ACROSS NORTH AMERICA TRACER EXPERIMENT (ANATEX)
VOLUME II: AIRCRAFT-BASED SAMPLING

Abstract. Aircraft-based sampling was an integral part of ANATEX. The data are useful for establishing the initial tracer path and for providing vertical tracer distributions. Because there were few, if any, ground-level sampling sites near the sources, the aircraft sampling was done within about 450 km of the two release sites (Glasgow, MT and St. Cloud, MN) and between altitudes near the ground to 2800 m above ground. One or two aircraft sampled 26 of the 33 Glasgow plumes. Usually one flew above the other to obtain vertical tracer profiles. The GGW plume was traversed at least once for 23 of the 26 releases sampled, with 30% of all the samples near GGW containing excess tracer. One aircraft sampled 16 St. Cloud plumes, with tracer concentrations above background reported for all 16 releases. Fifty percent of all the samples of the STC plume contained excess tracer. The instrumentation, operations, and data quality assurance are discussed. The complete archived dataset, consisting of aircraft position data, tracer data, and meteorological data, is included in the report. In addition, data summaries for all flights are displayed in a tabular format.

1. INTRODUCTION

The ANATEX field experiment was designed to produce a comprehensive database for the evaluation and verification of long-range atmospheric transport and dispersion models. Perfluorocarbon tracer gases (PFTs) were released for 3-h periods near the surface every 2½ days from Glasgow, MT (GGW) and St. Cloud, MN (STC) between January 5 and March 26, 1987. Perfluorotrimethylcyclohexane (PTCH) was released from GGW and ortho-perfluorodimethylcyclohexane (oPDCH) from STC. Perfluoromethylcyclohexane (PMCH) was also released from STC with every other release. PFT concentrations were obtained from ground-level air samples taken in the United States and Canada at distances of about 500 km to 3000 km downwind of GGW (the primary sites), from Bermuda and from several sites along the west coasts of Europe and North America (the remote sites), from aircraft within about 450 km of the release sites, and on towers at distances nearly 1600 km downwind. Figure 1 shows the locations of the ground-level samplers in the United States and Canada and the regions in which the aircraft sampled. A complete description of the experiment, the primary ground-level air sampler analysis and results, and archived meteorological data is found in Draxler and Heffter (1989). Results of the tower and remote ground-level sites are found in Heffter and Draxler (1989b). Daily surface synoptic maps with superimposed ground-level PFT concentrations are given in Draxler (1988).

This report describes the ANATEX aircraft program. The main purpose of the aircraft data is to provide 3-dimensional data on initial transport and dispersion. PFT data in the vertical may be critical to understanding the ground-level data farther downwind, especially since tracer was frequently released into strong surface-based inversions. Aircraft samples were also valuable for collecting tracer initially heading away from the ground-level sampling network, thus establishing a link if the tracer later returned.

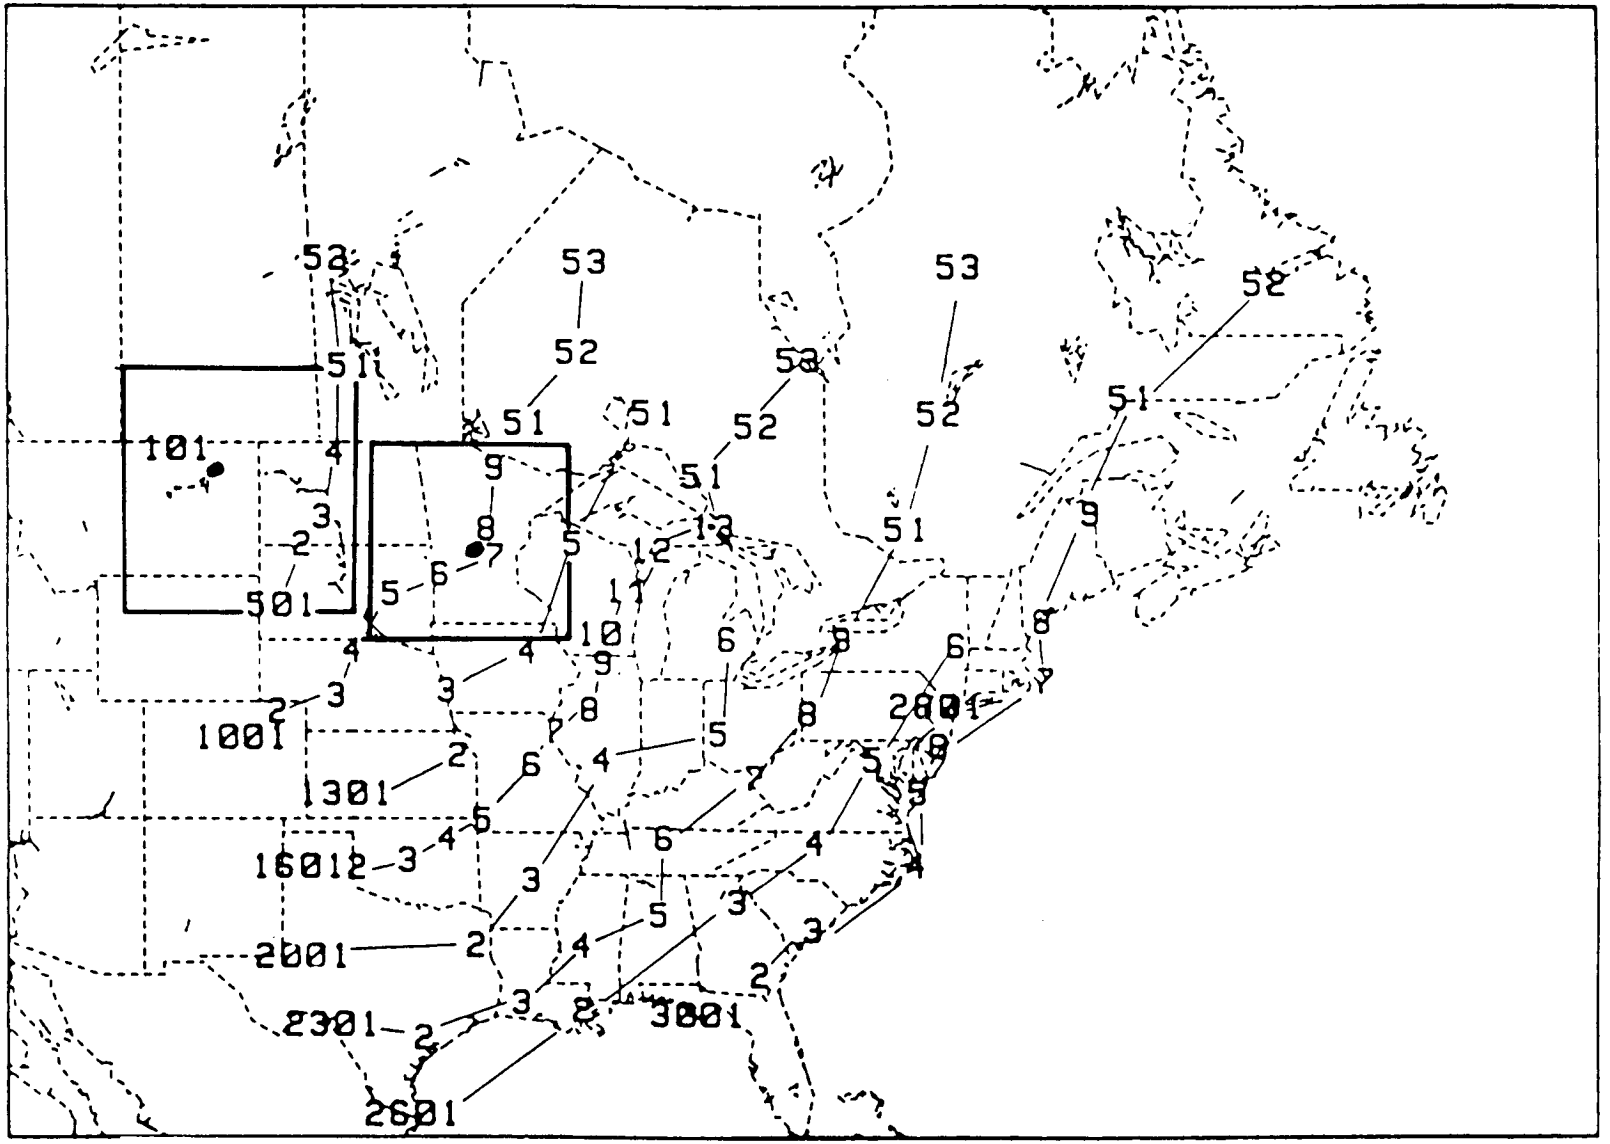

Figure 1. ANATEX ground-level sampler locations and regions for aircraft sampling near the release sites. The GGW and STC release sites are indicated by a dot.

Details on aircraft instrumentation, operations, PFT analysis and results, and the archived data are discussed here.

2. INSTRUMENTATION

Two aircraft were based at Miles City, MT, about 225 km SSE of GGW and one aircraft was based in the Minneapolis, MN area, about 100 km SE of STC. Sequential air samplers (SAS) on all three aircraft could automatically collect up to 20 samples which were later sent to a laboratory for perfluorocarbon tracer analysis. In addition, one aircraft at each release site had a 2-trap air-sampler/PFT analyzer for "real-time" tracer plume detection. All aircraft were equipped with a Loran-C navigation system. Some meteorological and other environmental measurements were also made from the aircraft.

The primary GGW aircraft was equipped with a Rosemount temperature sensor, a dew point hygrometer, and a pressure transducer. These devices, along with the Loran-C system, were interfaced with a data acquisition system consisting of a Pacific Northwest Laboratory (PNL) designed data logger coupled to a Hewlett-Packard 9816 microcomputer. Raw data and event signals from the 2-trap analyzer and SAS were recorded onto micro floppy disks for post-flight data reduction (Lee et al., 1989).

The STC aircraft was equipped with instruments to measure static and dynamic pressure, temperature, dew point, solar radiation, SO_2, and O_3. These instruments, along with Loran-C information and 2-trap output, were interfaced through a model DAS-64 data acquisition system manufactured by Particle Measuring Systems, Inc. Data on fast analog channels were sampled every 0.5 seconds, and every 5 seconds on slow analog channels. Data were recorded on magnetic tape cartridges via Algo, Inc. recorders every 5 seconds.

2.1 Sequential Air Sampler (SAS)

The perfluorocarbons used as tracers in ANATEX are extremely stable non-toxic compounds, measurable at very low concentrations by gas chromatography (GC) and electron capture detection (ECD). The tracer is recovered from a sampling tube by thermal desorption before chromatographic separation and electron capture counting. Air concentration is calculated from this recovered tracer.

The SAS used in the aircraft was designed by the NOAA Air Resources Laboratory (ARL) and the Department of Energy's Environmental Measurements Laboratory, and built by the engineering/electronics division of the National Weather Service. It weighs about 14 kg, is about 25 x 29 x 41 cm in size and contains 21 glass sampling tubes, 20 for samples and one extra tube downstream of the others to seal the sampling chamber. The 21 tubes in the SAS for one flight are referred to as a "string" of tubes. A pre-assigned string number was used for bookkeeping purposes since the string was kept intact throughout its use in sampling and in laboratory analysis. The sampling tubes are about 5 cm in length and 4 mm in diameter and a plastic cap seals both ends. The center third of the tube is packed with Ambersorb, which traps all PFTs in the air flowing through the tube. An internal pump pulls air from the intake port through one of the 20 sampling tubes and through the 21st tube; then the air

exits through the exhaust port. The intake and exhaust lines must be at the same pressure for the SAS to maintain a constant mass flow through the sampler. A constant mass flow is required through the sampler because, in the laboratory, PFT volume is based on PFT mass at STP. At higher altitudes where the air is less dense, more air must flow through the sampling tube to maintain a constant mass flow rate. The pressure drop is measured across a critical orifice in the flow between the intake and exhaust ports. The pressure drop is maintained at a constant value to control the air flow. The flow rate can be preset over the range 0.1 L/min to 0.5 L/min with a specific critical orifice. For ANATEX the maximum 0.5 L/min was chosen. Differences in pre- and post-experimental instrument flow calibrations were at most 10%. Details of the flow rates and their uncertainties are discussed later in section 4.1.3 and section 4.5.

The controls on the SAS are limited to setting sample duration and delay start time, power on/off and start/stop switches. The sample duration and delay start time can be set at intervals of 0.1 h between 0.1 and 999.9 h, and 0.1 and 99.9 h, respectively. The SAS is designed for automatic operation but could be operated manually. For ANATEX, operation with sampling times 0.1 or 0.2 h were used. Sometimes 0.2 h samples were taken until the plume was located and then 0.1 h samples were taken for better resolution. The 0.5 L/min flow rate implies 3 or 6 liter samples for the 0.1 and 0.2 h sampling times, respectively. Usually sampling began when the start/stop switch was set to start, instead of setting a delay start time. Before each flight the 21 sampling tubes were manually inserted into the unit, then removed after the flight to be sent to the laboratory for tracer analysis as described for the ground-level samples (Crawford and Start, 1989). The time between collection and analysis for the aircraft-based samples ranged from about 1½ to 18 months. Effects of this delay on concentration uncertainty are discussed in section 4.5.

2.2 Two-Trap Sampler/Analyzer

The purpose of the 2-trap analyzer, which collects and measured PFTs in ambient air on a "real-time" basis, was to enable on-board scientists to adjust the flight path to optimize plume traversal.

2.2.1 GGW primary aircraft

The two-trap analyzer consists of an adsorption trap module, with two adsorption traps, interfaced with a gas chromatograph to sequentially collect and measure PFTs in ambient air. Its characteristics and operational features have been described previously (Allwine et al., 1985). Under conditions employed during ANATEX, samples were collected and analyzed over a 12-min operational cycle. Material collected on one of the traps during the first 6 min of the cycle was measured following thermal desorption and injection into the carrier gas stream of the gas chromatograph. Coincident with sample injection, the second trap was positioned for sample collection. Lee et al. (1989) give 2-trap analyzer results for the flights on March 4, 1987.

2.2.2 STC aircraft

An older version of the Brookhaven National Laboratory (BNL) 2-trap analyzer consisted of two adsorbent traps, packed with the same material used

in the ground-level sampler and the aircraft SAS, and an in situ ECD chromatograph. While one trap was sampling at 1 L/min for 5 min, the other was heated to recover and analyze the collected PFTs. Since the traps reversed position every 5 min, no tracer was lost. A newer version of this real-time analyzer was built in 1983 for the fall CAPTEX experiment (Ferber et al., 1986); improvements allowed the separation of 3 PFTs. The unit was able to measure ambient levels of PMCP (perfluoromethylcyclopentane) and PMCH, indicative of the limit of detection of about 10 fL (D'Ottavio et al., 1986; Dietz et al., 1989). One fL (femtoliter) is 10^{-15} L.

2.3 Environmental Measurements

The primary GGW and STC aircraft both measured temperature and dew point. These data are included in the data listing in Appendix A for easy reference. The STC aircraft also measured solar radiation, SO_2 and O_3, which are available upon request from: R.L. Gunter, NOAA/ARL/Geophysical Monitoring for Climatic Change, Air Quality Group, 325 Broadway, Boulder, CO 80303.

3. OPERATIONS

PNL operated its Cessna 320 twin-engine aircraft for GGW sampling (the "primary" GGW aircraft) and directed the operation of a contractor twin-engine aircraft (the "contract" GGW aircraft) which usually "shadowed" the primary aircraft by flying 500 to 1000 ft higher. They flew at speeds of about 200 km/h. Aircraft at GGW were available for all 33 releases, but due to maintenance problems or poor weather conditions, sampling was done only for about three-fourths of the releases. Sampling at STC was done from the NOAA Beechcraft King Air, a twin-engine aircraft, for 16 of the 17 releases for which it was available. It usually sampled while flying about 250 km/h. Sampling this many releases from both sites exceeded our original expectations for an experiment of this magnitude and complexity.

Experimental operations generally consisted of the following. ARL scientists designed flight paths based on regional meteorological conditions, surface winds at the release site, 06 GMT and 18 GMT soundings at the GGW and STC National Weather Service (NWS) stations, and predicted tracer trajectories using forecast wind fields from the NWS National Meteorological Center Nested Grid Model. Sampling usually occurred soon after the release, but for several nighttime releases during conditions of strong surface-based inversions with light winds, sampling was delayed until the next day, when the plume mixed high enough for aircraft sampling. The aircraft frequently flew perpendicular to the plume, back-and-forth along a line at the same or different altitudes. Sometimes a second sampling flight was conducted after refueling, dependent, in part, on the weather conditions, plume speed, and the total flight hours available. In addition to automatic data logging, on-board personnel manually recorded on a "data sheet" whether tracer was detected by the 2-trap analyzer during periods corresponding to the SAS samples. Personnel on both GGW aircraft also recorded the aircraft position (latitude, longitude and altitude) corresponding to each sample start and end position on the data sheet during each flight. Personnel on the STC aircraft recorded the aircraft position on the data sheet after the flight using data automatically logged during the flight.

Table 1 summarizes the aircraft sampling flights, or sorties, by release and by source giving sampling time in terms of hours from the start of the release, and mean distance and azimuth from the release site. Sometimes during a sortie, sampling was stopped for a short time, then started again; Table 1 only gives the overall sampling time. Figure 2 is a box plot of sampling distances from the release. Sampling at GGW covered a wider range of downwind distances than at STC: 80% of the samples at GGW were within about 60 to 325 km of the release site whereas 80% of the STC samples were within about 60 to 250 km of the release site.

4. SAS PFT CONCENTRATION AND QUALITY ASSURANCE

Although the same PFTs were analyzed by the laboratories for both the ground and SAS aircraft samples, subsequent analysis and quality assurance procedures differed for two important reasons. First of all, with much less air sampled in an individual sampling tube from the aircraft, 3 or 6 L vs. 72 L at ground-level sites, measurements of background levels of PTCH and oPDCH were not generally possible as samples were at or below GC-analyzer detection limits. Secondly, concentrations in the plumes sampled from aircraft were typically about 2 orders of magnitude greater than the ground-level samples, 100 to 1000 fL/L vs. 1 to 10 fL/L. At high concentrations of the primary tracers, some of the other analyzed PFTs used for quality assurance with ground-level samples were also above ambient background levels because they were present at a small fraction in the released tracer. These factors limited the quality assurance procedures and made it impossible to define an objective uncertainty since no unambiguous reference tracer was available. However, given the large concentrations in the plume it was usually quite clear whether a sample was collected in the plume.

4.1 Concentration

A computer program was developed to compute PFT concentrations and for data quality assurance. The program plotted the time series of 6 analyzed PFT computed concentrations (PMCP, PMCH, oc-PDCH, mt-PDCH, pt-PDCH, and PTCH (c = cis, t = trans, m = meta, p = para)) for each aircraft flight on a computer screen. (For simplicity oc-PDCH, mt-PDCH, and pt-PDCH will be referred to as oPDCH, mPDCH, and pPDCH, respectively.) In this way, background measurements of PFTs that were not deliberately released (mPDCH and pPDCH at both release sites and PMCH at GGW) that deviated from the known ambient background and anomalies in the other PFTs for a given sample were prominent. Concentration was computed in units of dfL/L since the laboratories reported PFT volume in dfL. A description of the PFT analysis system is given in Dietz et al. (1989).

4.1.1 Sample contamination

Analysis of the concentration time series showed three different forms of contamination. One was an apparent uniform contamination of the entire string of sampling tubes in the sampler for a given flight; another was individual sample tube contamination, and the third was cross-contamination due to other PFTs present in the released tracer (see section 4.1.2). For all types of contamination the levels were such that the primary interference

occurred near ambient background levels rather than the high concentration distinct in plumes.

The first step in the analysis was to remove the contamination over the entire string from the individual PFT volumes reported for each sample. The overall contamination volume was estimated from the tracer volumes reported for sampling tubes that were not used during the flight (blanks). If there were no blanks but the samples appeared to be contaminated, the contamination was estimated from the prior flight and the following flight contamination. Contamination for the entire string was apparent for PMCH, oPDCH and mPDCH for many flights, particularly from STC. Contamination of mPDCH was below background levels, but PMCH and oPDCH contamination levels were sometimes up to a few times background. The greater contamination levels of the STC samples may have occurred because the aircraft was based in a much more industrial area than at GGW. All sampling tubes would have been briefly exposed to the ambient environment while the SAS was loaded before each flight.

PMCH contamination of individual sampling tubes was observed for samples from both release sites. The contaminated samples were usually apparent for all the GGW and the STC nighttime releases when PMCH was not deliberately released. Typically PMCH and PMCP were both contaminated. For STC daytime releases when PMCH was released, if oPDCH and PMCH were both above background, it was impossible to determine if the PMCH was contaminated. PMCH concentrations are not reported when the contamination was observed. This occurred in about 8% and 5% of the GGW and STC samples, respectively. The contamination could be from residual tracer remaining in the tubes used in previous experiments.

4.1.2 Tracer cross-contamination

The aircraft SAS PFT data of interest are PTCH from GGW, oPDCH from STC, and PMCH from the STC daytime releases. Trace amounts of oPDCH and PMCH in the GGW tracer and PMCH in the nighttime STC tracer are termed "cross-contaminants." For instance, if oPDCH is measured from the GGW aircraft, the amount from STC is the measured tracer minus that coming from GGW. mPDCH and pPDCH are also cross-contaminants because they were in both the GGW and STC tracers. Cross-contamination must be known either to obtain the primary PFT concentrations or for quality assurance.

Table 2 gives a mean GGW tracer cross-contamination in terms of percent PTCH for the primary PFTs analyzed by the two laboratories, BNL and the ARL Field Research Division (FRD). The values were obtained from the ratios of the PFT to PTCH from the aircraft samples that were well within the PTCH plume. Though the tracer released was almost all PTCH, the data showed at most about 0.1% PMCH and oPDCH, depending on the laboratory. The laboratory differences are likely due to GC analysis/integration or calibration differences because the contamination levels in the released tracer were assumed to be uniform throughout the entire experiment. mPDCH cross-contamination of BNL data was about 0.5%. Figure 3 shows two cumulative concentration distributions of mPDCH for samples analyzed by BNL. The original higher mPDCH concentrations are reduced to that shown by the dashed line when the cross-contamination is removed.

Table 2. Cross-contamination of primary PFTs in GGW releases.

PFT	Percentage of PTCH	
	BNL*	FRD**
PMCH	.028	.14
oPDCH	.13	.031

*Brookhaven National Laboratory
**NOAA/ARL Field Research Division

Similarly for STC, Table 3 gives the cross-contamination in terms of percent oPDCH released based on the nighttime data. The same PMCH cross-contamination was assumed to occur in the day release tracer since daytime STC release data could not be used because PMCH and oPDCH were released in nearly equal amounts. mPDCH cross-contamination of BNL data was about 17%. Figure 4 shows two cumulative concentration distributions of mPDCH for samples analyzed by BNL. The highest mPDCH values are nearly all removed after accounting for the amount in the release and the final distribution looks almost identical to that in Fig. 3 at GGW where essentially no mPDCH was present. Other differences in the distributions will be discussed later.

Table 3. Cross-contamination of primary PFTs in STC releases.

PFT	Percentage of oPDCH	
	BNL*	FRD**
PMCH	2.7	7.9

*Brookhaven National Laboratory
**NOAA/ARL Field Research Division

4.1.3 Sample air volume

The initial assumption was that the flow rate through the sampler remained constant from sample to sample during one flight because altitude changes during a flight were relatively small and no extreme flow deviations were expected with the SAS sampler. Under this assumption, the air sample volume was simply the product of the flow rate (0.5 L/min) and the sample duration (min). pPDCH was the reference PFT used to verify the air volume for samples analyzed by BNL. Of the analyzed PFTs, pPDCH was the best choice as a reference because it was the smallest cross-contaminant in the tracer for both release sites.

For most of the GGW flights, the constant flow assumption of 0.5 L/min appeared valid because the calculated pPDCH concentrations were essentially at background. However, for about one-fourth of the flights that were analyzed

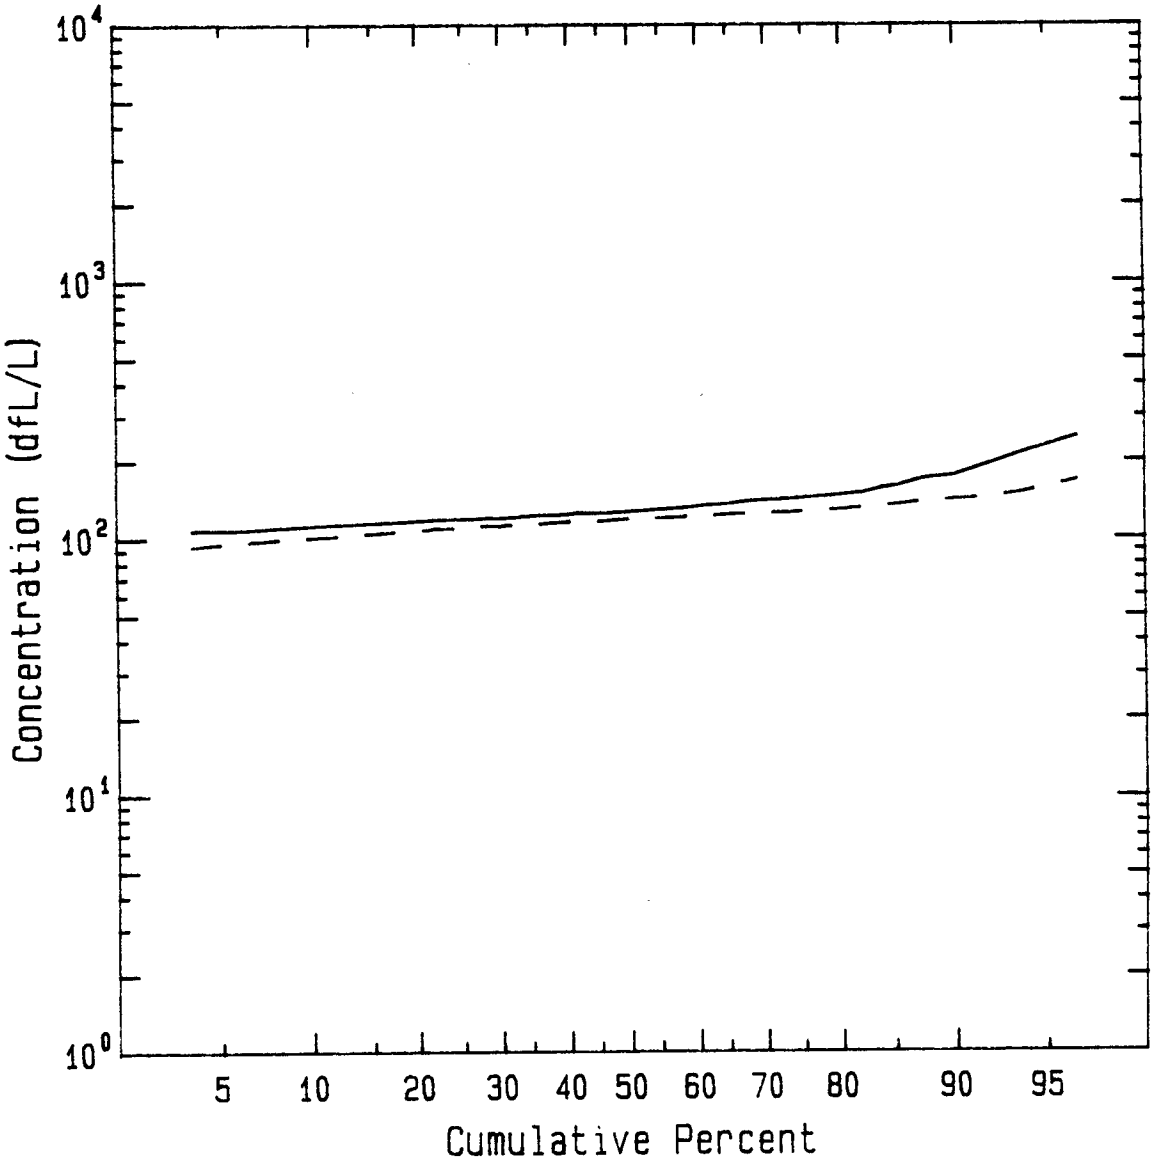

Figure 3. mPDCH cumulative concentration distribution for BNL-analyzed data at GGW. Solid line is the result with a constant flow of 0.5 L/min. Dashed line is the result after removing cross-contamination and using a better flow basis.

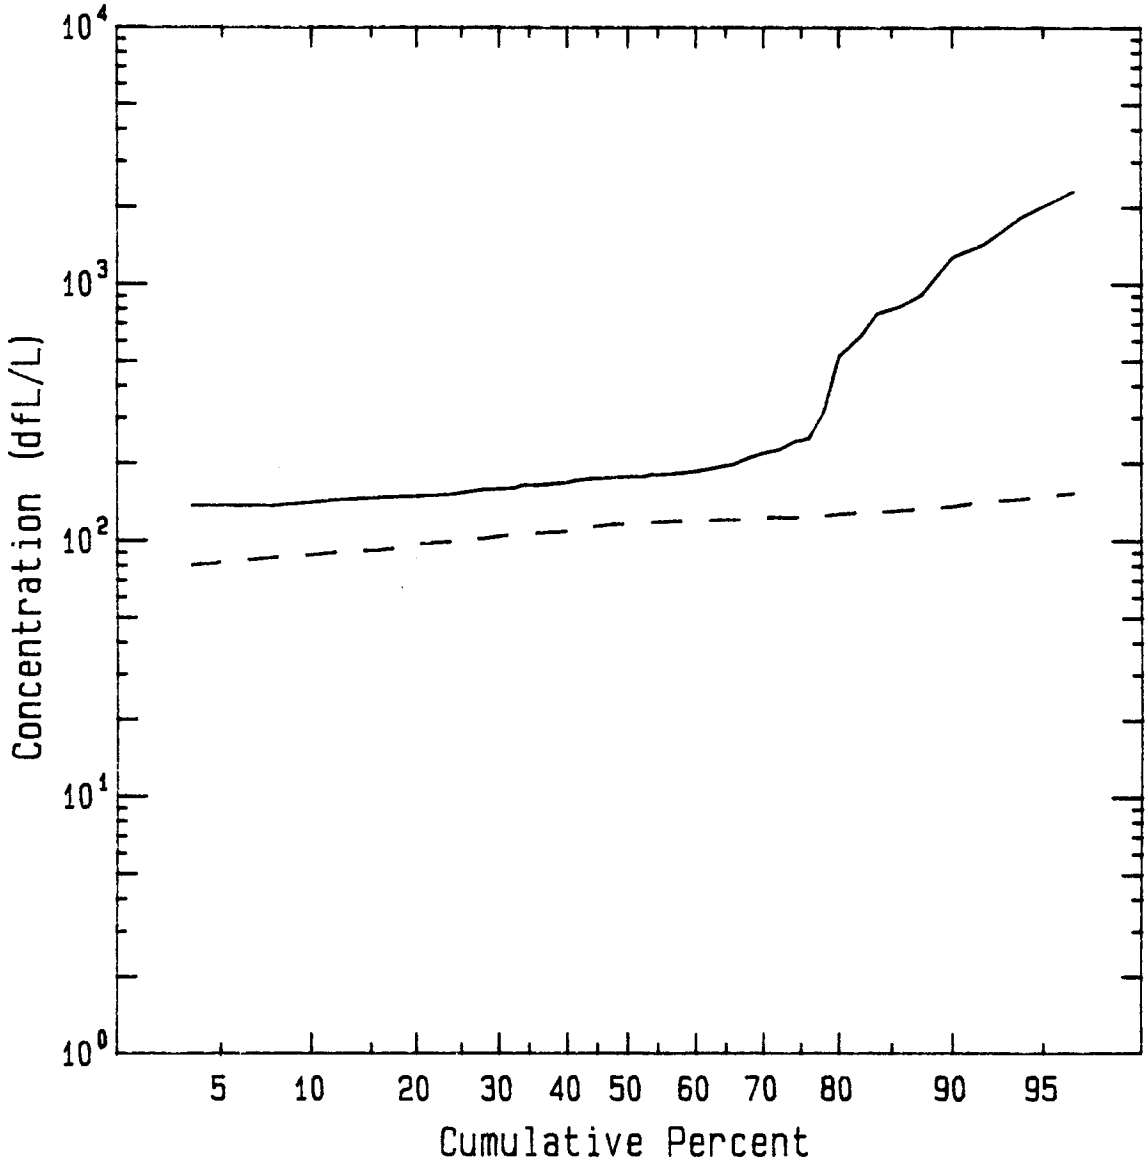

Figure 4. As Fig. 3, but at STC.

by BNL, the flow appeared to be constant, but higher, up to a maximum of about 0.8 L/min. For the high flow cases, the air volume sampled was computed by dividing the known pPDCH background (4.5 fL/L) into an estimated baseline pPDCH volume for that flight.

Similarly at STC, the flow appeared to be constant but generally somewhat higher than 0.5 L/min. For the STC flights with BNL-analyzed data, the flow rates ranged from 0.55 to 0.7 L/min.

pPDCH was not used as a reference for samples analyzed by FRD because the reported pPDCH values were consistently lower than those analyzed by BNL. Air volume computation based on pPDCH gave values far below what would be acceptable. Analysis differences in the other PDCH isomers were also observed. The pPDCH differences from the two laboratories are evident in the cumulative concentration distributions shown in Fig. 5 for GGW. Concentrations shown in the figure were calculated assuming 0.5 L/min constant flow and did not account for contamination nor was the pPDCH from the release removed. No other analyzed PFT could be used as a reference because the others were released (PMCH, oPDCH, and PTCH). Hence a constant flow rate of 0.5 L/min was assumed. Since the ideal constant flow appeared valid for most of the BNL data, it is probably a reasonable assumption that the sequential air sampler worked in a similarly satisfactory manner for the samples analyzed by FRD.

4.1.4 PTCH

Figures 6 and 7 show the cumulative PTCH volume distributions for GGW and STC, respectively, where the volumes have been normalized to a release of 100% PTCH. Both figures show a difference between the two laboratories at the lower end of the distributions. The FRD analysis-integration procedure included an interferant of about 100 dfL, independent of the sample duration (or air sample volume), while the BNL procedure did not. Above background tracer plumes at GGW are clearly evident for volumes greater than about 200 to 300 dfL. No clear PTCH plume samples are apparent at STC. Although the theoretical limit of detection is 35 dfL PTCH for the BNL analysis (Dietz et al., 1989), under actual operating conditions, volumes up to 200 to 300 dfL may have significant uncertainty (personal communication with R. Dietz, BNL, 1989). PTCH background is not measurable because aircraft samples would then have about 10 or 20 dfL PTCH for 3 or 6 L air samples, respectively. The laboratory analysis systems are simply not capable of resolving these low levels. With the difficulty in the low-level PTCH analysis and since plume concentrations are almost certainly much higher than background, we set samples having PTCH volumes less than 300 dfL to background, or zero excess concentration, and defined plume as that above 300 dfL.

4.1.5 Summary and results

The concentration (C) of a particular PFT for each aircraft sample is

$$C = (V - R - T - K) / (F * D). \quad (1)$$

The numerator may be considered as the net PFT volume, where V is the measured tracer volume from the laboratory analysis; R is the volume of the PFT attributed to cross-contamination; T is the threshold volume for PTCH only (300 dfL); and K is the contaminant volume, if any, the same for all samples

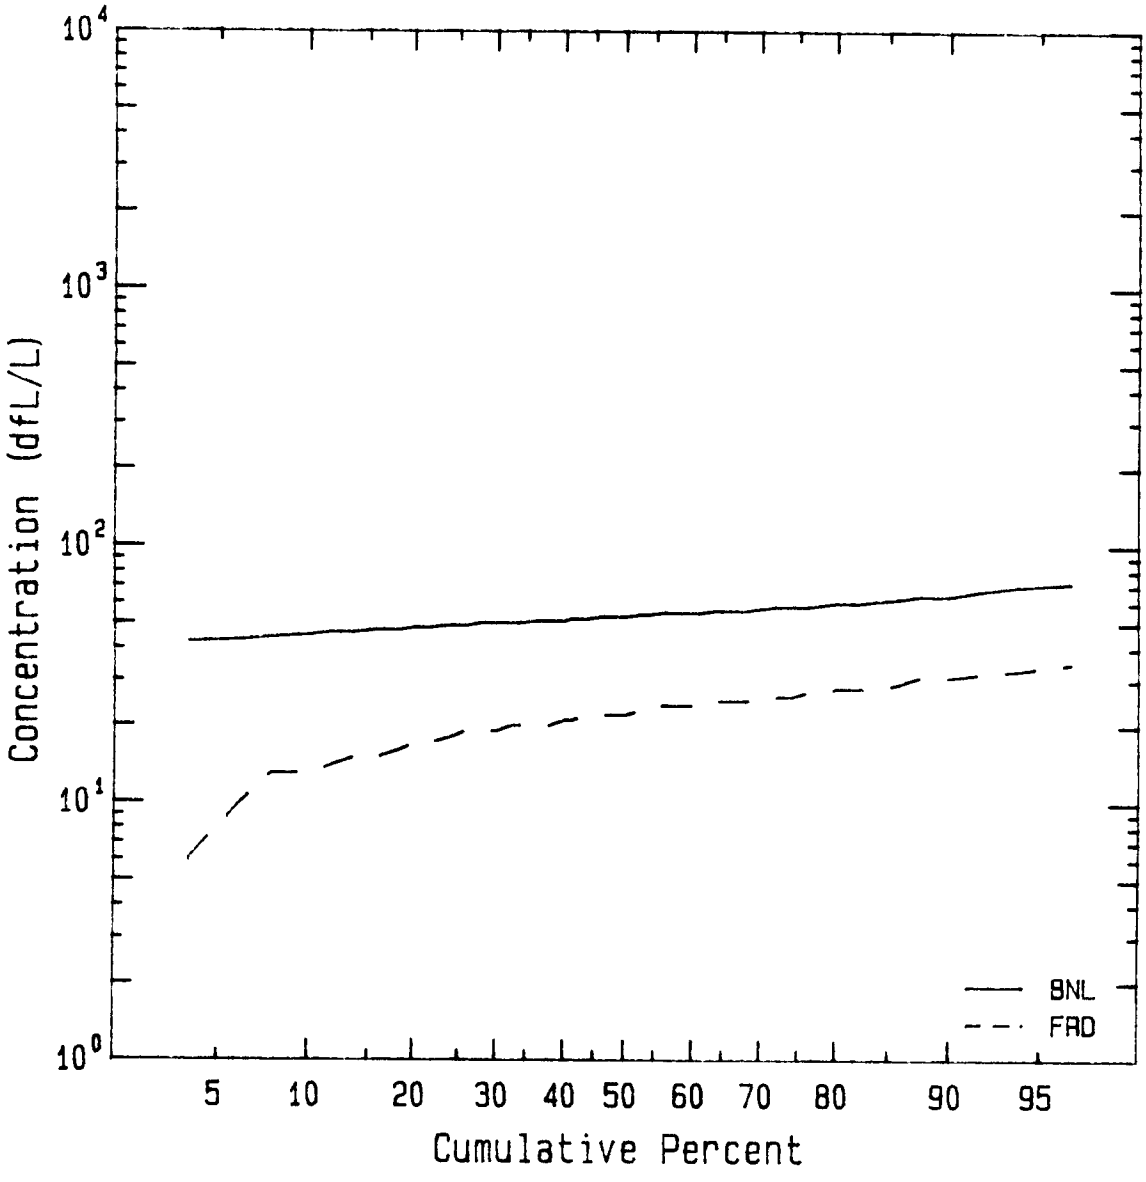

Figure 5. pPDCH cumulative concentration distribution for BNL (solid line) and FRD (dashed line) at GGW.

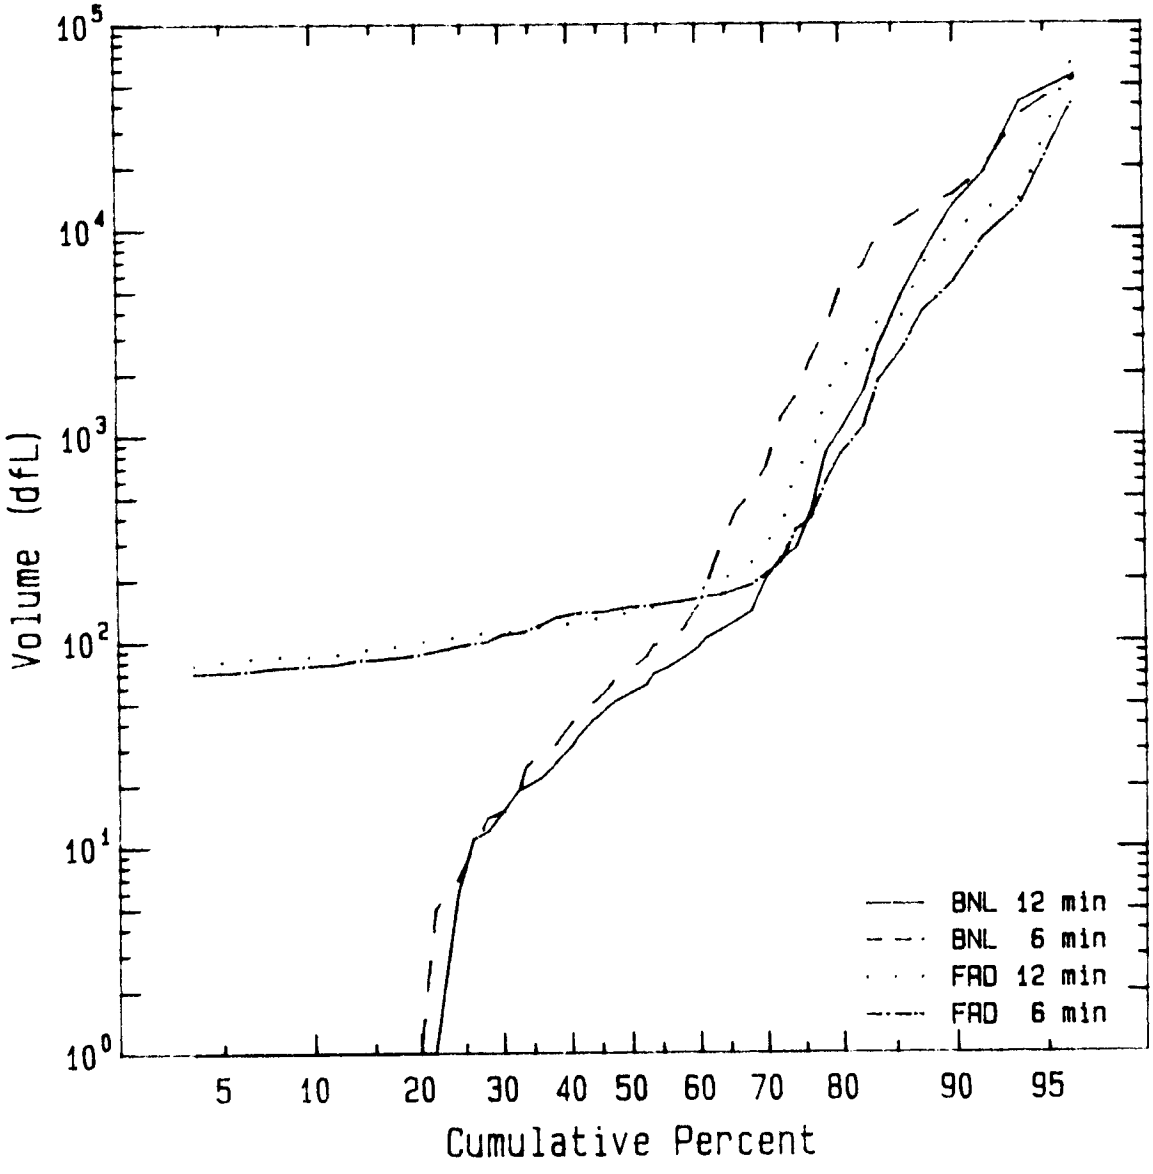

Figure 6. PTCH cumulative volume distribution for all GGW data by laboratory (BNL and FRD) and by sample duration.

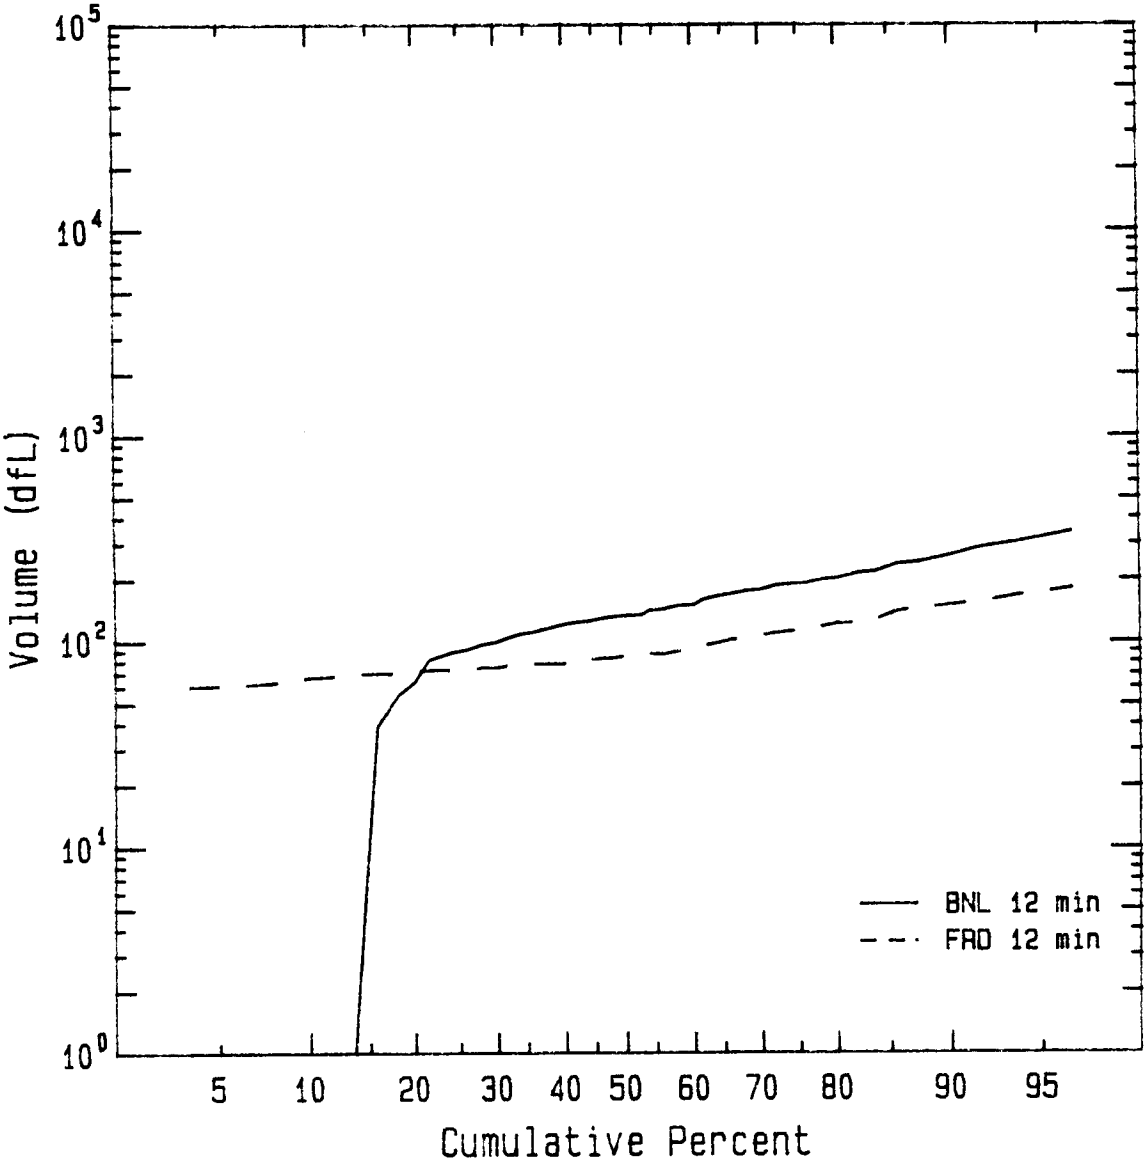

Figure 7. As Fig. 6, but for STC.

in a string. The denominator is the calculated air sample volume--the product of F, the flow rate through the sampling tube, and D, the sample duration. The flow rate for all samples during one aircraft flight is either the ideal constant flow rate or is a constant flow based on pPDCH. Details of these parameters were discussed in previous sub-sections to section 4.1.

In both Figs. 3 and 4, differences between the two cumulative concentration distributions shown in each figure are also due to using calculated flow rates rather than the ideal constant flow assumption. An earlier discussion noted the differences at the high end because of cross-contamination.

Cumulative concentration distributions of the resulting concentrations of PMCH, oPDCH and PTCH for GGW and STC using BNL-analyzed data are shown in Figs. 8 and 9, respectively. These figures are used for quality assurance by noting the slope of the distribution near ambient background and then comparing the background to known ambient levels. They show how many samples were collected in the tracer plume. If the distributions reflected constant ambient background concentrations, they would be flat, except for PTCH because of the 300 dfL threshold, then slope rapidly upward, indicating excess above background. However, analysis uncertainty and flow variations are reflected in the slight increases in background slopes in the figures. The much greater slope in the oPDCH compared to PMCH in both figures indicates greater uncertainty near the oPDCH background, a factor of 10 lower than PMCH. For comparison with the known background, we defined the concentration at the 40% cumulative concentration (30% for oPDCH at STC) to be the best estimate from the data of background, since it is clearly not excess and it is well above occasional steep slopes occurring at the very low end of the distributions due to analysis uncertainty. Table 4 compares the 40th percentile cumulative concentration for PMCH and the three analyzed PDCH isomers by release site and by laboratory to the ambient background concentration. PTCH is not included because it is not measurable at background in the aircraft samples. Comparisons with the ambient levels are fairly good, though as discussed earlier, FRD-reported PDCH values tended to be lower than those reported by BNL. Figure 8 also shows that about 30% of the GGW samples contained PTCH plume and possibly small fractions contained oPDCH and PMCH, although as stated above, the large slope of the oPDCH distribution suggests large uncertainties. Figure 9 shows about 50% oPDCH, 30% PMCH, and a few percent PTCH at STC.

Table 4. 40th percentile PFT concentrations compared to ambient background (dfL/L)

PFT	Glasgow		St. Cloud		ambient background
	BNL	FRD	BNL	FRD	
PMCH	40	34	35	47	36
oPDCH	4	3	10*	6*	3
mPDCH	116	75	109	81	125
pPDCH	48	21	47	23	45

*30th percentile

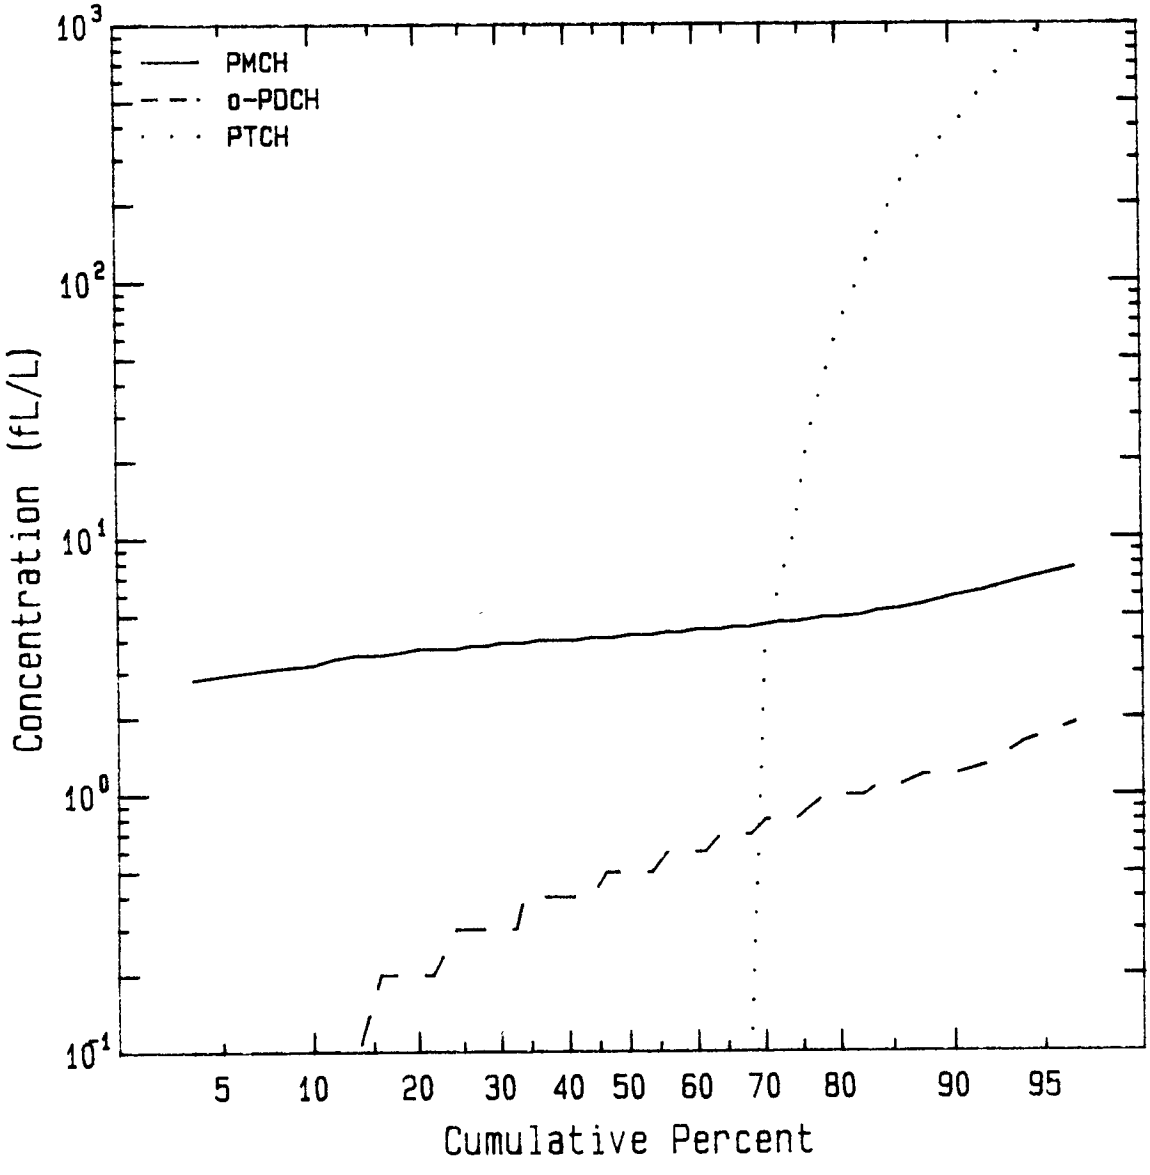

Figure 8. Cumulative concentration distributions of the three primary tracers. Results are from BNL analysis of GGW aircraft samples.

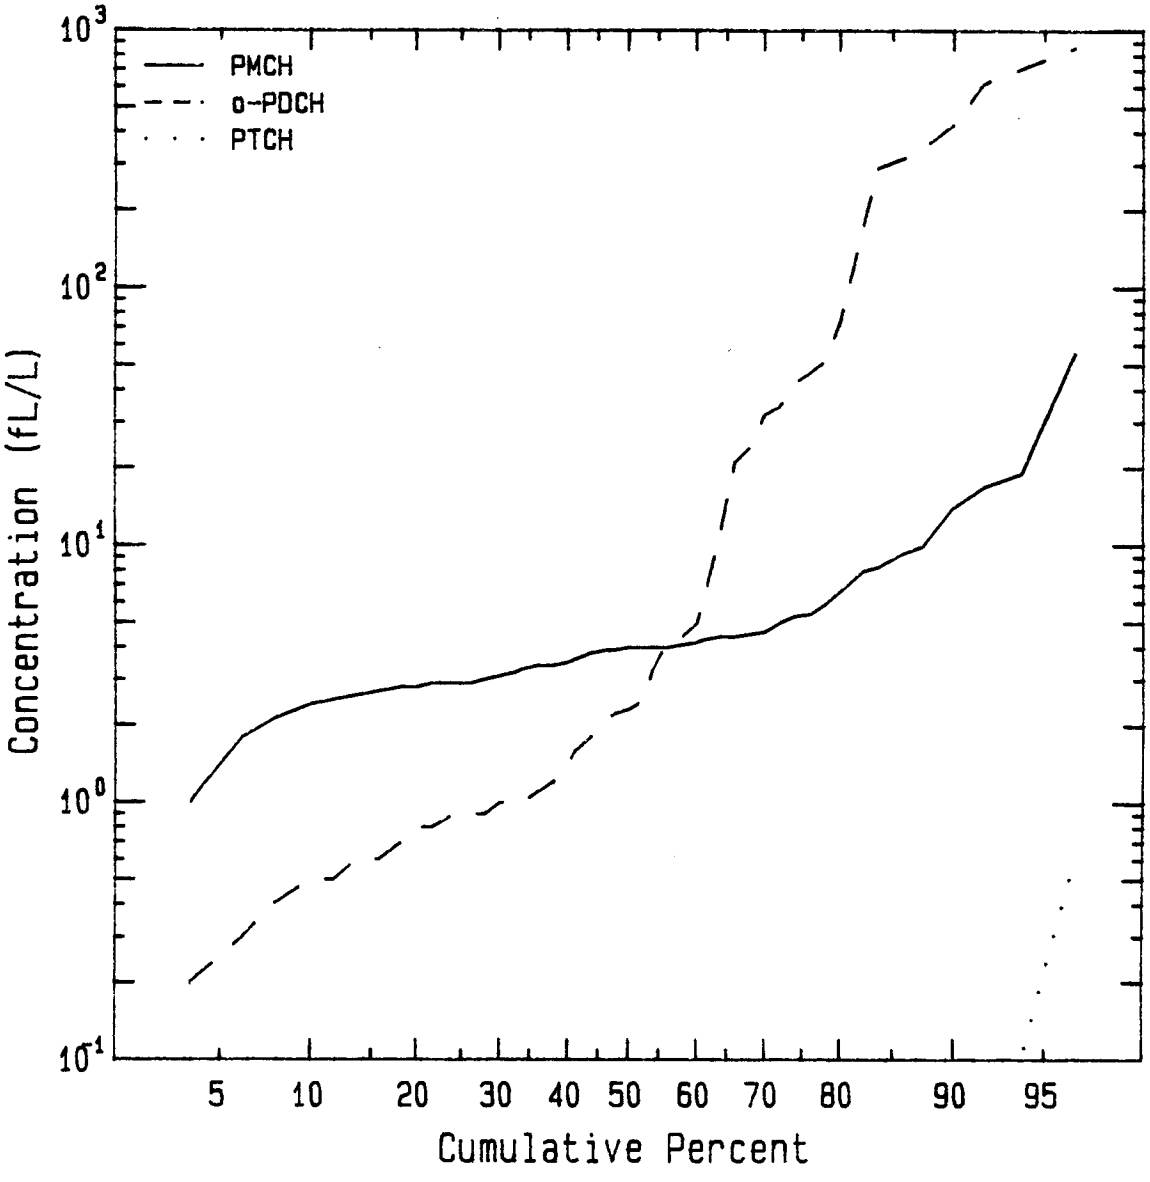

Figure 9. As Fig. 8, but for STC.

4.2 Excess Concentration

The excess concentration (X) is defined similar to that reported for ground-level samples except for no uncertainty term

$$X = C - B. \qquad (2)$$

The excess concentration (fL/L) is the calculated concentration (C) from Eq. 1 minus the background (B), where B is 3.6 fL/L PMCH, 0.3 fL/L oPDCH and 0 fL/L PTCH.

Analysis of oPDCH near background levels has large uncertainties because of the small amount of oPDCH collected (Dietz et al., 1989). These uncertainties coupled with the generally high plume concentrations suggest reporting oPDCH in units of fL/L. On the other hand, background measurements of PMCH were possible because the background (3.5 fL/L) is much higher compared to PTCH and oPDCH. However, due to greater uncertainty (see section 4.5) and with relatively high plume concentrations, samples having excess less than 5 fL/L were assigned an excess of zero.

Excess concentration boxplots for PMCH, oPDCH, and PTCH at GGW and STC using all the data are shown in Fig. 10. Clearly the tracer released closer to the aircraft was predominant, i.e., PTCH at GGW; oPDCH and, to a lesser extent, PMCH at STC. About 50% of the samples at STC contained oPDCH and about 30% at GGW contained PTCH.

4.3 Error Flags

The error flag associated with each reported tracer concentration indicates if FRD flagged the sample during the analysis because of an unknown chemical interferant. BNL did not report this quantity. A flag of "0" indicates a BNL sample or a good FRD sample; a "1" indicates the interference.

4.4 SAS Efficiency/Contamination (Tube 21)

Since air from all the sampling tubes in the SAS flows through tube 21 before leaving the sampler, the tracer on tube 21 is either that which was not collected in the 20 sampling tubes or contamination from the sampling chamber, the tube itself, or from the downstream end of the SAS. For the primary ANATEX tracers, in general, no more than a few percent of the sum of the tracer volumes in all the sampling tubes was observed on tube 21. This suggests that nearly all the tracer in the air flowing through the individual sampling tubes was collected.

4.5 Uncertainty

The uncertainty associated with each reported tracer concentration cannot be objectively determined. Uncertainties in the PFT volume analyzed by the laboratories, the cross-contamination, the PTCH threshold, the uniform contamination, the flow rate, and the time between sample collection and analysis all contribute to the overall uncertainty. In general, the uncertainty in the analyzed PFT volumes as determined by the laboratories is about 10% when the tracer volume sampled was less than 400 fL and about 6% for greater volumes of tracer. The contamination removed during the analysis

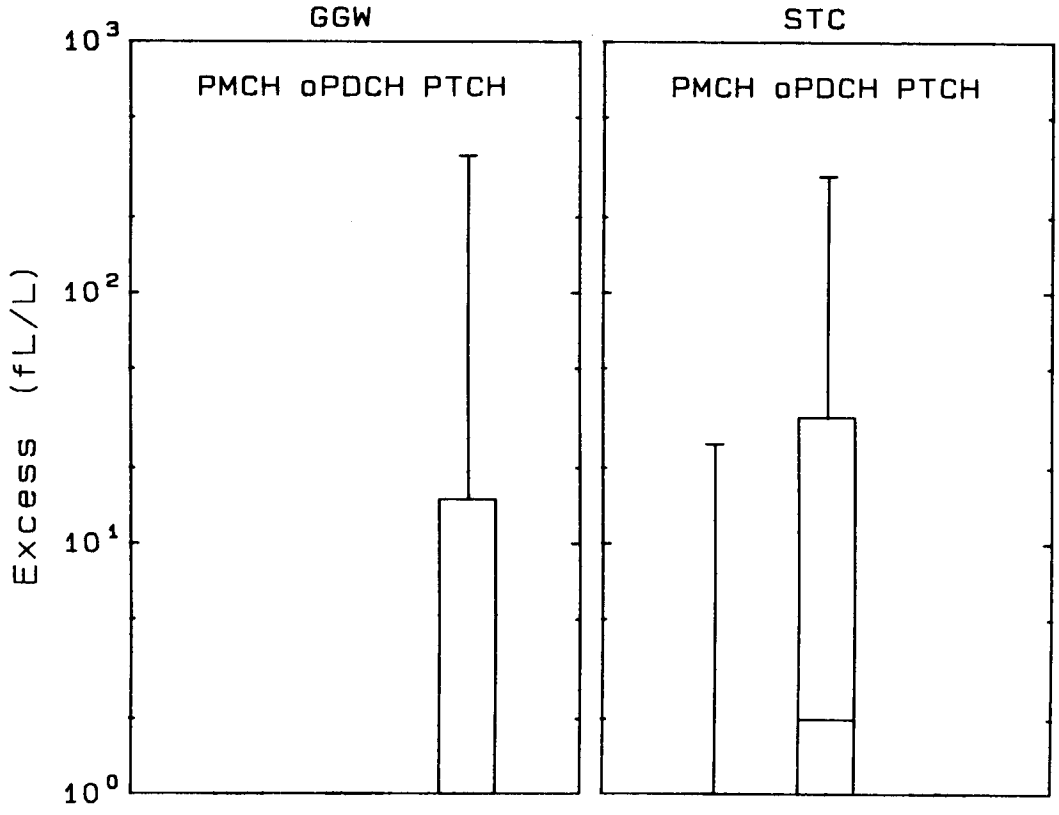

Figure 10. Excess concentration boxplots for PMCH, oPDCH, and PTCH at GGW and STC using all data. Plots show 10th, 25th, 50th, 75th, and 90th percentiles when excess is greater than 1 fL/L.

procedure was a small fraction of the tracer volumes. Uncertainty in flow rates for BNL-analyzed data should be relatively low because pPDCH was used as a reference; uncertainty for FRD-analyzed data could likely be higher because pPDCH could not be used as a reference (section 4.1.3). Measured differences of up to 10% between pre- and post-experimental SAS flow calibrations (section 2.1) would then have little or no effect on BNL-analyzed data, but for FRD-analyzed data would imply a corresponding ±5% concentration uncertainty. Ideally all samples should have been analyzed soon after the experiment. However, some were not analyzed for about 1½ years (section 2.1). Although it is not known if tracer desorbed from the Ambersorb in the sampling tubes over these large lapse times, we suspect desorption would be small, especially in comparison to the high tracer concentrations usually measured from the aircraft. Sampling tubes not exposed, but stored for similarly long periods, showed no tracer had adsorbed on the Ambersorb.

With the aircraft data, most of the primary tracer excess concentrations are large; it was usually quite clear if the aircraft was sampling in the plume. Samples with concentrations near background were not measurable for PTCH, and for oPDCH have high uncertainty since the oPDCH sample volumes were near the limit of detection of the GC. However, using the method for determining concentration described earlier and reporting excess in units of fL/L should result in relatively low uncertainty for the low-level plume samples. PMCH uncertainty may be higher, in part because of contamination in individual tubes. In addition, the PMCH/oPDCH mixture released for the daytime STC releases was not uniform (Heffter and Draxler, 1989a). The short duration aircraft samples near the release site sometimes indicated much more of one of the tracers.

4.6 PFT Data

Out of 1500 aircraft samples processed (20 sampling tubes per flight times 75 flights), 1304 (87%) are included in the archived data. The remaining 13% are not included for the following reasons: all data from two flights were lost due to apparent operator error on the contract aircraft at GGW; 112 sampling tubes were not used due to such problems as ending the flight because of inclement weather, mechanical problems, or timing constraints; 29 samples from STC were not included because the sample either began before take-off or ended after landing; data from a few samples were not available due to problems with a GC; and the sampler flow rate was apparently constricted enough for a few samples that the flow could not be determined.

The PFT data (PTCH for GGW and oPDCH for STC) for all the flights are displayed in Appendix B using a tabular format. These are given as an aid to visualize the complex spatial/temporal dataset for each flight. Corresponding approximate altitude and downwind distance and direction are also given. If both aircraft flew near GGW, data from both are shown.

5. ARCHIVED DATA

The GGW and STC data are archived on an MS-DOS diskette and sorted chronologically by flight in two separate files: AC-GGW.DAT and AC-STC.DAT. Aircraft position, PMCH, oPDCH, and PTCH excess concentration and flags, temperature and dew point are given. Missing temperature and dew point are

indicated by -999; -9 indicates missing values for all other parameters. The data are also included in Appendix A for easy reference.

Copies of the data may be obtained by written request to:

Each archived SAS sample excess concentration is identified by flight, tracer release, aircraft, laboratory, and sample start date/time. The flight number uniquely identifies each flight by one aircraft flying one sortie. It is used to easily distinguish between two different aircraft flying at the same time or between two sorties flown by one aircraft for a given tracer release. GGW has 50 flights; STC has 22. Up to 20 air samples were collected during each flight. Refer to Table 1 for a list of all the sorties. Note that the two sorties at STC for release 32 are archived as one flight because of the relatively short time between the sorties and the SAS was loaded with 20 sampling tubes only before the first sortie; about half the samples were collected in each sortie. Table 1 also gives the release number, date, and time. Odd-numbered releases occurred during the day and even-numbered releases occurred at night. Code numbers for the aircraft and analysis laboratory are also given for each flight. The three aircraft are STC (1), primary GGW (2), and contract GGW (3). The two laboratories are BNL (1) and FRD (2). For GGW when both aircraft flew together, the data for the primary aircraft are given first, then the contract aircraft.

The aircraft position data give sample start and end time (GMT), latitude, longitude, mean terrain height, and altitude in meters (msl) and millibars. For STC and GGW, altitude was reported in pressure (mb) and height (m), respectively, because of different instrumentation on the aircraft. The other altitude parameter was computed by integrating the hydrostatic equation given sea level pressure and station elevation. Although the aircraft generally flew no lower than 150 m above the ground, comparison of altitude and mean terrain shows that aircraft at GGW were sometimes flying within 150 m of the mean terrain or, for a few SAS samples, slightly below mean terrain. This may be due to several factors. First, the aircraft did fly close to the ground during several flights. Second, the archived mean terrain may not always be a good reference when flying close to the ground. Terrain data at a resolution of 0.5 min latitude by 0.5 min longitude were averaged to a one-quarter degree latitude by one-quarter degree longitude grid. The mean terrain given in the archive is the nearest mean terrain value to the aircraft latitude/longitude position. If the aircraft were following the terrain, it could possibly go below the mean terrain. Finally, altitude differences between that automatically logged in the primary GGW aircraft and that manually recorded were usually small, less than 100 m. These differences would be more important when the aircraft flew close to the ground. It should also be noted that the STC aircraft usually began each flight by flying a vertical profile up to at least the top of the boundary layer. Sometimes the SAS was started near the beginning of the profile, sometimes after the profile.

The dew point data should be used qualitatively, for instance to aid in identifying air mass boundaries, because of the difficulty in its measurement, particularly at temperatures below 0°C. For about 30% of the SAS sample data at both GGW and STC the mean dew point is greater than the mean temperature. However, about one-third of these at GGW and one-half at STC are within 1°C. Differences in instrument response time and accuracy may explain some of the suspect data. On the STC aircraft the temperature sensor is accurate to 0.1°C and has a response time of 1 sec; the dew point sensor has an accuracy of 1.0°C and a response time of 5 sec. Both the primary GGW and STC aircraft use the optical condensation hygrometer as the dew point instrument. The condensate surface is electronically maintained in vapor pressure equilibrium with the surrounding air and surface condensation then detected optoelectronically. The dew point temperature is then that temperature at which the rate of condensate equals the rate of evaporation. At temperatures below 0°C, ice forms on the mirror surface and the surface temperature is interpreted as the frost point temperature. More time is required to form a stable frost layer than a dew layer because the mirror temperature first senses the dew point and then slowly rises to the frost point as the condensate freezes. Under conditions of near saturation, the condensation hygrometer gives poor performance, especially for frost point measurements.

The following describes the archive data organization, and record format:

FILE ORGANIZATION:

1X means 1 space.

6. ACKNOWLEDGMENTS

We wish to thank the many people who contributed to the production of the ANATEX aircraft data archive. In particular, we thank R. Lee (Pacific Northwest Labs.), and D. Wellman and L. Gunter (NOAA/ARL/Geophysical Monitoring for Climatic Change) for their success as on-board scientists for the GGW and STC flights, respectively, and the ARL/Field Research Division staff who managed the hundreds of sampling tubes and created the aircraft position database. We appreciate the expertise of R. Dietz (Brookhaven National Laboratory) and G. Start (FRD) for the tracer analysis. Finally, we wish to thank the pilots who were willing to fly at low altitudes to measure the tracer.

This research was funded by the U.S. Air Force Technical Applications Center and the U.S. Department of Energy, Office of Health and Environmental Research.

Appendix A - Archived Data

Archived data for GGW and STC are given. The following are included for each SAS sample:

F	= flight
R	= release
DATE	= sampling start date (YRMODY)
A	= aircraft (1=STC, 2=primary GGW, 3=contract GGW)
L	= laboratory (1=BNL, 2=FRD)
TIME	= start/end time (HHMMSS, GMT)
LAT	= start/end latitude (°N*100)
LON	= start/end longitude (°W*100)
E	= start/end mean terrain elevation (m)
HT	= start/end altitude (m, msl)
P	= start/end altitude (mb*10)
PMCH-F	= excess (fL/L) and flag (0=OK, 1=interference)
oPDCH-F	= excess (fL/L) and flag (0=OK, 1=interference)
PTCH-F	= excess (fL/L) and flag (0=OK, 1=interference)
T	= temperature (°C*10)
TD	= dew point (°C*10)

Missing = -9 or -999

GGW

Appendix B - Data Summary

The SAS PFT data (PTCH for GGW and oPDCH for STC) for all the flights are displayed in a tabular format. Downwind distance (D, km), angle with respect to the release site (A, deg), and excess concentration (fL/L) and height above ground (m) are given for 1 or 2 aircraft (C1, H1; C2, H2). The data are printed as a function of time, which is given below the box. The sampling date and release number are given at the left side of the box. The time after the start of the release (h) is shown above the box for 1 sample near the beginning of each flight. If the aircraft flew a back-and-forth type pattern or flew at different downwind distances for part or all of the flight, the segments are divided by the vertical lines.

In a simplified format these tables describe the complex spatial/temporal tracer patterns measured. The data in the tables clearly show if the plume was traversed during the flight, if concentrations at different altitudes were measured, if 2 aircraft flew near GGW, and indicate other general features such as plume size. Details in the data archive should also be obtained for the following reasons:

(1) The flightpath may not be a simple back-and-forth pattern.

(2) When 2 aircraft were flying near GGW, they were usually together, but at different altitudes. An asterisk (*) indicates they were not together for part or all of the flight. The distance and angle are given for only 1 aircraft.

(3) Although the GGW and STC aircraft flew about 200 and 250 km/h, respectively, distance travelled between the SAS sample start and end positions do not always imply these speeds, particularly if the aircraft were turning or changing altitude during a sample. Crosswind integrated concentrations based on these speeds without referring to the flightpath may lead to incorrect conclusions.

(4) For some GGW releases (18-21, 23) when both aircraft flew together (or one aircraft made two flights associated with a release), data from the two aircraft (or two flights), were analyzed by the two different laboratories. Due to differences in the laboratory analyses discussed in section 4, these data should be compared cautiously.

NOAA Technical Memorandum ERL ARL-177
Across North America Tracer Experiment (ANATEX)
Vol. II: Aircraft-Based Sampling

Some terrain elevations listed in Appendix A for STC flights 16, 17, 18, and 20 are incorrect. The corrected elevations are included in the following list. The archived MS-DOS file AC-STC.DAT includes these corrections.

STC
