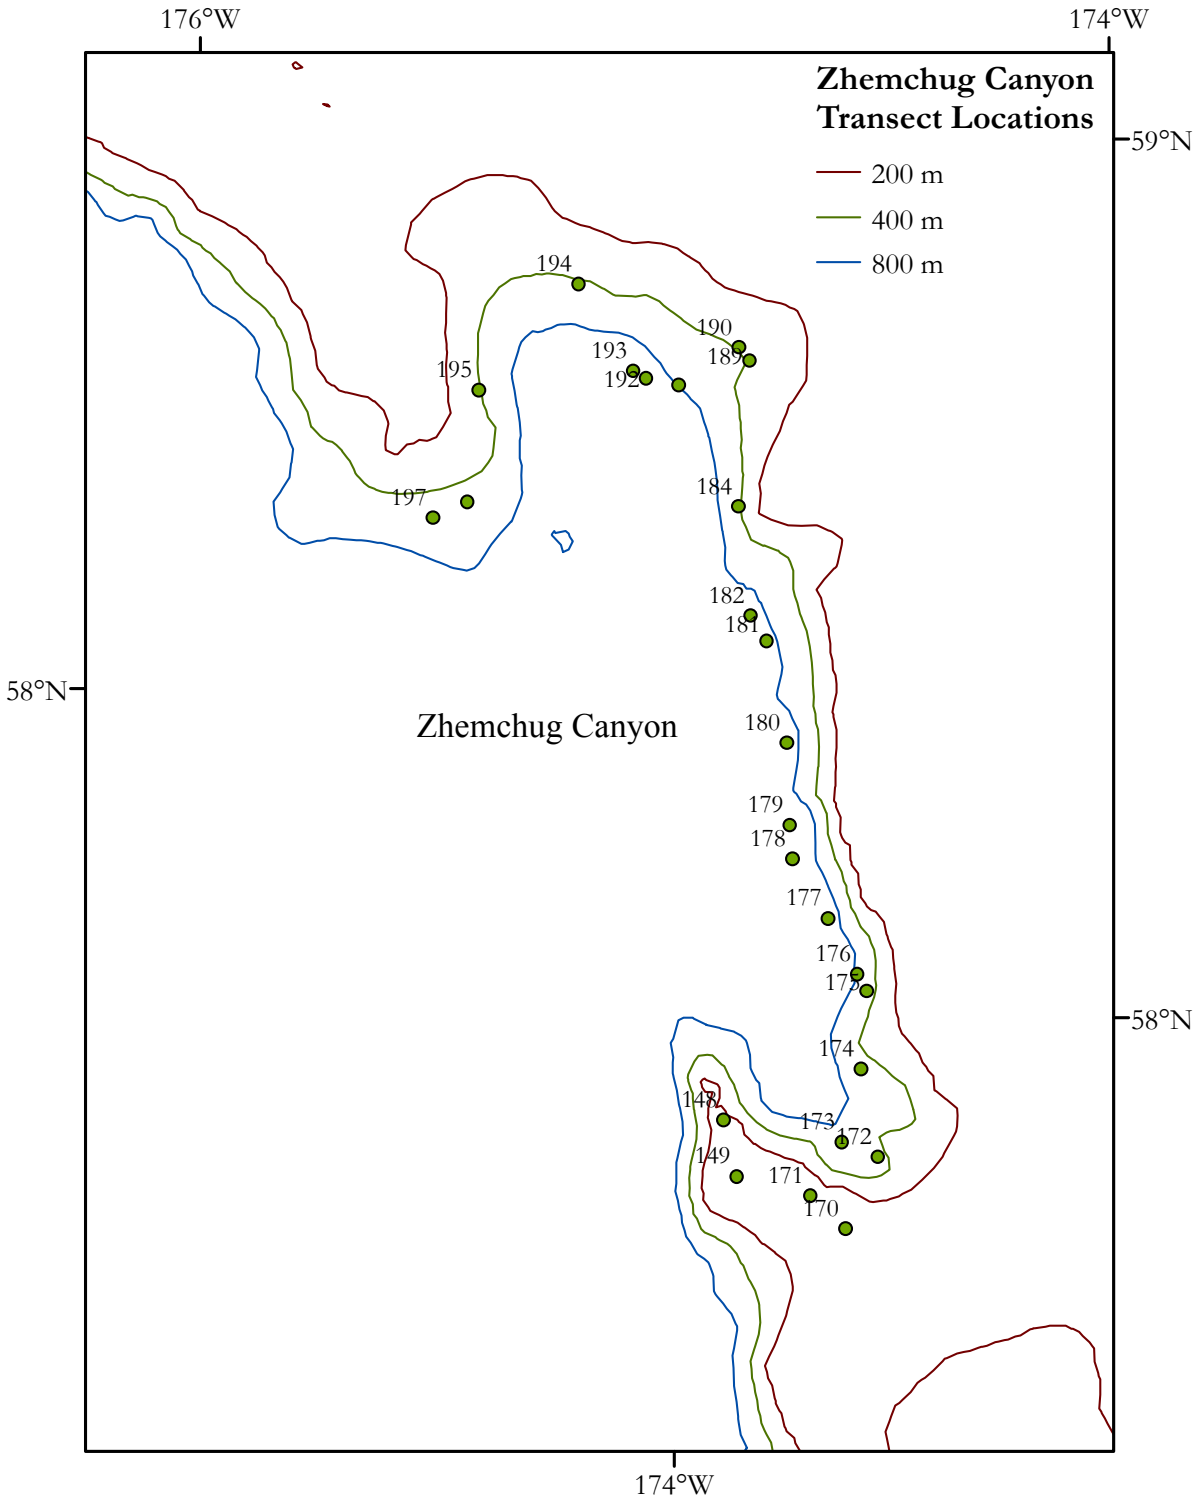

Figure 18. -- Survey transect locations, Zhemchug Canyon.

SITE SUMMARY: Zhemchug Canyon

Zhemchug Canyon is known for its rugged steep walls. The elongated canyon runs almost parallel to the shelf break. It cuts a gorge 106 km long and 30 km wide, with 2,600 m of relief and a floor 10 km wide (Karl et al. 1996).

Twenty-three distinct substrates were identified in Zhemchug Canyon (Table 21). The primary substrate was sand with mud, gravel, cobble, boulders, mixed coarse, and bedrock mixed in. Transect 149 was the most diverse in the canyon with 13 different substrates being identified and boulders comprising 48% of the composition.

Fish and crab composition was also diverse with thirty-one taxa being identified (Table 22). Pacific ocean perch ($n = 846$) and harlequin rockfish ($n = 11$) were the most abundant, of which 813 were identified at transect 149. Northern rockfish ($n = 167$) were also present at this transect.

Demospongiae ($n = 9,294$) from transect 149 were the most abundant of the corals, sponges, and sea whips (Table 23). Heights ranged from 1.7 cm to 134.5 cm with *Halipteris* being the shortest and Demospongiae being the tallest (Table 24). *Swiftia* sp. was the only coral observed other than *Halipteris*

Sea whips and Demospongiae were distributed throughout the canyon (Figs. 19, 21). The one Plexauridae (*Swiftia* sp.) was located in the southern tip of the canyon (Fig. 20).

Table 21. -- Summary of substrates observed at transects ($n = 25$) in Zhemchug Canyon.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observations
Sand.mud	153 - 744	18	64%
Sand*	288 - 659	5	12%
Sand.gravel	122 - 485	7	10%
Sand.mixed coarse	288 - 744	3	4%
Sand.cobble	121 - 130	3	3%
Boulder.high bedrock	129 - 129	1	2%
Mixed coarse	121 - 121	2	1%
Cobble.sand	129 - 129	1	1%
Sand.boulder	121 - 121	8	1%
Gravel.sand	129 - 129	2	<1%
High bedrock.boulder	121 - 129	1	<1%
Gravel*	129 - 129	1	<1%
Low bedrock.boulder	121 - 121	1	<1%
Boulder.low bedrock	129 - 129	1	<1%
Mixed coarse.boulder	121 - 121	1	<1%
Sand.low bedrock	288 - 288	3	<1%
Cobble.low bedrock	129 - 129	1	<1%
Boulder.sand	129 - 129	2	<1%
High bedrock	121 - 121	1	<1%
Sand.high bedrock	485 - 485	1	<1%
Cobble.boulder	129 - 129	1	<1%
Mixed coarse.sand	121 - 121	1	<1%
Low bedrock	121 - 121	1	<1%

*Primary and secondary substrates were the same.

Table 22. -- Summary of fishes and crabs identified at transects (n = 25) in Zhemchug Canyon.

Species/Grouping	Number of occurrences	Number of transects with occurrences	Mean transect depth range (m)	Mean density (individuals/m^2)
Pacific ocean perch	846	6	121 - 402	0.10
Eelpout unid.	168	16	251 - 744	0.01
Northern rockfish	168	2	121 - 288	0.06
Poacher unid.	115	21	129 - 744	0.01
Popeye grenadier	84	4	659 - 737	0.02

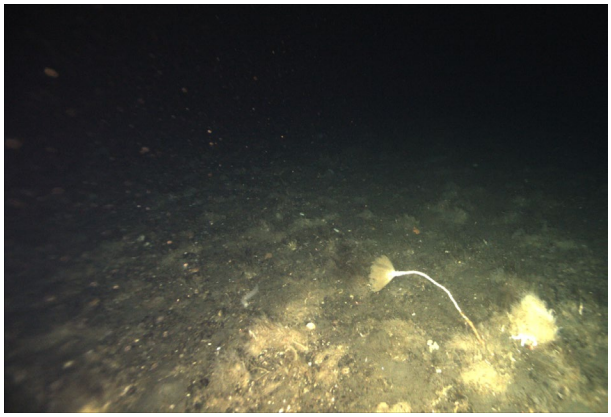
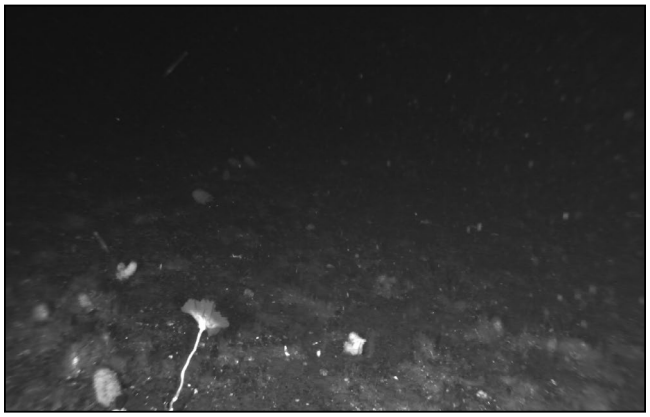
Images





Summary - description of transect

Transect 148: Primary and secondary substrates for 75% of the transect were sand and mixed coarse. The remaining substrate consisted entirely of mixed coarse. Species density was extremely low (0.01) individuals/m^2. Only two fish were identified. Sponge densities were 0.29 individuals/m^2, with 20 Demospongiae and 90 Hexactinellida identified. One Demospongiae was measured (21.0 cm) and the mean height of 15 measured Hexactinellida was 15.7 cm. No corals were observed.

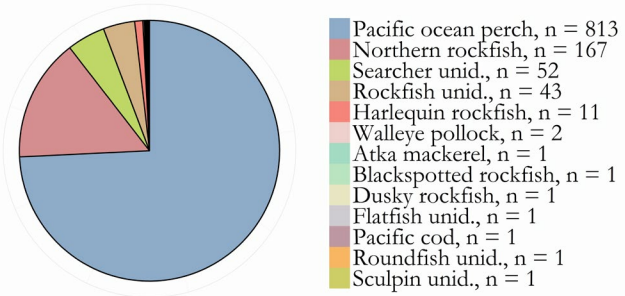
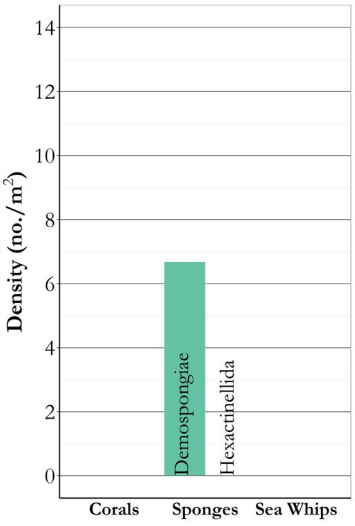
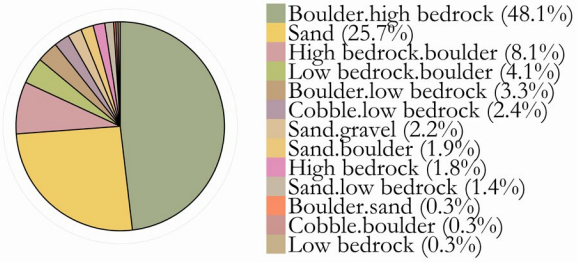
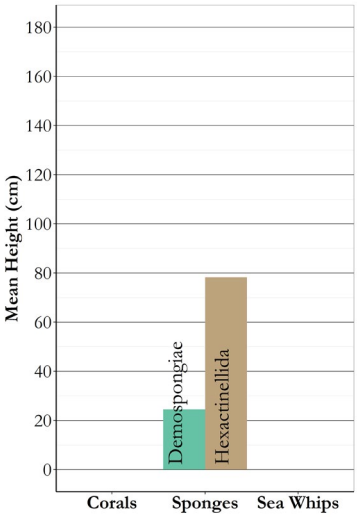
Fish and Crab Composition (n = 1095)



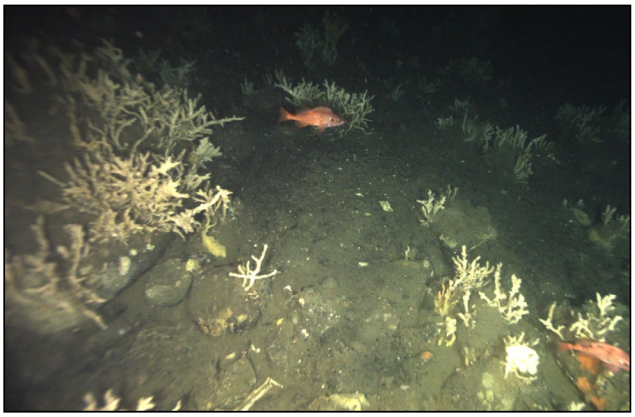


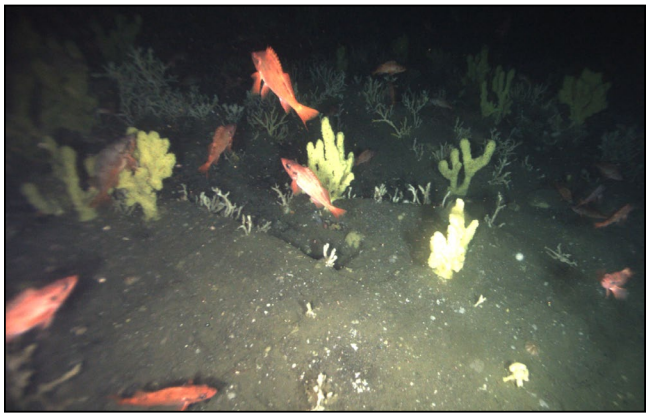
Substrate Composition





Images





Summary - description of transect

Transect 149: Substrate composition for this transect was very diverse. Almost 50% of the substrate consisted of boulder and high bedrock. Another 26% of the substrate was sand. Of the 1,095 individuals counted, 813 were Pacific ocean perch and 167 were northern rockfish, accounting for 89% of all fishes counted. Fish density was 0.79 individuals/m^2. Vertical habitat was composed of four Hexactinellida and 9,294 Demospongiae for a density of 6.678 individuals/m^2. Mean height for 233 measured Demospongiae was 24.5 cm. One Hexactinellida was measured (78.2 cm). No corals were identified.

Area: Zhemchug Canyon					Transect 170
Date (mm/dd/yy)	Start Position (DD)		Area (m^2)	Mean Depth (m)	Mean Temp (°C)

Summary - description of transect

Transect 197: Primary and secondary substrates consisted entirely of sand and mud. Of the 30 individuals counted, poachers were the most abundant. One skate, 1 crab, and 3 Greenland turbot were also identified in this transect. Species density was 0.02 individuals/m^2. Vertical habitat consisted of 67 sea whips (2 damaged). Mean height for 21 measured sea whips was 16.2 cm. No other corals or sponges were identified.

Zhemchug to Pervenets Canyon

Fifteen transects were completed between Zhemchug Canyon and Pervenets Canyon. Depths ranged from 215 m to 770 m. Twenty-three taxa of fishes and crabs were identified (Table 26). Very little vertical habitat was observed (Table 27). Heights ranged from 3.8 cm to 46.8 cm (Table 28).

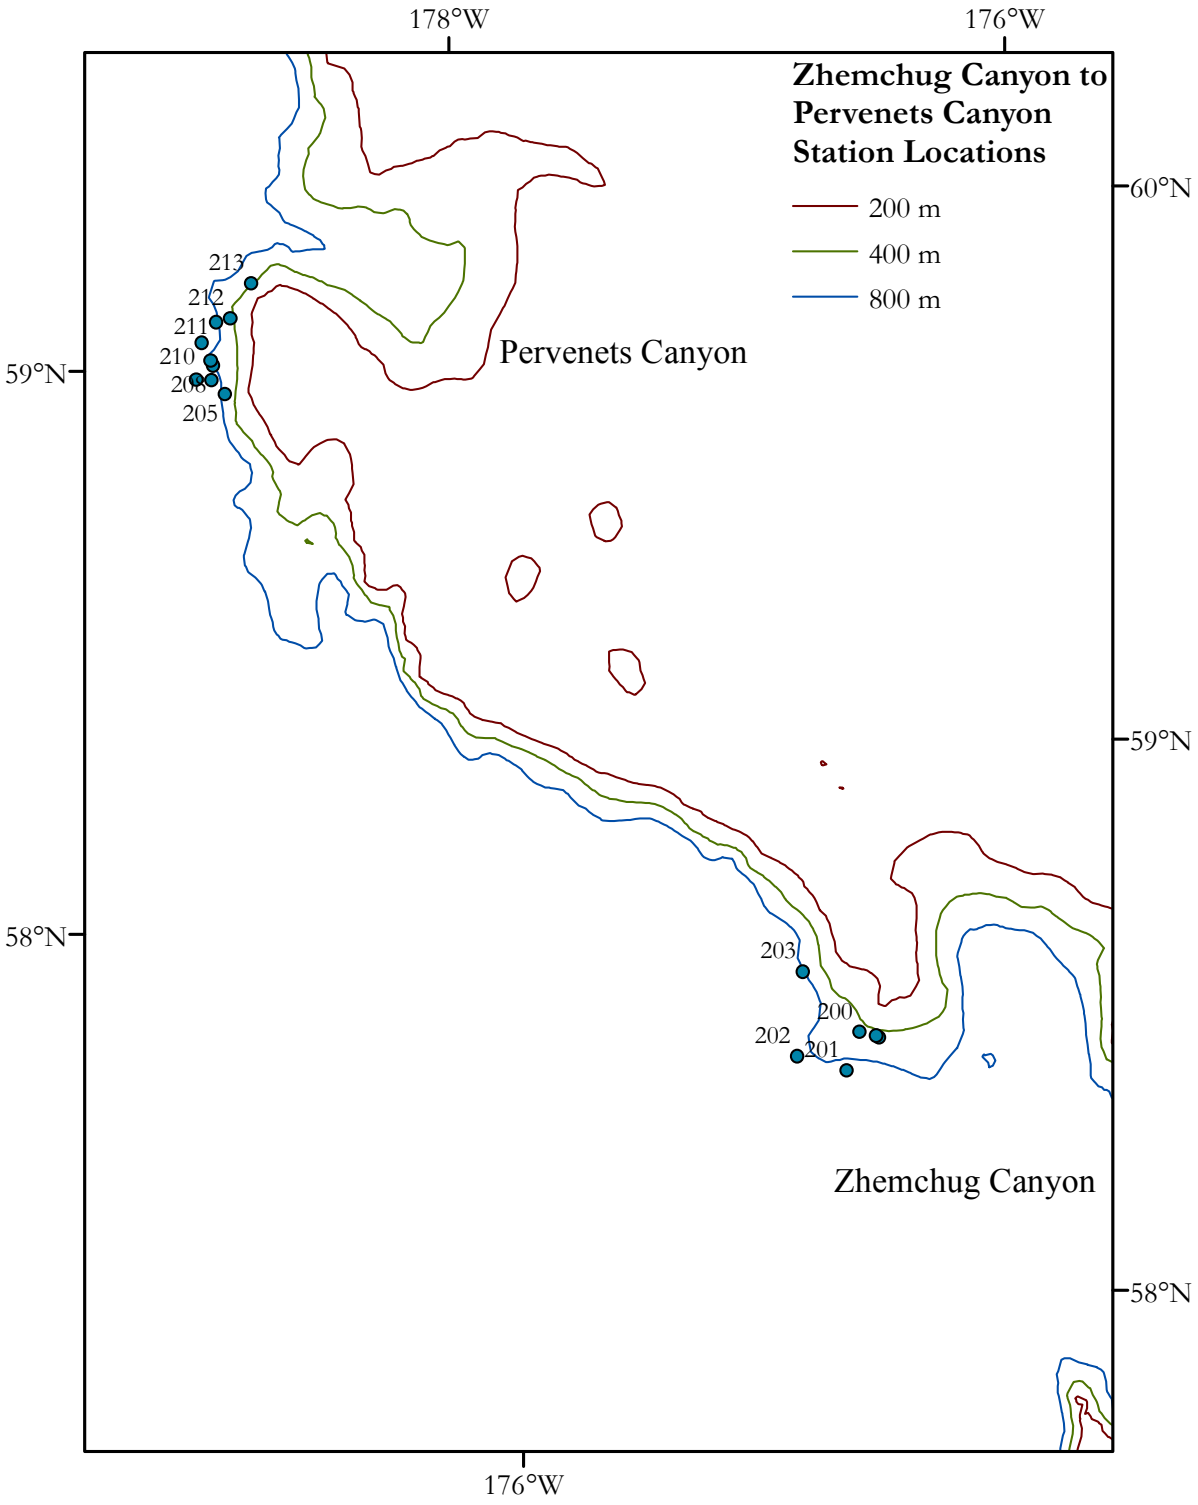

Figure 22. -- Survey transect locations, Zhemchug to Pervenets Canyon.

SITE SUMMARY: Zhemchug Canyon to Pervenets Canyon

Transects between Zhemchug Canyon to Pervenets Canyon were concentrated around the northern and southern ends of the region due to time constraints (Fig. 22). All substrates observed contained sand as the primary substrate. Boulders were identified in two transects (Table 25).

Popeye grenadiers was the most abundant species of crabs or fishes observed, occurring at a mean depth of greater than 571 m (Table 26). Eelpouts and sculpins were the next most frequently identified. Overall, twenty-three taxa of fish and crabs were identified.

Demospongiae and *Halipteris* provided the only vertical habitat (Table 27, Figures 23 and 24). Heights ranged from 3.8 cm to 46.8 cm with *Halipteris willemoesi* being the tallest (Table 28).

Table 25. -- Summary of substrates observed at transects ($n = 15$) between Zhemchug Canyon and Pervenets Canyon.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observed substrate
Sand.mud	215 - 770	15	97%
Sand*	571 - 571	1	2%
Sand.gravel	571 - 571	1	1%
Sand.mixed coarse	571 - 571	1	<1%
Sand.boulder	571 - 723	2	<1%

*Primary and secondary substrates were the same.

Summary - description of transect

Transect 213: Primary and secondary substrates consisted of sand and mud. Only 25 individuals were identified, and 52% were sculpins and flatfishes. Species density was 0.03 individuals/m^2. Vertical habitat consisted of 87 sea whips and 7 Demospongiae (1 damaged). Sponge and sea whip density was 0.10 individuals/m^2. One Demospongiae was measured (20.3 cm), and the mean height of 41 measured sea whips was 7.9 cm.

Pervenets Canyon

Twelve transects were completed in Pervenets Canyon. Depths ranged from 261 m to 748 m. Sixteen taxa of fishes and crabs were identified (Table 30). Very little vertical habitat was observed (Table 31). Heights ranged from 3.8 cm to 46.8 cm (Table 32).

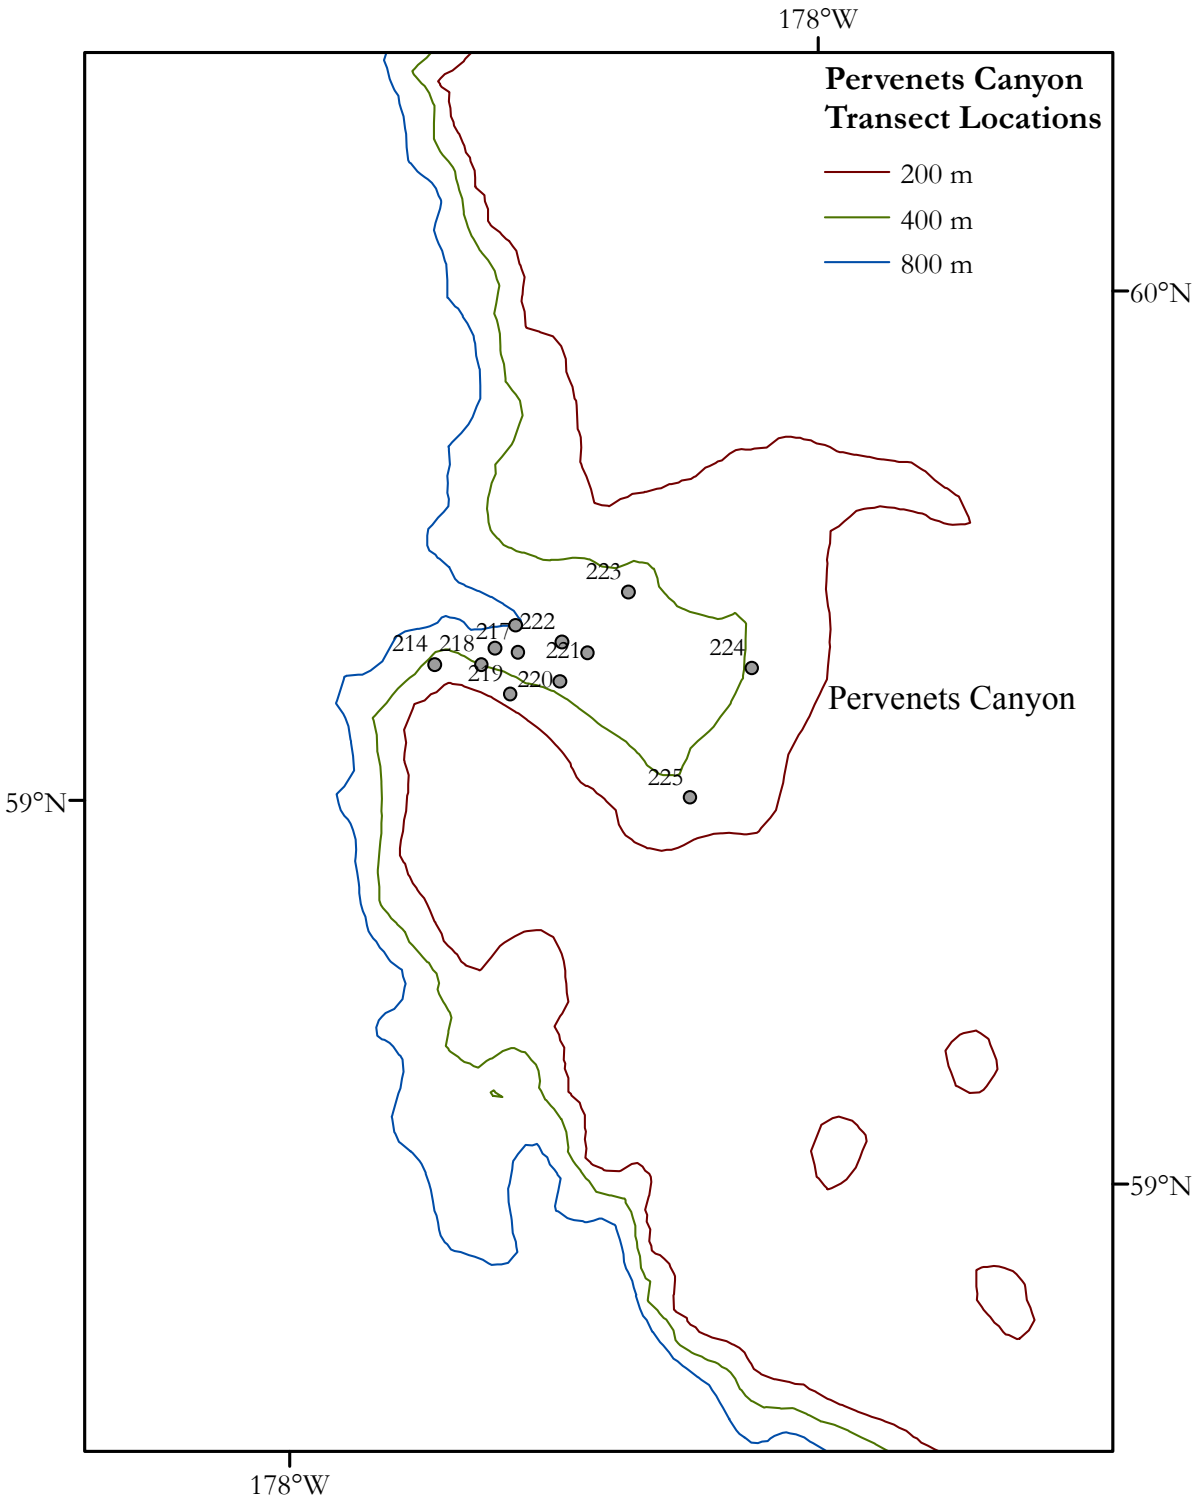

Figure 25. -- Survey transect locations, Pervenets Canyon.

SITE SUMMARY: Pervenets Canyon

Pervenets Canyon is 70 km across on the shelf at its widest point. It narrows to 40 km at the shelf break. There are two main channels that merge to form one channel at 600 m and then join Navarin Canyon at 3,500 m. Pervenets has a volume of 1,700 km^3 which is approximately one third the size of Navarin Canyon to the north (Karl et al. 1996).

Seventy percent of the observed substrates in Pervenets Canyon were comprised of sand (Table 29). Mud was present at 4 transects (29% of observations).

Fish and crab diversity was lower than Zhemchug and Pervenets Canyons with only sixteen taxa identified (Table 30). Popeye grenadier, *Chionoecetes*, and eelpouts were the top three species present.

Vertical habitat diversity was low with only *Halipteris*, Demospongiae, and Hexactinellida present (Table 31, Figs. 26-27). Demospongiae and Hexactinellida both occurred at the same two transects (223, 224). Ninety-eight percent of the *Halipteris* were identified at transect 219 (Fig. 26).

Table 29. -- Summary of substrates observed at transects ($n = 12$) in Pervenets Canyon.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observations
Sand.mud	364 - 748	6	53%
Mud*	261 - 561	4	29%
Sand*	273 - 602	2	17%
Sand.gravel	738 - 738	1	1%
Sand.cobble	611 - 611	1	<1%

*Primary and secondary substrates were the same.

Table 30. -- Summary of fishes and crabs identified at transects ($n = 12$) in Pervenets Canyon.

Species/Grouping	Number of occurrences	Number of transects with occurrences	Mean transect depth range (m)	Mean density (individuals/m^2)
Popeye grenadier	465	5	561 - 748	0.09
Chionoecetes sp.	393	8	364 - 748	0.04

Summary - description of transect

Transect 225: Primary and secondary substrates consisted of mud. Only 3 fish were identified resulting in a low density (< 0.01 individuals/m^2). No vertical habitat was identified.

Sixty-seven transects were completed on the Outer Shelf. Depths ranged from 91 m to 513 m. Twenty-eight taxa of fishes and crabs were identified (Table 34). Vertical habitat was dominated by Demospongiae and sea whips (Table 35). Heights ranged from 2.7 cm to 230.1 cm (Table 36).

Outer Shelf

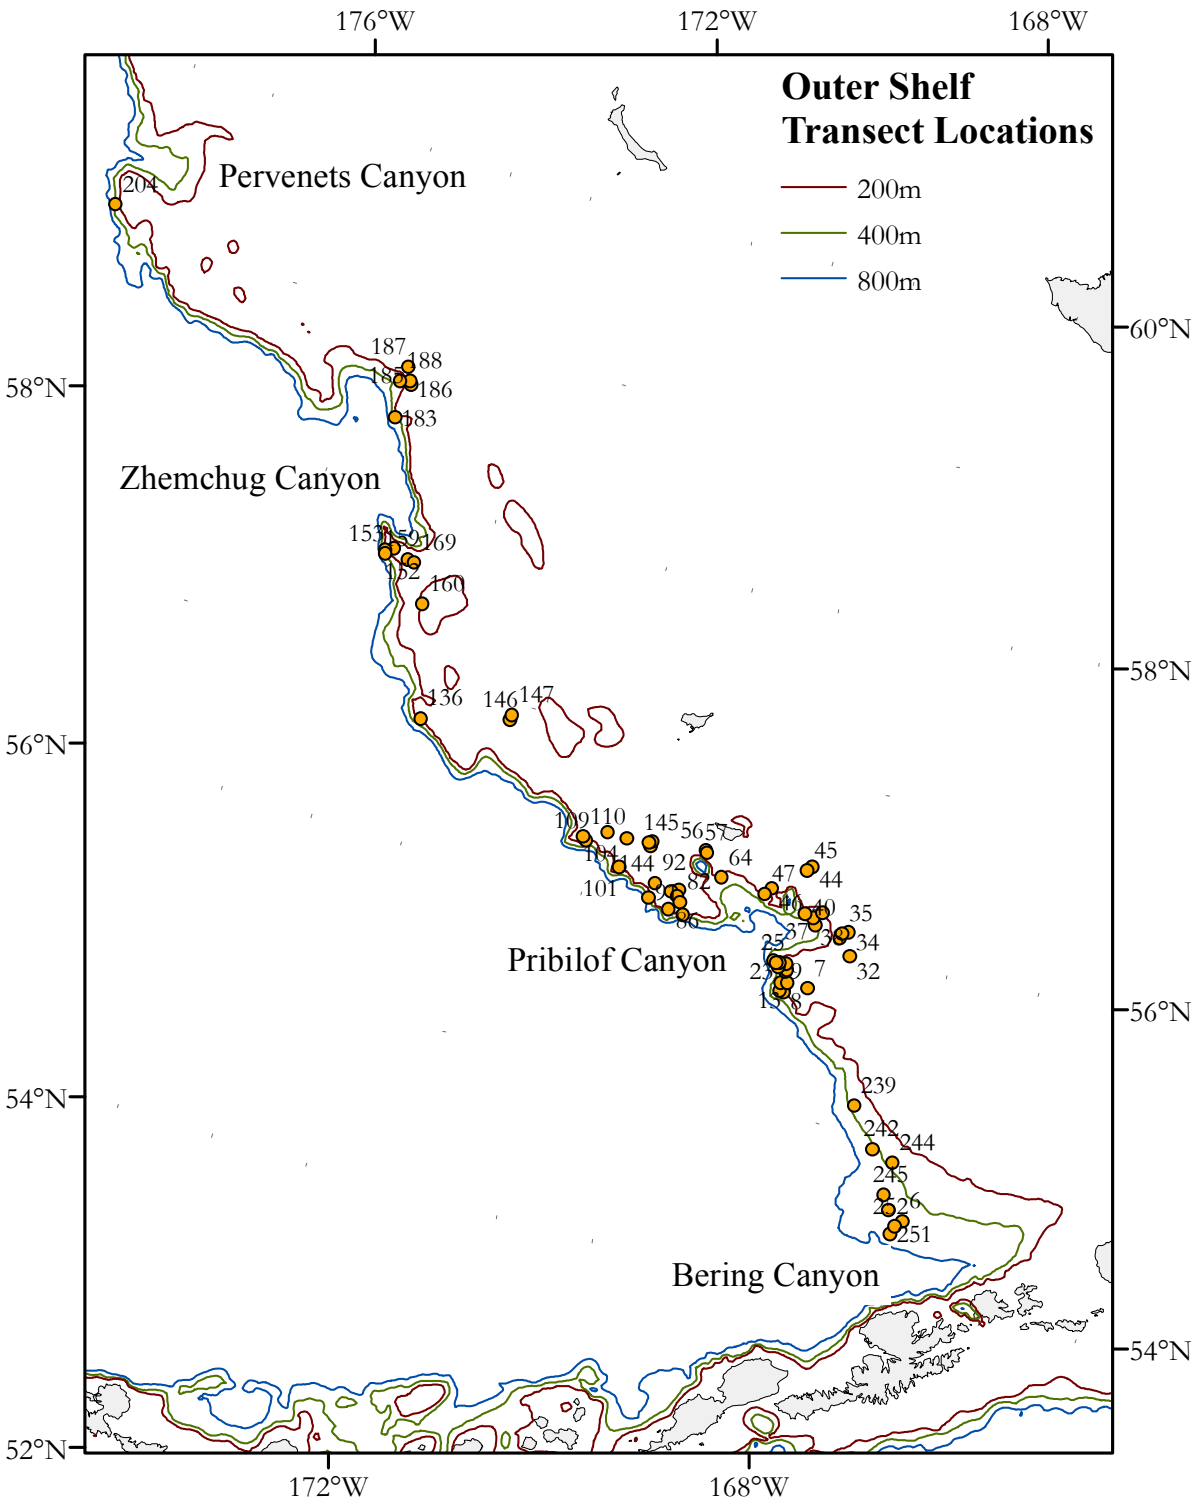

Figure 28. -- Survey transect locations, Outer Shelf.

SITE SUMMARY: Outer Shelf

Transects in the Outer Shelf region had the largest spread in latitude, occurring as far south as 166.99°N and as far north as 178.29°N (Fig. 28). The boundaries of the outer shelf are defined in Sigler et al. 2015.

The Outer Shelf substrate was dominated by sand and mud. Over 80% of the primary substrate was identified as sand (Table 33). Boulders and bedrock were observed in less than 2% of the images.

Chionoecetes sp. were identified more than any other fish or crab occurring at 49 of 67 transects (Table 34). Although *Halipteris* sp. occurred at more transects (25) than Demospongiae (29), the frequency of occurrences of Demospongiae was almost twice as much as *Halipteris* (Table 35). *Halipteris willemoesi* and Demospongiae dominated the vertical habitat with heights ranging from 4-230 cm and 10-73 cm, respectively.

Sea whips and sponges were distributed throughout the region (Figs. 29, 31). Primnoidae (*Plumarella* sp.) was the only coral present, occurring at transect 40 (Fig. 30).

Table 33. -- Summary of substrates identified at transects ($n = 67$) in the Outer Shelf region.

Substrate	Depth range (m)	Number of transects with observed substrate	Percent of observed substrate
Sand.mud	91 - 451	57	72%
Mud*	278 - 513	8	11%
Sand*	110 - 174	14	6%
Mixed coarse	174 - 252	6	6%
Sand.mixed coarse	171 - 181	4	2%
Boulder.high bedrock	110 - 110	1	1%
Mixed coarse.sand	181 - 181	1	1%
Gravel.mixed coarse	181 - 181	1	<1%
Sand.gravel	146 - 181	2	<1%
Sand.boulder	110 - 171	4	<1%
High bedrock.boulder	110 - 110	1	<1%
Sand.cobble	158 - 158	1	<1%
Boulder*	110 - 110	1	<1%

*Primary and secondary substrates were the same.

Table 34. -- Summary of fishes and crabs identified at transects ($n = 67$) in the Outer Shelf region.

Species/Grouping	Number of occurrences	Number of transects with occurrences	Mean transect depth range (m)	Mean density (individuals/m^2)

Summary - description of transect

Transect 7: Primary and secondary substrates consisted of sand and mud, respectively. Five crabs and 19 fish were counted for this transect, resulting in a density of 0.01 individuals/m^2. Eelpouts and *Chionoecetes* sp. accounted for 42% of all species seen. Vertical habitat consisted of 1132 sea whips (26 damaged), and 1 Demospongiae. Sea whip and sponge density was 0.33 individuals/m^2. The mean height of 256 measured sea whips was 143.3 cm. Although the Demospongiae was alone, it contributed 73.1 cm to the vertical habitat. No other corals were identified.

Area: Outer Shelf					Transect 8
Date (mm/dd/yy)	Start Position (DD)		Area (m^2)	Mean Depth (m)	Mean Temp (°C)

Summary - description of transect

Transect 80: Primary and secondary substrates consisted of sand and mud. Overall fish and crab density was 0.12 individuals/m^2. Species composition was dominated by eelpouts. The next most abundant taxa were flatfishes. Vertical habitat consisted of 23 sea whips, 13 of which were damaged. Two sea whips were measured at 9.8 cm and 132.7 cm. No other corals or sponges were observed.

Summary - description of transect

Transect 251: Primary and secondary substrates consisted entirely of mud. Fish density for the transect was 0.05 individuals/m^2, and snailfishes were the most abundant taxa. Vertical habitat consisted of 10 Demospongiae, averaging 11.6 cm height. No corals were identified.

Area: Outer Shelf					Transect 252
Date (mm/dd/yy)	Start Position (DD)		Area (m^2)	Mean Depth (m)	Mean Temp (°C)
9/5/14	54.49	-167.02	356	472	3 7

Summary - description of transect

Transect 252: Primary and secondary substrates consisted entirely of mud. Only seven fish were identified in this transect, resulting in a transect density of 0.02 individuals/m^2. Five Demospongiae were identified and 3 were measured (16.2 cm). No corals were identified.
