1. INTRODUCTION

Dissolved low molecular weight (LMW) aliphatic hydrocarbons, C₁ - C₄, were measured on the Alaskan Continental shelf as a part of the Outer Continental Shelf Environment Assessment Program (OCSEAP) sponsored by the Bureau of Land Management (BLM) and administered by the National Oceanic and Atmospheric Administration (NOAA). The purpose of the program was to establish the spatial distributions and temporal (seasonal and diel) variations in the dissolved gaseous hydrocarbon fraction composed of methane, ethane, ethene, propane, propene, iso- and n-butane. These data were collected in order to establish baseline levels of naturally occurring hydrocarbons in the offshore lease areas prior to development of fossil fuel reserves. The ease with which they are measured and their relative abundance in oil and natural gas have made these compounds attractive as tracers of petroleum introduced to the marine environment as a consequence of offshore oil and natural gas exploration, development, production, or transportation.

This data report summarizes light hydrocarbon concentrations made during 13 cruises from 1975 to 1979. The cruise numbers, geographic locations, inclusive dates, and number of samples analyzed for each cruise are shown chronologically in table 1. Spatial and temporal hydrocarbon distributions were obtained in seven geographical areas of the Alaskan shelf. These areas include the northeast Gulf of Alaska, Cook Inlet, Kodiak Shelf, Shelikof Strait, southeast Bering Sea, Norton Sound, and Chukchi Sea as shown in figure 1.

Vertical profiles at each station usually included samples taken at the surface and within 5 m of the bottom. The number of samples taken at intermediate depths depended on the depth of the water column. Diel variability in hydrocarbon concentrations was determined at one or more 24 to 48 hour time series stations during most visits. Time series stations are listed in table 2.

Table 1. Summary of Cruises in Chronological Order

2. METHODS

2.1 Sampling

Water samples were collected using standard 5- or 10-l Niskin[®] bottles mounted with a Plessey Environmental Systems Model 9040 CTD on a General Oceanics Rosette sampler. The bottles were rinsed by raising and lowering them routinely from 20 to 10 m.

Once on deck, water was transferred to clean 1-l glass-stoppered bottles such that air bubbles were not trapped. Approximately 200 mg of sodium azide (NaN_3) was added to each bottle before it was stoppered, shaken to disperse the NaN_3 , and stored in the dark at approximately 5°C. The NaN_3 was added to inhibit biological activity in the sample.

Although storage time varied, samples were never stored for more than a few days. It was determined that storage in the dark for periods of a few days resulted in no significant changes in hydrocarbon composition (Katz, 1980).

2.2 Low Molecular Weight Hydrocarbon Analysis

2.2.1 Preconcentration

Analysis of LMW aliphatics, using a procedure adopted from that proposed by Swinnerton and Linnenbom (1967), was accomplished routinely in both the field and laboratory. A detailed discussion of the methods can be found in Katz (1980). The dissolved gases removed from solution by helium stripping were passed through Ascarite[®], Anhydrene[®], and Tenax G.C.[®] traps to remove carbon dioxide, water vapor, and heavier hydrocarbons respectively. The LMW hydrocarbons were subsequently concentrated on an Activated Alumina[®] trap at -196°C. The trap was then warmed to 100°C and the gases backflushed directly into a gas chromatograph. Quantitative removal of the gases from solution was accomplished in approximately ten minutes with a helium flow rate of 150 ml min^{-1} .

2.2.2 Gas Chromatography

Separation and detection of components were carried out on a Hewlett-Packard 5710A gas chromatograph equipped with flame ionization detectors (FID). Separation was originally effected on a Porapak Q[®], 60- to 80-mesh column (1.2 m x 0.48 cm), in series with an activated alumina column (0.3 m x 0.48 cm) impregnated with silver nitrate (1% by weight). This column configuration (charge transfer complexing) allowed resolution of the alkenes from their corresponding alkanes (e.g., ethene from ethane). However, due to its relatively low decomposition temperature (250°C) and relatively high-bleed characteristics at lower temperatures, the Porapak Q[®] column was replaced with an activated alumina, 60- to 80-mesh column (1.8 m x 0.48 cm) prior to 1978 field work. Chromatographic separation of all components was effected in approximately eight minutes with a column flow rate of 50 ml min⁻¹ and a temperature-programming sequence as follows: two-minute hold at 100°C followed by an 8°C min⁻¹ temperature rate increase to 170°C.

2.2.3 Quantitation

Identification and quantitation of components were obtained by comparing retention times and relative responses of standard hydrocarbon gas mixtures with those of the sample. Standard hydrocarbon mixtures prepared in helium by Matheson Gas Products were reported to $\pm 10\%$ (relative standard deviation) accuracy. One of the standards was also calibrated by the National Bureau of Standards (NBS) and was used to calibrate the other standards. Based on the NBS and Matheson intercalibration, the accuracy of measurement is $\leq 10\%$ for each component. The total sampling and analytical precision was determined to be $\leq 8\%$ for all components. The detection limit of this method based on a signal-to-noise ratio of 2 is 0.05 nl l⁻¹ for components other than methane. The detection limit for methane is near 1 nl l⁻¹ because of baseline noise and a lower detector response.

2.3 Salinity-Temperature Data

Conductivity and temperature versus depth data were collected using Plessey model 9040 systems with model 8400 data loggers. These systems sampled five times per second for values of temperature, conductivity, and pressure. Data were recorded during the down-cast using a lowering rate of 30 m min^{-1} . Nansen bottle samples were taken on every other cast to provide temperature and salinity calibration. The precision of the salinity and temperature data are $\pm 0.01 \text{ g kg}^{-1}$ and $\pm 0.01^\circ\text{C}$ respectively.

3. GENERAL RESULTS

In general, LMW hydrocarbons showed spatial and seasonal variability. Ranges in concentrations for all geographic areas on the Alaskan shelf were: 10 to 4085 nL L^{-1} methane; trace (below detection limit) to 21.0 nL L^{-1} ethane, trace to 6.9 nL L^{-1} ethene; trace to 11 nL L^{-1} propane; and trace to 9.5 nL L^{-1} propene. Butane concentrations were typically at or near the detection limit of 0.05 nL L^{-1} . The highest concentrations of methane, ethane, and propane measured over the Alaskan shelf were observed in upper Cook Inlet (Katz, 1980). Summer concentrations increased over spring and fall values. The concentration increases were more pronounced for methane, ethene, and propene which is related to their biological and/or photochemical origin.

4. ORGANIZATION AND EXPLANATION OF DATA TABLES

The data presented in Appendices A-G are organized in a hierarchy of geographic location, cruise (chronological order), station, and depth distribution. Each geographical location is presented in a separate appendix. Within each appendix cruises are headed by cruise number and inclusive dates (local) of the cruise. Station data include: station number, latitude and longitude to the nearest tenth of a degree, local date and time of sampling, Greenwich mean-time zone, and depth to the bottom in meters. Depth information includes: depth of sample in

meters; methane, ethane, propane, and propene concentrations in nanoliters per liter STP (values below the detection limit of 0.05 nl l^{-1} are tabulated as "trace" (T)); water temperature in degrees centigrade; salinity in grams per kilogram; and the methane solubility ratio C/C*. The methane solubility ratio, C/C*, is the ratio of the observed methane concentration (C) to the equilibrium methane concentration (C*) calculated from equations given by Yamamoto et al. (1976) and from the atmospheric methane mixing ratio of 1.4 parts per million by volume (Ehhalt, 1974).

During the early stages of the program, chromatographic separation of ethane from ethene and propane from propene was not possible. This occurred during cruise RP-4-DI-75B-III (Appendix E.1) and for Station PM004, Cruise RP-4-DI-76A-III (Appendix B.1). In these cases, the tabulated values are the sums: ethane + ethene; and propane + propene.

Butane concentrations measured in most areas were at or below the analytical detection limit of 0.05 nl l^{-1} . Butane concentrations significantly above these levels were measured only in upper Cook Inlet and in the vicinity of the Norton Sound gas seep (Cline and Holmes, 1977). The butane data for these areas are tabulated (nanoliter per liter STP) in Appendix H.

¹ A star (*) indicates no data.

5. ACKNOWLEDGMENTS

The authors would like to thank Anthony Young for the design and construction of the LMW hydrocarbon analysis equipment. Those participating in the sample analyses included S. Hamilton, L. Keister, M. Lamb, L. Ohler, J. Quan, and A. Young. We would like to thank Mark Moehring for help in developing the computer programs for data processing. A special thanks goes to the captains and crews of the NOAA ship DISCOVERER, R/V MOANA WAVE, and R/V ACONA for their assistance in the field program.
